Body oblong, creeping, naked, often inclosed in a tube, furnished with lateral fascicles or tufts and branchies; mouth placed before, furnished with lips, without teeth, and protruding a clavate proboscis; feelers numerous, ciliate, capillary, seated round the mouth.

There are 11 species, viz. cincta, lapidaria, conchilega, complanata, carunculata, rostrata, flavia, rubra, aphroditea, bicornis, and stellata.

lapidaria. Of these the terebella lapidaria, or stone-piercer, is called by the French Pinceau de Mer, the sea pencil, is thus described by Barbot. "From the midst of the hairs issues the head of this small animal, supported by a long neck, and putting forth two small branching horns. The mouth, which is round, is armed with small teeth, like those of the echinini marini, with which it masticates its food. The hairs are very fine, soft as silk, and form a tuft, from the middle of which issues the neck, and then its head. The body is shaped like that of a worm, is very long, and terminates at one end in a point, which very much resembles the stick end of a painting brush. The small head of our terebella appears underneath, drawn back as in the snail. It walks or crawls by the help of five small feet, placed on each side of the large part of its body, at the rising of the tuft of hairs, and close to each other."

36. TRITON.

Body oblong; mouth with an involute spiral proboscis, having 12 tentacula, 6 on each side, divided nearly to the base, the hind ones being ciliate.

There is only one species, viz. littorea, found on the shores of Italy.

37. SEDIA.

Body fleshy, receiving the breast in a sheath, having a tubular aperture at its base; arms 8, beset with numerous warts or suckers; and besides, in most species, 2 pedunculated tentacula; head short; eyes large; mouth resembling a parrot’s beak. Cuttle-fish.

Cuvier divides the genus sepsia into two, which he calls seiche, comprehending most of the species enumerated by Linnæus under sepsia, and poupe, comprising two species. The former have a sac, with a kind of fin on each side, and they contain towards the back a peculiar body of a friable or cartilaginous substance, transparent in the living animal, which is placed within in the flesh, without adhering to it; and proceeding from one side to the other without any articulation. The head is round, and provided with two large moveable eyes, the organization of which is almost as perfect as that of the eyes of warm-blooded animals. The mouth is situated at the top of the head, and has two similar jaws, in form and substance resembling the beak of a parrot, and surrounded with eight conical tentacula, furnished with suckers, by means of which the animal fixes itself to the rocks or other substances, so firmly, that it is often easier to tear away one of these arms than to induce the animal to quit its hold. The two others are very long, and have no suckers except at their extremity. These last seem to serve the animal for anchors to hold by.

Just before the neck there is a sort of funnel, which closes up the entrance of a sac, and seems to be the anus. These animals have internally a liver, a muscular gizzard, a cæcum, and a short intestinal canal. The circulation in these animals is carried on by very singular organs; there is a heart placed at the bottom of a sac, by which the blood is distributed to every part of the body, by means of arteries, and to which it is returned by veins, through a large vena cave, which divides itself for the purpose of conveying the blood to two
other two hearts, one on each side, which distribute it
to the gills, from whence it is passed to the first heart.

The female produces eggs that are arranged in the form
of a bunch of grapes.

These animals, when they perceive the approach of
danger, emit a quantity of inky fluid, furnished by a
particular vessel, and by thus obscuring the water, ren-
der their escape more easy, while from the bitterness of
this liquid their foe is induced to give over the pursuit.

There seems little doubt that the opinion of Swammer-
dam, that this liquor furnishes the Indian or Chian ink,
is just; for if this ink be dissolved in water, in any
considerable quantity, it very soon acquires a very high
degree of opacity, which seems to prove that it is formed
of some animal substance; and none seems better calcu-
lated for the purpose than this black liquor.

The second genus of Cuvier differs from the sepia,
properly so called, in wanting the solid bony substance
in the back, and the two long arms; but the eight ten-
taculae are much longer in the individuals of this genus
than in those of the sepia.

The male cuttle-fish always accompanies the female;
and when she is attacked, he braces every danger,
and will attempt her rescue at the hazard of his own life;
but as soon as the female observes her partner to be
wounded, she immediately makes off. When dragged
out of the water, these animals are said to utter a sound
like the grunting of a hog.

The hard substance, or bone as it is called, in the
back of the cuttle-fish, when dried and powdered, is
employed to form moulds, in which silversmiths cast
small articles, such as spoons, rings, &c.; and it forms
the useful article of stationery called pounce.

In the Systema Naturae there are described eight spe-
cies of sepia, viz. *octopus*, *officinalis*, *unguiculata*,
*hexapus*, *mediterranea*, *sepia*, and *tunicata*.

*officinalis*. *octopus*.

The officinalis was in great esteem among the ancients
as an article of food, and is still used by the Italians.

The sepia octopus, or eight-armed cuttle-fish, which
inhabit the seas of warm climates, is a most formidable
animal, being sometimes of such a size as to measure 12
feet across its centre, and to have each of its arms be-
tween 40 and 50 feet long. It is said that he will
sometimes throw these arms over a boat or canoe, which
he would infallibly drag to the bottom, with those who
are in it; did not the Indians, who are aware of this
danger, carry with them a hatchet to cut off the
arms.

Body naked, free, and floating, furnished with a fin on
each side; head distinct, and having gills at the sur-
f ace of the fins.

The above character of clio is that of Cuvier, who
has written an able account of this and two other ge-
era of his new order of mollusca, which he calls pter-
podida, or mollusca pinnata, in the 4th vol. of Ann. de
Mus. Nat.

Gmelin enumerates six species of clio, viz. caudata,
pyramidata, retusa, borealis, helicina, and limacina.

Body oblong, creeping, flat beneath; mouth anterior;

39. OCHIDIDUM.

Body oblong, creeping, flat beneath; mouth anterior;

Feeler two, above the mouth; arms two, at the sides
of the head; vent behind, and inferior.

Species two, viz. typhoe, described by Dr Buchanan,
5th vol. Lin. Trans.; and peronii, described by Cuvier,
Ann. de Mus. Nat.

40. Lloaria

Body lobate, convex above, flat below.

One species, viz. quadriroba, having a tail with four
lobes; and found in the north seas.

41. Lernax

Body oblong, somewhat cylindrical, naked; tentacula
or arms, two or three on each side and round, by
which it affixes itself; ovaria two, projecting like
tails from the lower extremity.

There are 15 species, viz. brachialis, *cyprinaceae*,
salmones, *asellina*, *huchonis*, clavata, unciata, gobia,
radiata, nodosa, cornuta, pectoralis, lutea, cyclop-
terina, and pinnarum.

42. Scylla

Body compressed and grooved on the back; mouth con-
sisting of a terminal toothless aperture; tentacula,
three on each side, placed beneath.

Two species, viz. pelagica and gompodensis.

43. Aphrodita

Body creeping, oblong, covered with scales, and furni-
ished with numerous bristly fasciculate feet, on each
side; mouth terminal, cylindrical, retractor; feelers
two, setaceous, annulate; eyes four.

There are 5 species, viz. *aculeata*, *acabra*, *squamata*,
imbricata, plans, *lepidota*, cirroa, violaceas,
and longs.

The aculeate aphrodite, by some called the sea mouse,
*oculeata*, is of an oval form, grows to the length of four or five
inches; the belly is covered with a naked skin and
somewhat prominent in the middle; its substance is
somewhat firm. It is clothed with hairy filaments,
which are short on the middle of the back, but longer
at the sides; they are all somewhat rigid and firm;
those on the back stand erect, like the quills of a por-
cupine; those on the sides lie flat, and are of a great
variety of colours; a beautiful blue and lively green
are very distinct in them, but a golden yellow is most
predominant; on the back they are darker, and in
many places of a grayish brown. It dwells in the Eu-
ropian ocean, living upon shell-fish, and has 32 fasci-
culated projectors, resembling feet, on each side.

44. Amphiurita

Body projecting from a tube and annulate; peduncles
or feet small, numerous; feelers two, approximate,
feathered; eyes none.

There are seven species, viz. reniformis, penicillus,
ventilabrum,
45. Spio.
Body projecting from a tube, jointed, and furnished with dorsal fibres; peduncles rough, with bristles, and placed towards the back; feelers two, long, simple; eyes two, oblong.

There are two species, viz. seticornis and filicornis.

46. Nereis.
Body long, creeping, with numerous lateral peduncles on each side; feelers simple, rarely none; eyes two or four, rarely none.

The species are 29 in number, and are divided into three sections.

A. Mouth furnished with a claw;

B. Mouth furnished with a proboscis;
Containing *cerulea*, *viridea*, maculata, crassa, stellifera, punctata, alba, flavo, longa, prismatica, bifrons, cecum, ebranchiata, lamelligera, and ciliata.

C. Mouth furnished with a tube;
Containing one species, viz. prolifera.

One of the most remarkable of these species is the noctiluca, of which we shall here give a short account.

*noctiluca*.
Body blue green, with 23 segments, so small as to be scarcely visible to the naked eye.—This is one of those phosphorescent animals that illuminate the ocean in the dark. Their numbers and wonderful agility, added to their shining quality, do not a little contribute to these illuminations of the sea; for myriads of these animacula are contained in a small cup of sea water. Innumerable quantities of them lodge in the cavities of the scales of fishes; and to them, probably, the fishes owe their noctilucent quality. “I have observed with great attention (says Barbut) a fish just caught out of the sea, whose body was almost covered with them; and have examined them in the dark: they twist and curl themselves with amazing agility, but soon retire out of our contracted sight; probably their glittering dazzling the eye, and their extreme minuteness eluding our researches. It is to be observed, that when theunctuous moisture which covers the scales of fishes is exhausted by the air, these animals are not to be seen, nor are the fishes then noctilucent, that matter being perhaps their nourishment when living, as they themselves afford food to many marine animals. They do not shine in the day-time, because the solar rays are too powerful for their light, however aggregate, or immense their number.”

47. Nais.
Body creeping, long, linear, depressed, and bellulcid; peduncles, with small bristles on each side; no tentacula; eyes two or none.

There are 10 species, viz. vermicularis, *serpentina*, *probusides*, elinguis, *digitata*, *barbata*, *cucum*, littoralis, marina, and quadricuspidata.

48. Physasornia.
Body gelatinous, pendent from an aerial vesicle, with gelatinous sessile members at the sides; numerous tentacula beneath.

There are three species, viz. hydrostatica, rosaces, and filiformis.

49. Medusa.
Body gelatinous, orbicular, and generally flat underneath; mouth central, beneath.

These animals have been denominated sea netales, from the opinion that the larger species, when touched, excite a tingling sensation, and slight redness of the skin. They are supposed to form the chief food of the cetaceous fish; and many of them shine with great brilliancy in the water. The form of their body, while at rest, is that of the segment of a sphere, of which the convex surface is smooth, and the flat part provided with several tentacula. The body is transparent, and so gelatinous, that it is reduced almost to nothing, by evaporation, when left dry upon the shore. Several coloured lines may be seen within; but there is nothing which gives marks of a circulation going on. The lines, indeed, towards the borders are more numerous, but they seem to be appendages of the alimentary cavity. These animals swim very well, and appear to perform that motion by rendering their body alternately more or less convex; and thus striking the water. When left upon the shore, they lie motionless, and look like large flat cakes of jelly.

The species are distributed into two sections.

A. Body with ciliated ribs.
This contains four species, viz. infundibulum, pilum, cucumis, and ovum.

B. Body smooth.

50. Lucernaria.
Body gelatinous, wrinkled, branched; mouth placed beneath.

There are three species, viz. quadricornis, phrygis, and auricula.

51. Asterias.
Body depressed, covered with a coriaceous crust; muriicate, with tentacula, and grooved below; mouth central, and five-rayed.

These
These animals, which are usually called star-fish, or sea-stars, constitute one of the most numerous genera of the mollusca. They are very curious in their forms, but are almost all radiated, as stars are usually painted; and some of them, from the minuteness of their rays, make a very beautiful appearance.

By the coriaceous crust, with which they are covered, they are defended from the attacks of the smaller animals, that inhabit the seas in which they reside. Each of the rays has a great number of short, soft, and fleshy tubes, that serve for tentacula, and seem not only designed for taking prey, but also for enabling it to cling to the rocks, and thus resist the force of the waters. These tentacula have been found to exceed 1,500 in a single animal; they are situated on the lower surface, and when the animal is laid on its back, they may be seen to be pushed out and withdrawn like the horns of snails. The rays enable them to swim, but they move very slowly. These rays are very brittle, and are easily broken off; but when this happens, their power of reproduction is so great, that they are speedily renewed. The mouth is armed with bony teeth, for breaking the shells of the small fish on which they feed; and from the mouth a canal proceeds through each of the rays, becoming narrower as it approaches the tip.

For preserving these animals, Mr. Barbot advises that they be drowned in brandy or other spirits, taking care to keep the rays all the time extended. Then it is easy to draw out the entrails by the mouth with a pair of forceps; and after this is done, the animal may be dried.

There are 45 species distinguished, according as their circumference is more or less divided.

A. Lunata,

Comprehending four species, viz. nobilis, pulvillus, militaris, and luna.

B. Stellata,

C. Radiata,

Many of these are extremely beautiful; but one of the most showy is the caput medusa, or orbiculatus star-fish.

Having five rays, each subdivided, dichotomous; rays and disk granulate; mouth depressed (Vid. fig. 112.).—This extremely singular species is occasionally met with in most seas; but it is not very common. It has five equidistant, thick, jointed rays, proceeding from the centre; and each of them is divided into two other smaller, and each of these again subdivided in a similar manner; and this subdivision is carried, in the most beautiful and regular gradation, to a vast extent, so that the extreme ramifications sometimes amount to several thousands. Mr. Bingley speaks of a specimen that was three feet across, and had 512 extremities to each ray, making in all 2,560. By this curious structure, the animal becomes, as it were, a living net, and is capable of entangling such creatures as are designed for its prey, by the sudden contraction of these numerous ramifications, by the intricacy of which they are prevented from escaping.

The colour of the living animal is a reddish or deep carnation; but when dead it is more of a gray colour. To preserve this curious animal whole and undamaged for cabinets, it should be taken far out at sea, and the fishermen should be careful not to break off any of the limbs, and to keep it as still as possible. It should be dried in the shade in some open place, as in the sun it is apt to melt away, and if too much in the shade, to become putrid.

This species is so valuable, that the fishermen at the Cape get from six to ten rix-dollars for a specimen.

52. Echinus.

Body roundish, covered with a bony crest, and generally furnished with moveable spines; mouth placed beneath, and commonly five-valved.

The animals of this genus are called sea urchins or sea hedgehogs, from the spines which grow on their external covering; they are also called sea eggs, probably from many of them being eatable. They are all inhabitants of the seas; and are so nearly alike in character, that a description of one species will serve to illustrate the whole family.

There are no less than 109 species, which are subdivided as follows.

A. Vent vertical, and all the tentacula simple.

1. Globular or hemispherical,

b. Shaped somewhat like a shield;

Four species, viz. * sinecatus, semiglobulus, quinquilabius, and conoides.

B. Having the vent beneath and no tentacula at the mouth.

a. Base circular, with the vent in the circumference,

Containing five species, viz. alba-grabrus, depressus, * vulgaris, quadrifasciatus, and sexfasciatus.

b. Base exactly circular;

One species, viz. obvolutis.

c. Base oval;

Three species, viz. cycloptomus, semilunaris, and sentiformis.
d. Base oval and acute; vent opposite the mouth;

e. Base irregular, with five expanded petal-shaped marks on the surface.
   1. Margin with angular sinuosities;
      Two species, viz. rosaceus and attus.
   2. Ovate; margin entire;
      Two species, viz. oviformis and orbicularis.

f. Flat on both sides, with petal-shaped avenues; mouth central, flat, and toothed; crown with four pores.
   1. Having a sinuated margin and perforated surface;
      Seven species, viz. birois, pentaporus, hexaporus, emarginatus, auritus, insaurus, and tetraporus.
   2. Having a sinuated margin and entire surface;
      Five species, viz. *laganum*, subrotundus, reticulatus, orbicularis, and gorallatus.

3. Having a toothed margin;
   Three species, viz. decadactylus, octadactylus, orbiculus.

  g. With ten avenues on the crown; rays straight, biporous, and stellate; mouth and vent near each other in the middle of the base;
     13 species, viz. nucleus, centralis, erum, cranialis, turcicus, vicia, ovulum, lathyrus, equinus, minutus, salica, inequalis, raminus, and bunopus.

C. Vent lateral, with pencilled tentacula at the mouth.
   a. Circular; mouth central, vent square;
      One species, viz. placenta.
   b. Heart-shaped, with the crown grooved;
      Two species, viz. cor anguinum and lacunous.
   c. Heart-shaped, with the crown not grooved;
      Eight species, viz. radiatus, purpurus, pusillus, complanatus, *subglobulos*, anachnæus, bicordatus, and carinatus.

c. Ovate, with grooved avenues;
    One species, viz. spatagus.

d. Ovate, with the avenues not grooved;
    Eight species, viz. bissoideis, teres, oliva, amygdala, ovalis, pyriformis, lapiscaneri, and patellaria.

Many of the above have hitherto been found only in a fossil state.

Subglobular, with 10 avenues of pores; and the intermediate spines, covered with small tubercles, supporting the spines (fig. 13.).—This animal, which lodges in cavities of rocks, just within low water mark, on most of the British coasts, is nearly of a globular shape, having its shell marked into ten partitions or divisions, not much unlike those of an orange. The mouth is situated in the lower part, and armed with five strong and sharpened teeth. The stomach and intestines, which are of consi-derable length, are disposed in a somewhat circular form; and the whole body is supported entirely by a set of upright bones or columns.

On the right side of the shell is a prodigious number of sharp moveable spines, of a dull white and greenish colour, curiously articulated, like ball and socket, with tubercles on the surface, and connected by strong filaments to the skin or epidermis, with which the shell is covered. The spines are the instruments by which the animal conveys itself at pleasure from one place to another; and by means of these it is enabled to move at the bottom of the water with great swiftness. It generally employs those about the mouth for this purpose, keeping that opening downwards; but it is also asserted to have the power of moving forwards, by turning on itself like a wheel. When any thing alarms these animals, they immediately move all their spines towards it, and wait an attack, as an army of pikemen would with their weapons. The number of muscles, fibres, and other apparatus necessary to the proper management of these must be very great, and are exceedingly wonderful. So tenacious are the searchings of the vital principle, that on opening one of them, it is no uncommon circumstance to observe the several parts of the broken shell, move off in different directions.

Between the spines, and disposed in a continued longitudinal series on the several divisions or regions of the shell, are an infinite number of very small knobs, communicating with an equal number of tentacula placed above them. These are the instruments by which the creature fixes itself to any object, and stops its motion. They are possessed of a very high degree of contractile power, and are furnished at the extremities with an expansive part, which may be supposed to operate as a spinition, or as the tail of a leech, in fastening the animal securely to rocks and other substances to which they choose to adhere.

The shell of this animal, when deprived of the spines, which easily fall off in dying, is of a pale reddish tinge, and the tubercles on which the spines are fixed, appear like so many pearly protuberances on the surface.

At Marseilles, and in some other towns on the continent, this species is exposed for sale in the markets, as oysters are with us, and is eaten boiled like an egg. It forms an article of food among the lower class on the sea coasts of many parts of this country; but does not seem to have made its way to the tables of the great.

This order of Mollusca contains 32 genera, and about 433 species.

**Order IV. Zoophyta.**

The creatures ranked under this order seem to hold a middle rank between animals and vegetables. Most of them are, like the latter, fixed by a root to a certain spot, from which they never move, and where they sprout and grow; many of them propagate, like plants, by buds, or slips; and some of them appear only to be entitled to rank as animal bodies by their possessing a degree of irritability a little superior to the sensitive plant. Few of them enjoy the faculty of locomotion, though the agility with which they seize their prey, and the instinct which directs them in search of it, shew them to be really animal bodies.
Chap. II.

HELMINTHOLOGY.

55. Millepora.

Animal an hydra or polype; coral mostly branched, and covered with cylindrical, turbinated pores.

56. Cellepora.

Animal an hydra or polype; coral somewhat membranaceous, and composed of round cells.

There are eight species, viz. ramulosa, spengelii, * pumicosa, verrucosa, ciliata, hyalina, nitida, and annulata.

57. Isis.

Animal growing in the form of a plant; stem stony and jointed; the joints longitudinally streaked, united by horny junctures and covered with a soft, porous cellular flesh or bark; the mouths of which are beset with oviparous polyps.

There are six species, viz. hippocirrus, dichotoma, ochracea, * entrocha, * asteria, and cocinea.

58. Antipathes.

Animal growing in the form of a plant; stem expanded at the base, horny within, and beset with small spines; externally covered with a gelatinous flesh beset with numerous polyps bearing tubercles.

There are 13 species, viz. spiralis, ulex, subspinata, myriophylla, alloeocorroides, cupressus, erica, dichotoma, clathrata, flavula, penaea, ericoides, and senilicuare.

59. Gorgonia.

Animal growing in the form of a plant; leathery, corky, woody, horny, or bony; composed of glassy or stony fibres; streaked, tapering, dilated at the base, covered with a cellular flesh or bark, and becoming spongy and friable when dry; mouths covering the surface of the stem and polype-bearing.

There are 41 species, viz. lepadifera, verticillaris, * placomus, mollis, succinia, americana, extasia, patola, ceratothyla, juncea, flammae, embraculum, purpurea, sazappa, planum, radicata, suberosa, coralloides, elongata, scorpius, setacea, viminalis, muricata, * verrucosa, antipathes, * aniceps, nobilis, crassa, pinnata, sanguinolenta, violacea, setosa, pectinaria, pectinata, abietina, caliculata, briaeae, ventalina, reticulum, clathrata, and * flavula.

60. Alcyonium.

Animal generally growing in the form of a plant; stem fixed, fleshy, gelatinous, spongy or leathery, and beset with sessile cells bearing polyps.

There
HELMINTHOLOGY.

61. Spongia.

Animal fixed, flexible, torpid, of various forms, composed either of reticulate fibres, or masses of small spines interwoven together, and clothed with a gelatinous flesh, full of small mouths on its surface, by which it absorbs and rejects water.

The sponges consist of a ramified mass of capillary tubes, that were long supposed to be the production of a species of worms, which are often found within these cavities; an idea, however, which is now nearly exploded. Others have imagined them to be only vegetables; but that they are possessed of animality, appears evident from the circumstances of their pores, alternately contracting and dilating, and from their even shrinking in some degree from the touch, when examined in their native situations. Their structure properly enables them to absorb nourishment from the surrounding fluid.

These animals are certainly the most torpid of all the zoophytes. The individuals differ very much from each other, both in form and structure. Some of them, as the common sponge, are of no determinate figure; but others are cup-shaped, tubular, &c.

*officinalis.* Irregularly formed, porous, rough, lobed, and woolly.

—The official sponge is elastic, and very full of holes; it grows into irregular lobes of a woolly consistence, and generally adheres, by a very broad base, to the rocks. It is chiefly found about the islands in the Mediterranean, where it forms a considerable article of commerce. A variety of small marine animals pierce and gnaw into its irregular winding cavities. These appear on the outside, by large holes raised higher than the rest. When it is cut perpendicularly, the interior parts are seen to consist of small tubes, which divide into branches as they appear on the surface. These tubes, which are composed of reticulated fibres, extend themselves in every way, by this means increasing the surface of the sponge, and ending at the outside in an infinite number of small circular holes, which are the proper mouths of the animal. Each of these holes is surrounded by a few erect pointed fibres, that appear as if woven in the form of little spines. These tubes, with their ramifications, in the living state of the sponge, are clothed with a gelatinous substance, properly called the flesh of the animal. When the sponge is first taken it has a strong fishy smell, and the fishermen take great care in making it perfectly clean, in order to prevent its growing putrid.

62. Flustra, Sea Mat-Weed, or Horn-Wrack.

Animal a polyp, proceeding from porous cells; stem fixed, foliaceous, membranous, composed of numerous rows of cells, united together, and woven like a mat.

63. Tubularia.

Stem tubular, simple or branched, fixed by the base; animal proceeding from the end of the tube, and having its head crested with tentacula.

There are 26 species, viz. *magnifica*, cornucopiea, *indivisa*, *ramosa*, *ramea*, *fistulosa*, *fragilis*, *musoides*, *papyracea*, *pennicillia*, *acetabulum*, *spalacea*, *coryna*, *affinis*, *fabricia*, *longicornis*, *multicornis*, reperne, *campanulata*, *repanta*, *sultana*, *stellaris*, *simplex*, *spallanzanii*, *membranacea*, and *flabelliformis*.

Of these, by far the largest, and probably the most beautiful species, is the magnifica, which is thus characterised by Dr. Shaw.

With a simple whitish tube, and very numerous tentacula, variegated with red and white. Fig. 14. Plate ccl.xi. Fig. 14.

It is found in various parts of the coast of Jamaica, adhering to the rocks. It is very shy, and on being approached, instantly recedes within its elastic tube, which on a farther alarm also retires into the rock, and specimens can be procured only by breaking off such parts of the stone as contain them. These being put into tubs of sea water, may be kept for months in perfect preservation.

64. Corallina.

Animal growing in the form of a plant; stem fixed, with calcareous subdivided branches, mostly jointed.

65. Sertularia.

Animal growing in the form of a plant, stem branched, producing polypes from cup-shaped denticles or minute cells.

There are 77 species, which are distributed into two sections.

A. Stem horny, tubular, fixed by the base, beset with cup-shaped denticles, and furnished with vesicles or ovaries containing polypes, eggs, or the living young.

*Rosacea*, *pomila*, *opercula*, *tamarica*, *abietina*,
HELMINTHOLOGY

B. Stem crustaceous, resembling stone, and composed of rows of cells; no vesicles, but instead of them small globules. Cellularria.

66. PENTATULA, the Sea-pen.

Animal not fixed, of various shapes; supported by a bony part within; naked at the base; the upper part having generally lateral ramifications furnished with rows of tubular denticles, with radiate polypes from each tube.

There are 18 species, viz. coccina, grisea, phosphores, pilosa, robins, mirabilis, sagitta, antennula, stellifera, phaloides, arundinacea, scioxia, junco, granida, argentea, encirrus, cyanomorium, and reniformis.

67. HYDRA, the Polyp.

Animal fixing itself by the base: linear, gelatinous, naked, contractile, and furnished with setaceous tentacula; inhabiting fresh waters, and producing its deciduous offspring from its sides. Fig. 15.

These animals are among the most curious productions of nature, chiefly as exhibiting the most surprising example of diffused vitality. Though not so formidable as the hydra destroyed by Hercules, they are rendered equally prolific by being cut in pieces.

There are about five species, viz. viridis, * fusca, * grisea, gelatinosa, and pallens.

The three first species are those on which the greatest number of experiments have been made; and their shapes are so various, that it is by no means easy to describe them. They are generally found in ditches. Whoever has carefully examined these when the sun is very powerful, will find many little transparent lumps of the appearance of jelly, and size of a pea, and flatted upon one side. The same kind of substances are likewise to be met with on the under side of the leaves of plants that grow in such places. These are the polypes in a quiescent state and apparently inanimate. They are generally fixed by one end to some solid substance, with a large opening, which is the mouth, at the other, having several arms fixed round it, projecting as rays from the centre. They are slender, pellucid, and capable of contracting themselves into very small compass, or of extending to a considerable length. The arms are capable of the same contraction and expansion as the body, and with these they lay hold of minute worms and insects, bringing them to the mouth, and swallowing them. The indigestible parts are again thrown out by the mouth.

The green polype was that first discovered by M. Trem-viridis; and the first appearances of spontaneous motion were perceived in its arms, which it can contract, expand, and twist about in various directions. On the first appearance of danger they contract to such a degree, that they appear little longer than a grain of sand, of a fine green colour, the arms disappearing entirely. Soon afterwards, he found the grisea, and afterwards the fusca. The bodies of the viridis and grisea diminish almost insensibly from the anterior to the posterior extremity; but the fusca is for the most part of an equal size for two-thirds of its length from the anterior to the posterior extremities, from which it becomes abruptly smaller, and then continues of a regular size to the end. These three kinds have at least six, and at most twelve or thirteen arms. They can contract themselves till their bodies do not exceed one-fourth of an inch in length, and they can stop at any intermediate degree of expansion or contraction. They are of various sizes, from an inch to an inch and a half long. Their arms are seldom longer than their bodies, though some have them an inch, and some even eight inches long. The thickness of their bodies decreases as they extend themselves, and vice versa; and they may be made to contract themselves either by agitating the water in which they are contained, or by touching the animals themselves. When taken out of the water they all contract so much, that they appear only like a little lump of jelly. They can contract or expand one arm, or any number of arms, independent of the rest; and they can likewise bend their bodies or arms in all possible directions. They can also dilate or contract their bodies in various places, and sometimes appear thick set with folds, which, when carelessly viewed, appear like rings. Their progressive motion is performed by that power which they have of contracting and dilating their bodies. When about to move, they bend down their heads and arms, lay hold by means of them on some other substance to which they design to fasten themselves; then they loosen their tail, and draw it towards the head; then either fix it in that place, or stretching forward their heads as before, repeat the same operation. They ascend or descend at pleasure in this manner upon aquatic plants, or upon the sides of the vessel in which they are kept; they sometimes hang by the tail from the surface of the water, or sometimes by one of the arms; and they can walk with ease upon the surface of the water. On examining the tail with a microscope, a small part of it will be found to be dry above the surface of the water; and, as it were in a little concave space, of which the tail forms the bottom; so that it seems to be suspended on the surface of the water on the same principle that a small pin or needle is made to swim. When a polype, therefore, means to pass from the sides of the glass to the surface of the water, it has only to put that part out of the water by which it is to be supported, and give it time to dry, which it always does upon these occasions; and they attach themselves so firmly by the tail to aquatic plants, stones, &c., that they cannot be easily disengaged: they often further strengthen these attachments.
The stomach of the polype is a kind of bag or gut into which the mouth opens, and goes from the head to the tail. This, in a strong light, is visible to the naked eye, especially if the animal be placed between the eye and a candle; for these animals are quite transparent whatever their colour may be: the stomach, however, appears to more advantage through a powerful magnifier. M. Trembley, by cutting one of these animals transversely into three parts, satisfied himself that they were perforated throughout. Each piece immediately contracted itself, and the perforation was visible through a microscope. The skin which encloses the stomach is that of the polype itself; so that the whole animal, properly speaking, consists only of one skin, in the form of a tube, and open at both ends. No vessels of any kind are to be distinguished.

The mouth is situated at the anterior end in the middle between the shooting forth of the arms, and assumes different appearances according to circumstances; being sometimes lengthened out in the form of a nipple, at others appearing truncated; sometimes the aperture is quite closed, at others there is a hollow; though at all times a small aperture may be discovered by a powerful magnifier.

The skin of a polype, when examined with a microscope, appears like shagreen, or as if covered with little grains, more or less separated from each other, according to the degree of contraction of the body. If the lips of a polype be cut transversely, and placed so that the cut part of the skin may be directly before the microscope, the skin throughout its whole thickness will be found to consist of an infinite number of grains, and the interior part is found to be more shagreened than the exterior ones; but they are not strongly united to each other, and may be separated without much trouble. They even separate of themselves, though in no great numbers, in the most healthy animals of this kind; for where they are observed to separate in large quantities, it is a symptom of a very dangerous disorder. In the progress of this disorder, the surface of the polype becomes gradually more and more rough and unequal, and no longer well defined or terminated as before. The grains fall off on all sides, the body and arms contract and dilate, and assume a white shining colour; and at last the whole dissolves into a heap of grains, which is more particularly observed in the green polype. By a careful examination we find, that the skin of the polype is entirely composed of grains, cemented by means of a kind of gummy substance; but it is to the grains entirely that the polype owes its colour. The structure of the arms is analogous to that of the body; and they appear shagreened, when examined by the microscope, whether they be in a state of contraction or expansion; but, if very much contracted, they appear more shagreened than the body, though almost quite smooth when in their utmost state of extension. In the green polype the appearance of the arms is continually varying; and these variations are more sensible towards the extremity of the arm than at its origin, but more scattered in the parts further on. The extremity is often terminated by a knob, the hairs of which cannot be observed without a powerful magnifier. They have a remarkable inclination for turning towards the light, so that if that part of the glass, on which they are, be turned from the light, they will quickly remove to the other.

That species named the *fuscus* has the longest arms, *fuscus*, and makes use of the most curious manœuvres to seize its prey. They are best viewed in a glass seven or eight inches deep, when their arms commonly hang down to the bottom. When this or any other kind is hungry, it spreads its arm in a kind of circle to a considerable extent, inclining in this, as in a net, every insect which has the misfortune to come within the circumference. While the animal is contracted by seizing its prey, the arms are observed to swell like the muscles of the human body when in action. Though no appearance of eyes can be observed in the polype, they certainly have some knowledge of the approach of their prey, and shew the greatest attention to it as soon as it comes near them. It seizes a worm the moment it is touched by one of the arms; and in conveying it to the mouth, it frequently twists the arm into a spiral like a cork-screw, by which means the insect is brought to the mouth in a much shorter time than otherwise it would be; and so soon are the insects on which the polypes feed killed by them, that M. Fontana thinks they must contain the most powerful kind of poison; for the lips scarce touch the animal when it expires, though there cannot be any wound perceived on it when dead. The worm, when swallowed, appears sometimes single, sometimes double, according to circumstances. When full, the polype contracts itself, hangs down as in a kind of stupor, but extends again in proportion as the food is digested, and the excrements part is discharged. The bodies of the insects, when swallowed, are first macerated in the stomach, then reduced into fragments, and driven backwards and forwards from one end of the stomach to the other, and even into the arms, which, as well as the other parts of this remarkable creature, are a kind of hollow guts or stomachs. In order to observe this motion, it is best to feed the polypes with such food as will give a lively colour; such, for instance, as those worms which are furnished with a red juice. Some bits of a small black snail being given to the polype, the substance of the skin was soon dissolved into a pulp consisting of small black fragments; and on examining the polype with a microscope, it was found that the particles were driven about in the stomach, and that they passed into the arms, from thence back into the stomach; then to the tail, from whence they passed again into the arms, and so on. The grains of which the body of the polype consists, take their colour from the food with which it is nourished, and become red or black as the food happens to afford the one or the other. They are likewise more or less tinged with these colours in proportion to the strength of the nutritive juices; and it is observable that they lose their colour if fed with aliments of a colour different from themselves. They feed on most insects, and fish or flesh, if cut into small bits. Sometimes two polypes lay hold of the same worm, and each begins to swallow its own end till their mouths meet, and the worm breaks. But should this happen not to be the case, the one polype will sometimes devour the other along with its portion.
HELMINTHOLOGY.

Chap. II.

Species. It appears, however, that the stomach of one polyp is not fitted for dissolving the substance of another; for the one which is swallowed always gets clear again after being imprisoned an hour or two.

The manner in which the polypes generate is most perceptible in the grisea and fusca, as being considerably larger than the viridis. If we examine one of them in summer, when the animals are most active, and prepared for propagation, some small tubercles will be found proceeding from its sides, which constantly increase in bulk, until at last in two or three days they assume the figure of small polypes. When they first begin to shoot, the excrescence becomes pointed, assuming a conical figure, and deeper colour than the rest of the body. In a short time it becomes truncated, and then cylindrical, after which the arms begin to shoot from the anterior end. The tail adheres to the body of the parent animal, but gradually grows smaller, until at last it adheres only by a point, and is then ready to be separated. When this is the case, both the mother and young ens fix themselves to the sides of the glass, and are separated from each other by a sudden jerk. The time requisite for the formation of the young ones is very different, according to the warmth of the weather and the nature of the food eaten by the mother. Sometimes, they are fully formed, and ready to drop off in 24 hours; in other cases, when the weather is cold, 15 days have been requisite for bringing them to perfection.

It is remarkable, that there is a reciprocal communication of food between the young and old, before they are separated. The young ones, as soon as they are furnished with arms, catch prey for themselves, and communicate the digested food to the old ones, who on the other hand do the same to the young ones. This was fully verified by the following experiment. One of the large polypes of the fusca kind being placed on a slip of paper in a little water, the middle of the body of a young one growing out from it was cut open; when the superior part of that end which remained fixed to the parent was found to be open also. But cutting over the parent polype on each side of the shoot, a short cylinder was obtained, open at both ends; which being viewed through a microscope, the light was observed to come through the young one into the stomach of the old one. On cutting open the portion of the cylindrical portion lengthwise, not only the hole of communication was observed, but one might see through the end of the young one also. On changing the situation of the two pieces, the light was seen through the hole of communication. This may be seen between the parent polypes and its young ones after feeding them; for after the parents have eaten, the bodies of the young ones swell as if they themselves had been eating.

The polypes produce young ones indiscriminately from all parts of their bodies, and five or six young ones have frequently been produced at once; nay, M. Trembley has observed nine or ten produced at the same time.

Nothing like copulation among these creatures was ever observed by M. Trembley, though for two years he had thousands of them under his inspection. To be more certain on this subject, he took two young ones

Vol. X. Part I.

the moment they came from their parent, and placed them in separate glasses. Both of them multiplied, not only themselves, but also their offspring, which were separated and watched in the same seventh generation. They have ever the same power of generation, while adhering to their parent. In this state the parent, with its children and grandchildren, exhibits a singular appearance, looking like a shrub thick set with branches. Thus several generations sometimes are attached to one another, and all of them to one parent. Mr Adams gives a figure of one polyp with 19 young ones hanging at it; the whole group being about one inch broad, and one inch and a half in length; the old polypate about 12 monocii per day, and the young ones about 20 among them.

When a polyp is cut transversely or longitudinally into two or three parts, each part in a short time becomes a perfect animal; and so great is this prolific power, that a new animal will be produced even from a small portion of the skin of the old one. If the young ones be mutilated while they grow upon the parent, the parts so cut off will be reproduced; and the same property belongs to the parent. A truncated portion will send forth young ones before it has acquired a new head and tail of its own, and sometimes the head of the young one supplies the place of that which should have grown out of the old one. If we slit a polyp longitudinally through the head to the middle of the body, we shall have one formed with two heads; and by again slit ting these in the same manner, we may form one with as many heads as we please.

A still more surprising property of these animals is, that they may be grafted together. If the truncated portions of a polyp be placed end to end, and gently pushed together, they will unite into a single one. The two portions are first joined together by a slender neck, which gradually fills up and disappears, the food passing from one part into the other; and thus we may form polypes, not only from different portions of the same animal, but from those of different animals. We may fix the head of one to the body of another, and the compound animal will grow, eat and multiply, as if it had never been divided. By pushing the body of one into the mouth of another, so far that their ends may be brought into contact, and kept in that situation for some time, they will at last unite into one animal, only having double the usual number of arms. The Hydra furca may be turned inside out like a glove, at the same time that it continues to eat and live as before. The lining of the stomach now forms the outer skin, and the former epidermis constitutes the lining of the stomach. If previous to this operation the polype have young ones attached to it, such are newly beginning to vegetate turn themselves inside out, while the larger ones continue to increase in size till they reach beyond the mouth of the parent, and are then separated in the usual manner from the body. When thus turned, the polyp combines itself in many different ways. The fore part frequently closes and becomes a supernumerary tail. The animal, which was at first straight, now bends itself, so that the two tails resemble the legs of a pair of compasses, which it can open and shut. The old mouth is placed as it were at the joint of the compasses, but loses its power of action; to supply which

Z z
HELMINTHOLOGY.

Species. Infusoria.

a new one is formed in its neighbourhood, and in a little time there is a new species of hydra found with several mouths.

The sides of a polype which has been cut through in a longitudinal direction, begin to roll themselves up, usually from one of the extremities, with the outside of the skin inwards; but in a little time they unroll themselves, and the two cut edges join together, sometimes beginning at one extremity, and sometimes approaching throughout their whole length. As soon as the edges join, they unite so closely that no scar can be perceived. If a polype be partly turned back, the open part closes, and new mouths are formed in different places. Every portion of a polype is capable of devouring insects, almost as soon as it is cut off, and the voracity of the whole tribe is astonishing; for Mr Adams observes, that most of the insects on which they feed bear the same proportion to the mouth of a polype, that an apple the size of a man's head bears to the mouth of a man.

The hydra pallens is very rarely met with, and is described by Mr Roiselle. It is of a pale yellow colour, growing gradually smaller from the bottom; the tail is round or knobbed; the arms are about the length of the body, of a white colour, generally seven in number, and are apparently composed of a chain of globules. The young are brought forth from all parts of its body.

The order Zoophyta contains 15 genera and 489 species.

ORDER V. INFUSORIA.

We have already, under the article ANIMALCULE, treated of the general character and habits of the animals composing this order, and we can add little here to what has been said in that article. We shall therefore merely give the classification of the genera and species, and briefly notice a few of the more remarkable individuals.

Few writers have written expressly on this order; but the principal are Muller, Bruijier, in the Encyclopedie Methodique, and Baker and Adams on the Microscope.

68. Brachionus.

Body contractile, covered with a shell, and furnished with rotatory cilia.

There are about 12 species, viz. urceolaris, patella, cirratus, tripus, uncinatus, macronatus, cornua, calycifloris, tubifex, quadridenatus, patis, and striatus.

The patis is extremely bright and splendid, has a large body, a crystalline and nearly circular shell, without either incision or teeth, only towards the apex it falls in so as to form a smooth notch. A double glittering organ, with ciliated edges, projects from the apex; both of them of a conical figure, and standing as it were upon a bellucida substance, which is divided into two lobes, between which and the rotatory organ there is a silver-coloured crenulated membrane. Two small claws may likewise be discovered near the mouth.

The striatus has an oblong, bellucida shell, capable of altering its figure. The apex is truncated, with six small teeth on the edge of it, 12 longitudinal streaks down the back, the base obtuse and smooth. The teeth are occasionally protruded or retracted; and there are two small spines or horns on the other side of the shell. The animal itself is of a yellow colour, crystalline, and muscular; now and then putting out from the apex two or three little bundles of playing hairs, the two lateral ones shorter than that in the middle; on the outer side we may observe a forked deglutitory muscle, and two rigid points when the apex is drawn in. It is found in sea water.

69. Vorticella.

Body contractile, naked, and furnished with ciliate, rotatory organs.

There are about 37 species, which are arranged under three sections.

A. Seated on a pedicle or stem.

29 species, viz. racemosa, polypina, anastatica, conglomerata, pyraia, opercularia, tuberosa, bians, bellis, umbellaria, berberina, digitalis, fasciculata, annularia, nutans, gellula, nebulifera, convallaria, lusaria, globularia, inclinans, ringens, pyriformis, stellata, vaginata, citrina, cyathina, putrida, and patellina.

B. Furnished with a tail.

14 species, viz. fuscousa, socialis, stenotrema, hyacinthina, auriculata, furcata, sents, catulus, felis, vermicularia, macoura, rotatoria, inaequala, and acculata.

C. Without tail or stem.

14 species, viz. amulla, cratagaria, caniculata, nasuta, crateriformis, truncatella, limacina, discina, cornuta, cineta, polymorpha, viridia, bursata, and nigra.

The polypina, when viewed through a small magnifying glass, appear like so many little trees; the upper part, or heads, are egg-shaped, the top truncated, the lower part filled with intestines; the branches thick set with little knobs. Fig. 16.

The fasciculata has a rotatory organ, which may sometimes be seen projecting beyond the aperture; there is a little head at the apex, and the pedicle is twisted and very slender. A congealed green mass which is often found swimming about in ditches is composed of myriads of these animals, which are not visible to the naked eye, and when magnified appear like a bundle of green flowers.

The socialis, when considerably magnified, appears like a circle surrounded with crowns or ciliated heads, tied by small thin tails to a common centre, from whence they advance towards the circumference, where they turn very briskly, occasioning a kind of whirlpool, which brings its food. When one of them has been in motion for some time, it stops, and another begins; sometimes two or three may be perceived in motion at once; they are frequently to be met with separate, with the tail sticking in the mud. The body contracts and dilates very much, so as sometimes to have the appearance of a cudgel, at others to assume almost a globular form.

The
The flosculosa appears to the naked eye like a yellow globule adhering to the ceratephyllion like a little flower or a heap of yellow eggs. When magnified, they are seen to consist of a congeries of animulae constituting a sphere from a monolyth centre. They contract and unroll the bodies either alone or in society, and excite a vortex in the water by means of a disk. When they quit the society and act singly, they may be observed to consist of a head, abdomen, and tail; the head being frequently drawn back into the abdomen so far that it cannot be seen, only exhibiting a broad kidney-shaped disk standing out. The abdomen is olbong, oval, and transparent; the tail sharp, twice as long as the abdomen, sometimes rough and annulated, or altogether smooth.

Trichoda.

70. TRICHODA.

Animal invisible to the naked eye, pellucid, hairy, or horned.

There are about 60 species, which are divided into three sections.

A. Hairy.

B. Furnished with cirri.

C. Horned.

The grandinella is a very small pellucid globule, with the intestines scarcely visible; the top of the surface furnished with several small bristles not easily discoverable, as the creature has a power of extending or drawing them back in an instant. It is found in pure water as well as in infusions of vegetables.

The sol is small, globular, and crystalline; beset everywhere with diverging rays longer than the diameter of the body; the inside full of molecules. The body contracts and dilates, but the creature remains confined to the same spot. It was found with other animulae in water which had been kept three weeks.

The proteus is that which Mr Baker distinguishes by the same name, and of which an account is given under the article ANIMALCULE. It is found in the slimy matter adhering to the sides of the vessel in which vegetables have been infused, or animal substances preserved. That described by Mr Adams was discovered in the slime produced from the water where small fishes, water snails, &c. had been kept. The body resembled that of a snail, the shape being somewhat elliptical, but pointed at one end, while from the other proceeded a long, slender, and finely proportioned neck, of a size suitable to the rest of the animal.

71. CERCARIA.

Animal invisible to the naked eye, pellucid, and furnished with a tail.

The lema varies its form so much, that it might be mistaken for the proteus of Baker, described under the article ANIMALCULE: though in fact it is totally different. The body sometimes appears of an olbong, sometimes of a triangular, and sometimes of a kidney-shape. The tail is generally short, thick, and annulated; but sometimes long, flexible, cylindric, and without rings; vibrating, when stretched out, with so much velocity, that it appears double. A small pellucid globule, which Muller supposes to be its mouth, is observable at the apex; and two black points not easily discovered, he thinks, are its eyes. It walks slowly after taking three or four steps, and extends the tail, erecting it perpendicularly, shaking and bending it, in which state it very much resembles a leaf of the lema.

72. LEUCOPHRA.

Animal invisible to the naked eye, and every where ciliate.

73. GONIUM.

Animal very simple, flat, angular, but invisible to the naked eye.

There are five species; viz. *pectorale, *pulvinatum, *polysphericum, *truncatum, and *rectangulum.

The pectorale is founded in pure water, and moves al-pectorale, alternately towards the right and left. It is quadrangular and pellucid, with 16 spherical molecules, of a greenish colour, set in a quadrangular membrane, like the jewels in the breast-plate of the high priest, reflecting light on both sides.

74. COLPODA.

Animal invisible to the naked eye, very simple, pellucid, sinuate.

There are seven species; viz. lamella, rostrum, *measgris, *coccus, ren, *pyrum, and hypocrepis.

The coccus is found in vegetable infusions, and in sedid hay, moving in all directions, and commonly with great velocity. It is very pellucid, and has a well defined margin, filled with little bright vesicles differing in size, and of no certain number. Its figure is commonly oval, with the top bent into a kind of beak, sometimes olbong, but most commonly obtuse. It has in the inside from 8 to 24 bright little vesicles not discernible in such as are young. Some have sup
HELMINTHOLOGY.

Chap. II.

There are 15 species; viz. viridis, punctifera, nodulosa, fuscum, seminum, ovulum, pyrum, fusus, trilus, caudata, epistemum, retrograda, truncus, spatula, and papula.

80. BACILLARIA. 88

Body consisting of cylindrical straw-like filaments, placed parallel to each other, and frequently changing their position.

There is only one species; viz. paradoxa.

81. VOLVEx. 89

Worm invisible to the naked eye; simple, pellucid, spherical.

There are nine species; viz. globulus, pilula, sphaera, aca, lunula, dimidiatus, globator, pileus, and bulla.

The globator, or spherical membraneous volvox, is globator, found in great numbers in the infusions of hemp and tremella, and in stagnant waters in spring and summer. It was first observed and dissected by Leewenhoek; but the descriptions of it given by authors differ considerably from each other. The following is that of Mr. Baker. "There is no appearance of either head, tail, or fins. It moves in every direction, backwards, forwards, up or down, rolling over and over like a ball, spinning horizontally like a top, or gliding along smoothly without turning itself at all: sometimes its motions are very slow, at other times very swift; and when it pleases it can turn round as upon an axis very nimbly, without moving out of its place. The body is transparent, except where the circular spots are placed, which are probably its young. The surface of the body in some is as if all dotted over with little points, and in others as if granulated like shagreen. In general it appears as if set round with short movable hairs." Another author informs us, that "they are first very small, but grow so large that they can be discerned with the naked eye; they are of a yellowish green colour, globular figure, and in substance membraneous and transparent; and in the midst of this substance several small globes may be perceived. Each of these are smaller animalcula, which have also the diaphanous membrane, and contain within themselves still smaller generations, which may be distinguished by means of very powerful glasses. The larger globules may be seen to escape from the parent, and then increase in size."

This little animal appears like a transparent globule of a greenish colour, the fetus being composed of smaller greenish globules. In proportion to its age it becomes whiter and brighter, and moves slowly round its axis; but to the microscope its surface appears as if granulated; the roundest molecules fixed in the centre being largest in those that are young. The exterior molecules may be wiped off, leaving the membrane naked. When the young ones are of a proper size, the membrane opens, and they pass through the fissure, after which the mother melts way. Sometimes they change their spherical figure, and become flat in several places.

They
HELMINTHOLOGY.

They contain from 8 to 30 and 40 globules within the membrane.

82. MONAS.

Worm invisible to the naked eye; most simple, pellucid, resembling a point.

There are five species; viz. *atomus, punctum, *mica, *lens, and termo.

This order contains 15 genera and 220 species.

How many kinds of these invisibles there may be (says Mr Adams), is yet unknown; as they are discerned of all sizes, from those which are barely visible to the naked eye, to such as resist the force of the microscope as the fixed stars do that of the telescope, and with the greatest powers hitherto invented, appear only as so many moving points. The smallest living creatures our instruments can shew, are those which inhabit the waters; and though animalcula equally minute may fly in the air, or creep upon the earth, it is scarce possible to get a view of them; but as water is transparent, by confining the creatures within it we can more easily observe them by applying a drop of it to the glasses.

Animalcula in general are observed to move in all directions with equal ease and rapidity; sometimes obliquely, sometimes straight forward; sometimes moving in a circular direction, or rolling upon one another, removing backwards and forwards through the whole extent of the drop, as if diverting themselves; at other times greedily attacking the little parcels of matter they meet with. Notwithstanding their extreme minuteness, they know how to avoid obstacles, or to prevent any interference with one another in their motions: sometimes they will suddenly change the direction in which they move, and take an opposite one; and by inclining the glass on which the drop of water is, as it can be made to move in any direction, so the animalcula appear to move as easily against the stream as with it. When the water begins to evaporate, they flock towards the place where the fluid is, and show a great anxiety and uncommon agitation of the organs with which they draw in the water. These motions grow languid as the water fails, and at last cease altogether, without a possibility of renewal if they be left dry for a short time. They sustain a great degree of cold as well as insects, and will perish in much the same degree of heat that destroys insects. Some animalcula are produced in water at the freezing point, and some insects live in snow. By mixing the least drop of urine with the water in which they swim, they instantly fall into convulsions and die.

The same rule seems to hold good in these minute creatures, which is observable in the larger animals, viz. that the larger kinds are less numerous than such as are smaller; while the smallest of all are found in such multitudes, that there seem to be myriads for one of the others. They increase in size, like other animals, from their birth until they have attained their full growth; and when deprived of proper nourishment, they in like manner grow thin and perish.

EXPLANATION OF FIGURES.

Fig. 1. *Ascaris Lumbricoides*, entire, and nearly of its natural size; *a*, the head; *b*, the tail; *c*, the depressed band; *d*, the punctiform aperture; *e*, the line extending from the head to the tail; *f*, the gyrate apparatus as it appears through the skin of the worms.

Fig. 2. Represents the viscera of the worm in their natural situation; *a*, the head; *b*, the gullet; *c*, the intestinal canal; *d*, the lines of the body of the worm; *e*, the uterus, and its convoluted apparatus.

Fig. 3. *Ascaris Vermiculata* of its natural size.

Fig. 4. The same viewed by the microscope; *a*, the head; *b*, the tail; *c*, the pistilliform stomach; *d*, a convoluted apparatus surrounding the intestinal canal; *e*, an orifice which is probably the anus; *f*, the external part of the organs of generation.

Fig. 5. *Trichurus Hominis*, of its natural size.

Fig. 6. The same considerably magnified; *a*, *a*, the head; *b*, the tail; *c*, the proboscis; *d*, the intestinal canal; *e*, a hollow tube; *f*, the ovary.

HEL

HELLEON. HELHEN

HELLEON. HELHEN

HELOISE, celebrated on account of her unfortunate affection for her tutor Abelard, and for her Latin letters to him after they had retired from the world. She died abbess of Paraclet in 1163. See ABELARD.

HELOS, in Ancient Geography, a maritime town of Locris, situated between Trinacria and Messenia, in the time of Pausanias. The district was called Helotes, and the people Helotes, Helotes, Helotes, and Helotes, by Stephanus; and Iotes, by Livy. Being subdued by the Lacedaemonians, they were all reduced to a state of public slavery, or made the slaves of the public, on these conditions, viz. that they neither could recover their liberty nor be sold out of the territory of Sparta.

Hence
Hence the term helotes, in Harpocracy, for being in a state of slavery; and hence also the Lacedaemonians called the slaves of all nations whatever helotes. Helotus is the epithet.

HELOTS, in Grecian antiquity, the slaves of the Spartans. See Helos.—The freemen of Sparta were forbidden the exercise of any mean or mechanical employment, and therefore the whole care of supplying the city with necessaries devolved upon the Helots.

HELSINBURG. See Elsinburg.

HELSINGIA, a province of Sweden, bounded on the north by Jemteland and Medelpada, on the east by the Bothnic gulf, and on the south and west by Dalecarlia and Gestricia. It is full of mountains and forests, and the inhabitants are almost constantly employed in hunting and fishing. It has no cities; the principal towns are, Hudwikvall, Alta, and Dilsbo.

Helsingic character, a peculiar kind of character found inscribed on stones in the province of Helsingia. The Runic and Helsingic characters may be easily transformed into each other.

HELSTON, a town of Cornwall in England, seated on the river Cober, near its influx into the sea, one of the towns appointed for the coinage of tin, and the place of assembly for the west division of the county. It had formerly a priory and a castle, and sent members to parliament in the reign of Edward I. but was not incorporated till the time of Queen Elizabeth. It was re-incorporated in 1774. A little below the town there is a tolerable good harbour, where several of the tin-ships take in their lading. King John exempted this place from paying toll any where but in the city of London. It contained 2297 inhabitants in 1811, and sends two members to parliament.

HELVELLA, a genus of the natural order of fungi, belonging to the cryptogamia class of plants. See Botany Index.

HELVETIC, something that has a relation to the inhabitants of the Swiss cantons, who were anciently called Helvetii.—The Helvetic body comprehends the republic of Switzerland, consisting of 13 cantons, which make so many particular commonwealths. By the laws and customs of the Helvetic body, all differences between the several states and republics are to be decided within themselves, without the intervention of any foreign power. The government of this body, before its subjugation to France, was chiefly democratic, with some mixture of the aristocratic.

HELVETII, a people of Belgia, in the neighbourhood of the Allourges and the Provincia Romana; famed for bravery and a turn for war. Called Civis Helvetii, and divided into four pagi or cantons; situated to the south and west of the Rhine, by which they were divided from the Germans; and extending towards Gaul, from which they were separated by Mount Jura on the west, and by the Ithodan and Lucus Lemanus on the south, and therefore called a Gallic nation (Tacitus, Caesar, Strabo, Piolemey, Pliny). Formerly a part of Celtic Gaul, but by Augustus assigned to Belgica.

HELVETIUS, Claud-Adrian, a man of letters, and celebrated French philosopher, was born at Paris, in the year 1715. After receiving the rudiments of his education in his father's house, he was sent to the college of Louis the Great, where he discovered greater indications of genius than any of his fellow students, and thus gained the esteem of the professor of rhetoric, by whom particular attention was paid to his education. By his elegant and graceful exterior he endeavoured to ingratiate himself with the fair sex; but he was soon convinced, that although external accomplishments may dazzle for the moment, nothing short of intellectual accomplishments can secure the conquest. The circumstance which led him to perceive the absolute necessity of mental improvement in order to be truly esteemed and admired, is worthy of notice. When walking alone in one of the public gardens, he discovered a most extravagant figure amidst a circle of young and amiable ladies. This was M. Maupertuis, who engaged all the care and attention of this charming group, notwithstanding the ridiculous and grotesque singularity of his dress. This convinced Helvetius that if he wished to be sincerely admired or esteemed, dancing, tennis, and all other bodily exercises must give place to the decoration of his mind. He therefore immediately became a solitary, silent student, and the mathematics in particular first attracted his notice; and in a short time he was deemed a fit companion for some of the first and most distinguished literary characters of the period in which he flourished. Voltaire and Montesquieu were among his early intimates; with the latter of whom he contracted a cordial and lasting friendship.

The first literary performance of M. Helvetius was of the poetic kind, consisting of epistles on happiness, but these were not communicated to the public till after his decease. When read in private, however, they were very much admired, and Voltaire considered them as a strong proof of the didactic and philosophical powers of their author. When the L'Esprit des Lois of Montesquieu appeared in public, it was studied by Helvetius with the utmost care and attention, and his only fault to it was, that it did not contain the first ideas of the things of which it professed to treat. Instead of examining systems of legislation, and comparing them with each other, Helvetius was of opinion, that the nature of man should be first studied, and the laws for governing him founded on his own nature. This was true philosophy, and such ideas determined him to undertake a work which might supply what he conceived to be defects in the publication of Montesquieu. In the year 1752 this work made its appearance, under the title of De l'Esprit, &c. which was condemned by the parliament of Paris, because it was considered as degrading the nature of man; but this impolitic method of suppressing his labours made them sought for with avidity all over France, as well as other European countries, and gave them more importance than perhaps they would have otherwise acquired.

To avoid the malice of his enemies, he came over to England in the year 1752, and in the following year he went to Prussia, where he was received by the king with every mark of respect, who gave him lodgings in the palace, and admitted him into his familiar parties. He was uncommonly liberal to the indigent, some of whom but ill required him, on which occasions he was wont to say to his friends, "If I were a king, I would correct them; but as I am only rich, and they are poor, I did my duty in relieving them." Notwithstanding his constitution was excellent, from which his friends concluded that they would long enjoy the happiness of
HEMIDIANS, a sect of ancient heretics, denominated from their leader Helvidius, a disciple of Auerentius the Arian, whose distinguishing principle was, that Mary, the mother of Jesus, did not continue a virgin, but had other children by Joseph.

HELOET-SLUYS, a sea-port town of the United Netherlands, seated on the island of Voorn, in the province of Holland, and where the English packet-boat always goes. It is but a small place, consisting only of a handsome quay, and two or three little streets. But it is very well fortified, and esteemed the safest harbour in the country. The largest men of war may come up to the middle of the town; and yet it has but very little trade, because the merchants choose to live higher up the country. It surrendered to the French in 1795.

HEMAT, or Hamath, in Ancient Geography, the name of a city (whose king was David's friend, 2 Sam. ix.) to the south of Lebanon, from which a territory was called Hemath, on the north of Canaan and south of Syria, as appears by the spies, Numb. xii. 1 Kings viii. Ezek. xlvii. Whether one or more cities and districts of this name lay in this tract, neither interpreters nor geographers are agreed. The eastern part was called Hemath-woba, 2 Chron. viii. unless we suppose that there was a city in Loba of this name, fortified by Solomon. In defining the boundary of Palestine, it is often said, from the entering of Hamath; as a province to be entered into through a strait or defile. And if there was such, the next question is, From what metropolis it was called Hemath. Antioch, capital of Syria, is supposed to be called Hemath or Amathas, (Jonathan, Targum, &c.) and again, Epiphania (Josephus). Both were to the north of Lebanon; consequently not the Hamath of Scripture, the immediate boundary of Palestine to the north, and lying to the south of Lebanon.

HEMATITES, an ore of iron. See Hematites, Mineralogy Index.

HEMEROBAPISTS, a sect among the ancient Jews, thus called from their washing and bathing every day, in all seasons, and performing this custom with the greatest solemnity, as a religious rite necessary to salvation.

Epiphanius, who mentions this as the fourth heresy among the Jews, observes, that in other points these heretics had much the same opinions as the Scribes and Pharisees; only that they denied the resurrection of the dead, in common with the Saducees; and retained a few other of the improprieties of these last.

The sect who pass in the East under the denomination of Sabians, calling themselves Mandai Tishri, or the disciples of John, and whom the Europeans entitle the Christians of St. John, because they yet retain some knowledge of the gospel, is probably of Jewish origin, and seems to have been derived from the ancient Hemero-baptists; at least it is certain, that that John, whom they consider as the founder of their sect, bears no sort of similitude to John the Baptist, but rather resembles the person of that name whom the ancient writers represent as the chief of the Jewish Hemero-baptists. These ambiguous Christians dwell in Persia and Arabia, and principally at Bassora; and their religion consists in bodily washings, performed frequently, and with great solemnity, and attended with certain ceremonies, by which the priests mingle with this superstitious service.

HEMEROBIUS, a genus of insects belonging to the neuroptera order. See Entomology Index.

HEMEROCAILLIS, Das-Lily, or Lily Asphodel; a genus of plants belonging to the hexandria class, and in the natural method ranking under the 10th order, Coronaria. See Botany Index.

HEMEROEROMI, (compound of ιωμη, "day," and ἑσποε, "course," &c.) among the ancients, were sentinels or guards, appointed for the security and preservation of cities and other places. They went out of the city every morning, as soon as the gates were opened, and kept all day patrolling round the place; sometimes also making excursions farther into the country, to see that there were no enemies lying in wait to surprise them.

HEMEROEROMI were also a sort of couriers among the ancients, who only travelled one day, and then delivered their packets or dispatches to a fresh man, who ran his day, and so on to the end of his journey. The Greeks had couriers of this kind, which they derived from the Persians, who were the inventors thereof, as appears from Herodotus. Augustus had the same; at least he established couriers, who, if they did not relieve each other from day to day, yet did it from space to space, and that space was not very great.

HEMEROOTROPHIS, in antiquity, a measure of capacity, the same with the choinix. It was so called from its holding one day's food. The word is compounded of ιωμη, a day, and ἑσποε, food.

HEMI, a word used in the composition of divers terms. It signifies the same with semis or demi, viz. "half;" being an abbreviation of ιωμης, hemis, which signifies "the same." The Greeks retrenched the last syllable of the word ιωμης in the composition of words; and after their example, we have done so too in most of the compounds borrowed from them.

HEMOCRANIA, in Medicine, a species of cephalalgia, or headach; wherein only one side of the head is affected; and owing to a congestion of blood in the vessels of that half.

HEMICYCLE, Hemicyclium, composed of ιωμης, half, and ιως, circle; a semicircle.

Hemicycle is particularly applied, in Architecture, to vaults in the cradle form; and arches or sweeps of vaults, constituting a perfect semicircle. To construct an arch of hewn stone, they divide the hemicyle into so many voussoirs; taking care to make them an uneven number, that there be no joint in the middle, where the key-stone should be. See Key and Bridge.
HEMICYCLiUM was also a part of the orchestra in the ancient theatre. Scaliger, however, observes, it was no standing part of the orchestra; being only used in dramatic pieces, where some person was supposed to be arrived from sea, as in Plautius's "Rudens."

The ancients had also a sort of sun-dial, called hemicycliun. It was a concave semicircle, the upper end or cusp whereof looked to the north. There was a style, or gnomon, issuing from the middle of the hemicycle, whereof that point corresponding to the centre of the hemicycle represented the centre of the earth; and its shadow projected on the concavity of the hemicycle, which represented the space between one tropic and another, the sun's declination, the day of the month, hour of the day, &c.

HEMINERIS, a genus of plants belonging to the didynamia class. See Botany Index.

HEMINA, in Roman antiquity, a liquid measure, which, according to Arbuthnot, was equal to half a wine pint English measure; its contents being 2.818 solid inches.

HEMIBOLON, a weight often mentioned by the ancient writers in medicine, and expressing the half of their obolus, or the twelfth part of a drachm, that is, five grains.

HEMIONITIS, a genus of plants of the order of sylices, belonging to the cryptogamia class. See Botany Index.

HEMIPLEGIA, or HEMPLEXIA, among physicians, a palsy of one half of the body. See Medicine Index.

HEMIPTERA, derived from τρισμος, half, and πτερος, wing, in the Linnaean system, the second order of insects, comprehending the blatta, mantis, gryllus, &c. See Entomology Index.

HEMISPHERE, (HEMISPHERIUM, compounded of θρων, half, and σφαιρος, sphere), in Geometry, is one half of a globe or sphere, when divided into two by a plane passing through its centre.

HEMISPHERE, in Astronomy, is particularly used for one-half of the mundane sphere.

The equator divides the sphere into two equal parts, called the northern and southern hemispheres. The horizon also divides the sphere into two parts, called the upper and the lower hemispheres.

HEMISPHERE is also used for a map, or projection, of half the terrestrial globe, or half the celestial sphere, on a plane. Hemispheres are frequently called planispheres.

HEMISTICH, in Poetry, denotes half a verse, or a verse not completed.

Of this there are frequent examples in Virgil's Æneid; but whether they were left unfinished by design or not is disputed among the learned: such are, Ferro accincta vocat, Æn. ii. 614. And, Italian non opere sequor, Æn. iv. 361.

In reading common English verses, a short pause is required at the end of each hemistich or half verse.

HEMITON, in the ancient music, was what we now call a half note or semitone.

HEMITOR, in Medicine, a kind of fever, denoting the same as semi-tertian, returning twice every day. The word is Greek, and compounded of ἑμι, "half," and τριτεριας, "third or tertian."

HEMLOCK. See Cicuta and Conium, Botany Index.

HEMOPTETON. See Oratory, No. 77.

HEMP. See Cannabis, Botany Index.—It does not appear that the ancients were acquainted with the use of hemp, in respect of the thread it affords. Pliny, who speaks of the plant in his natural history, lib. xx. cap. 23. says not a word of this; contenting himself with extolling the virtues of its stem, leaves, and root. In effect, what some writers of the Roman antiquities remark, viz. that the hemp necessary for the use of war was all stored up into two cities of the western empire, viz. at Ravenna and Vienne, under the direction of two procurators, called procuratores linicius, must be understood of linen or flax.

The use of hemp is so extensive and important, that vast quantities of it are annually imported into this and other kingdoms from those countries where it grows in greatest plenty, at which Russia is one. In the year 1763, the quantity imported into England alone amounted to 11,000 tons. Sir John Sinclair informs the Annals of us, that in the year 1755, the quantity exported from Petersburg in British ships was as follows:

<table>

Now, allowing 63 poods to a ton, the quantity just mentioned will amount to 17,695 tons; and supposing it to take five acres to produce a ton of hemp, the whole quantity of ground requisite for this purpose would amount to 88,475 acres.

By other accounts, the annual export of hemp to the American colonies amounted to 400,000 bushels; but by a computation Agricultural of the whole imported into Britain and Ireland in 1788, it would seem that a considerably greater quantity must fall to the share of England. In that year the quantity amounted to no less than 58,945 tons; which at 201. per ton amounted to £269,260. We cannot wonder at this vast consumption, when it is considered that the sails and cordage of a first-rate man of war require 180,000 lb. of rough hemp for their construction; but even this will scarce account for the enormous consumption in France, which in the year 1783 is said to have amounted to upwards of 400 millions of pounds, or 200,000 tons; of which more than one-third was imported.

Only the coarser sorts of hemp are employed in making cordage, the better sorts being used for linen, which, though it can never be made so fine as that from flax, is yet incomparably stronger, and equally susceptible of bleaching both in the old and new way. Cloths made of hemp have also this property, that their colour improves by wearing, while that of linen decays. The prices of hemp linen are various; from 10d. to 4s. 6d. per yard. The low-priced kinds are very generally worn in Suffolk, where hemp is cultivated, by husbandmen, farmers, &c., those from 1s. 6d. to 2s. by farmers and tradesmen; and those from 2s. 6d. to 4s. 6d. are frequently preferred by gentlemen to flaxlinen,
Hemp. An acre produces on an average 36 or 38 stone. The abbé Brulé, in a treatise upon the Cultivation and Management of Hemp, printed by order of the lords of the committee of council for trade and foreign plantations, informs us, that the season for sowing it extends from the 25th of March to the 15th of June. The seed ought always to be sown thin, not exceeding two bushels to an acre; and if you have the advantage of a drill plough, still less will answer. As there are two kinds of hemp, the male and female, of which the former only produces seed, some regard must be had to this circumstance. In Sussex the male and female are pulled together about 13 weeks after the sowing, but in the fens they are frequently separated. This last method is recommended by the abbé Brulé, who, for the more easy accomplishment of it, directs that little paths should be made lengthwise through the field at about seven feet distance from each other, to allow a passage for the person who pulls up the female hemp from among the other; the latter requiring to stand more than a month after for the purpose of ripening the seeds. The female hemp is known to be ripe by the fading of the flowers, the falling of the stamens, and some of the stalks turning yellow. After the whole of this kind is pulled up, it must be manufactured according to the direction of being afterwards dried, and ought to be worked if possible while green; the hemp thus produced being much finer than that which is previously dried. The reason of this is, that the plant contains a great quantity of glutinous matter; which being once dried, agglutinates the fibres in such a manner that they can never be afterwards perfectly separated. The female hemp, however, is always in smaller quantity than the male; and therefore where the crop is large, it will be impossible to work the whole as fast as it is pulled or cut. It is known to be ripe by the stems becoming pale; but it must be remembered, that hemp of any kind will be much less injured by pulling the plants before they are ripe, than by letting them stand too long.

The male hemp being stripped of its leaves, &c. as afterwards directed, will soon be dry for storing by the heat of the atmosphere, though sometimes it may be necessary to use artificial means; but where these are used, the utmost care must be taken, hemp when dry, being exceedingly inflammable. The stored to be dried hemp must be steeped and treated in every other respect as though it had been green; whence it is evident that this operation ought never to be used but in cases of necessity. It is likewise impossible to make hemp which has been dried previous to its being steeped so white as that which has been worked green.

With regard to the perfecting of hemp-seed for a Miller's Hours subsequent season, it would seem proper to set apart a demesne, piece of ground for this purpose: for M. Amien, from vol. vi. 40 plants raised in the common way, had only a pound and a half of seed, though the plants from which it was taken might be deemed fine; whereas, from a single plant which grew by itself, he had seven pounds and a half. Some are of opinion, that by putting the clusters which contain the hemp-seed to heat and sweat, the quality is improved; as many of those seeds which would otherwise wither and die may thus arrive at perfection. This, however, seems to be very problematical; as there are no experiments which show that seeds

When
Hemp. When separated from the vegetable producing them, have any power of mellowing themselves.

After the hemp is pulled, it must be taken in large handfuls, cutting off the roots (though this is not absolutely necessary), the leaves, seeds, and lateral branches, being dressed off with a wooden sword or ripple. It is then to be made up into bundles of twelve handfuls each, in order to be steeped, like flax, in water. This, or something similar, is absolutely necessary, in order to separate the bark; which is properly the hemp, from the reed or woody part. In Suffolk, this operation is called water-rettign; but sometimes a mere exposure to the air is substituted in its place, turning the hemp frequently during the time it is exposed. This is called dew-rettign; but the former method is universally deemed preferable. Such hemp as is designed for seed is seldom water-rettined, though in the opinion of the manufacturer already quoted, it would be better if it were so. Dew-rettined hemp is generally stacked and covered during the winter: in January and February it is spread upon meadow land, and whitens with the frost and snow; though it is always much inferior to the other, and proper for coarser yarns only.

The length of time required for steeping hemp is various, and a complete knowledge of it can only be attained by practice. In Suffolk, it is usual to continue the immersion, four, five, or six days; standing water is preferred, and the same water will steep hemp three times during the season, but the first has always the best colour. The abbé Brulle prefers clear and running water, especially if overhung with trees. The bundles are to be laid crosswise upon each other, taking particular notice of the manner in which they lie when put in, that they may be taken out without difficulty. His time of steeping is from six to 11 days; and here we must observe, that it is much better to let it remain too long in the water than too short a time. The slendereat hemp requires the most soaking. The operation is known to be finished by the reed separating easily from the bark.

After the hemp is thoroughly steeped, the next operation is to separate the bark from the reed or woody part; and this may be done in two ways, viz. either pulling out the reed from every stalk with the hand, or drying and breaking it like flax. The abbé Brulle is very particular in his directions for this last operation, which he calls reeding, and which may be performed either in a trough under water or upon a table. The whole, however, may be reduced to the following, viz. pressing down the bundles either in the trough or on a table by proper weights, to keep the hemp steady in the middle and top end. Then beginning at the upper parts of the bundle, pull out the reeds one by one. As you proceed, the rind which remains will press closely upon the remaining unreed hemp, and keep it more steady; so that you may take two, four, or even six stalks, at a time. The weight is then to be removed from the top, and all the pieces of reed which remain there having broken off in the former operation, are to be taken out. Lastly, the middle weight is to be taken off, and any small pieces which remain there taken out. If the reeding is performed on a table, the bundle must be weeded frequently, though slightly; a continual dropping of water would perhaps be the best method.

After the hemp is reeded, it must next be freed from the mucilaginous matter with which it still abounds. This is done by pouring water through it, squeezing out the liquid after every allusion, but taking care not to let the threads twist or entangle each other, which they will be very apt to do. The abbé is of opinion, that soft soap should be dissolved in the last water, in the proportion of an ounce to three pounds of dry hemp, which though not absolutely necessary, contributes much to the softening and rendering the hemp easy and pleasant to dress.

Hemp is broken by machinery, after being steeped, in a manner similar to flax; but the instruments used for this purpose in Suffolk are all worked by the hand. That which breaks in the operation is called shorts, and is about half the value of the long hemp. The best water-rettined hemp sells for about 8s. 6d. per stone; the other kind from one to two shillings lower.

Beating of hemp is the next operation, which formerly was performed entirely by hand, but now in most places by a water-mill, which raises three heavy beaters that fall upon it alternately; the hemp being turned all the while by a boy in order to receive the strokes equally. The finer it is required to make the tow, the more beating is necessary. It is then dressed or combed by drawing it through heckles formed like the combs of wool manufacturers, only fixed. Sometimes it is divided into two or three sorts of tow, and sometimes the whole is worked together into one sort; the prices varying from 6d. to 12s. per pound.

The hemp thus manufactured is sold to spinners, who reel their yarn as follows:

| 2 yards made | 1 thread |
| 40 threads | 1 lea |
| 20 less | 1 skin |
| 3 skains | 1 clve of 4800 yards |

It is next delivered to the bleachers, who return it bleached on receiving 20 or 21 clives for every 120. bleached. The prices of the hemp-yarn are as follow:

| 1 clve from a pound | 7d. or 6d. |
| 1½ from do. | 8d. or 9d. |
| 2 from do. | 9d. or 9d. |
| 2½ from do. | 10d. or 10d. |
| 3 from do. | 12d. |

Chinese Hemp, a species of cannabis, of which an account is given in the 72d volume of the Philosophical Transactions, p. 46. In that paper Mr. Fitzgerald, vice-president of the society for encouraging arts, mentions having received the seeds from the late Mr. Elliot, which being sown, according to his directions, produced plants 14 feet high, and nearly seven inches in circumference. These being pulled up in November, and steeped for a fortnight in water, were placed against a southern wall to dry. After this the hemp was found to separate easily from the woody part; and so great was the produce, that 32 plants yielded three pounds and a quarter. In consequence of this success, Mr. Fitzgerald applied to the directors of the India Company to procure some of the seeds from China; which being complied with, the society were furnished, in 1785, with some more of the seeds, which were distributed.
HEMSTEAD, a town of Hertfordshire in England, in a hilly country, upon a small river called the Gade, and 20 miles north-west of London. It was, in the time of the Saxons, called by the name of Henamsted, or Hen-Hemsted, i.e. High-Hemstead; in William the Conqueror's time, by the name of Hemleamsted. Henry VIII. incorporated this village by the name of a bailiff; and he empowered the inhabitants to have a common seal, and a pye-powder court during its market and fairs. It has been reckoned one of the greatest markets for wheat in this county, if not in England. Eleven pair of mills stand within four miles of the place, which produce a great trade. Population 3240 in 1811.

HEMSKERCK, EGBERT, called the Old, a celebrated Flemish painter of humorous conversations, of whom, though so universally known, we have no information as to the time in which he flourished, or the school in which he was taught. Though the taste of his compositions is but low, yet it ought to be considered that he took his subjects from nature; from persons in the meanest occupations, whose dress, actions, and manners, could not furnish the imagination with any ideas of elegance: and to express their passions and undisguised humours, seems to have been the utmost of his ambition. By frequenting fairs, merry-meetings, gaming-houses, and inns, he acquired a surprising power of connecting humorous circumstances. He designed and drew correctly, and his pictures have a strong effect from his accurate management of the chiaro oscuro. Some of his pictures have suffered from unskilful cleaners, and many things are sold as his which displease him; but his genuine works, well preserved, have a clearness and force equal to any of the Flemish artists.

Hen-Harrer. See Falco, Ornithology Index.
Hen-Mould Soil, in Agriculture, a term used by the husbandmen of Northampton and adjacent counties, to express a black, hollow, spongey, and mouldering earth, usually found at the bottom of hills. It is an earth much fitter for grazing than for corn, because it will never settle close enough to the grain to keep it sufficiently steady while it is growing up, without which, the farmers observe, it either does not grow well; or, if it seem to thrive, as it will in some years, the growth is rank, and yields much straw, but little ear. It is too moist, and to that is principally to be attributed this rankness of the crop in some years; and the occasion of its retaining so much moisture is, that it usually has a bed of stiff clay, which will not let the water run off into the under strata.

In some places they also give this name to a black, rich, and dense earth, with streaks of a whitish mould in many parts. This sort of hen-mould is usually found very rich and fertile.

HENAUT, CHARLES JOHN FRANCIS, an ingenuous French writer, was the son of John René Henaut, lord of Moussey, and was born at Paris in 1889. He early discovered a slyly benevolent disposition, and by his penetration and aptness soon distinguished itself by the success of his studies. Claude de Lisle, father of the celebrated geographer, gave him the same lessons in geography and history which he had before given to the duke of Orleans, afterwards regent; and which have been printed in seven volumes, under the title of "Abridgement of Universal History." On quitting college, Henaut entered the Oratory, where he soon attached himself to the study of eloquence; and, on the death of the abbé René, reformer of La Trappe, he undertook to pronounce his panegyric; which not meet-
Henault undertook to collect and publish the result of his inquiries, and he is deservedly accounted the first framer of chronological abridgements: in which, without stopping at detached facts, he attends only to those which form a chain of events that perfect or alter the government and character of a nation, and traces only the springs which exalt or humble a nation, extending or contracting the space it occupies in the world. His task had the fortune of those literary phenomena, where novelty and merit united excited many; after glory, and fire the ardour of young writers to press after a guide whom few can overtake. The first edition of the work, the result of 40 years’ reading, appeared in 1744, under the auspices of the chancellor Daguessaud, with the modest title of an Essay. The success it met with surprised him. He made continual improvements in it, and it has gone through nine editions, and been translated into Italian, English, and German, and even into Chinese. As the best writings are not secure from criticism, and are indeed the only ones that deserve it, the author read to the academy of Belles Lettres a defence of his abridgement. All the ages and events of the French monarchy being present to his mind, and his imagination and memory being a vast theatre wherein he beheld the different movements and parts of the actors in the several revolutions, he determined to give a specimen of what passed in his own mind, and to reduce into the form of a regular drama one of the periods of French history, the reign of Francis II, which, though happily by being short, appeared to him one of the most important by its consequences, and most easy to be confined within the stage bounds. His friend the chancellor highly approved the plan, and wished it to be printed. It accordingly went through five editions; the harmony of dates and facts is exactly observed in it, and the passions interested without offence to historic truth.

In 1755, he was chosen an honorary member of the academy of Belles Lettres, being then a member of the academies of Nanci, Berlin, and Stockholm. The queen appointed him superintendent of her house. His natural uprightness relieved her from the serious attendance on his private morning lectures. The company of persons most distinguished by their wit and birth, a table more celebrated for the choice of the guests than its delicacies, the little comedies suggested by wit, and executed by reflections, united at his house all the pleasures of an agreeable and innocent life. All the members of this ingenious society contributed to render it agreeable, and the president was not behind any. He composed three comedies: *La Petite Maison, La Jalous de Soi-meme*, and *La Revell d’Epimene*. The subject of the last was the Cretan philosopher, who is pretended to have slept 27 years. He is introduced fancying that he had slept but one night, and astonished at the change in the age of all around him: he mistakes his mistress for his mother; but discovering his mistake, offers to marry her, which she refuses, though he still continues to love her. The queen was particularly pleased with this piece. She ordered the president to restore the philosopher’s mistress to her former youth: he introduced Hebe, and this episode produced an agreeable entertainment. He was now in such favour with her majesty, that on the place of superintendent becoming vacant by the death of M. Bernard de Con-
burt master of requests, and the sum he had paid for it being lost to his family, Hensault solicited it in favour of several persons, till at last the queen bestowed it on him, and consented that he should divide the profits with his predecessor’s widow. On the queen’s death he held the same place under the dauphiness.

A delicate constitution made him liable to much ill health; which, however, did not interrupt the serenity of his mind. He made several journeys to the waters of Plombieres: in one of those he visited the deposed king Stanislaus at Lunéville; and in another accompanied his friend the marquis de Pauliny, ambassador to Switzerland. In 1763 he drew near his end. One morning, after a quiet night, he felt an oppression, which the faculty pronounced a suffocating cough. His confessor being sent to him, he formed his resolution without alarm. He has since said that he recollected having then said to himself, “What do I regret?” and called to mind that saying of Madame de Sévigné, “I leave here only dying creatures.” He received the sacraments. It was believed the next night would be his last; but by noon next day he was out of danger. “Now (said he) I know what death is. It will not be new to me any more.” He never forgot it during the following seven years of his life, which, like all the rest, were gentle and calm. Full of gratitude for the favours of providence, resigned to its decrees, offering to the Author of his being a pure and sincere devotion; he felt his infirmities without complaining, and perceived a gradual decay with unabated firmness. He died Dec. 24. 1771, in his 86th year. He married in 1714 a daughter of M. le Bas de Moctargis keeper of the royal treasure, &c. who died in 1726 without leaving any issue.

HENDECAGON, in Geometry, a figure having eleven sides and as many angles.

HENED-PENNY, in our writers, a customary payment of money, instead of hens at Christmas. It is mentioned in a charter of King Edward III. Mon. Ang. tom. ii. p. 337. Du Cange is of opinion it may be heren-penny, golinagreat, or a composition for eggs; but Cowell thinks it is misprinted hened-penny for hered-penny or herd-penny.

HENIOCHAS, or HENIOCHUS, a northern constellation, the same as Auriga.

HENLEY, a town of Oxonshire in England, seated on the river Thames, over which there is a handsome bridge. It sends malt, corn, and other things, to London in barges. W. Long. o. 40. N. Lat. 51. 34.”

HENLEY, a town of Warwickshire in England, seated on the river Aire, in W. Long. o. 40. N. Lat. 52. 18.

HENLEY, John, better known by the appellation of Orator Henley, a very singular character, was born at Melton-Mowbray, Leicestershire, in 1691. His father, the Rev. Simon Henley, and his grandfather by his mother’s side (John Dowel, M. A.), were both vicars of that parish. Having passed his exercises at Cambridge, and his examination for the degree of B. A. with the particular approbation of Mr Field, Mr Smales, and the master of the college, he returned to his native place, where he was first desired by the trustees of the school in Melton to assist in, and then to take the direction of that school; which he increased and raised from a declining to a flourishing condition. He established here a practice of improving elocution by the public speaking of passages in the classics, morning and afternoon, as well as orations, &c. Here he was invited by a letter from the Rev. Mr Newcombe to be a candidate for a fellowship in St John’s; but as he had long been absent, and therefore lessened his personal interest, he declined appearing for it. Here likewise he began his “Universal Grammar,” and finished ten languages, with dissertations prefixed, as the most ready introduction, to any tongue whatever. In the beginning of this interval he wrote his poem on “Esther,” which was approved by the town, and well received. He was ordained a deacon by Dr Wake, then bishop of Lincoln; and after having taken his degree of M. A. was admitted to priest’s orders by Dr Gibson, his successor at that see. He formed an early resolution to improve himself in all the advantages of books and conversation the most effectually, on the first opportunity, at London. But he laid the basis of future proficiency in assisting at the curacy of his native town; where he preached many occasional sermons, particularly one at the assizes at Leicester; he then gave a voluntary warning for the choice of a new master and curate, and came to town recommended by above 30 letters from the most considerable men in the country, both of the clergy and laity; but against the inclination of his neighbours and his school, which was now, as from his first entrance upon it, still advancing: and his method being established and approved, one of his own scholars was appointed to succeed him. In town he published several pieces, as a translation of Pliny’s Epistles, of several works of Abbé Vertot, of Montaiglon’s Italian Travels in folio, and many other lucubrations. His most generous patron was the earl of Macclesfield, who gave him a benefice in the country, the value of which to a resident would have been above 80l. a year; he had likewise a lecture in the city; and preached more charity sermons about town, was more numerous followed, and raised more for the poor children, than any other preacher, however dignified or distinguished. But when he pressed his desire and promise from a great man of being fixed in town, it passed in the negative. He took the people (it seems) too much from their parish-churches; and as he was not so proper for a London divine, he was very welcome notwithstanding all difficulties, to be a rural pastor. But it was not for a second rustication, as he informs us, that he left the fields and the swains of Arcadia to visit the great city: and as he knew it was Transact. as lawful to take a license from the king and parliament at Hicks’s-hall as at Doctors Commons (since the ministratory powers of this kingdom are and ought to be Parliamentary only), he freely, without compulsion, or being desired or capable of being compelled to reside in the country, gave up his benefice and lectures, certainties for an uncertainty: believing the public would be a more hospitable protector of learning and science, than some of the upper world in his own order.

Mr Henley, in answer to a cavil (that he borrowed from books), proposed, “that if any person would single out any celebrated discourse of an approved writer, dead or living, and point out what he thought excellent in it, and the reasons; he would submit it to the world, whether the most famed composition might not be..."
HENLY, a town of Germany, in the circle of Hanseberg Franconia, which gives title to a county of the same name, with a castle. E. Long. 9° 17'. N. Lat. 50° 40'.

HENNEBERG, a town of Germany, in the department of Morbihan, and situated on the river Blavet. It enjoys a considerable trade, and contains 4600 inhabitants. It is 62 miles west from Paris, in W. Long. 3° 11'. N. Lat. 47° 48'.

HENETICUM, ('Hermes, q. d. "reconciliative;" of hence, "I unite"), in church history, a famous edict of the emperor Zeno, published A. D. 482, and intended to reconcile and reunite the Eutychians with the Catholics. It was procured of the emperor by means of Acacius, patriarch of Constantinople, with the assistance of the friends of Peter Mongsus and Peter Trullo. The sting of this edict lies here; that it repeats and confirms all that had been enacted in the councils of Nice, Constantinople, Ephesus, and Chalcedon, against the Arians, Nestorians, and Eutychians, without making any particular mention of the council of Chalcedon. It is in form of a letter, addressed by Zeno to the bishops, priests, monks, and people of Egypt and Libya. It was opposed by the Catholics, and condemned in form by Pope Felix II.

HENRICANS, in ecclesiastical history, a sect so called from Henry its founder, who, though a monk and hermit, undertook to reform the superstition and vices of the clergy. For this purpose he left Lausanne in Switzerland, and removing from different places, at length settled at Toulouse in the year 1147, and there exercised his ministerial function, till being overcome by the opposition of Bernard abbot of Clairval, and condemned by Pope Eugenius III. at a council assembled at Rheims, he was committed to a close prison in 1148, where he soon ended his days. This reformer rejected the baptism of infants; severely censured the corrupt manners of the clergy; treated the festivals and ceremonies of the church with the utmost contempt, and held clandestine assemblies for inculcating his peculiar doctrines.

HENRY, or CAPE-HENRY, the south cape of Virginia, at the entrance of Chesapeake bay. W. Long. 74° 50'. N. Lat. 37° 0'.

HENRY, the name of several emperors of Germany, and kings of England and France. See ENGLAND, FRANCE, and GERMANY.

HENRY IV. emperor of Germany in 1056, styled the Great, was memorable for his quarrels with Pope Gregory II., whom at one time he deposed, for having presumed to judge his sovereign; but at another, dreading the effects of the papal anathemas, he had the weakness to submit to the most humiliating personal solicitations and penances to obtain absolution; which impolitic measure increased the power of the pope, and alienated the affections of his subjects: thus circumstanced, he reassumed the hero, but too late; marched with an army to Rome, expelled Gregory, deposed him, and set up another pope. Gregory died soon after; but Urban II. and Pascal II. successively, excited his ambitious sons, Conrad and Henry, to rebel against him, and the latter was crowned emperor by the title of Henry V. in 1106; and he had the inhumanity to arrest his father, and to deprive.
swear rather to die with famine than to admit Henry. The scarcity of provisions in Paris at last degenerated to an universal famine; bread had been sold, whilst any remained, for a crown the pound, and at last it was made from the bones of the charnel-house of St. Innocents; human flesh became the food of the obstinate Parisians, and mothers ate the dead bodies of their children. In fine, the duke of Mayenne, seeing that neither Spain nor the league would ever give him the crown, determined to assist in giving it to the lawful heir. He engaged the states to hold a conference with the chiefs of both parties; which ended in Henry's abjuration of the Protestant religion at St. Dennis, and his consecration at Chartres in 1593. The following year Paris opened its gates to him; in 1596, the duke of Mayenne was pardoned; and in 1598, peace was concluded with Spain. Henry now showed himself doubly worthy of the throne, by his encouragement of commerce, the fine arts, and manufactures, and by his patronage of men of ingenuity and sound learning of every country: but though the fermentations of Romish bigotry were calmed, the leaven was not destroyed; scarce a year passed without some attempt being made on this real father of his people; and at last the monster Ravailloc stabbed him to the heart in his coach, in the streets of Paris, on the 14th of May 1610, in the 37th year of his age and 22d of his reign.

Henry VIII, king of England, was the second son of Henry VII, by Elizabeth the eldest daughter of Edward IV. He was born at Greenwich, on the 28th of June 1491. On the death of his brother Arthur, in 1502, he was created prince of Wales; and the following year betrothed to Catharine of Aragon, Prince Arthur's widow, the pope having granted a dispensation for that purpose. Henry VIII ascended the throne, on the death of his father, the 22d of April 1509, and his marriage with Catharine was solemnized about two months after. In the beginning of his reign he left the government of his kingdom entirely to his ministers; and spent his time chiefly in tournaments, balls, concerts, and other expensive amusements. We are told that he was so extravagant in his pleasures, that, in a very short time, he entirely dissipated 1,800,000l. which his father had hoarded. This will seem less wonderful, when the reader is informed, that gaming was one of his favourite diversions. Nevertheless he was not so totally absorbed in pleasure, but he found leisure to sacrifice to the resentment of the people two of his father's ministers, Empson and Dudley. A house in London, which had belonged to the former of these, was in 1510 given to Thomas Walsy, who was now the king's almoner, and who from this period began to insinuate himself into Henry's favour. In 1513, he became prime minister, and from that moment governed the king and kingdom with absolute power. In this year Henry declared war against France, gained the battle of Spurs, and took the towns of Terenouen and Tourna; but before he embarked his troops, he beheaded the earl of Suffolk, who had been long confined in the Tower. In 1521, he sacrificed the duke of Buckingham to the resentment of his prime minister Walsy, and the same year obtained from the pope the title of Defender of the Faith.
H N

Henry, having been 18 years married, grew tired of his wife, and in the year 1527 resolved to obtain a divorce; but after many fruitless solicitations, finding it impossible to persuade the pope to annul his marriage with Catharine, he espoused Anne Boleyn in the year 1531. During this interval his favourite Wolsey was disgraced, and died; Henry threw off the papal yoke, and burnt three Protestants for heresy. In 1535, he put to death Sir Thomas Moore, Fisher, and others, for denying his supremacy, and suppressed all the lesser monasteries.

His most sacred majesty, having now possessed his second queen about five years, fell violently in love with Lady Jane Seymour. Anne Boleyn was accused of adultery with her own brother, and with three other persons: she was beheaded the 19th of May 1536. He married Jane Seymour the day following. In 1537, he put to death five of the noble family of Kildare, as a terror to the Irish, of whose disloyalty he had some apprehensions; and in the year following he executed the marquis of Exeter, with four other persons of distinction, for the sole crime of corresponding with Cardinal Pole. In 1538 and 1539, he suppressed all the monasteries in England, and seized their revenues for his own use. The queen having died in child-bed, he this year married the princess Ann of Cleves; but disliking her person, immediately determined to be divorced; and his obsequious parliament and conviction unanimously pronounced the marriage void, for reasons too ridiculous to be recited; but this was not all: Henry was so incensed with his minister and quondam favourite, Cromwell, for negotiating this match, that he revenged himself by the hand of the executioner. Yet this was not the only public murder of the year 1540. A few days after Cromwell’s death, several persons were burnt for denying the king’s supremacy, and other articles of heresy.

His majesty being once more at liberty to indulge himself with another wife, fixed upon Catharine Howard, niece to the duke of Norfolk. She was declared queen in August 1540; but they had been privately married some time before. Henry, it seems, was so entirely satisfied with this lady, that he daily blessed God for his present felicity; but that felicity was of short duration: he had not been married above a year, before the queen was accused of frequent prostitution, both before and since her marriage: she confessed her guilt, and was beheaded in February 1542. In July 1543, he married his sixth wife, the lady Catharine Parr, the widow of John Nevil Lord Latimer, and lived to the year 1547 without committing any more flagrant enormities; but finding himself now approach towards dissolution, he made his will; and that the last scene of his life might resemble the rest, he determined to end the tragedy with the murder of two of his best friends and most faithful subjects, the duke of Norfolk and his son the earl of Surrey. The earl was beheaded on the 19th of January; and the duke was ordered for execution on the 29th; but fortunately escaped by the king’s death on the 28th. They were condemned without the shadow of a crime; but Henry’s political reason for putting them to death, was his apprehension that, if they were suffered to survive him, they would counteract some of his regulations in religion, and might be troublesome to his son. Henry died on the 28th of January 1547, in the 56th year of his age, and was buried at Windsor.

As to his character, it is pretty obvious from the facts above related. Lord Herbert palliates his crimes, and exaggerates what he calls his virtutes. Bishop Burnet says, “he was rather to be reckoned among the great than the good princes.” He afterwards acknowledges, that “he is to be numbered among the ill princes; but adds, “I cannot rank him with the worst.” Sir Walter Raleigh, with infinitely more justice, says, “If all the pictures and patterns of a merciless prince were lost to the world, they might again be painted to the life out of the history of this king.” He was indeed a merciless tyrant, a scurrilous politician, a foolish bigot, a horrible assassin. See England, No. 253—292.

Henry of Huntington, an English historian, of the 12th century, was canon of Lincoln, and afterwards archdeacon of Huntington. He wrote, 1. A history of England, which ends with the year 1154. 2. A continuation of that of Bede. 3. Chronological tables of the kings of England. 4. A small treatise on the contempt of the world. 5. Several books of epigrams and love-verses. 6. A poem on herbs; all which are written in Latin.—His invocation of Apollo and the goddess of Temple, in the exordium of his poem on herbs, may not be unacceptable as a specimen of his poetry.

* Vatum magne parent, herbarum Phoebè repertor,*
* Vosque, quibus resonant Tempe jocosa, Dem!*
* Si mihi sertis prius hederae florenti pabatur,*
* Ecce meos flores, sorte para saevo.*

Henry of Susa, in Latin de Sogusio, a famouscivilian and canonist of the 13th century, acquired such reputation by his learning, that he was called the source and splendour of the law. He was archbishop of Embrun about the year 1258, and cardinal bishop of Ostia in 1262. He wrote A summary of the canon and civil law; and a commentary on the book of the decretas, composed by order of Alexander IV.

Henry the Minstrel, commonly called Blind Harry, an ancient Scottish author, distinguished by no particular surname, but well known as the composer of an historical poem reciting the achievements of Sir William Wallace. This poem continued for several centuries to be in great repute; but afterwards sunk into neglect, until very lately that it has been again released from its obscurity by a very neat and correct edition published at Perth under the inspection and patronage of the earl of Buchan.

It is difficult to ascertain the precise time in which this poet lived, or when he wrote his history, as the two authors who mention him speak somewhat differently. Dempster, who wrote in the beginning of the 17th century, says that he lived in the year 1361; but Major, who was born in the year 1446, says that he composed this book during the time of his infancy, which we must therefore suppose to have been a few years posterior to 1446; for if it had been composed that very year, the circumstance would probably have been mentioned. As little can we suppose, from Mr. Dempster’s words, that Henry was born in 1361; for though he says that he lived in that year, we must naturally

of similes with which Homer abounds so much; and few miraculous interpositions are to be found in his poem, though the prophecies of Thomas Lertmont commonly called The Rhymner, and a prophetic dream of Wallace himself are introduced, as well as the ghost of Fawdon, a traitor who had joined Wallace, and whom the latter in a fit of passion had killed. In other respects, the same inextinguishable thirst of blood which Homer ascribes to his hero Achilles is ascribed to Wallace, though in all probability the mind of Wallace was too much enlightened to admit of such sentiments. A vast degree of courage and personal strength are ascribed to him, by means of which the exploits of the whole army are in effect transferred to a single person. As long as he is invested with the command, the Scots are victorious and irresistible; when deprived of it, they are enslaved and undone. After struggling for some time against an inveterate and powerful faction, disdaining to feign submission, he is taken by treachery, and died a martyr to the freedom of his country. The poem, on the whole, is valuable, on account of our being able to trace, by its means, the progress which the English language had made at that time in Scotland: the manners of the Scots in that age: as the favourite dress of green which at that time was the taste of the inhabitants of Scotland, &c. With regard to the authenticity of his relations, it is impossible to suppose any other thing than that they are partly true and partly false. The general thread of the story may undoubtedly be looked upon to be genuine, though embellished with poetical fictions and exaggerations; and his constant appeals to the book already mentioned, though it is now lost, must be looked upon as a strong testimony in his favour: for we cannot suppose that at the time he lived, when we may say that the transactions which he relates were recent, he would have had the confidence to appeal to a book which had not been generally known to have an existence; and its being now lost can never be an argument against it, when we consider the difficulty there was of preserving books before the invention of printing; the confusions in which Scotland was frequently involved; and that the exploits of Wallace, who must be supposed to have been a kind of rival to the great Bruce, could not be so agreeable to the court as those of the more successful hero; and therefore the history of them might be suffered to fall into oblivion, though written in elegant Latin, while a most ridiculous poem in that language on the battle of Bannockburn has been preserved to this day.

HENRY Prince of Wales, eldest son of King James VI. of Scotland by his queen Anne sister of the king of Denmark, and one of the most accomplished princes of the age in which he lived, was born on the 17th of February 1594. The birth of the prince was announced by embassies to many foreign powers, with invitations to be present at the ceremony of his baptism, which was thus delayed for a considerable time. Mr Peter Young, who, along with the celebrated George Buchanan, had been preceptor to his majesty, was sent to the courts of Denmark, Brunswick, and Mecklenburg, the duke of Mecklenburg being grand-grandfather to the prince by the mother's side; the Laird of East Weems to France and England; and Sir Robert Keith, and Captain Murray provost of St Andrew's, to the States General, who at that time were struggling against the Spanish tyranny, and not yet declared a free state. All these ambassadors were cordially received, and others appointed in return except by the courts of France and England. Henry IV. at that time king of France, though the Scots ambassador had formerly been one of his own servants, neither made any present, nor appointed an ambassador. Queen Elizabeth had designed to act in the same manner till she heard of the behaviour of Henry; after which she honoured James by appointing an ambassador of very high rank, Robert earl of Sussex. This ambassador, however, was so long of making his appearance, that the queen imagined the ceremony would be over before his arrival; for which reason she sent a message to the earl, commanding him in that case not to enter Scotland nor deliver her present. But James had been more obsequious; and not only delayed the ceremony till the English ambassador arrived, but distinguished him from the rest by having a canopy carried over his head at the procession, supported by the lairds of Cessford, Buccleugh, Duddoys, and Treanour. The ceremony was performed with great magnificence; after which the ambassadors presented their gifts. That from the United States was the most valuable. It consisted of two gold cups worth 12,400 crowns, with a box of the same metal, weighing in all about 400 ounces, containing besides the grant of a pension of 3000 florins annually to the prince for life. The English ambassador gave a cupboard of plate curiously wrought, and valued at 3000l. sterling; and the Danish ambassador two gold chains, one for the queen and another for the prince. The baptism was celebrated on the 6th of September 1594, and the child named Frederick-Henry and Henry-Frederick.

The young prince was now committed to the care of the earl of Mar, who was assisted in this important charge by Annabella countess-dowager of Mar, daughter of William Murray of Tulibardine, and paternal ancestor of the present Duke of Atholl. This lady was remarkable for the severity of her temper, so that the prince met with little indulgence while under her tuition; notwithstanding which, he showed great affection for his governess all the time she had the care of him. Next year, however (1595), the queen engaged the chancellor, Lord Thirlestane, in a scheme to get the prince into her own power: but the king having found means to dissuade her majesty from the attempt, showed afterwards such marks of displeasure to the chancellor, that the latter fell into a languishing disorder and died of grief.

In his sixth year Prince Henry was committed to the care of Mr Adam Newton a Scotsman, eminently skilled in most branches of literature, but particularly distinguished for his knowledge of the Latin language. Under his tutorage the prince soon made great progress in that language, as well as in other branches of knowledge; insomuch that before he had completed his sixth year, his father wrote for his use the treatise entitled Basilicorum Doron, thought to be the best of all his works.

In his seventh year, Prince Henry began his correspondence with foreign powers. His first letter was to the States of Holland; in which he expressed his regard and gratitude for the good opinion they had conceived of him, and of which he had been informed.
by several persons who had visited that country; concluding with a request that they would make use of his interest with his father in whatever he could serve them, promising also his service in every other respect in which he could be useful, until he should be able to give farther instances of his good-will and affection.

At this early period the prince began to add to his literary accomplishments some of the more martial kind, such as riding, the exercise of the bow, pike, &c. as well as the use of fire-arms; and indeed such was the attachment he showed throughout his whole lifetime to military exercises, that had he attained the years of maturity, there can scarce be a doubt that he would have distinguished himself in a most eminent manner. In all his exercises he made surprising progress; and not only in those of the military kind, but in singing, dancing, &c. On his ninth birth-day he sent a letter in Latin to the king, informing him that he had read over Terence’s Hecyra, the third book of Phaedrus’s Fables, and two books of Cicero’s Epistles; and that now he thought himself capable of performing something in the commendatory kind of epistles. His accomplishments were soon spoken of in foreign countries; and these, along with the general suspicion that James favoured the Catholic party, probably induced Pope Clement VIII to make an attempt to get him into his hands. With this view he proposed, that if James would entrust him with the education of the young prince, he would advance such sums of money as would effectually establish him on the throne of England. This happened a little before the death of Elizabeth; but James, notwithstanding his ambition to possess the crown of England, of which he was not yet altogether certain, withstood the temptation. He alleged, that it would be unnatural for him, as a father, to allow his son to be brought up in the belief of a doctrine which he himself did not believe: and even though he should act in his private capacity in such an unnatural manner, he could not answer for it to the nation, he being heir-apparent to the crown, and the kingdom at large much interested in whatever concerned him. On the death of the queen of England, James was obliged to leave Scotland in such haste, that he had not time to take a personal leave of his son, and therefore did so by letter, which was answered by the prince in Latin. The queen, however, who had desired to follow the king to London in three weeks, but to leave the prince in Scotland, thought proper to make another attempt to get her son into her own power. With this view she took a journey to Stirling, where the prince resided, but was opposed in her designs by the friends of the house of Mar; and this affected her so much, that she miscarried of a child of which she was then pregnant. The king, hearing of this misfortune, ordered the prince to be delivered to his mother; but refused to inflict any punishment on the earl of Mar, which the queen insisted upon, that nobleman having been with the king at London, and entirely innocent of the whole affair. Instead of punishing him, therefore, he caused him to be acquitted by an act of the public council at Stirling; invested him with the order of the Garter; made him a grant of several abbey and other church lands; and raised him to the post of lord, high treasurer after the disgrace of the earl of Somerset; in which employment he continued till he could no longer perform the duties of his office through age and infirmity.

In the month of July this year (1603) Prince Henry was invested with the order of the Garter; after which he was presented to the queen in his robes, and greatly commended by all who saw him on account of his majestic carriage and religious behaviour at the altar, as well as the quickness of his understanding and ready answers. Being obliged to leave London on account of the plague, he retired to Otelands, a royal palace near Weybridge in Surrey, where a separate household was appointed for him and his sister Elizabeth. The appointment consisted at first of 70 servants, of whom 22 were to be above stairs and 48 below. In some weeks the number was augmented to 104, of whom 51 were above stairs and 53 below; but before the end of the year they were augmented to 141, of whom 56 were above stairs and 85 below. From Otelands he removed the same year to Nonsuch in Surrey, and from thence to Hampton Court, where he resided till Michaelmas 1604; after which he returned to his house at Otelands, his servants having all this time been kept on board-wages.

In the tenth year of his age, Henry began to show a wonderful desire of becoming master of all those accomplishments which are necessary to constitute a great prince. Without desiring from his attention to polite literature, he applied himself in the most assiduous manner to the knowledge of naval and military affairs. To give him the first rudiments of the former, a small vessel was constructed 28 feet long and 12 broad, curiously painted and carved; on board of which he embarked with several of the principal nobility, and sailed down as far as Paul’s Wharf, where with the usual ceremonies, he was baptized by the name of the Dismas. Mr Pett, the builder of this ship, was recommended to the prince by the high admiral in such strong terms, that his highness took him immediately into his service, and continued his favour to him as long as he lived.

Prince Henry now began to show himself equally a patron of military men and of learning. His martial disposition induced him to take notice of Colonel Edmondson, a brave Scots officer in the Dutch service, who had raised himself solely by his merit. To him he applied for a suit of armour to be sent over from Holland: but though the colonel executed his commission, he reaped no benefit from his highness’s favour, dying in a short time after the armour was purchased, before he had any opportunity of sending it over. In matters of literature the prince appears to have been a very good judge. He patronized divines, and appears to have been naturally of a religious turn of mind. His attachment to the Protestant religion appears to have been excessive; as it never was in the power of the queen, who favoured the Catholic party, to make the least impression upon him. Her machinations for this purpose were discovered by the French ambassador; who, in a letter dated June 7. 1604, informed his master of them, and that the Spaniards were in hopes of being able by her means to alter the religion in England, as well as to prejudice the prince against France, which the queen said she hoped that her son would one day be able to conquer like another Henry V. By another letter, of date 22d October the
same year, the ambassador, after taking notice of the queen's immoderate ambition, adds, that she used all her efforts to corrupt the mind of the prince, by flattering his passions, diverting him from his studies, and representing to him, out of contempt to his father, that learning was inconsistent with the character of a great general and conqueror; proposing at the same time a marriage with the infants of Spain. Notwithstanding these remonstrances, however, the prince continued to behave as usual, and to patronise the learned no less than before. He presented John Johnston, one of the king's professors at St Andrew's with a diamond, for having dedicated to him an Historical Description of the kings of Scotland from the foundation of the monarchy to that time; after which the professor added a *carmen encomiasticum*, which was transmitted to his highness in November 1605. Many other authors also sought and obtained his countenance. In 1666 Mr John Bond ushered his edition of Horace into the world with a polite dedication to the prince, whom he highly compliments on account of the progress he had made in learning. In 1669 a book was sent over to him from France by Sir George Carew, the British ambassador there, tending to disprove the doctrine of the Catholics concerning the church of Rome being the first of the Christian churches. The same year the learned Thomas Lydyst published his *Emendatio Temporum*, which appeared under the patronage of the prince; and with this performance his highness was so well pleased, that he took the author into his family to read to him, and made him his chronographer and cosmographer. Paul Buys or Busius also sent him a letter with a dedication of the second part of his *Pandecta*; in which he bestows upon him the highest compliments on the great expectations which were formed of him, and of the hopes entertained by the reformed Christian churches that he would prove a powerful support to their cause, and antagonist to the errors of Rome. In 1611 Dr Tooker, in his dedication of an Answer to Becanus a Jesuit, who had written against a piece done by his majesty himself, styles his highness "the Maccenas of all the learned." Another treatise against the same Becanus was also printed this year, and dedicated to the prince.

Many other authors, whom our limits will not allow us to take notice of, were fond of dedicating their performances to his highness; nor was his correspondence less extensive than his erudition. We have already taken notice of his having written his first public letter to the states of Holland. He was congratulated by the elector palatine, afterwards married to the princess Elizabeth, on the discovery of the gunpowder-plot. On the same occasion also Lord Spencer wrote him a letter, accompanying it with the present of a sword and target; "instruments (says he) fit to be about you in those treacherous times; from which, I trust, God will ever protect your most royal father, &c." Previous to this he had corresponded in Latin with the doge of Venice, the landgrave of Hesse, and the king of Denmark; in French with the duke of Savoy, and in Latin with the duke of Brunswick and Uladislaus king of Poland; besides a number of other eminent persons too tedious to enumerate.

The great accomplishments of Henry soon caused him to be taken notice of by the most eminent princes in Europe. In 1606 Henry IV. of France ordered his ambassador to pay him special regard on all occasions. He desired him likewise to salute the prince in the name of the dauphin, afterwards Louis XIII. and to inform him of the regard the latter had for him. A message was also sent by the same ambassador to M. de St Anthoine, appointed to be riding-master to his highness, enjoining him to do his duty in that office, and assuring him that his majesty would be as much pleased with it as if the service had been done to himself. To these messages the prince returned very proper answers; and afterwards performed his exercise in the riding-school before the ambassador himself, that the latter might send an account thereof to his master. On this occasion he mounted two horses, and acquitted himself so well that the ambassador in a letter to M. de Villeroy, the French secretary, gave him the character of "a prince who promised very much, and whose friendship could not but be one day of advantage." Having then set forth the propriety of cultivating a good understanding with him, he tells the secretary, that the dauphin might make a return for some dogs which the prince had sent him, by a suit of armour well gilt and enamelled, together with pistols and a sword of the same kind; also two horses, one of them a barb.--

This year also the prince waited on his uncle the king of Denmark, who had come to England on a visit to King James; and this monarch was so much pleased with his company, that he presented him at parting with his vice-admiral and best fighting ship, valued at no less than 2500l. also with a rapier and hanger, valued at 2000 marks. The states of Holland were equally ready to show their attachment. On the 25th of August this year they sent a letter to the prince in French, accompanied with the present of a set of table-linen, which they thought, as being the produce of their own country, would be agreeable to him; and they requested his love and favour towards their state: in return for which they promised to be always ready to show their regard for him, and to do him all possible service; as the ambassador himself was ordered more particularly to declare. About this time the prince himself wrote a letter to Henry IV. acknowledging the kindness which his majesty had shown him for several years, and confirmed of late by the latter offering him under his own royal hand his friendship and that of the dauphin.

While James was this year employed in hunting, the French ambassador, who had been obliged to quit London on account of the plague, took frequent opportunities of waiting upon his highness, as did also the Spanish ambassador, whose only visible reason was to inform him about some horses which were to be sent him from Spain. The prince's partiality towards France, however, was so evident, that the French ambassador, in a letter dated 31st October 1606, mentions, that "as far as he could discover, his highness's inclination was entirely towards France, and that it would be wrong to neglect a prince who promised such great things. None of his pleasures (continued he) savour the least of a child. He is a particular lover of horses and whatever belongs to them: but is not fond of hunting; and when he goes to it, it is rather for the pleasure of galloping than that which the dogs give him. He plays willingly enough at tennis, and another Scottish
diversion very like mail; but this always with persons elder than himself, if he despised those of his own age. He studies two hours a day, and employs the rest of his time in tossing the pike, or leaping, or shooting with the bow, or throwing the bar, or vaulting, or some other exercise of the kind, and he is never idle. He shows himself likewise very good-natured to his dependants, supports their interests against any persons whatever, and pushes whatever he undertakes for them or others with such zeal as gives success to it. For besides his exerting his whole strength to compass what he desires, he is already feared by those who have the management of affairs, and especially by the earl of Salisbury, who appears to be greatly apprehensive of the prince's ascendant; as the prince, on the other hand, shows little esteem for his lordship." In this letter the ambassador further goes on to remark, that some of the prince's attendants had formerly been made to expect pensions from France; and he was of opinion that they ought to be gratified on account of the interest they had with the prince. He adds, that the queen had less affection for Prince Henry than for his brother the duke of York, afterwards Charles I.; which the prince seemed to have discovered, and sometimes used expressions to that purpose: that the king also seemed to be jealous of his son's accomplishments, and to be displeased with the quick progress he made.

In 1607 the prince received the arms and armour which Henry IV. sent him as a present, and these being accompanied with a letter, the prince returned an answer by a Mr Douglas, who was introduced to the king of France by the ambassador Sir George Carew. His majesty, contrary to custom, opened the prince's letter immediately; and was so much surprised at the beauty of the character, that he could not be satisfied that it was the prince's hand until he compared the signature with the rest of the writing. In his letter to the British court on this occasion, the ambassador speaks forth in strong terms the affection expressed by the French monarch for the prince; "accounting of him as of his own son, as he hoped that his good brother of Great Britain would do the like: of the Dauphin." The French ambassador also gave a character of his highness similar to that already mentioned; remarking, "that the prince had great accomplishments and courage; would soon make himself talked of, and possibly give jealousy to his father, and apprehensions to those who had the greatest ascendant at court." With regard to the pensions to his attendants, he was at first of opinion that they ought to be granted; but afterwards altered his mind, perceiving that there was little probability of the prince being influenced by any of his attendants, as he was much more inclined to be guided by his own judgment than by the suggestions of others. In the month of July this year the Dutch ambassadors came recommended to Prince Henry by the States, who wrote to him that they had ordered their ambassadors to kiss his highness's hands on their part, and desired him to continue his friendship to their republic, and to allow their ambassadors a favourable audience, and the same credit as to themselves.

All this attention paid him by foreign powers, all his attention to his own improvements in learning and the military art, and all the temptations which we cannot but suppose a youth in his exalted station to have been exposed to, seem never to have shaken the mind of this magnanimous prince in the least, or to have at any time made him deviate from the strict line of propriety. We have already mentioned his attachment to the Protestant religion; and this appears not to have been grounded upon any prejudice or opinion inculcated upon his infant mind by those who had the care of him, but from a thorough conviction of the truth of the principles which he professes. On the discovery of the gunpowder-plot, he was so impressed with gratitude towards the Supreme Being, that he never afterwards omitted being present at the sermon preached on the occasion. In his 14th year the prince showed himself capable of distinguishing the merit of religious discourses, and paid particular regard to such divines as were most remarkable for their learning and abilities. Among others, he honoured with his attention the learned and eloquent Mr Joseph Hall, then rector of Halstead in Suffolck, afterwards dean of Worcester, and successively bishop of Exeter and Norwich. His highness was so much pleased with a book of Meditations published by that divine, that he pressed him to preach before him; and having heard two of his sermons, he engaged him as one of his chaplains; inviting him afterwards to stay constantly at his court, while the other chaplains waited only in their turns; promising, moreover, to obtain from the king such preferments as should fully satisfy him. Mr Hall, however, from a reluctance to leave his new patron Lord Deny, afterwards earl of Norwich, did not accept of these honourable and advantageous proposals.

In his family the prince took the utmost care to preserve decency and regularity. He ordered boxes to be kept at his three houses of St James's, Richmond, and Nonsuch, for the money required of those who were heard to swear; the fines levied on such offenders being given to the poor. He had, indeed, a particular aversion to the vice of swearing and profanation of the name of God. When at play, he never was heard to do so; and on being asked why he did not swear at play as well as others; he answered, that he knew no game worthy of an oath. The same answer he is said to have given at a hunting-match. The stag, almost quite spent, crossed a road where a butcher was passing with his dog. The stag was instantly killed by the dog; at which the huntsmen were greatly offended, and endeavoured to irritate the prince against the butcher; but his highness answered coolly, "What if the butcher's dog killed the stag, what could the butcher help it?" They replied, that if his father had been so served, he would have sworn so that no man could have endured. "Away," cried the prince, "all the pleasure in the world is not worth an oath."

The regard which Prince Henry had for religion was manifest from his attachment to those who behaved themselves in a religious and virtuous manner. Among these was Sir John Harrington, whose father had been knighted by Queen Elizabeth, and created by King James a baron of England in 1623 by the title of Lord Harrington of Exton in Rutland. He was entrusted with the care of the Princess Elizabeth after her marriage with the elector palatine, whom he attended to Heidelberg in 1613, and died at Worms on the 24th of August following. His son, who in the
year 1604 had been created knight of the Bath, was, as soon as he came to the years of discretion, remarkable for his piety; insomuch that he is said to have kept an exact diary of his life, and to have examined himself every week as to the progress he had made in piety and virtue, and what faults he had committed during that time. He was affable and courteous to all, and remarkable for his humanity to those in distress; all which good qualities so endeared him to the prince, that he entered into as strict a friendship with him as the disproportion between their stations would allow. There are still several letters extant which passed between them, chiefly upon classical subjects. This worthy and accomplished nobleman died in February 1614.

In his friendship Prince Henry appears to have been very sincere, and inviolably attached to those whom he once patronised. He had a great regard for the unfortunate Lady Arabella Stewart, sister of Henry Lord Darnley, the king's father; and there is still extant a letter from this lady to the prince in return for some kindness he had bestowed on a kinsman of hers at her recommendation. He expressed much compassion for her misfortunes; she having excised the king's jealousy on account of her marriage with Mr William Seymour, afterwards earl and marquis of Hertford, and restored in 1662 to the dukedom of Somerset. But on her attempting to escape from the house in Highgate where she was confined, and to go abroad with her husband, his highness expressed some resentment against her; though in all probability his apprehensions, as well as those of the king, were unfounded.

As early as the year 1605, the prince, though then only in his 11th year, manifested his gratitude and attachment to those who had served him, in the instance of his tutor Mr Newton already mentioned. That gentleman had been promised by his majesty the deanery of Durham upon the demise of the archbishop of York. On this promise Mr Newton had relied for two years; and as soon as the prelate died, his highness took care to put the king in mind of his promise; in consequence of which, Mr Newton was installed in his office on the 27th of September 1605.

Mr Pett, the gentleman who first instructed the prince in naval affairs, having been involved with many others in an enquiry concerning their conduct in their respective employments in the royal navy, the prince showed a laudable desire of protecting their innocence. The inquiry was set on foot by the earl of Northampton, lord privy seal and warden of the cinque ports, who had received a commission from the king for the purpose. It was carried on by his agents, however, with such violence and malice, as not only occasioned great trouble and expense to the parties concerned, but almost ruined the navy, besides augmenting his majesty's expenses much more than formerly. Mr Pett's trial began on the 28th of April 1609; at which time the reports being very favourable to him, the king determined to examine into the state of the matter himself. For this purpose he went to Woolwich on the 8th of May, attended by the prince; and appointed Sir Thomas Chaloner, his highness's governor, and Sir Henry Briggs then professor of geometry in Gresham college, to decide the controversy which was then agitated about the proportion of the ships. The measures declared in favour of Mr Pett, on which the prince exclaimed, "Where are now those perjured fellows, that dare thus to abuse his majesty with false informations? Do they not worthily deserve hanging?" During the whole time he stood near Mr Pett to encourage him; and when the king declared himself satisfied of his innocence, the prince took him up from his knees, expressing his own joy for the satisfaction which his father had received that day; protesting that he would not only countenance Mr Pett for the future, but provide for him and his family as long as he lived.

The courage, intrepid disposition, and martial turn of this prince, were manifest from his infancy. It is related of Alexander the Great, that at a very early period of his life he showed more skill than all his father's grooms in the breaking of his favourite horse Bucephalus. An anecdote somewhat similar is recorded of Prince Henry. He was hardly ten years of age, when he mounted a very high-spirited horse, in spite of the remonstrances of his attendants; spurred the animal to a full gallop; and having thoroughly wearied him, brought him back at a gentle pace, asking his servants at his return, "How long shall I continue in your opinion to be a child?" From the very first time that he embarked on board the small vessel formerly mentioned, he continued to pay the utmost attention to naval affairs. In August 1607, he visited the royal navy at Woolwich, where he was received by Mr Pett, and conducted aboard the Royal Anne, where he had 31 large pieces of ordnance ready to be fired. This was done unexpectedly as soon as the prince reached the poop; at which he expressed great satisfaction. After visiting the dock-yard, and surveying what was done of a ship then building for himself, he went aboard, and having partaken of an entertainment prepared for him by Mr Pett, he was by him conducted to the mount, where the ordnance were again charged and ready to be placed for firing. The prince insisted upon an immediate discharge, but suffered himself to be persuaded against it by Mr Pett's representation of the danger of firing so many ordnances loaded with shot while his highness stood close by: on a signal given by him, however, by holding up his handkerchief, after he had removed to a proper distance with his barge, the ordnance were discharged as he had desired. In his 16th year he paid several visits to Woolwich, in order to see the above-mentioned ship which was building for himself. When finished, it was the largest that had ever been seen in England: the keel being 114 feet in length, and the cross-beam 44 feet; carrying 64 pieces of great ordnance; the burden about 1400 tons; and the whole curiously ornamented with carving and gilding. His highness having received this ship in a present from his majesty, went to see it launched on the 24th of September 1609. The narrowness of the dock, however, having prevented its being done at that time, the prince, who staid behind the rest of the company in order to prepare for the ceremony next morning, returned by three o'clock through a storm of rain, thunder, and lightning; and standing on the poop while the ship was launched, gave it the name of the Prince Royal.

In 1611 his highness made a private visit to Chatham,
About the middle of January 1612, Prince Henry ordered all his majesty's master-shippers and builders to attend him, to consider of a proposition concerning the building of ships in Ireland made by a Mr Burrell. Some of his propositions were, that he should build any ship from 100 to 600 tons, with two decks and a half, at the rate of five pounds per ton; that he would build any ship from 600 to 1000 tons, with three whole decks, at the rate of seven pounds per ton; that he should build a ship of 600 tons within a certain time, &c. Mr Pett was employed to see that this contract was fulfilled on the part of Mr Burrell. Among the prince's papers, a list of the royal navy was found after his death, with an account of all the expenses of fitting out, manning, &c. which must now be accounted a valuable addition to the naval history of those times. His passion for naval affairs naturally led him to a desire of making geographical discoveries; of which, however, only two instances have reached our times. One was in 1607, when he received from Mr Tindal his gunner, who had been employed by the Virginia company, a draught of James's river in that country, with a letter dated 22d June the same year. In this letter Mr Tindal remarks, that his fellow-adventurers had discovered that river; and that no Christian had ever been there before; that they were safely arrived and settled; that they found the country very fruitful; and that they had taken a real and public possession in the name and to the use of the king his highness's father. The other instance was in the year 1612, the same in which he died, when he employed Mr Thomas Button, an eminent mariner, to go in quest of a north-west passage. Mr Button accordingly set sail with two ships, named the Resolution and Discovery; the same designations with those in which the late Captain Cook made his last voyage. Both of them were victualled for 18 months; but wintering in these northern regions, they did not return till after the prince's decease, so that Captain Button was never sent on another voyage: nevertheless, he returned fully convinced of the existence of such a passage; and even told the celebrated professor Briggs of Gresham college, that he had convinced the king of his opinion.

The martial disposition of the prince, which was conspicuous on all occasions, eminently displayed itself on the occasion of his being invested in the principality of Wales and duchy of Cornwall, which took place in the year 1610. Previous to this ceremony, he, under the name and character of Mædiades, lord of the isles, caused a challenge to be given, in the romantic style of those times, to all the knights in Great Britain. The challenge, according to custom, was accepted; and on the appointed day, the prince, assisted only by the duke of Lenox, the earls of Arundel and Southampton, Lord Hay, Sir Thomas Somerset, and Sir Richard Preston, who instructed his highness in arms, maintained the combat against 56 earls, barons, knights, and esquires. Prince Henry himself gave and received 32 pushes of the pike, and about 360 strokes of swords, performing his part very gracefully, and to the admiration of all who saw him, he being not yet 16 years of age. Prizes were bestowed upon the earl of Montgomery, Mr Thomas Darry, and Sir Robert Gordon, for their behaviour at this combat. The ceremony of installation was performed on the 4th of June 1610, at which time every kind of magnificence that could be devised was displayed. Among other pageants used on this occasion was that of Neptune riding on a dolphin and making speeches to the prince; also of a sea-goddess upon a whale. After the ceremony the prince took his place on the left hand of his majesty; sitting there in his royal robes, with the crown on his head, the rod in one hand, and in the other the patent creating him prince of Wales and duke of Cornwall. A public act was then read, testifying that he had been declared prince of Great Britain and Wales. He was afterwards served at table with a magnificence not unworthy of royalty itself; the whole concluding with a grand masquerade and tournament.

In one instance, the extreme desire which Prince Henry had of being instructed in military affairs, carried him beyond those bounds which European nations have prescribed to one another. In 1627 the prince de Joinville, brother to the duke of Guise, came to England, having been obliged to leave France in consequence of his having made love to the countess de Moret the king's mistress. After having been for a few weeks magnificently entertained at court, he departed for France in the beginning of June. The prince took an opportunity of sending to Calais in the train of the prince an engineer in his own service, who took the opportunity of examining all the fortifications of the town, particularly those of the Sizy-Banc. This was discovered by the French ambassador, who immediately gave notice of it to court, but excused the prince, as supposing that what he had done was more out of curiosity than any thing else; and the court seemed to be of the same opinion, as no notice was ever taken of the affair, nor was the friendship between King Henry and the prince in the smallest degree interrupted. The martial disposition of his highness was greatly encouraged by some people in the military line, who put into his hands a paper entitled "Propositions for War and Peace." Notwithstanding this title, however, the aim of the author was evidently to promote war rather than peace; and for this the following arguments were used. 1. Necessity; for the preservation of our own peace, the venting of furious spirits, and instructing the people in arms. 2. The benefits to be derived from the spoils of the enemy, an augmentation of revenue from the conquered countries, &c. This was answered by Sir Robert Cotton in the following manner. 1. That our wisest princes had always been inclined to peace. 2. That foreign expeditions were the causes of invasions from abroad, and rebellions at home, endless taxation, vassalage, and danger to the state from the extent of territory, &c. It
does not appear, however, that the prince was at all moved by these pacific arguments: on the contrary, his favourite diversions were tilting, charging on horseback with pistols, &c. He delighted in conversing with people of skill and experience in war concerning every part of their profession; caused new pieces of ordnance to be made, with which he learned to shoot at a mark; and was so careful to furnish himself with a breed of good horses, that no prince in Europe could boast of a superiority in this respect. He was solicited by Sir Edward Conway to direct his attention to the affairs of the continent, where Sigismund III. of Poland threatened, in conjunction with the king of Denmark, to attack Gustavus Adolphus, the young king of Sweden; but the death of this prince, which happened this year, prevented all interference of this kind.

To his other virtues, Prince Henry added those of frugality without avarice, and generosity without extravagance. As early as the year 1655 he began to show an attention to his interest, as Duke of Cornwall, and to take proper measures for securing his revenues there. In 1610 he settled and appointed the officers of his household, making his choice with the greatest prudence, and giving orders for the management and regulation of his affairs with all the wisdom and gravity of an old counsellor. Some lands were now allotted to him for his revenues; and instead of diminishing his income during the short time he was in possession of them, they were found at his death to be some thousands of pounds better than when he obtained them. At this time he showed much reluctance to gratify any of his servants except by promise, not thinking himself yet authorized to give any thing away; but a short time before his death, he conferred pensions on some of them; and there is no reason to doubt, that his life been prolonged he would have rewarded them all according to their merit.

Though Prince Henry never interfered much in public business, yet in any little transactions he had of this kind, he always displayed great firmness and resolution, as well as absolute propriety of conduct. In a letter from Sir Alexander Seton, Earl of Dunfermling, he is commended for the firmness and resolution with which he repelled the calumnies of some who "had rashly, and with the highest intemperance of tongue, endeavoured to wound the Scottish nation." By this he alluded to some very gross and scurrilous invectives thrown out against the whole body of the Scots by Sir Christopher Pigot, in a debate in the house of commons on an union between the two kingdoms. This gentleman declared his astonishment at the proposal of uniting a good and fertile country to one poor, barren, and in a manner disgraced by nature; and for associating rich, frank, and honest men, with such as were beggars, proud, and generally traitors and rebels to their king with many other shameful expressions of the same kind. His majesty was highly offended with the whole council; and Sir Christopher, after being obliged in parliament to retract his words, was expelled the house and imprisoned; in consequence of which, the king was addressed by the states of Scotland, who thanked him for the zeal he had manifested for the honour of their country. In another instance, where the prince wished Mr. Fullerton, a Scotsman, to supersede Sir Robert Car, one of the attendants of his brother the duke of York, contrary to the inclination of the king and earl of Salisbury, his highness carried his point, by persuading Sir Robert of himself to give up the place in question.

Under this year, 1611, the elegant Latin historian of Great Britain from 1572 to 1628, Robert Johnston, places a story, which, though unsupported by any authority but his own, and improbable in itself, must not be omitted here. The prince, according to this writer, requested the king that he might be appointed to preside in the council. This demand was acceded to by the king's favourite, Car Viscount Rochester, who urged his majesty to lay his son's request before the council. But the earl of Salisbury, jealous of the growing power of Rochester, and a thorough master of artifice and dissimulation, used all his efforts to defeat whatever measures were proposed by his rival; and being asked soon after his opinion upon this point, whether it was for the public interest that the prince should preside in the council, answered, that he thought it dangerous to divide the government, and to invest the son with the authority of the father. Many others of the privy council having delivered their opinions on the same question, that of the earl of Salisbury was adopted by the majority. But his lordship soon took an opportunity, in a secret conference with the prince, to lament his own situation, and to persuade his highness that Lord Rochester had the only influence in the palace, and privately counteracted all his designs. The prince, on his part, represented the denial of his request, and his exclusion from public business. It was not long before Lord Rochester discovered the earl of Salisbury's practice against him with the prince; to whom he therefore went to clear himself; but his highness turned from him with great indignation, and would not hear his justification. The queen likewise, highly displeased with the viscount, refused to see him, and sought all means of lessening his power. This forwardness imputed to the prince by the historian, in endeavouring to intrude himself into the management of public affairs, is not (as Dr. Birch remarks) at all suitable to the character of his highness, or to any other accounts which we have of him; nor ought it to be believed upon the credit of a writer who cites no authority for it, nor indeed for scarce any other assertions in his history, how extraordinary so ever they appear to be, and who frequently ventures to enlarge upon subjects which it was impossible for him to have known. However, it is not much to be doubted, that the prince had no great esteem for Lord Rochester, whose rise to the power of a favourite and a minister he so much disliked, if we may believe a satirical writer of Memoirs, that he was reported either to have struck his lordship on the back with a racket, or very hardly forborne it. And another historian, not much less satirical, Arthur Wilson, mentions the bickerings between the prince and the viscount; and that Sir James, James Elphinstone one day observing his highness to be discontented with the viscount, offered to kill him; for which the prince reproved him, and said that if there were cause he would do it himself. But to wave such very suspicious authorities, it will be sufficient, in order to judge of his highness's opinion of the viscount, and his administration at the very height of it, to hear what himself says in a letter to Sir Thomas Edmondes of...
Henry of the 10th of September 1612: "As matters go now here, I will deal in no businesses of importance for some respects."

It is not to be supposed but that the marriage of a prince so accomplished and so much admired would engage the attention of the public. This was indeed the case. The queen, who favoured the interest of Spain, proposed a match with the infants, and the king of Spain himself seemed to be inclined to the match. In 1611 a proposal was made for a double marriage between the prince of Wales and the eldest daughter of the house of Savoy, and between the prince of Spain and the lady Elizabeth; but these overtures were very coolly received, being generally disagreeable to the nation. Sir Walter Raleigh, at that time prisoner in the Tower, wrote two excellent treatises against these matches; in one of which he styles the prince The most excellent and hopeful, as he does also in the introduction to his Observations on the royal navy and sea-service. About the year 1612, his marriage became an object of general attention. In this affair the king seems to have inclined to match his son with the princess who promised to bring the largest dowry; the nation at large to have been influenced by motives of religion; and the prince himself to have remained entirely passive, and to have been willing to bestow his person with the most perfect indifference on whatever princes should be chosen for him. This appears from a letter to the king dated 5th October 1612, in which he considers the match with the second princess of France as in a manner concluded. Proposals had indeed been made of sending her over to England for her education, she being only nine years of age at that time; but Villeroi the French minister was of opinion, that this ought to be delayed for a year longer. The reasons assigned by the prince for wishing her coming to England at that time were merely political:

1. Because the French court, by having the princess in their power, might alter her mind as they pleased: 2. That there would thus be a greater likelihood of converting her to the Protestant religion; and 3. That his majesty's credit would be better preserved when both daughters (the eldest being promised to the prince of Spain) should be delivered at the same time, though the conclusion of the one marriage might be much later than of the other. With regard to the exercise of her religion, the prince expressed himself rather in severe terms, wishing his majesty only to allow her to use it in "her most private and secret chamber." He then argues with the most philosophic indifference of the propriety of a match with the French princess rather than with one of the house of Savoy: concluding at last in the following words; "If I have incurred in the same error that I did last by the indifference of my opinion, I humbly crave pardon of your majesty, holding it fitter for your majesty to resolve what course is most convenient to be taken by the rules of the state, than for me who am so little acquainted with subjects of that nature: and besides, your majesty may think, that my part to play, which is to be in love with any of them, is not yet at hand." On the whole, it appeared, that there never was any real design in the king or prince to bring this matter to a conclusion; and that the proposal had been made only with a view to break off the match of the eldest daughter with the prince of Spain, which could not now be done.

Prince Henry, notwithstanding his indifference in matrimonial matters, applied himself with the utmost assiduity to his former employments and exercises, the continual fatigue of which was thought to impair his health. In the 15th year of his age his constitution seemed to undergo a remarkable change: he began to appear pale and thin, and to be more retired and serious than usual. He complained now and then of a coldness and heavy pain in his forehead, which obliged him to stroke up his brow before he put on his hat: he frequently bled at the nose, which gave great relief, though the discharge stopped some time before his death. These forebodings of a dangerous malady were totally neglected both by himself and his attendants, even after he began to be seized at intervals with fainting fits. Notwithstanding these alarming symptoms, he continued his usual employments. On the arrival of Count de Nassau in England, he waited upon him as though nothing had been the matter; and when the subject of the princess Elizabeth's marriage came to be canvassed, he interested himself deeply in the affair, and never desisted till the match with the elector palatine was concluded. In the beginning of June 1612, the prince went to Richmond, where he continued till the progress: and notwithstanding the complaints above mentioned, he now took the opportunity of the neighbourhood of the Thames to learn to swim. This practice in an evening, and after supper, was disapproved by several of his attendants; and was supposed to have stopped the bleeding at the nose, from which he had experienced such salutary effects. He could not, however, be prevailed upon to discontinue the practice; and took likewise great pleasure in walking by the river side in moon-light to hear the sound and echo of the trumpets, by which he was undoubtedly too much exposed to the evening dews. Through impatience to meet the king his father, he rode 60 miles in one day; and having rested himself during the night, he rode the next day 36 miles to Belvoir Castle, where he met the king at the time appointed. During the heat of the season also he made several other fatiguing journeys, which must undoubtedly have contributed to impair his health. At the conclusion of the progress, he gave a grand entertainment to the court from Wednesday till Sunday evening, when the king and queen with the principal nobility attended at supper. Next day he hastened to his house at Richmond, where he expected the elector palatine, and began to give orders for his reception, also to take measures for rewarding his servants. To some of these he gave pensions, and promised to gratify the rest as soon as possible. From this time, however, his health daily declined. His countenance became more pale, and his body more emaciated: he complained now and then of drowsiness; which frequently made him ask his attendants concerning the nature and cure of an epidemic fever, probably of the putrid kind, which at that time prevailed in England, and was supposed to have been brought thither from Hungary. He now began frequently to sigh, as is usual for persons afflicted with disorders of that kind. The malady increased in the beginning of October, though he used his utmost endeavours to conceal
conceal it, and occupied himself as usual; only that now, instead of rising early in the morning as before, he would commonly keep his bed till nine. On the 10th of that month he had two slight fits of an ague, which obliged him to keep his chamber; and on the 13th his distemper seemed to be augmented by a violent diarrhœa, which, however, gave so much relief next day, that he insisted upon being removed from Richmond to St James’s, in order to receive the elector palatine. On his arrival there, some of his attendants began to be alarmed by the signs of sickness which appeared upon him, though he himself made no complaint, and even allowed his physician to go to his own house. The elector arrived on the 16th, and the prince waited upon him at Whitehall; but his disease had now gained so much ground, that his temper underwent a very considerable alteration, and he became peevish and discontented with almost everything: nevertheless he still continued to give orders about what related to the ceremony of his sister’s marriage; and kept company as much as he could with the elector and the count de Nassau, with whose conversation he seemed to be particularly delighted. So great was his activity even at this time, that he played a match at tennis on the 24th of October. At this time he exposed himself in his shirt, seemingly without any inconvenience; but at night he complained of a greater degree of languor than usual, and of a pain in his head. Next day, being Sunday, he attended divine service, and heard two sermons; after which he dined with his majesty, seemingly with a good appetite, but the paleness and ghastly appearance of his countenance were much remarked. About three in the afternoon he was obliged to yield to the violence of his distemper; being seized with a great faintness, shivering, and headache, with other symptoms of a fever, which from that time never left him. Several physicians were called; but they differed much in their opinions, if indeed any agreement amongst them, considering the state of medicine at that time, could have been of service. On the first of November he was bled; an operation which Dr Butler, one of his physicians, had hitherto opposed, but now consented to in compliance with his fellows. The impropriety of it was manifest by the thin and dissolved state of the blood which was taken away, and still more by becoming much worse next day. As at that time the Peruvian bark, the great antidote in putrid diseases, was unknown, and no proper methods of treatment seem to have been employed, it is not to be wondered that he sunk under the disease. Among other absurd remedies used on this occasion was “a cock cloven by the back, and applied to the soles of her feet.” He expired on the 6th of November 1612, at the age of 18 years 8 months and 17 days. On opening his body, the lungs were found black, spotted, and full of corrupted matter; the diaphragm was also thickened in many places; the blood-vessels in the hinder part of the head were distended with blood, and the ventricles full of water; the liver was in some places pale and lead-coloured; the gall-bladder destitute of bile, and distended with wind; and the spleen in many places unnaturally black. His funeral was not solemnized till the 7th of December following. Many funeral sermons were published in honour of him, and the two universities published collections of verses on this occasion. The most eminent poets of that age also exerted themselves in honor of the deceased prince; particularly Donne, Brown, Chapman, Drummond of Hawthornden, Dominic Baudius of Leyden, &c.

His highness’s family continued together at St James’s till the end of December 1612, when it was dissolved; and upon the day of their dissolution, Mr. Joseph Hall, his chaplain, preached to them a most pathetic farewell sermon on Rev. xxvi. 3. In this he speaks of his deceased master in the highest terms of commendation, as the glory of the nation, ornament of mankind, hope of posterity, &c.; and that he, who was compounded of all loveliness, had infused an harmony into his whole family, which was “the most loving and entire fellowship that ever met in the court of any prince.” The exhortation, with which the preacher concludes, is: “Go in peace, and live as those that have lost such a master, and as those that serve a master whom they cannot lose.”

Prince Henry was of a comely stature, about five feet eight inches; of a strong, straight, well-made body, with somewhat broad shoulders and a small waist; of an amiable and majestic countenance: his hair of an auburn colour; he was long-faced, and had a broad forehead, a piercing eye, a most gracious smile, with a terrible frown. He was courteous, loving, and affable; naturally modest, and even shame-faced; patient; which he showed both in life and death; slow to anger, so that even when he was offended he would govern it and restrain himself to silence. He was merciful to offenders, after a little punishment to make them sensible of their faults. His sentiments of piety were strong and habitual; and his zeal for the interests of religion was such, that he would, if he had lived, have used his endeavours for reconciling the divisions among its professors. He usually retired three days a week for his private devotions, and was scarce once a month absent from the public prayers, where his behaviour was highly decent and exemplary, and his attention to the preacher the most fixed imaginable. He had the greatest esteem for all divines whose character and conduct corresponded with their profession; but could not conceal his indignation against such as acted inconsistently with it, and he above all things abhorred flattery and vain-glory in them. He had a thorough detestation for popery, though he treated those of that religion with great courtesy; showing, that his hatred was not levelled at their persons, but their opinions. And he was so immovable in his attachment to the Protestant religion, that not long before his death, as Sir Charles Cornwallis assures us, “Discoursus quodiam princeps juravit et cernimus quod si propter religionem in matrimonio coniugii vocatus fuerit, non cum quilibet virgine e veteri et invito se convertas ad religionem veteris.”

He died, by the 10th of April 1612, at the age of 18 years 8 months and 17 days. On opening his body, the lungs were found black, spotted, and full of corrupted matter; the diaphragm was also thickened in many places; the blood-vessels in the hinder part of the head were distended with blood, and the ventricles full of water; the liver was in some places pale and lead-coloured; the gall-bladder destitute of bile, and distended with wind; and the spleen in many places unnaturally black. His funeral was not solemnized till the 7th of December following. Many funeral sermons were published in honour of him, and the two universities published collections of verses on this occasion. The most eminent poets of that age also exerted themselves in honour of the deceased prince; particularly Donne, Brown, Chapman, Drummond of Hawthornden, Dominic Baudius of Leyden, &c.

And he was so immovable in his attachment to the Protestant religion, that not long before his death, as Sir Charles Cornwallis assures us, "Discoursus quodiam princeps juravit et cernimus quod si propter religionem in matrimonio coniugii vocatus fuerit, non cum quilibet virgine e veteri et invito se convertas ad religionem veteris."
same age ever went beyond this prince; and fewer still in a right judgment of what he was taught. When he began to have some knowledge of the Latin tongue, being desired to chuse a motto out of several sentences collected by his tutor for his use, after reading over many good ones, he pitched upon that of Silius Italicus, Faut mentis honesta gloria. And being asked by the king one day, which were the best verses that he had learned in the first book of Virgil's Aeneid, he answered these:

Rex erat Aeneas nobis, quo justior alter
Nec pietate fuit, nec bello major & armis.

Reading likewise another verse of the same poet,

Tuo Tyrius mihi nihil discrimine ageretur,
he said he would make use of it with this alteration,

Anglus Scotus mihi nullo discrimine ageretur.

Besides his knowledge of the learned languages, he spoke the Italian and French; and had made a considerable progress in philosophy, history, fortification, mathematics, and cosmography; in the two last of which he was instructed by that excellent mathematician Mr. Edward Wright. He loved and endeavoured to do somewhat of every thing, and to be excellent in the most excellent. He greatly delighted in all rare inventions and arts, and military engines both at land and sea; in shooting and levelling great pieces of ordnance; in the ordering and marshalling of armies; in building and gardening; in music, sculpture, and painting, in which last art he brought over several works of great masters from all countries.

He had a just opinion of the great abilities of Sir Walter Raleigh; and is reported to have said, that, "no king but his father would keep such a bird in a cage." And it is affirmed, that his highness, but a few months before his death, obtained the lands and castle of Sherburn in Dorsetshire, the confiscated estate of Sir Walter, with an intention of returning it to him. That eminent writer, soldier, and statesman, had a reciprocal regard for the prince, to whom he had designed to address a discourse, "Of the Art of War by Sea," which his highness's death prevented the author from finishing. He had written likewise to the prince another "Discourse of a Maritimal Voyage, with the passages and incidents therein!" But this has never yet appeared in print. He had also intended, and, as he expresses it, hewn out a second and third volume of his General History, which were to have been directed to his highness: "but it has pleased God (says he) to take that glorious prince out of this world, to whom they were directed; whose unspakable and never-enough lamented loss hath taught me to say with Job, Verus est in lactum cithara mea, & organum meum in veneer strumentum."

In the government of his household and management of his revenues, though he was so very young, his example deserved to be imitated by all other princes. He not only gave orders, but saw almost every thing done himself: so that there were scarce any of his domestics whom he did not know by name. And among these there was not one even suspected papist; his directions being very peremptory for setting down the names of all communicants, that he might know if there
there were any of his family who did absent themselves from the communion. His family was large, consisting of few less than 500, many of them young gentlemen born to great fortunes, in the prime of their years, when their passions and appetites were strong, their reason weak, and their experience little. But his judgment, the gravity of his princely aspect, and his own example, were sufficient restraints upon them; and his very eye served instead of a command, and his looks alone had more effect than the sharpest reprehensions of other princes. If any disputes or contests arose among his servants, he would put a stop to them at the beginning by referring them to some of his principal officers, whom he thought most intelligent in points of that nature, and to understand best what compensation was due to the injured, and what reproof to the offender; so that in so numerous a family there was not so much as a blow given, nor any quarrel carried to the least height.

Though he loved plenty and magnificence in his house, he restrained them within the rules of frugality and moderation, as we have already noticed. By this economy he avoided the necessity of being rigid to his tenants, either by raising their farms or fines, or seeking or taking advantage of forfeitures. Now was he tempted to make the profit which both law and right afforded him, of such who had in the time of former princes purchased lands belonging to his duchy of Cornwall, which could not by law be alienated from it; for he gave them, upon resuming these lands, a reasonable satisfaction. Neither did his economy restrain him from being liberal where merit or distress called for it; at the same time he was never known to give, or even promise, anything, but upon mature deliberation. Whatever abuses were represented to him, he immediately redressed, to the entire satisfaction of the persons aggrieved. In his removal from one of his houses to another, and in his attendance on the king on the same occasions, or in progresses, he would suffer no provisions or carriages to be taken up for his use, without full consentment given to the parties. And he was so solicitous to prevent any person from being prejudiced or annoyed by himself or any of his train, that whenever he went out to hawk before harvest was ended, he would take care that none should pass through the corn; and, to set them an example, would himself ride rather a furlong about.

His speech was slow, and attended with some impediment, rather, as it was conceived, by custom and a long imitation of some who first instructed him, than by any defect of nature, as appeared from his having much corrected it by using at home amongst his servants, first short discourses, and then longer, as he found himself enabled to do it. Yet he would often say of himself, that he had the most unserviceable tongue of any man living.

He had a certain height of mind, and knew well how to keep his distance; which indeed he did to all, admitting no near approach either to his power or his secrets. He expressed himself, upon occasions offered, to love and esteem most such of the nobility as were most ancienly descended, and most nobly and honestly disposed. He had an entire affection for his brother the duke of York, and his sister Elizabeth; though sometimes, by a kind of rough play with the former, and an appearance of contradicting the latter in what he discerned her to desire, he took a pleasure in giving them, in their tender years, some exercise of their patience. A writer of less authority than Sir Charles Cornwallis, from the latter of whom we have these particulars, adds, that the prince seemed to have more affection for his sister than his brother, whom he would too often taunt till he made him weep, telling him that of King John he should be a bishop, a gown being fittest to hide his jowls, which were subject in his childhood to be crooked.

With regard to any unlawful passion for women, to the temptations of which the prince's youth and situation peculiarly exposed him, his historian, who knew him, and observed him much, assures us, that having been present at great feasts made in the prince's house, to which he invited the most beautiful ladies of the court and city, he could not discover by his highness's behaviour, eyes, or countenance, the least appearance of a particular inclination to any one of them; nor was he at any other time witness of such words or actions as could justly be a ground of the least suspicion of his virtue; though he observes, that some persons of that time, measuring the prince by themselves, were pleased to conceive, and report, other inclinations. It is indeed asserted by the writer of Antonius Cognatarius, believed upon good grounds to be William Saunders, Esq., author of the "Complete History of Mary Queen of Scotland, and her son and successor King James," that the prince made court to the countess of Essex (afterwards divorced from the earl, and married to the viscount Rochester), before any other lady then living. And Arthur Wilson mentions the many amorous glances which the prince gave her, till discovering that she was captivated with the growing fortunes of Lord Rochester, and grounded more hope upon him than the uncertain and hopeless love of his highness, he soon slighted her. The learned and pious antiquary, Sir Simonds D'Ewes, in a manuscript life of himself, written with his own hand, and brought down to the year 1637, is positive, that, "notwithstanding the inestimable Prince Henry's martial desires and initiation into the ways of godliness, the countess, being set on by the earl of Northampton his father's uncle, first caught his eye and heart, and afterwards prostituted herself to him, who first repaid the fruits of her virginity. But those sparks of grace which even then began to show their lustre in him, with those more heroic innate qualities derived from virtue, which gave the law to his more advised actions, soon raised him out of the slumber of that distemper, and taught him to reject her following temptations with indignation and superciliousness." But these authorities, Dr. Birch observes, ought to have little weight to the prejudice of the prince's character, against the direct testimony in his favour from so well informed a writer as Sir Charles Cornwallis.

The immortal death of the prince concurred with the public apprehensions of the power of the papists, and the ill opinion which the nation then had of the court, gave immediate rise to suspicions of its being hastened by poison. And these suspicions were heightened by the very little concern shown by some persons in great stations. "To tell you (says Richard earl of Dorset in a letter to Sir Thomas Edmondes, of the
Who likewise, in another work, his *Memoirs*, after styling the prince "the darling of mankind, and a youth of vast hopes and wonderful virtues," remarks, that it was the general rumour at the time of his death, that his highness was poisoned; and that there is in print a sermon preached at St James's upon the dissolution of his family, that boldly insinuated some such thing. By this sermon Dr Welwood must mean that of Mr Hall cited above, in which, however, at least as it is reprinted in the London edition of his works in 1617, in folio, there is not to be found any expression that carries the least insinuation of that kind. The writer of the memoir adds, that Sir Francis Bacon, in his speech at the trial of the earl of Somerset, had some reflections upon the intimacy of that lord with Sir Thomas Overbury, which seemed to point that way; there being several expressions left out of the printed copy that were in the speech. Bishop Burnet likewise tells us, that he was assured by Colonel Titus, that he had heard King Charles I declare, that the prince his brother was poisoned by the means of the viscount Rochester, afterwards earl of Somerset. But it will be perhaps sufficient to oppose to all such suggestions the unanimous opinion of physicians who attended the prince during his sickness, and opened his body after his death; from which, as Dr Welwood himself observes, there can be no inference drawn that he was poisoned. To which may be added the authority of Sir Charles Cornwallis, who was well informed, and above all suspicion in this point, and who pronounces the rumors spread of his highness's having been poisoned vain; and was fully convinced that his death was natural, and occasioned by a violent fever.

Henry, Philip, a pious and learned nonconformist minister, was the son of Mr John Henry, page of the back-stairs to James duke of York, and was born at Whitehall in 1631. He was admitted into Westminster school at about 12 years of age; became the favourite of Dr Bushby, and was educated by him, with some others, in collecting materials for the Greek grammar he afterwards published. From thence he was removed to Christ-church, Oxford; where, having obtained the degree of master of arts, he was taken into the family of Judge Poleston, atEmerald in Flintshire, as tutor, to his sons, and to preach at Worthebury. His son married the only daughter and heiress of Mr Daniel Matthews of Broad-oak near Whitchurch, by whom he became possessed of a competent estate. When the king and episcopacy were restored, he refused to conform, was ejected, and retired with his family to Broad-oak: here, and in the neighbourhood, he spent the remainder of his life, about 28 years, relieving the poor, employing the industrious, instructing the ignorant, and exercising every opportunity of doing good. His moderation in his unconformity was eminent and exemplary; and upon all occasions he bore testimony against uncharitable and schismatical separation. In church-government he wished for Archbishop Usher's reduction of episcopacy. He thought it lawful to join in the common prayer in public assemblies; which, during the time of his silence and retirement, he commonly attended with his family with reverence and devotion.

Henry, Matthew, an eminent dissenting minister and author, was the son of the former, and was born
in the year 1662. He continued under his father’s care till he was 18 years of age; in which time he became well skilled in the learned languages, especially in the Hebrew, which his father had rendered familiar to him from his childhood; and from first to last the study of the Scriptures was his most delightful employment. He completed his education in an academy kept at Islington by Mr. Doollittle, and was afterwards entered in Gray’s Inn for the study of the law; where he became well acquainted with the civil and municipal law of his own country, and from his application and great abilities it was thought he would have become very eminent in that profession. But at length, resolving to devote his life to the study of divinity, in 1685 he retired into the country, and was chosen pastor of a congregation at Chester, where he lived about 25 years, greatly esteemed and beloved by his people. He had several calls from London, which he constantly declined; but was at last prevailed upon to accept an unanimous invitation from a congregation at Hackney. He wrote, 1. Expositions of the Bible, in 5 vols. folio. 2. The life of Mr. Philip Henry. 3. Directions for daily communion with God. 4. A method for prayer. 5. Four discourses against vice and immorality. 6. The communicant’s companion. 7. Family hymns. 8. A scriptural catechism. And 9. A discourse concerning the nature of schism. He died of an apoplexy at Nantwich, when upon a journey, in 1714, and was interred at Trinity-church in Chester.

HENRY, Dr. Robert, author of the “History of Great Britain, written on a new plan,” was the son of James Henry farmer at Muitown in the parish of St. Ninian’s, North Britain, and of Jean Galloway daughter of—— Galloway of Borrowmeadow in Stirlingshire. He was born on the 18th of February 1718; and having early resolved to devote himself to a literary profession, was educated first under Mr. John Nicolson at the parish-school of St. Ninians, and for some time at the grammar-school of Stirling. He completed his course of academical study at the university of Edinburgh, and afterwards became master of the grammar-school of Annan. He was licensed to preach on the 27th of March 1746, and was the first licentiate of the presbytery of Annan after its erection into a separate presbytery. Soon after, he received a call from a congregation of Presbyterian dissenters at Carlisle, where he was ordained in November 1748. In this station he remained 12 years, and on the 13th of August 1760 became pastor of a dissenting congregation in Berwick upon Tweed. Here he married, in 1763, Ann Balderston daughter of Thomas Balderston surgeon in Berwick; by whom he had no children, but with whom he enjoyed to the end of his life a large share of domestic happiness. He was removed from Berwick to be one of the ministers of Edinburgh in November 1768; was minister of the church of the New Grey Friars from that time till November 1776; and then became colleague-minister in the Old church, and remained in that station till his death. The degree of Doctor in Divinity was conferred on him by the university of Edinburgh in 1770; and in 1774 he was unanimously chosen moderator of the general assembly of the church of Scotland, and is the only person on record who obtained that distinction the first time he was a member of assembly.

From these facts, which contain the outlines of Dr. Henry’s life, few events can be expected to suit the purpose of the biographer. Though he must have been always distinguished among his private friends, till he was translated to Edinburgh he had few opportunities of being known to the public. The composition of sermons must have occupied a chief part of his time during his residence at Carlisle, as his industry in that station is known to have rendered his labours in this department easy to him during the rest of his life. But even there he found leisure for other studies; and the knowledge of classical literature, in which he eminently excelled, soon enabled him to acquire an extent of information which qualified him for something more important than he had hitherto in his view.

Soon after his removal to Berwick, he published a scheme for raising a fund for the benefit of the widows and orphans of Protestant dissenting ministers in the north of England. This idea was probably suggested by the prosperity of the fund which had almost 30 years before been established for a provision to ministers’ widows, &c. in Scotland. But the situations of the clergy of Scotland were very different from the circumstances of dissenting ministers in England. Annuities and provisions were to be secured to the families of dissenters, without subjecting the individuals (as in Scotland) to a proportional annual contribution, and without such means of creating a fund as could be the subject of an act of parliament to secure the annual payments. The acuteness and activity of Dr. Henry surmounted these difficulties; and, chiefly by his exertions, this useful and benevolent institution commenced about the year 1762. The management was entrusted to him for several years; and its success has exceeded the most sanguine expectations which were formed of it. The plan itself, now sufficiently known, it is unnecessary to explain minutely. But it is mentioned here, because Dr. Henry was accustomed in the last years of his life to speak of this institution with peculiar affection, and to reflect on its progress and utility with that kind of satisfaction which a good man can only receive from “the labour of love and of good works.”

It was probably about the year 1753 that he first conceived the idea of his History of Great Britain: a work already established in the public opinion; and which will certainly be regarded by posterity, not only as a book which has greatly enlarged the sphere of history, and gratifies our curiosity on a variety of subjects which fall not within the limits prescribed by preceding historians, but as one of the most accurate and authentic repositories of historical information which this country has produced. The plan adopted by Dr. Henry, which is indisputably his own, and its peculiar advantages, are sufficiently explained in his general preface. In every period, it arranges, under separate heads or chapters, the civil and military history of Great Britain; the history of religion; the history of our constitution, government, laws, and courts of justice; the history of learning, of learned men, and of the chief seminaries of learning; the history of arts; the history of commerce, of shipping, of money or coin, and of the price of commodities; and the history of
He was an insuperable obstacle to the minute researches which the execution of his plan required. His situation there excluded him from the means of consulting the original authorities; and though he attempted to find access to them by means of his literary friends, and with their assistance made some progress in his work, his information was notwithstanding so incomplete, that he found it impossible to prosecute his plan to his own satisfaction, and was at last compelled to relinquish it.

By the friendship of Gilbert Laurie, Esq., lord provost of Edinburgh, and one of his majesty's commissioners of excise in Scotland, who had married the sister of Mrs Henry, he was removed to Edinburgh in 1763; and it is to this event that the public are indebted for his prosecution of the History of Great Britain. His access to the public libraries, and the means of supplying the materials which these did not afford him, were from that time used with so much diligence and perseverance, that the first volume of his History in quarto was published in 1771, the second in 1774, the third in 1777, the fourth in 1781, and the fifth (which brings down the History to the accession of Henry VIII.) in 1785. The subject of these volumes comprehends the most intricate and obscure periods of our history; and when we consider the scanty and scattered materials which Dr Henry has digested, and the accurate and minute information which he has given us under every chapter of the work, we must have a high opinion both of the learning and industry of the author, and of the vigour and activity of his mind: especially when it is added, that he employed no amanuensis, but completed the manuscript with his own hand; and that, excepting the first volume, the whole book, such as it is, was printed from the original copy. Whatever corrections were made on it, were inserted by interleavings, or in revising the proof sheets. He found it necessary, indeed, to confine himself to a first copy, from an uncertain tremon in his hand, which made writing extremely inconvenient, which obliged him to write with his paper on a book placed on his knee instead of a table, and which unhappily increased to such a degree that in the last years of his life he was often unable to take his victuals without assistance. An attempt which he made after the publication of the fifth volume to employ an amanuensis did not succeed. Never having been accustomed to dictate his compositions, he found it impossible to acquire a new habit; and though he persevered but a few days in the attempt, it had a sensible effect on his health, which he never afterwards recovered.—An author has no right to claim indulgence, and is still less intitled to credit, from the public, for any thing which can be ascribed to negligence in committing his manuscripts to the press; but considering the difficulties which Dr Henry surmounted, and the accurate research and information which distinguished his history, the circumstances which have been mentioned are far from being uninteresting, and must add considerably to the opinion formed of his merit among men who are judges of what he has done. He did not profess to study the ornaments of language; but his arrangement is uniformly regular and natural, and his style simple and perspicuous. More than this he has not attempted, and this cannot be denied him. He believed that the time which might be spent in polishing or rounding a sentence, was more usefully employed in investigating and ascertaining a fact: And, as a book of facts and solid information, supported by authentic documents, his history will stand a comparison with any other history of the same period.

But Dr Henry had other difficulties to surmount than those which related to the composition of his work. Not having been able to transact with the booksellers to his satisfaction, the five volumes were originally published at the risk of the author. When the first volume appeared, it was censured with an unexampled acrimony and perseverance. Magazines, reviews, and even newspapers, were filled with abusive remarks and invectives, in which both the author and the book were treated with contempt and severity. When an author has once submitted his work to the public, he has no right to complain of the just severity of criticism. But Dr Henry had to contend with the inveterate scorn of malignity. In compliance with the usual custom, he had permitted a sermon to be published which he had preached before the society in Scotland for propagating Christian knowledge in 1773; a composition containing plain good sense on a common subject, from which he expected no reputation. This was eagerly seized on by the adversaries of his History, and torn to pieces with a virulence and asperity which no want of merit in the sermon could justify or explain. An anonymous letter had appeared in a newspaper to vindicate the History from some of the unjust censures which had been published, and asserting from the real merit and accuracy of the book the author's title to the approbation of the public. An answer appeared in the course of the following week, charging him, in terms equally confiding and indecent, with having written this letter in his own praise. The efforts of malignity seldom fail to defeat their purpose, and to recoil on those who direct them. Dr Henry had many friends, and till lately had not discovered that he had any enemies. But the author of the anonymous vindication was unknown to him, till the learned and respectable Dr Macqueen, from the indignation excited by the confiding petulance of the answer, informed him that the letter had been written by him. These anecdotes are still remembered. The abuse of the History, which began in Scotland, was renewed in some of the periodical publications in South Britain; though it is justice to add (without meaning to refer to the candid observations of English critics), that in both kingdoms the asperity originated in the same quarter, and that paragraphs and criticisms written at Edinburgh were printed in London. The same

Henry. spirit appeared in strictures published on the second and third volumes; but by this time it had in a great measure lost the attention of the public. The malevolence was sufficiently understood, and had long before become fatal to the circulation of the periodical paper from which it originally proceeded. The book, though printed for the author, had sold beyond his most sanguine expectations; and had received both praise and patronage from men of the first literary characters in the kingdom: and, though, from the alarm which had been raised, the booksellers did not venture to purchase the property till after the publication of the fifth volume, the work was established in the opinion of the public, and at last rewarded the author with a high degree of celebrity, which he happily lived to enjoy.

In an article relating to Dr Henry's life, not to have mentioned the opposition which his History encountered, would have been both affectation and injustice. The facts are sufficiently remembered, and are unfortunately too recent to be more minutely explained. That they contributed at first to retard the sale of the work is undeniable, and may be told without regret now that its reputation is established. The book has raised itself to eminence as a History of Great Britian by its own merits; and the means employed to obstruct its progress have only served to embellish its success.

Dr Henry was no doubt encouraged from the first by the decided approbation of some of his literary friends, who were allowed to be the most competent judges of his subject; and in particular by one of the most eminent historians of the present age, whose history of the same periods justly possesses the highest reputation. The following character of the first and second volumes was drawn up by that gentleman, and is well intituled to be inserted in a narrative of Dr Henry's life. "Those who profess a high esteem for the first volume of Dr Henry's history, I may venture to say, are almost as numerous as those who have perused it, provided they be competent judges of a work of that nature, and are acquainted with the difficulties which attend such an undertaking. Many of those who had been so well pleased with the first were impatient to see the second volume, which advances into a field more delicate and interesting; but the Doctor hath shown the majority of his judgment, as in all the rest, so particularly in giving no performance to the public that might appear crude or hasty, or composed before he had fully collected and digested the materials. I venture with great sincerity to recommend this volume to the perusal of every curious reader who desires to know the state of Great Britian in a period which was hitherto been regarded as very obscure, ill supplied with writers, and not possessed of a single one that deserves the appellation of a good one. It is wonderful what an instructive, and even entertaining, book the Doctor has been able to compose from such unpromising materials: T antiquum series juncturaque pollet. When we see those barbarous ages delineated by so able a pen, we admire the oddness and singularity of the manners, customs, and opinions, of the times, and seem to be introduced into a new world; but we are still more surprised, as well as interested, when we reflect that those strange personages were the ancestors of the present inhabitants of this island. — The object of an antiquary hath been commonly distinguished from that of an historian; for though the latter should enter into the province of the former, it is thought that it should only be quanto basta, that is, so far as is necessary, without comprehending all the minute disquisitions which give such supreme pleasure to the more antiquary. Our learned author hath fully reconciled these two characters. His historical narrative is as full as those remote times seem to demand, and at the same time his inquiries of the antiquarian kind omit nothing which can be an object of doubt or curiosity. The one as well as the other is delivered with great perspicuity, and no less propriety, which are the true ornaments of this kind of writing. All superfluous embellishments are avoided; and the reader will hardly find in our language any performance that unites together so perfectly the two great points of entertainment and instruction." — The gentleman who wrote this character died before the publication of the third volume. — The progress of his work introduced Dr Henry to more extensive patronage, and in particular to the notice and esteem of the earl of Mansfield. That venerable nobleman, who is so well intituled to the gratitude and admiration of his country, thought the merit of Dr Henry's History so considerable, that, without any solicitation, after the publication of the fourth volume, he applied personally to his majesty to bestow on the author some mark of his royal favour. In consequence of this, Dr Henry was informed by a letter from Lord Stormont, the secretary of state, of his majesty's intention to confer on him an annual pension for life of 100 l. "Considering his distinguished talents and great literary merit, and the importance of the very useful and laborious work in which he was so successfully engaged, as titles to his royal countenance and favour." The warrant was issued on the 28th of May 1781; and his right to the pension commenced from the 5th of April preceding. This pension he enjoyed till his death, and always considered it as inferring a new obligation to perseverce steadily in the prosecution of his work. From the earl of Mansfield he received many other testimonies of esteem both as a man and as an author, which he was often heard to mention with the most affectionate gratitude. The octavo edition of his history, published in 1778, was inscribed to his lordship. The quarto edition had been dedicated to the king. — The property of the work had hitherto remained with himself. But in April 1786, when an octavo edition was intended, he conveyed the property to Messrs Cadell and Strachan; reserving to himself what still remained unsold of the quarto edition, which did not then exceed eighty-one complete sets. A few copies were afterwards printed of the volumes of which the first impression was exhausted, to make up additional sets: and before the end of 1786, he sold the whole to Messrs Cadell and Strachan. By the first transaction he was to receive 1000 l. and by the second between 300 l. and 400 l. about 1400 l. in all. These sums may not be absolutely exact, as they are set down from memory; but there cannot be a mistake of any consequence on the one side or the other. — Dr Henry had kept very accurate accounts of the sales from the time of the original publication; and af-
HEP

HEPATIC, in Medicine and Anatomy, any thing belonging to the liver.

HEPATIC Air, or Sulphurated Hydrogen Gas, a permanently elastic fluid of a very disagreeable odour, somewhat like that of rotten eggs. See CHEMISTRY, No. 442.

HEPATIC Aloes, the inspissated juice of a species of ALOE. See Materia Medicæ Index.

HEPATIC Stone. See LIVER Stone.

HEPATIC Water. See SULPHURIC WATERS, CHEMISTRY, p. 706.

HEPATICA, a species of Anemone. See Botany Index.

HEPATITIS, in Medicine, an inflammation of the liver. See Medicine Index.

HEPATOSCOPIA, (formed of from liver, and ἴσανις, I consider), in antiquity, a species of divination, wherein predictions were made by inspecting the livers of animals.

HEPATOSCOPIA is also used as a general name for divination by entrails.

HEPHAESTIA, in Grecian antiquity, an Athenian festival in honour of Vulcan, the chief ceremony of which was a race with torches. It was performed in this manner: The antagonists were three young men, one of whom, by lot, took a lighted torch in his hand, and began his course; if the torch was extinguished before he finished the race, he delivered it to the second; and he in like manner to the third: the victory was his who first carried the torch lighted to the end of the race; and to this successive delivering of the torch we find many allusions in ancient writers.

HEPHTHEMIMERIS (composed of in, seven, seven, half, and pass, parts), in the Greek and Latin poetry, a sort of verse consisting of three feet and a sylable; that is, of seven half feet.

Such are most of the verses in Anacreon:

| Θελκ  | θελκεν | θελκυ  | θελκε | &c. |

And that of Aristophanes, in his Plutus:

Et furris agitatus amor, et conscia virtus.

They are also called trimetri cataleptici.

HEPHTHEMIMERIS, or Hephthemimeres, is also a censura after the third foot; that is, on the seventh half-foot. It is a rule, that this syllable, though it be short in itself, must be made long on account of the censura, or to make it an Hephthemimeris. As in that verse of Virgil,

Et furris agitatus amor, et conscia virtus.

It may be added, that the censura is not to be on the fifth foot, as it is in the verse which Dr Harris gives us for an example:

Ille lotus nivium molliis suis Hyacintho.

This is not a hephthemimeris censura, but a hennanemimeris, i. e. of nine half feet.

HEPTACHORD, in the ancient poetry, signifies verses that were sung or played on seven chords, that is, on seven different notes. In this sense it was applied to the lyre when it had but seven strings. One of the intervals is also called an heptachord, as containing
holding the same number of degrees between the extrema.

HEPTAGON, in Geometry, a figure consisting of seven sides and as many angles. In fortification, a place is termed a heptagon, that has seven bastions for its defence.

HEPTAGONAL NUMBERS, in Arithmetic, a sort of polygonal numbers, wherein the difference of the terms of the corresponding arithmetical progression is 5. One of the properties of these numbers is, that if they be multiplied by 40, and 9 be added to the product, the sum will be a square number.

HEPTANDRIA, in Botany, (from hepta, septem, and andros, a man); the seventh class in Linnaeus's sexual method, consisting of plants with hermaphrodite flowers, which have seven stamens or male organs. See Classification under Botany.

HEPTANGULAR, in Geometry, an appellation given to figures which have seven angles.

HEPTARCHY (compounded of the Greek hepta, "seven," and archos, imperium, "government"), a government composed of seven persons, or a country governed by seven persons, or divided into seven kingdoms.

The Saxon heptarchy included all England, which was cantoned out into seven independent petty kingdoms, peopled and governed by different clans and colonies, viz. those of Kent, the South Saxons, West Saxons, East Saxons, Northumberland, the East Angles, and Mercia. The heptarchy was formed by degrees from the year 455, when the first kingdom of Kent was erected, and Hengist assumed the title of king of Kent immediately after the battle of Eglesford; and it terminated in 827 or 828, when King Egbert reunited them into one, made the heptarchy into a monarchy, and assumed the title of king of England. It must be observed, however, that though Egbert became monarch of England, he was not perfectly absolute. The kingdom which he actually possessed consisted of the ancient kingdoms of Wessex, Sussex, Kent, and Essex, that had been peopled by Saxons and Jutes. As for the other three kingdoms, whose inhabitants were Angles, he contented himself with preserving the sovereignty over them, permitting them to be governed by kings who were his vassals and tributaries.

The government of the heptarchy, reckoning from the founding of the kingdom of Mercia, the last of the seven Anglo-Saxon kingdoms, lasted 243 years; but if the time spent by the Saxons in their conquests from the arrival of Hengist in 449 be added, the heptarchy will be found to have lasted 378 years from its commencement to its dissolution. The causes of the dissolution of the heptarchy were the great inequality among the seven kingdoms, three of which greatly surpassed the others in extent and power; the default of male heirs in the royal families of all the kingdoms, that of Wessex excepted; and the concurrence of various circumstances which combined in the time of Egbert.

HERACLEA, an ancient city of Turkey in Europe, and in Romania, with the see of an archbishop of the Greek church, and a sea-port. It was a very famous place in former times, and there are still some remains of its ancient splendour. Theodosius Lascaris took it from David Comnenus, emperor of Trebizond, when it fell into the hands of the Genoese, but Mahomet II. took it from them; since which time it has been in the possession of the Turks. It is near the sea. E. Long. 27° 58' N. Lat. 40° 59'.

HERACLEONITES, a sect of Christians, the followers of Heracleon, who refined upon the Gnostic divinity, and maintained that the world was not the immediate production of the Son of God, but that he was only the occasional cause of its being created by the demiurgus. The Heracleonites denied the authority of the prophecies of the Old Testament, maintaining that they were mere random sounds in the air; and that St John the Baptist was the only true voice that directed to the Messiah.

HERACLEUM, MADNESS, or Hogweed; a genus of plants belonging to the pentandria class; and in the natural method ranking under the 45th order, Umbellula. See BOTANY Index.

HERACLIDÆ, the descendants of Hercules, greatly celebrated in ancient history. Hercules at his death left to his son Hyllus all the rights and demands which he had upon the Peloponnesus, and permitted him to marry Iole as soon as he came of age. The posterity of Hercules were not more kindly treated by Euristeus than their father had been, and they were obliged to retire for protection to the court of Ceyx, king of Trachinia. Euristeus pursued them thither; and Ceyx, afraid of his resentment, begged the Heraclids to depart from his dominions. From Trachinia they came to Athens, where Theseus, the king of the country, who had accompanied their father in some of his expeditions, received them with great humanity, and assisted them against their common enemy Euristeus. Euristeus was killed by the hand of Hyllus himself, and his children perished with him, and all the cities of the Peloponnesus became the undisputed property of the Heraclids. Their triumph, however, was short; their numbers were lessened by a pestilence; and the oracle informed them, that they had taken possession of the Peloponnesus before the gods permitted their return. Upon this they abandoned Peloponnesus, and came to settle in the territories of the Athenians, where Hyllus, obedient to his father's commands, married Iole the daughter of Eurytus. Soon after he consulted the oracle, anxious to recover the Peloponnesus; and the ambiguity of the answer determined him to make a second attempt. He challenged to single combat Ateus, the successor of Euristeus on the throne of Mycene; and it was mutually agreed that the undisturbed possession of the Peloponnesus should be ceded to whoever defeated his adversary. Echemus accepted the challenge for Ateus, and Hyllus was killed, and the Heraclids a second time departed from Peloponnesus. Cleodenus the son of Hyllus made a third attempt, and was equally unsuccessful; and his son Aristomachus some time after met with the same unfavourable reception, and perished in the field of battle. Aristodemus, Teneus, and Chersophon, the three sons of Aristomachus, encouraged by the more expressive word of an oracle, and desirous to revenge the death of their progenitors, assembled a numerous force, and with a fleet invaded all Peloponnesus. Their expedition was attended with much success; and after some decisive battles, they became masters of all the peninsula. The recovery of the Peloponnesus by the descendants of Hercules.
Another of his expeditions was against the Tigris, and he fought a battle near the site of the ancient Nineveh in 627, about the end of the year, at which time he gained a complete victory over the Persians, having slain three of their chiefs with his own hand. He recovered 300 Roman standards, and set a vast number of captives at liberty. In 625, he made the Persian king put an end to the persecution of the Christians, renounce the conquests of his father upon the Roman empire, and restore the true cross taken from Jerusalem. When at Emma, he first heard of the name of Mahomet, who invited him to embrace his new faith, but without success. He brought a reproach on his name by adhering to the doctrine of the Mooloolites, but chiefly by espousing his niece Martina for his second wife, by whose influence he divided the succession between Constantine and Herculona, his son by Martina. He fell into a drearful complaint, by which he was carried off in the month of February 641, in the 31st year of his reign.

HERALD, says Verstegan, is derived from the Saxon word Heresault, and by abbreviation Herol, which in that language signifies the champion of an army; and, growing to be a name of office, it was given to him who, in the army, had the special charge to denounce war, to challenge to battle and combat, to proclaim peace, and to execute martial messages. But the business of heralds with us is as follows, viz. to marshal, order, and conduct all royal cavalcades, ceremonies at coronations, royal marriages, installations, creations of dukes, marquises, earls, viscounts, barons, baronets, and dubbing of knights; embassies, funeral processions, declarations of war, proclamations of peace, &c.; to record and blazon the arms of the nobility and gentry; and to regulate any abuses therein through the English dominions, under the authority of the earl marshal, to whom they are subservient. The office of Windsor, Chester, Richmond, Somerset, York, and Lancaster heralds, is to be assistants to the kings-at-arms, in the different branches of their office: and they are superior to each other, according to creation, in the above order.

Heralds were formerly held in much greater esteem than they are at present; and were created and christened by the king, who, pouring a gold-cup of wine on their head, gave them the herald-name: but this is now done by the earl marshal. They could not arrive at the dignity of herald without having been seven years pursuivant; nor could they quit the office of herald, but to be made king-at-arms.

Richard III. was the first who formed them, in this kingdom, into a college; and afterwards great privileges were granted them by Edward VI. and Philip and Mary.

The origin of heralds is very ancient. Stater is represented by Homer as herald of the Greeks, who had a voice louder than 50 men together. The Greeks called them σημαντος, and σημαντος; and the Romans, fasces. The Romans had a college of heralds, appointed to decide whether a war were just or unjust; and to prevent its coming to open hostilities, till all means had been attempted for deciding the difference in a peaceful way.
HERALDRY.

A science which teaches how to blazon, or explain in proper terms, all that belongs to coats-of-arms; and how to marshal, or dispose regularly, divers arms on a field. It also teaches whatever relates to the marshalling of solemn cavalcades, processions, and other public ceremonies at coronations, installations, creations of peers, nuptials, christenings of princes, funerals, &c.

Arms, or coats-of-arms, are hereditary marks of honour, made up of fixed and determined colours and figures, granted by sovereign princes, as a reward for military valour, a shining virtue, or a signal public service; and which serve to denote the descent and alliance of the bearer, or to distinguish states, cities, societies, &c. civil, ecclesiastical, and military.

Thus heraldry is the science, of which arms are the proper object; but yet they differ much both in their origin and antiquity. Heraldry, according to Sir George Mackenzie, "as digested into an art, and subjected to rules, must be ascribed to Charlemagne and Frederick Barbarossa, for it did begin and grow with the feudal law." Sir John Ferne is of opinion, that we did borrow arms from the Egyptians; meaning, from their hieroglyphics. Sir William Dugdale mentions, that arms, as marks of honour, were used by great commanders in war, necessity requiring that their persons should be notified to their friends and followers.

The learned Alexander Nisbet, in his excellent system of heraldry, says, that arms owe their rise and beginning to the light of nature, and that signs and marks of honour were made use of in the first ages of the world, and by all nations, however simple and illiterate, to distinguish the noble from the ignoble. We find in Homer, Virgil, and Ovid, that their heroes had divers figures on their shields, whereby their persons were distinctly known. Alexander the Great, desirous to honour those of his captains and soldiers who had done any glorious action, and also to excite an emulation among the rest, did grant them certain badges to be borne on their armour, pennons, and banners, ordering, at the same time, that no person or potentate, through his empire, should attempt or presume to give or tolerate the bearing of those signs upon the armour of any man, but it should be a power reserved to himself; which prerogative has been claimed ever since by all other kings and sovereign princes within their dominions.

After these and many other different opinions, all that can be said with any certainty is, that in all ages, men have made use of figures of living creatures, or symbolical signs, to denote the bravery and courage either of their chief or nation, to render themselves the more terrible to their enemies, and even to distinguish themselves or families, as names do individuals. The famous C. Agrippa, in his treatise of the vanity of sciences, cap. 81. has collected many instances of these marks of distinction, anciently borne by kingdoms and states that were any way civilized, viz.

- The Egyptians, an ox,
- The Athenians, an owl,
- The Goths, a bear,
- The Romans, an eagle,
- The Franks, a lion,
- The Saxons, a horse.

The last is still borne in the arms of his present Britannic majesty. As to hereditary arms of families, William Camden, Sir Henry Spelman, and other judicious heralds, agree, that they began no sooner than towards the latter end of the 11th century. According to Father Menestrier's opinion, a French writer, whose authority is of great weight in this matter, Henry l'Oiseleur (the Falconer) who was raised to the imperial throne of the West in 920, by regulating tournaments in Germany gave occasion to the establishment of family-arms, or hereditary marks of honour, which undeniably are more ancient and better observed among the Germans than in any other nation. Moreover, this last author asserts, that with tournaments first came up coats-of-arms; which were a sort of livery, made up of several lists, fillets, or narrow pieces of stuff of divers colours, from whence came the fess, the bend, the pale, &c. which were the original charges of family-arms; for they who never had been at tournaments, had not such marks of distinction. They who inlisted themselves in the Croisades, took up also several new figures hitherto unknown in armorial ensigns; such as alerions, bezants, escarp-shell, martlets, &c. but more particularly crosses, of different colours for distinction's sake. From this it may be concluded, that heraldry, like most human inventions, was insensibly introduced and established; and that, after having been rude and unsettled for many ages, it was at last methodised, perfected, and fixed, by the Croisades and tournaments.

These marks of honour are called arms, from their being principally and first worn by military men at war and tournaments, who had them engraved, embossed, or depicted on shields, targets, banners, or other martial instruments. They are also called coats-of-arms, from the custom of the ancients embroidering them on the coats they wore over their arms, as heralds do to this day.

Arms are distinguished by different names, to denote the causes of their bearing; such as,

Arms of dominion or sovereignty are those which emperors, kings, and sovereign states, do constantly bear; being, as it were, annexed to the territories, kingdoms, and
The shield or escutcheon is the field or ground whereon are represented the figures that make up a coat of arms: for these marks of distinction were put on buckles or shields before they were placed on banners, standards, flags, and coat-armour; and wherever they may be fixed, they are still on a plane or supercicies whose form resembles a shield.

Shields, in Heraldry called escutcheons or escutcheons, from the Latin word scutum, have been, and still are, of different forms according to different times and nations. Among ancient shields, some were almost like a horse-shoe, such as is represented by no. 1 in the figure of Escutcheons; others triangular, somewhat rounded at the bottom, as no. 2. The people who inhabited Mesopotamia, now called Diarbeek, made use of this sort of shield, which is thought they had of the Trojans. Sometimes the shield was heptagonal, that is, had seven sides, as no. 3. The first of this shape is said to have been used by the famous triumvir M. Antony. That of knights-banneker was square, like a banner, as no. 4. As to modern escutcheons, those of the Italians, particularly of ecclesiastics, are generally oval, as no. 5. The English, French, Germans, and other nations, have their escutcheons formed different ways, according to the carver's or painter's fancy; see the various examples, contained from no. 6—16 of the figure. But the escutcheon of maids, widows, and of such as are born ladies, and are married to private gentlemen, is of the form of a lozenge: See no. 17—20. Sir George Mackenzie mentions one Muriel, countess of Strathern, who carried her arms in a lozenge, anno 1284, which shows how long we have been versant in heraldry.

Armorialists distinguish several parts or points in escutcheons, in order to determine exactly the position of the bearings they are charged with; they are here denoted by the first nine letters of the alphabet, ranged in the following manner:

A—the dexter chief.
B—the precise middle chief.
C—the sinister chief.
D—the honour point.
E—the fess point.
F—the nombril point.
G—the dexter base.
H—the middle precise base.
I—the sinister base.

The knowledge of these points is of great importance, and ought to be well observed, for they are frequently occupied with several things of different kinds. It is necessary to observe, that the dexter side of the escutcheon is opposite to the left hand, and the sinister side to the right hand of the person that looks on it.

CHAP. II. Of Tinctures, Pairs, Lines, and Differences.

SECT. I. Of Tinctures.

By tinctures is meant that variable hue of arms which is common both to shields and their bearings.
HERALDRY.

The French, and all other nations, do not admit such a multiplicity of names to this figure; but call them Besants, after an ancient coin struck at Constantinople, once Byzantins, if they are Or and Torteaux; or of any other tinture, expressing the same.

Sect. II. Of Furs.

FURS represent the hairy skin of certain beasts, prepared for the doublings or linings of robes and garments of state; and as shields were anciently covered with furred skins, they are therefore used in heraldry not only for the linings of the mantles, and other ornaments of the shields, but also in the coats of arms themselves.

There are three different kinds in general use, viz.
1. Ermine; which is a field argent, powdered with black spots, their tails terminating in three hairs. (Fig. ii. No. 11.)
2. Counter-ermine, where the field is sable, and the powdering white. (No. 12.)
3. Vair, (No. 15.), which is expressed by blue and white skins, cut into the forms of little bells, ranged in rows opposite to each other, the base of the white ones
admits of 7 only; but there are 14 distinct kinds, of lines.

The principal reason why lines are thus used in heraldry, is to difference bearings which would be otherwise the same; for an escutcheon charged with a chief engrailed, differs from one charged with a chief wavy, as much as if the one bore a cross and the other a salter.

As the fore-mentioned lines serve to divide the field, it must be observed, that if the division consists of two equal parts made by the perpendicular line, it is called partit per pale; by the horizontal line, partit per fess; by the diagonal dexter, partit per bend; by the diagonal sinister, partit per bend sinister; examples of which will be given in the sequel of this treatise.

If a field is divided into four equal parts by any of these lines, it is said to be quartered; which may be done two ways, viz.

Quartered or partit per cross; which is made by a perpendicular and horizontal line, which, crossing each other at the centre of the field, divide it into four equal parts called quarters. See Plate CCLIV. under fig. 1. (A).

Quartered or partit per saltier; which is made by two diagonal lines, dexter and sinister, that cross one another in the centre of the field, and likewise divide it into four equal parts. Ibid.

The escutcheon is sometimes divided into a greater number of parts, in order to place in it the arms of the several families to which one is allied; and in this case it is called a genealogical achievement. These divisions may consist of 6, 8, 12, and 16, quarters [as under fig. 1. (A)], and even sometimes of 20, 32, 64, and upwards; there being examples of such divisions frequently exhibited at pompous funerals. An extraordinary instance of this kind was exhibited at the pompous funeral of the Viscountess Townshend, whose corpse was brought from Dublin castle in Ireland to Rainhamhall in Norfolk, one of the principal tenants on horseback carrying before the hearse a genealogical banner, containing the quarterings of his lordship’s and her ladyship’s family, to the amount of upwards of 150 coats. Sir George Booth, rector of the valuable living of Ashton under Line, bears six distinct coats of arms in his shield; viz. those for Booth, Barton, Vemble, Mountfort, Ashton, Egerton; and has besides a right to 37 other coats: but Sir William Dugdale very justly objects to so many arms being clustered together in one shield or banner, on account of the difficulty of knowing and distinguishing one coat of arms from another.

Sect. III. Of the lines used in the parting of fields.

Escutcheons are either of one tincture, or more than one. Those that are of one only, that is, when some metal, colour, or fur, is spread all over the surface or field, such a tincture is said to be predominant: but in such as have on them more than one, as most have, the field is divided by lines; which, according to their divers forms, receive various names.

Lines may be either straight or crooked. Straight lines are carried evenly through the escutcheon: and are of four different kinds: viz. a perpendicular line \|; a horizontal, —; a diagonal dexter, \; a diagonal sinister, /.

Crooked lines are those which are carried unevenly through the escutcheon with rising and falling. French armorists reckon 11 different sorts of them; Guillim

(A) Bordures are still introduced into English coats of arms, but for particular reasons, which heralds can best explain. They are by the French frequently taken for a principal figure, and numbered among the rest of the ordinaries.
HERALDRY.

CHAP. II.

Sect. IV. Of the Differences of Costs of Arms.

ARMORISTS have invented divers differences or characteristic marks, whereby bearers of the same cost of arms are distinguished each from others, and their nearness to the principal bearer demonstrated. According to J. Guillim, these differences are to be considered either as ancient or modern.

Art. 1. Of Ancient Differences.

Those he calls ancient differences consist in bordures (A); which is a bearing that goes all round, and parallel to the boundary of the escutcheon, in form of a hem, and always contains a fifth part of the field in breadth. Bordures were used in ancient times for the distinguishing not only of one nation or tribe from another, but also to note a diversity between particular persons descended of one family and from the same parents. This distinction, however, was not expressly signified by invariable marks; nor were bordures always appropriated to denote the different degrees of consanguinity; for, as Sir Henry Spelman observes in his Aspilogia, p. 149, ancient heralds, being fond of periphrastic differences, often inverted the paternal tincture, or sometimes inserted another charge in the escutcheon, such as bends, creslotes, cantons, or the like; which irregularity has, I suppose, induced modern armorists to invent and make use of others.

There are bordures of different forms and tinctures, as in the examples, fig. 3.

1. "Sable, a Bordure Argent;" borne by the right hon. Sackville Tufton, earl of Thanet. —When a bordure is plain, you are not to mention it, as it is always understood so in heraldry, though it be not expressed; but if it has any other form, you are to signify it.

2. "Gules, a Bordure engrailed Argent;" borne by the right hon. Charles Gray, Lord Gray. —This is called engrailed, from the French word engravé, which signifies a thing the hail has fallen upon and broken off the edges, leaving it with little semicircles struck out of it.

3. "Gules, a Bordure engrailed Or;" borne by the right hon. George Talbot, earl of Shrewsbury. You must observe, that in a bordure or ordinary formed of these lines, the points are represented on all sides towards the field, and the semicircles turned towards the bordure or ordinary.

4. "Argent, a Bordure inducted Azure." —This is quite contrary to the last; for as the other turns its points from the bordure into the field, so contrarywise does this, by the inversion of the points from the field into the bordure. Such a charge or any other formed of these lines is seldom to be met with in English coats of arms.

5. "Gules, a Bordure indented Argent." —This word indented requires very little explanation, the significance being obvious to all persons, from its figure, which is composed of tracks resembling teeth, called in Latin dentes.

7. "Vert, a Bordure Vair."
8. "Ermine, a Bordure compny, or gobony, Or and Sable." —This is so termed from its being composed of small equal pieces. J. Guillim calls this bordure gobonated, which implies the same meaning; but the word being obsolete, is not used by modern heralds.

10. "Azure, a Bordure counter-compny Argent and Gules." —Observe, that the counter-compny does always consist of two tracks and no more.

11. "Or, a Bordure chequy Argent and Sable." —This has a great resemblance with the last bordure, having only one track more; therefore you must take care, before you blazon, to number them, or else you may easily err in taking the one for the other.

12. "Gules, a Bordure Argent, charged with eight Trefoils slipped proper, that is, Vert." —All nations use few terms in blazoning bordures; but English armorists, in order possibly to raise the dignity of this science, have perplexed it, and rendered it unintelligible to all foreigners, by introducing into it several mystical proper names, among which may be reckoned the following ones, viz. They call a bordure, if charged with eight plants, fruits, flowers, or leaves, verdis of such vegetables; or ensuroran of such birds; emuryn of beasts; perfloy of furs; and entoyre of inanimate things of what kind soever.

13. "Gules on a Bordure Azure, eight Stars Or."
14. "Argent, a Bordure compny of the last and Gules, the first charged with Roves of the second, barbed and seeded proper." This bordure is borne by his grace Charles Lenox duke of Richmond, &c.

15. "Ermine, with a Bordure engrailed Gules;" the coat of arms of the right hon. Henry-Benedict Barnewall, Viscount Kingsland, &c. of Ireland. This ancient and noble family is of French extraction, and allied to the dukes of Little-Bretagne, where the name continues still in great repute.

16. "Argent, a Bordure Sable charged with eight Besants;" borne by the right hon. Lord Ranelagh, of Ireland.

17. "Party per pale Argent and Gules, a Bordure charged with eight Escallops counterchanged;" the coat of arms of the right hon. William Maule, earl of Panmore, &c. of Ireland. This very ancient family is originally French, and derives its surname from the town and lordship of Maule in Normandy, where the same arms are still to be seen in the parish-church.

18. "Azure, a Bordure quarterly, the first and fourth Ermine, the second and third counter-compny Argent and Azure."

19. "purpere, a Bordure compny Or and Gules, each of the last charged with a Besant."
20. "Quarterly Or and Gules, within a Bordure Vért, charged with eight Escallops Or."

We shall conclude this head with observing, that a bordure is never of metal upon metal, and seldom of colour upon colour, but rather of the tincture which the principal bearing or charge is of. Thus Sir Dalziel of Glenae, whose predecessor was a younger brother of the noble family of Carnwath, has, within a Bordure Argent, the paternal coat of the ancient name of Dalziel, viz. "Sable, a hanged man with his arms extended, Argent;" formerly they carried him hanging
Chap. II. H E R A L D R Y.

Modern Differences.

In what part of the escutcheon these differences should be borne is not certain; for Guilielm, Morgan, and others, give us many different examples of their position. The honour-point would be the properest place, if the arms would admit of it; but that is not always the case, as that part may be charged with some figure in the paternal coat, which cannot with propriety receive the difference. There are instances where these are borne as perfect coats of arms, as the examples subjacent to the Table of Houses sufficiently show; which are to be blazoned thus:

The first is "Azure, a Label Argent."—When such a label is borne as a difference, the pendants, according to G. Leigh, signify that he is but the third person; the dexter pendant referring to his father, the sinister to his mother, and the middle one to himself.

The second is "Argent, a Label of five points Azure;" borne by the name of Houghton. If a label has more or less than three pendants or points, they are to be expressed as in the foregoing example.

The third is "Azure, a Crescent Argent," borne by the name of Lucy.—The reason G. Leigh assigns for the second son’s having a crescent for a difference is to show that he should increase the family by adding to its riches and reputation.

The fourth is "Argent, a Mullet Sable, on a Chief Azure, a Fleur-de-lis Or;" borne by the name of Rogers, in Gloucestershire.—A mullet or spur was appointed for the third son’s difference, as the last mentioned author says, to show that he should follow chivalry.

The fifth is "Azure, a Fleur-de-lis Argent," borne by the right hon. Henry Digby, Baron Digby of Castlereagh, in King’s county, Ireland.

These few examples, among many more that might be given, demonstrate the impropriety of adopting these modern differences, as they are called, for marks of cadency to distinguish the different branches of a family; for it is impossible to distinguish the uncle or granduncle, from the nephew, or grand-nephew, if each of them are second, third or fourth sons; and in the course of succession these differences would multiply to such a number, that it would be impossible to delineate them distinctly in most cases. But as they are given by most of the English writers on heraldry, though no foreign nation uses them, it was thought proper to insert them here.

Sisters, except of the blood-royal, have no other mark of difference in their coats of arms, but the form of the escutcheon (as observed before); therefore they are permitted to bear the arms of their father, even as the eldest son does after his father’s decease. The reason of which is by Guilielm said to be, that when they are married, they lose their surname, and receive that of their husbands.

Next to these diminutions, G. Leigh, J. Guilielm, and after them Dr Harris in his Lexicon Technicum, set forth at large divers figures, which they pretend were formerly added to the coats of such as were to be punished and branded for cowardice, fornication, slander, adultery, treason, or murder, for which they give them the name of abatements of honour; but as they produce but one instance of such whimsical bearings, we have not inserted them here. Besides, arms..."
HERALDRY.

Chap. III.

4. “Vert, a Chief undy Or.”
5. “Azure, a Chief nebule Argent.”
6. “Or, a Chief checkly Azure and Argent.”
7. “Ermine, a Chief quarterly Or and Gules,” borne by the name of Peckham.
8. “Argent, a Chief Sable, in the lower part thereof a Fillet of the Field.”
9. “Azure, pretty Argent, a Chief Or;” borne by the right hon. Hayes St Leger, Viscount Dunsraile, &c. of the county of Cork in Ireland. This ancient and noble family is of French extraction; and is descended from Sir Robert Sent Legere, knight, who, in 1566, accompanied William duke of Normandy in his expedition into England; and the family have a tradition, that he, with his own band, supported the said duke when he quitted the ship to land in Sussex.
10. “Argent, on a Chief engrailed Azure, a Tortoise passant Or;” borne by the name of Bidgood.
11. “Argent, on a Chief Gules, two Spur reveals Or;” borne by the right hon. John St John, Lord St John of Bletshoe, &c. Of this ancient family, which derive their surname from a place called St John, in Normandy, was John St John, Esq. who having a principal employment in the army of the Norman duke, attended him in his expedition into England.
12. “Argent, on a Chief Vert, two Spears Heads erect of the Field, the points imbrued Gules;” borne by the right hon. George Brodrick, Viscount Middleton, &c. of the kingdom of Ireland. This family is lineally descended from George de Brodrick, who came into England in the reign of William II.
13. “Or, on a Chief Sable, three Escallops of the field,” for the name of Graham; and borne quartered in the arms of his Grace William Graham, duke, marquis, and earl of Montrose, &c. with Argent three Roses Gules. According to the Scots writers this great and noble family is descended from the renowned Greme or Grame, who in the year 404 was general of King Fergus Il’s army, and in 420 forced his way through the wall built by the Romans between the rivers Firth and Clyde to keep out the Scots from molesting them in their possessions, and the said breach has ever since been called Grame’s Dyke.
14. “Argent, on a Chief indented Gules, three Crosses pattée of the Field;” borne by the right hon. John Percival earl of Egmont, &c. This very ancient and noble family is supposed, from circumstances little short of positive proof, to have sprung from a younger branch of the sovereign dukes of Bretagne in France, of the same name. They were transplanted into Normandy before the Conquest, possessed of great estates and power, and invested with the office of chief butler. Upon the Norman invasion, two of this family came over into England with the Conqueror, from one of which the descent of the present earl of Egmont is deduced by the clearest and most indisputable proofs of historians and records.
15. “Azure, on a Chief indented Or, three Spar-revels Gules;” borne by the right hon. Charles Moore, earl of Drogheda, &c. of the kingdom of Ireland. This noble family, which is of French extraction, came into England soon after the Conquest, and made their first
chap. III.

heraldry.

Of the first residence in the manor of Moore-court, in the county of Kent.

16. “Ermine, on a Chief indented Azure, three ducal coronets Or;” borne by the name of Lytton.

17. “Azure, on a Chief Or, three Martlets Gules,” for the name of Wray; and borne by Sir Cecil Wray, Bart. of Lincolnshire.

18. “Ermine, on a Chief Gules; five Lozenges of the first;” borne by the name of Dinside.

19. “Argent, fretty Gules, on a Chief of the second, three Leopards Faces Or;” borne by the right hon. Henry Liddel, Lord Ravensworth. This noble lord is descended from the ancient lords of Liddle-castle, in the county of Durham, where they have been proprietors of great coal-mines time out of mind.

20. “Ermine, a Chief party per pale Azure and Or; on the dexter the Sun in his splendour, on the sinister a Cross pattée Gules.” The arms of the bishopric of Raphoe, in the kingdom of Ireland.

art. 2. of the pale.

The pale is an ordinary, consisting of two perpendicular lines drawn from the top to the base of the escutcheon, and contains the third middle part of the field. Its diminutives are, the pallet, which is the half of the pale; and the endorse, which is the fourth part of a pale. This ordinary and the pallet may receive any charge, but the endorse should not be charged. The endorse, besides, is never used, according to J. Leigh, but to accompany the pale in pairs, as cotasses do the bend; but Sir John Ferne is of a different opinion. fig. 5.

Plate Ex. 1. “Gules, a Pale Or;” by the name of Grandmain.

2. “Party per Pale Argent and Gules, a Pale counterchanged.”

3. “Argent, a Pale between two Endorses Gules.”

4. “Party per Pale, 1st, Pale of six Argent and Sable, 2d, Azure;” borne by the name of Trencroft.

5. “Pale of six Or and Azure.”

6. “Argent, three Pallets undy Sable;” by the name of Downess.

7. “Party per Pale, Argent and Gules;” borne by the right honourable John Waldegrave, Earl Waldegrave, &c. This noble earl is descended from John de Waldegrave, who was sheriff of London in the year 1205, in the seventh year of King John.

8. “Party per Pale indented, Or and Gules;” borne by the right honourable Thomas Beringham, baron of Athebury, in the kingdom of Ireland. Of this ancient and noble family, which are of English extraction, and took their name from the town of Beringham in the county of Warwick, was William de Beringham, who was possessed of the town of that name in the reign of Henry II., which continued in that family till the reign of Henry VIII.

9. “Quarterly per Pale dove-tail, Gules and Or;” borne by the right honourable Thomas Bromley, Lord Montfort, &c. This noble lord is maternally descended from Sir Walter Bromley de Bromley, in the county of Stafford, who flourished in the reign of King John. Sir Thomas Bromley, another of his lordship’s ancestors, was constituted lord high chancellor of England, 21 Elizabeth; in which post he died, 29 Elizabeth.

10. “Argent, a Pale fylory counterfylory Sable.”

11. “Argent, a Pale lozengy Sable;” borne by the name of Savage.

12. “Argent, a Pale indented Vert;” borne by the name of Dickson.

13. “Argent, on a Pale engrailed Sable, three Crescents Or;” borne by the name of Ashly.

14. “Ermine on a Pale engrailed azure, three Lions Heads couped Or;” borne by the name of Avery.

15. “Vert, on a Pale radiant Or, a Lion rampant Sable;” borne by the right honourable James O’Hara, Lord Tyrwallay, &c. in the kingdom of Ireland. This noble lord is descended from Milesius king of Spain, by his eldest son Hibernia, who, with his brother Here- mon, established a colony in Ireland. Sir Charles O’Hara, father to the present lord, was created baron of Tyrwallay by Queen Anne, Jan. 10. 1706, being at that time a lieutenant-general, and colonel of the royal regiment of fusiliers: and the next year was made general in Spain, where his son, Lord James, was wounded at the battle of Almanza.

16. “Azure, a Pallet Argent.”

17. “Vert, an Endorse Or.”

18. “Argent on two Pallets Sable, six Cross-croslets fitchy Or;” borne by the name of Betunian, of the county of Salop.

19. “Argent, two Endorses Gules, in Chief three Mullets Sable;” borne by the name of Vautort.

20. “Azure, on a Pale walled with three pieces on each side Or, an Endorse Sable;” borne by the name of Sublet de Noyers, a family of distinction in France.

art. 3. of the bend and bend-sinister.

The bend is an ordinary formed by two diagonal lines, drawn from the dexter-chief to the sinister-base: and contains the fifth part of the field in breadth, if uncharged; but if charged, then the third. Its diminutives are, the bendlet, which is the half of a bend; the cost or cotice, when two of them accompany a bend, which is the fourth part of a bend; and the ribband, the moiety of a cost, or the eighth part of the field.

There is also the bend-sinister, which is of the same breadth as the bend, but drawn the contrary way; this is subdivided into a scrape, which is the half of the bend, and into a baton, which is the fourth part of the bend, but does not extend itself to the extremities of the field, there being part of it seen at both ends. See the examples, fig. 7. Plate Ex. 1. “Argent, a Bend wavy Sable;” borne by the right honourable John Wallop, earl of Portsmouth, &c. This noble earl is descended from the Wallops of Hampshire, a Saxon family, who were possessed of lands to a considerable value in the county at the time of the Conquest.

2. “Checky Or, and Azure, a Bend Ermine;” borne by the right honourable John Ward, Viscount Dudley and Ward, &c. The ancestors of this noble lord were anciently of the county of Norfolk, of which was Simon Ward, who had large possessions in the reign of Edward I., and was in France and Scotland in the reigns of King Edward II. and III.

3. “Azure, a Bend engrailed Argent, between two Cotises Or;” borne by the right honourable Matthew Fortescue, Lord Fortescue, as also by the right...
right honourable Hugh Fortescue-Aland, Baron Fortescue, in the kingdom of Ireland, this last nobleman bearing a crescent in his arms for difference. The family of Fortescue is descended from Sir Richard le Forte, a person of extraordinary strength and courage, who accompanied William Duke of Normandy in his invasion of England; and bearing a strong shield before the duke, at the battle of Hastings, had three horses killed under him, and from that signal event the name and motto of the family were assumed; for the Latin word, sevatum, or the old French word escuee "a shield," being added to forte, "strong," compose their name; and the motto is, Forte sevatum salus ducum.

4. "Sable, a Bend Argent between two Cotices indented Or;" borne by the name of French.

5. "Paly of six Or and Sable, a Bend counterchanged;" borne by the right honourable Frederick Calvert, Baron Baltimore. The original of this family is from an ancient and noble house of that surname in the earldom of Flanders, whereof Sir George Calvert, knight, among other honourable employments, was secretary of state to King James I. by whom he was created a baron, Feb. 20, 1524, and from whom he had a grant to him, and his heirs, of the province of Maryland and Avalon in America.

6. "Party per Bend crenelle Argent and Gules;" borne by the right honourable Edmund Boyle, earl of Cork and Orrery, &c. in the kingdom of Ireland. This noble lord is said to be descended from Sir Philip Boyle, a knight of Aragon, who, in the reign of King Henry VI, tilted at a tournament with Sir Joseph Astley, knight of the Garter.

7. "Argent, three Bendlets enhanced Gules;" as the English express it, but the phrase enhanced is used by no other nation. The proper blazon of this arms is, Parted per bend, 1st bendy of six gules, and argent; 2d of the last. Borne by the right honourable William Byron, Lord Byron. From Domsday-book it appears, that this family was possessed of numerous manors and lands in the reign of the Conqueror; and that Sir John Byron, one of his lordship's ancestors, attended King Edward III. in his wars in France.

8. "Ermine, a Bend voided Gules;" borne by the name of Ireton.

9. "Argent three Bendlets wavy Azure;" borne by the name of Wilbraham.

10. "Bendy of six pieces Argent and Azure." Observe, that when the shield is filled with an equal number of bendlets of metal and colour, it is called bendy; but if the number of them is unequal, they are to be blazoned by the name bendlets, and their number specified.

11. "Party per bend Azure and Argent, two Bendlets enbranched counterchanged;" borne by the name of French.

12. "Quarterly, Or and Gules, a Bend over-all Vair;" borne by his grace Lionel Cranfield Sackville, duke of Dorset and earl of Middlesex, &c. The ancestors of this family were lords of the town and seigniory of Sackville in Normandy, and came over with the Conqueror when he invaded England in 1066.

13. "Gules on a Bend Argent, three Trefoils slipped proper;" borne by the right honourable George William Hervey, earl of Bristol, &c. This noble lord derives his pedigree from Robert Fitz-Hervey, a younger son of Hervey duke of Orleans, who came over from France with William the Conqueror.

14. "Argent, on a Bend Gules cotised Sable; three pairs of Wings conjoined of the first;" borne by the right honourable Richard Wingfield, Viscount Powerscourt, in the kingdom of Ireland. This noble lord is descended from the manor of Wingfield in Suffolke, where they had a seat before the Norman conquest, called Wingfield-castle.

15. "Gules, on a Bend contre Ermine cotised Or, three Boars heads couped Argent;" borne by the right honourable George Edgcumbe, Lord Edgcumbe, &c. The ancestors of this noble lord received their name from the manor of Edgcumbe, in Devonshire. One of this lord's ancestors was Sir Richard Edgcumbe, who came over to England with the earl of Richmond, having a great share in the victory he obtained over King Richard III. at Bosworth, by which the earl made his way to the throne of England.

16. "Argent, a Bend-sinister Gules."

17. "Or, a Bendlet Gules."

18. "Argent, a Ribband Gules."—The name of this bearing corresponds well with its form, being both long and narrow, which is the shape of a ribband.

19. "Azure, a Scarf Or."—This bearing, as Guillim observes, is of that kind of ornament called now-a-days a Scarf, which is used by officers on duty, and usually worn after the same manner.

20. This contains three Beams. The first is company ermine and azure; set over the royal arms, for his grace William Fitzroy duke of Cleveland. The second is company argent and azure; set over the royal arms, for his grace Augustus Henry Fitzroy, duke of Grafton. The third is gules, charged with three roses argent, seeded and barbed proper; set over the royal arms, for his grace George Beauclerk, duke of St Albans. The grandfathers of these noble dukes being natural sons of King Charles II. is what entitles them to the royal arms.

Art. 4. Of the Fess and Bar.

The Fess is an ordinary which is produced by two parallel lines, drawn horizontally across the centre of the field, and contains in breadth the third part thereof. Some English writers say it has no diminutive for a bar is a distinct ordinary of itself.

The Bar, according to their definition, is formed of two lines, and contains but the fifth part of the field: which is not the only thing wherein it differs from the fess; for there may be more than one in an escutcheon, placed in different parts thereof, whereas the fess is limited to the centre-point; but in this the French differ from them. The bar has two diminutives; the barlet, which contains the half of the bar; and the closet, which is the half of the barlet. When the shield contains a number of bars of metal and colour alternate, of even number, that is called barry of so many pieces, expressing their number. See the examples, fig. 8.

No 1. is "Argent, a Fess indented Sable;" borne by the right honourable John West, Earl Delaware, &c. This noble family is descended from the Wests, a great family in the west of England; but in the reign of Edward II. they appear to have been seized of mas...
Of the arms and lands in the county of Warwick. Sir Thomas de West, knight, one of his lordship's ancestors, being at the battle of Cressy, and there taking John the French king prisoner, had granted him, for that remarkable action, an augmentation to his achievement, viz. a Crampette Or, distinguished by the chape of a sword in the middle; the chape being given him by the said king, as an acknowledgment of his becoming his prisoner: his cognizance was a rose parted per pale, argent, and gules; which two badges are still borne in the achievement of the present Lord Delaware.

2. "Argent, a Fess wreaht Azure and Gules," borne by the right honourable John Carmichael, Earl of Hyndford. Of this ancient family, which is said to assume their surname from the lands of Carmichael, in the county of Lanark, in Scotland, where they still have their chief seat, was Sir John Carmichael, who accompanied Archibald, Earl of Douglas, to the assistance of Charles VI. of France, against the English; and signifying his valour at the battle of Baughey in April 1421, and breaking his spear when the French and Scots got the victory, had thereupon added to his paternal coat, a dexter arm holding a broken spear, which is now the crest of the family.

3. "Party per Fess Or and Argent, a Fess nebule Gules," borne by the name of Astebish.

4. "Party per Fess indented Or and Azure," borne by the name of Swaunders.

5. "Cheeky Or and Azure on a Fess Gules, a Crescent Argent for difference," borne by the right honourable Hugh Clifford, Lord Clifford, of Chudleigh. This noble lord is descended from Walter de Clifford, of Clifford castle, in the county of Hereford, who came over into England with the Conqueror; of which family was fair Rosamond, mistress to King Henry II.

6. "Argent, on a Fess Azure, three Lozenges Or," borne by the right honourable Basil Fielding, Earl of Denbigh and Desmond, &c. This noble earl is descended from the ears of Hapsburg, in Germany. Geoffroy earl of Hapsburg, being oppressed by Rodolph emperor of Germany, came over into England, and one of his sons served King Henry III. in his wars, whose ancestors laying claim to the territories of Laufenburg and Rhin-Fielding, in Germany, he took the name of Fielding.

7. "Or, on a Fess Gules, three Fleurs-de-lis of the first," borne by the name of Lennard. This is in the first and fourth quarters of the right honourable Thomas Barret Lennard Lord Dacre's arms.

8. "Ermine, on a Fess Gules, a Lion passant Or," borne by the right honourable John Proby, Baron Carysfort, &c. in the kingdom of Ireland.

9. "Sable, a Fess Ermine, between three Crescents Or," borne by the right honourable George William Coventry, Earl of Coventry, &c. This noble earl is descended from John Coventry, a native of the city of Coventry, and afterwards mercer and lord mayor of London, in the reign of Henry V.; from whom descended Thomas Coventry, one of the justices of the court of common-pleas, in the reign of Queen Elizabeth; whose son Thomas was recorder of London, and afterwards lord keeper of the great seal in the reign of King Charles I.

10. "Sable, a Fess cheverly, Or and Azure, between three Besants," borne by the right honourable Ridge-Of the Fess way Pitt, Earl and baron of Londonderry, &c. Of this noble family, which were ancient of Banbury, in the county of Dorset, was Thomas Pitt, Esq. who, in the reign of Queen Anne, was made governor of Fort St George in the East Indies, where he resided many years, and purchased a diamond, which he sold to the king of France for 125,000 sterling, weighing 136 carats, and commonly known at this day by the name of Pitt's diamond.

11. "Or, on a Fess Sable, between three Muscovy Ducks proper, a Rose of the Field," borne by the right honourable John Bateman, Viscount Bateman, &c. Of this noble family, which was anciently seated at Halesbrook, near St Omers in Flanders, was Giles Bateman, Esq. whose son was a merchant of London, and was father to Sir James Bateman, knight, who in 1712, was chosen member of parliament for Ilchester in the county of Somerset, and re-chosen in 1713.

12. "Sable, on a Fess Argent, between three Leopards passant guardant Or, three Escallops Gules," borne by the right honourable Wills Hill, Earl of Hillsborough, &c. Of this family, which, in the reign of Queen Elizabeth, were of note in the county of Downe, was Sir Moses Hill, who, during O'Neill's rebellion, was one of those gentlemen who associated under the earl of Essex to suppress it; and afterwards served under Arthur Lord Chichester, lord deputy, and by King James I. was appointed provost-marshal of the whole province of Ulster in Ireland.

13. "Gules, two Bars Or," borne by the right honourable Simon Harcourt, Earl of Harcourt, &c. This noble earl is descended from the Harcourts of Normandy, who took their name from a place called Harcourt, in that province, where the family usually resided. Gervaise, count de Harcourt, with his two sons Jeffrey and Arnold, came over with the Conqueror, when he invaded England in 1066.

15. "Argent, two Bars indented Sable," borne by the right honourable Godart Ginkle, Earl of Athlone. Godart, who was the first earl, was descended of a very ancient family in the united provinces of Holland, where he was Baron de Reede and Ginkle, &c. In 1691, he was a lieutenant-general of King William's forces in Ireland; where, in June the same year, he took Ballymore for the English; and, in July following the Irish town of Athlone, which last exploit is one of the greatest recorded in history.

16. "Argent, three Bars, gemelas Gules," borne by the right honourable Richard Barry, Earl of Barrymore, &c. This noble family, who have been renowned for their loyalty and valour, are said to derive their surname from the island of Barry, in the county of Glamorgan, in Wales; and from their riches and estates have been called by the people Barrymore, or the Great Barry.

17. "Or, a Fess-coupe Gules, between two Lions passant Sable," borne by the right honourable Samuel Masham, Lord Masham, &c. This noble lord was descended from Sir John Masham, who flourished in the reign of King Henry VI. and was buried at Thornham, in the county of Suffolk, in 1455.
HERALDRY.

Of the Cheveron.

18. "Argent, a Lion rampant guardant Gules, debruised by a Fess Azure, between three Etoiles issuant out of as many Crescents of the second," borne by the right honourable Robert Dillon, earl of Roscommon, &c. in the kingdom of Ireland. This noble family is derived from Logan, surnamed Dilune or Delion, which signifies brave and valiant, to whom the duke of Aquitaine gave his daughter in marriage, in whose right, after her father's death, he became prince and sovereign of Aquitaine, which continued in his posterity till Henry II. married Alionora, daughter and heir to William V. duke of Aquitaine, and about 1172 obtained that principality by superior force; and, to prevent any disturbance, brought Sir Henry Delion or Dillon, and his brother Thomas, then infants, to England, their father being slain.

19. "Or, two Bars Azure, a Chief quarterly of the second and Gules, the 1st and 4th charged each with two Fleurs-de-lis of France; the 2d and 3d with a Lion of England;" borne by his grace John Manners, duke of Rutland, marquis of Granby, &c. This chief was anciently Gules; and the charge thereon is an honorary augmentation, showing his grace's descent from the blood-royal of King Edward IV.

20. "Barry of ten pieces Argent and Azure, over all six Escutcheons; 3, 2, 1, Sable, each charged with a Lion rampant of the first, armed, and langued Gules, a Crescent for difference;" borne by the right honourable James Cecil, earl of Salisbury, &c. This noble earl is descended from the famous William Cecil, Lord Burleigh, statesman in the reigns of Edward VI. and Elizabeth. This great man left two sons, Thomas and Robert, who were both made earls in one day, May 4, 1603. Robert, the younger son, ancestor of the present noble lord, was created earl of Salisbury in the morning; and Thomas, the eldest, earl of Exeter in the afternoon.

ART. 5. Of the Cheveron.

The Cheveron, which represents two rafters of a house well joined together, or a pair of compasses half open, takes up the fifth part of the field with the English, but the French give it the third. Its diminutives are, the cheveronel, which contains the half of a cheveron; and the couple close, which is the half of a cheveronel, that is, its breadth is but the fourth part of a cheveron. Leigh observes, that this last diminutive is never borne but in pairs, or with a cheveron between two of them. The French have but one diminution of this ordinary called Etaye, containing the third part of its breadth.

Examples of cheverons are given in fig. 9, viz. 1. "Argent, a Cheveron Gules between three Torteaux;" borne by the right honourable Bennet Sherard, earl of Harborough, &c. This noble earl is lineally descended from Sherard, who was possessed of manors and lands to a great value in the counties of Cheshire and Lancashire in the reign of William the Conqueror. Geoffroy, another of the earl's ancestors, was three times sheriff of Rutlandshire, in the reigns of King Edward IV. and King Richard III.

2. "Sable, a Cheveron between three Etoiles Argent;" borne by the right honourable Marmaduke Langdale, Lord Langdale. This noble lord is descended from the Langdales of Yorkshire, who resided in the town of Langdale, from whence they took their name, of the reign of King John; but his ancestor, who Cheveron makes the greatest figure in history, is Sir Marmaduke Langdale, who raised forces in the north of England in defence of King Charles I.; was victorious in numerous battles and sieges; and when his majesty, by the united forces of England and Scotland, was at length overpowered, he attended King Charles II. in his exile, and returned to England with his majesty at the restoration.

3. "Sable, a Cheveron between three Leopards Heads Or;" borne by the right honourable William Wentworth, earl of Stafford, &c. All genealogists agree, that the name of Wentworth is of Saxon original, and taken from the manor of Wentworth in Yorkshire, where, in the reign of William the Conqueror, lived Reginald de Wentworende, as it is spelt in Doomsday-book.

4. "Argent, a Cheveron between three Griffins passant Sable, a Crescent for difference;" borne by the right honourable Heneage Finch, earl of Ailesford, &c. This family is descended from Herbert Fitz-Herbert, earl of Pembroke, and chamberlain to King Henry I. They took the name of Finch in the reign of King Edward I. One of the ancestors of this family was the right honourable Heneage Finch, earl of Nottingham, who was constituted lord high-chancellor of England in 1665; and lord high-steward on the trials of Philip earl of Pembroke, and William Viscount Stafford, in 1680.

5. "Azure, a Cheveron Ermine, between three Escallops Argent;" borne by the right honourable George Townshend, Viscount Townshend, &c. This family is of Norman extraction, and came into England about the time of the Conquest. Charles, Lord Viscount Townshend, grandfather of the present viscount, was appointed principal secretary of state in the reign of King George I. in 1720, and continued so to the end of his majesty's reign; when, upon resigning the seals, they were returned to him again by his late majesty King George II. who continued him in that honourable office to the year 1730.

6. "Azure, a Cheveron between three Mullets Or;" borne by the right honourable John Cetwind Viscount Cetwind, &c. of the kingdom of Ireland. Of this family, which hath been of great antiquity in the county of Salop, taking their surname from Cetwynd in that county, was Adam de Cetwynd, who married Agnes daughter of John Lord Lovel, baron of Dockenges, and lord of Minster Lovel in Oxfordshire; and by her had issue Sir John de Cetwynd, who, in the 37th of Henry III. had a charter of free-warren, through all his demesne in the counties of Salop, Stafford and Warwick.

7. "Argent, a Cheveron Gules, between three square Buckles Sable;" borne by the right honourable Matthew Duce-Morton, Lord Duce, &c. This noble lord is descended from the Duces in Normandy. After they came into England, King Edward I. conferred on them the lordship of Morton in Staffordshire, and several other lordships and manors, which the family enjoyed for many years. Sir Robert Duce, one of his lordship's ancestors, was lord mayor of London in the reign of King Charles I. and though he lent his majesty 80,000l. which was lost by the king's being driven
Chapter III.

Heraldry.

Of the Cheveron.

1. Driven out of London, he died, however, worth 40,000l.

8. "Argent, a Cheveron Checky Gules, and of the Field, between three Bugle-horns strung Sable, garnished of the second," borne by the right honourable Lord Hugh Semple, Lord Semple. The principal family of this name was Semple of Ellioton in Renfrewshire, where they had large possessions and offices, as stewards and bailiffs under the family of Stewart, proprietors of that county before they came to the crown. The first Lord Semple was Sir Robert, who being made in favour with King James IV. was by him created Lord Semple in 1580.

9. "Argent, a Cheveron engrailed between three Lions passant Sable," borne by the right honourable and the reverend Philip Smithes, Viscount Strangford. One of this lord's ancestors was John Smithes, Esq. who acquired a considerable estate whilst he was farmer of the customs in the reign of Henry VIII. He left two sons, John and Sir Thomas; which last was sent ambassador by King James I. to the empress of Russia.

10. "Quarterly Argent and Azure, a Cheveron engrailed counter-changed;" borne by the name of Chamber.

11. "Party per Cheveron engrailed Gules and Argent, three Talbots Heads erased counter-changed;" borne by the right honourable Anthony Duncombe, Lord Ferversham, &c. His lordship is descended from the Duncombes of Barley-end in Buckinghamshire. Sir Charles Duncombe, uncle to the present lord, was lord mayor of London in 1709; and this nobleman was created Lord Ferversham and baron of Downton in Wiltshire, June 23, 1744.

12. "Paly of six, Argent and Gules, on a Cheveron Azure, three Cross-croslets Or;" borne by the name of Carpenter, Baron Carpenter, of Killalghi in Ireland. This ancient and noble family are of great antiquity in the county of Hereford, and have been lords of the manor of the Home, in the parish of Delwyn, near Wobury, for above 300 years. George, the first Lord Carpenter, was so created May 4, 1719.

13. "Azure, on a Cheveron Or, between three Nessants, a Bay Leaf Proper;" borne by the right honourable James Hope, earl of Hopetoun, &c. This noble family is descended from Henry Hope, a native of Holland, who, about two centuries ago, came over and settled in Scotland. Charles Hope, Esq. grandfather of the present earl, was created an earl by Queen Anne, April 15, 1703.

14. "Vert, on a Cheveron between three Unicorn's Heads erased Argent, horned and maned Or, three Mulletta Sable;" borne by the name of Ker, being the 1st and 4th quarters in the arms of his grace John Ker, duke of Roxburghe, &c. This ancient family is said to come from Normandy. John Ker, marquis of Beaumont and Cessford, the first duke of Roxburghe, was so created April 27, 1707.

15. "Azure, on a Cheveron Or, between three Bears Heads couped Argent, muzzled Gules, a Stag's Head erased between two Hands holding Daggers all proper;" borne by the right honourable Donald Mackay, Lord Reay. This family is said to derive their descent from Alexander, a younger son of Ochonacker, who, about the end of the twelfth cen-

VOL. X. Part II.

tery, came from Ireland; and the fourth in descent from him was Donald of Strathnavern, whose son was named Y More; and from him began the surname of Mac Y, Mackie, or Mackay. Donald, the first lord of this family, was created baronet in 1625, and on June 20, 1628, was created Baron Reay of the county of Caithness, by Charles I.

19. "Ermine, on a Cheveron Azure, three Foxes' Heads erased Or, and in a Canton of the second a Fleur-de-lis of the third;" borne by the right honourable Stephen, earl of Ilchester, &c. Of the family of Fox there have been many persons of note living in the counties of Dorset, Somerset, Wilts, and Hants, particularly Richard Fox, bishop of Winchester. His lordship was created Lord Ilchester and Baron Strange-ways, May 11, 1741, 14 George II. and earl of Ilchester in June 1759.

17. "Or, two Cheverons Sable, three Cross-croslets of the first;" borne by the right honourable John Monson, Lord Monson. This noble lord is descended from John Monson, who flourished in the reign of King Edward III. from whom descended another John, who attended King Henry V. in his wars in France. Sir John Monson, Bart. father of the present lord, was created Lord Monson, May 28, 1718.

18. "Or, on a Fess, between two Cheverons Sable, three Cross-croslets of the first;" borne by the right honourable George Walpole, earl of Orford, &c. This family took their name from Walpole in Norfolk, where they resided before the Conquest. Sir Robert Walpole was, in King George II.'s reign, elected knight of the Garter in 1726, and created earl of Orford, February 9, 1741-2.

19. "Azure, three Cheverons interlaced Or, and a Chief of the last;" borne by the name of Fitz-Hugh.

20. "Argent, three Cheverons Gules, in Chief a Label Azure;" borne by the right honourable William Wildman Barrington, Viscount Barrington, &c. This family is of Norman extraction; in which duchy, whilst it continued annexed to the English crown, there were to be seen the remains of a castle, bearing the name of Chute, or Shute, and formerly in the family, with other monuments in several towns of that duchy. John Shute, the late Viscount Barrington, was in 1708 made a commissioner of the customs, and succeeded to the estates of Francis Barrington, Esq. and of John Wildman of the county of Berks, who made him his heir; and in pursuance of the will of the former, he took the name and arms of Barrington. On June 11, 1729, he was created Viscount Barrington.

Art. 6. Of the Cross.

The Cross is an ordinary formed by the meeting of two perpendicular with two horizontal lines in the fess-point, where they make four right angles; the lines are not drawn throughout, but discontinued the breadth of the ordinary, which takes up only the fifth part of the field when not charged; but if charged, then the third. It is borne as well engrailed, indented, &c. as plain.

There is so great a variety of crosses used in heraldry, that it would be a difficult task to treat of them all. Guillim has mentioned 39 different sorts; De la Columbiere, 72; Leigh, 46; and Upton declares 3fc. he
he dares not ascertain all the various crosses borne in arms, for that they are almost innumerable; therefore, as their forms cannot be expected here, we will only take notice of such as are most commonly seen at present in coats-of-arms. See Fig. 10.

The first is "Quarterly, Ermine and Azure, a Cross Or;" borne by his grace Thomas Osborne, duke of Leeds, &c. This noble duke is descended from the honourable family of the Osbornes of Ashford, in the county of Kent; Sir Thomas Osborne, the grandfather to the present Duke, was advanced to the peerage by King Charles II.

2. "Gules, a Cross engrailed Argent, a Lozenge in the dexter-chief of the second;" borne by the right honourable Edward Leigh, Lord Leigh. This family took their surname from the town of High Leigh in Cheshire, where they resided before the Norman conquest. Sir Thomas Leigh, the first lord of this family, was created Baron Leigh of Stonely, by King Charles I, on July 1. 1643.

3. "Gules, a Cross Argent pretty Azure;" borne by the right honourable Nicholas Taske, Viscount Taske, of Corran, &c. in Ireland. Of this noble and ancient family was Richard Taske, who lived in 1282; as in 1306 did John Taske, who was archbishop of Armagh; and, in 1479, the order of the Garter being established in Ireland, Sir Nicholas Taske was one of the first members; and John, his son and heir, was created a baron and viscount by Charles I. August 1. 1628.

4. "Sable, a Cross raguly Or;" borne by the name of Stowey.

5. "Argent, on a Cross Sable, a Leopard's face Or;" borne by his grace Henry Brydges duke of Chandos, &c. The ancestors of this noble family took their name from the city of Bruges in Flanders; and one of them came over with William the Conqueror, and had a considerable share in the victory obtained near Hastings in Sussex, 1066. James, the father of the present duke, was created Viscount Wilton and earl of Caernarvon, October 19. 1714; and marquis of Caernarvon and duke of Chandos, 30. 1719.

6. "Or, on a Cross Sable, a patriarchal Cross of the Field;" borne by the right honourable Thomas Vesey, baron of Knapton in the kingdom of Ireland. The truly noble family of Vesey or Vesey, derives its origin from Charles the Great, king of France, and emperor of the West, who died at Aix-la-Chapelle in Germany, January 28. 814. His lordship's father was created a peer April 10. 1730.

7. "Argent, on a Cross Gules, five Escallops Or;" borne by the right honourable William Villiers earl of Jersey, &c. This noble earl is descended from the family of Villiers in Normandy, some of whom came over to England with the Conqueror; several manors and lands in England being soon after granted to Pagan de Villiers, one of this earl's ancestors. The first peer of this family was created a baron and viscount, March 20. 1690.

8. "Sable, on a Cross within a Bordure engrailed Or, five Pellets;" borne by the right honourable Francis Greville, earl of Brooke and Warwick, &c. The ancestors of this noble family are of Norman extraction, and came over with William the Conqueror, who conferred manors and lands on them in England, of a considerable value; and at length they obtained the government of the castle of Warwick, the present seat of the family. Sir Fulke, the first peer of this family, was created Baron Brooke by King James I. January 9. 1625.

9. "Argent, a Cross bottony Sable,;" borne by the name of Winwood.

10. "Or, a Cross-croslet Gules;" borne by the name of Taddington.

11. "Azure, a Cross potent fitchy Or." This ensign is said to have been borne by Ethelred king of the West Saxons; and crosses of this sort are frequently met with in coats of arms.

12. "Party per pale, Gules and Argent; a Cross potent quadrated in the Centre, between four Crosses patee counter-changed;" the arms of the episcopal see of Lichfield and Coventry. This see was originally fixed at Lichfield; from thence removed to Chester, and from both to Coventry. It contains the whole county of Stafford, except two parishes; all Derbyshire; the better part of Warwickshire, and near half Shropshire; divided into the four archdeaconries of Coventry, Stafford, Derby, and Salop. The parishes are 557 in number; but, including chapels, they amount to 643.

13. "Azure, a Cross moline Argent;" borne by his grace Cavendish Bentinck, duke of Portland, &c. This noble duke is descended from a very ancient and distinguished family in the United Provinces of Holland, of which was William Bentinck, Esq. who in his youth was page of honour to William prince of Orange, afterwards William III. king of Great Britain, and, on the accession of William and his consort, was made groom of the stole, privy-purse to his majesty, lieutenant-general of his majesty's army, &c. and also created baron of Cirencester, Viscount Woodstock, and earl of Portland, April 19. 1689.

14. "Argent, a Cross patonce Sable;" borne by the name of Rice.

15. "Sable, a Cross patee Argent;" borne by the name of Mapleden.

16. "Azure, a Cross flowery Or;" borne by the name of Cheney.—This is said to have also been the arms of Edwin, the first Christian king of Northumberland.

17. "Argent, six Cross-croslets fitchy 3, 2, 1, Sable, on a Chief Azure, two Mullets pierced Or;" borne by his grace Henry Clinton, duke of Newcastle, &c. This noble family is descended from Jeffrey de Clinton, lord chamberlain and treasurer to King Henry I. grandson to William de Tankerville, chamberlain of Normandy; from whom descended William de Clinton, chief justice of Chester, governor of Dover castle, lord warden of the king's forests south of Trent. Edward Lord Clinton, another of this noble earl's ancestors, was constituted lord high admiral of England for life, in the reign of Queen Elizabeth, who created him earl of Lincoln, May 4. 1572.

18. "Gules, a Cheveron between ten Crosses patee, six above and four below, Argent;" borne by the right honourable Frederick Augustus Berkeley, earl of Berkeley, &c. This noble family is descended from Robert Fitz-Harding, who obtained a grant of Berkeley.
Chap. III.

HERALDRY.

The arms of the bishoprick of Rochester.—This diocese, the least in England, comprehends only a small part of Kent, in which there are 150 churches and chapels; and the two parishes of Isellium in Cambridgeshire, and Frenchenham, in Suffolk. It has only one archdeacon, that of Rochester. For many years it was in the immediate patronage of the archbishop of Canterbury.

7. “Party per Saltiere, Azure and Argent, on a Saltier Gules, a Crescent of the second for difference;” quartered by the right hon. William Hall Gage, Viscount Gage, of Castle-Island in Ireland. This noble family is of Norman extraction, and derives descent from de Gage or Gage, who attended William I. in his expedition to England; and, after the conquest thereof, was rewarded with large grants of lands in the forest of Dean, and county of Gloucester, near which forest he fixed his residence, by building his seat at Gilerenwell, in the same place where the house of Gage now stands: he also built a great house in the town of Cirencester, at which place he died, and was buried in the abbey there. Sir Thomas Gage, the eighth baronet, was created baron of Castle-Bar, and Viscount Gage, 1721.

8. “Gules, on a Saltier Argent, a Rose of the first barbed and seeded proper;” borne by the right hon. George Neville, Lord Abergavenny, premier baron of England.

9. “Or, on a Saltier Azure, nine Lozenges of the first”; the paternal arms of the right hon. John Dalrymple, earl of Stair, &c. Of this family, which took their surname from the barony of Dalrymple, lying on the river Dun in Ayrshire, Scotland, was Adam de Dalrymple, who lived in the reign of Alexander III.

10. “Argent, on a Saltier engrailed Sable, nine Annulets Or;” borne by the name of Leek.

11. “Gules, a Saltier between four Crescents Or;” borne as the second and third quarters in the coat-of-arms of the right honourable Charles Kinnaird, Lord Kinnaird. George Kinnaird, Esq., one of the present lord’s ancestors, being of great service to King Charles II. during the usurpation of Oliver Cromwell, he was by that prince, at his restoration, made one of his privy-council; and December 28, 1682, created a baron.

12. “Argent, a Saltier engrailed between four Roses Gules,” for Lennox; and borne as first and fourth quarters in the coat-of-arms of the right hon. Francis Napier, Lord Napier. This family is said to be descended from the ancient thanes or stewards of Lennox in Scotland, but took the surname of Napier from the following event. King David II. in his wars with the English, about the year 1344, convocating his subjects to battle, the earl of Lennox sent his second son Donald, with such forces as his duty obliged him; and coming to an engagement, where the Scots gave ground, this Donald, taking his father’s standard from the bearer, and valiantly charging the enemy with the Lennox men, the fortune of the battle changed; and they obtained the victory: whereupon every one advancing, and reporting their acts, as the custom was, the king declared they had all behaved valiantly, but that there was one among them who bad n Peter, that is, no equal; upon which the said Donald took the

Plate CCLVII.

N° 1. is “Argent, a Saltier Gules;” borne by his grace James Fitz-Gerald, duke of Leinster, &c. This noble lord is descended from Otho, or Other, a rich and powerful lord in the time of King Alfred, descended from the dukes of Tuscany; who passing from Florence into Normandy, and thence into England, there the family flourished, until Richard Strongbow, earl of Pembroke, their kinsman, engaged them to partake in his expedition to Ireland, in which Maurice Fitz Gerald embarked, and was one of the principal conquerors of that kingdom, for which he was rewarded with a great estate in lands in the province of Leinster, and particularly the barony of Offaly, and the castle of Wicklow; and died, covered with honours, in the year 1177, 24 Henry II.

2. “Gules, a Saltier Argent, between twelve Crosses Or;” borne by the right hon. Other-Lewis Windsor Hickman, earl of Plymouth, &c. This noble earl is descended from Robert Fitz-Hicman, lord of the manor of Bloxham, Oxfordshire, in the 56 Hen. III. 1272; and he is maternally descended from the noble family of the Windsors, who were barons of the realm at the time of the Conquest.

3. “Vert, a Saltier wavy Ermine;” borne by the name of Wawkenman of Beckford, in Gloucestershire.

4. “Ermine, a Saltier counter-comony Or and Gules;” borne by the name of Ulmston.

5. “Argent, a Saltier Azure with a Beazant in the centre;” borne by the right hon. Philip Yorke, earl of Hardwicke, &c. He was in October 1733 constituted lord chief-justice of the king’s bench, and November 23. in the same year, created Baron Hardwicke of Hardwicke.

6. “Argent on a Saltier Gules an Escallop Or;”
name of Napier, and had, in reward for his good services, the lands of Gosfield, and other estates in the county of Fife.

13. "Gules, a Saltier Or, surmounted of another Vert," for the name of Andrew; and borne by Sir William Andrews, bart. of Dunton in Northamptonshire, who is descended from Sir Robert Andrews of Normandy, knight, who came into England with William the Conqueror. Sir William Andrews, the first baronet of this family, was created December 11, 1641.

14. "Azure, a Saltier quarterly quartered Or and Argent." The arms of the episcopal see of Bath and Wells.—The diocese of Bath and Wells contains all Somersetshire, except a few churches in Bristol. And in it are three archdeaconries, viz. those of Wells, Bath, and Taunton. The number of the parishes is 388, though, according to some, the total number of the churches and chapels amounts to 503.

15. "Party per Saltier Argent and Gules, a Saltier counter-changed." 

16. "Party per Pale indented Argent and Sable, a Saltier counter-changed;" borne by the name of Scot.

17. "Argent, three Saltiers couped and engrailed Sable;" borne by the name of Benton.

18. "Argent, a Saltier Gules, and a chief Ermine;" borne by the right hon. Francis Thomas Fitz-Maurice, earl of Kerry, &c. This very ancient and noble family is a branch of the family of Killarney, who are originally descended from the great duke of Tuscany, and of which was Otho, a noble baron of Italy, whose son Walter, attending the Norman conqueror into England, was made constable of the castle of Windsor. Raymond, one of the present earl's ancestors, had a principal hand in the reduction of Ireland to the subjection of Henry II. and Dermot Macarty, king of Cork, sought his aid against his son Cormac O'Lehanagh, which he undertook, and delivered the king from his rebellious son; for which that prince rewarded him with a large tract of land in the county of Kerry, where he settled his son Maurice, who gave his name to the county, which he called Clane-Maurice, and is enjoyed by the present earl of Kerry, who is Viscount Clane-Maurice. Thomas the first earl, and father of the last, was the 21st Lord Kerry, who was created earl January 17, 1722.

19. "Sable, a Saltier Argent, on a Chief Azure, three Fleurs-de-lis Or;" borne by the right hon. John Fitz-Patrick, earl of Upper Osory, and baron of Gowran in Ireland. This most ancient and princely family is descended from Heremon, the first monarch of the Milesian race in Ireland; and after they had assumed the surname of Fitz-Patrick, they were for many ages kings of Osory, in the province of Leinster. John, the first earl of this family, succeeded his father Richard as Lord Gowran, June 9, 1727, was created earl October 5, 1751, and died 1758.

20. "Party per Pale Argent and Gules, three Saltiers counter-changed;" borne by the name of Lane. These arms are also borne, without the least alteration, by the name of Kingsman; for which similitude we can no otherwise account, than by supposing there has been some mistake made through many transcriptions.

BESIDES the honourable ordinaries and the diminutions already mentioned, there are other heraldic figures, called sub-ordinaries, or ordinaries only, which, by reason of their ancient use in arms, are of worthy bearing; viz. the Gyron, Franc-quarter, Canton, Fairy, Fret, File, Orle, Inescutcheon, Treasure, Annulet, Flanches, Flasques, Voiders, Billet, Lozenge, Gutt, Fusil, Rostre, Mascel, Papillon, and Diaper. See Plate CCLIV. fig. 1. (A.)

The Gyron is a triangular figure formed by two lines, one drawn diagonally from one of the four angles to the centre of the shield, and the other is drawn either horizontal or perpendicular, from one of the sides of the shield, meeting the other line at the centre of the field.

Gyronny is said, when the field is covered with six, eight, ten, or twelve gyrons in a coat-of-arms: but a French author would have the true gyronny to consist of eight pieces only, as in the figure which represents the coat-of-arms of Flora Campbell countess of Loudon, &c. whose ancestor was created baron of Loudon in 1604 by James VI and earl of the same place, May 12, 1633, the 9th of Charles I.

The Franc-quarter is a square figure, which occupies the upper dexter quarter of the shield. It is but rarely carried as a charge. Silvestra Petra Sancta has given us a few instances of its use.

The Canton is a square part of the escutcheon, somewhat less than the quarter, but without any fixed proportion. It represents the banner that was given to ancient knights-banners, and, generally speaking, possesses the dexter-chief point of the shield, as in the figure; but should it possess the sinister corner, which it is but seldom, it must be blazoned a canton-sinister.

James Cotes reckons it as one of the nine honourable ordinaries, contrary to most heralds' opinion. It is added to coats of arms of military men as an augmentation of honour: thus John Churchill, baron of Eyemouth in Scotland, and one of the ancestors of the present duke of Marlborough, being lieutenant general to King James II. received from him a canton argent, charged with the red-cross of England, added to his paternal coat, "which is Sable, a lion rampant Argent."

The Fairy is a figure formed by the conjunction of the upper half of the saltier with the under half of the pale.

The Fret is a figure representing two little sticks in saltier, with a maecule in the centre interlaced. J. Gibson terms it, the heralds true-lovers knot; but many dissent from his opinion.

Fretty is said when the field or bearings are covered with a fret of six, eight, or more pieces, as in the figure. The word fretty may be used without addition, when it is of eight pieces; but if there be less than that number, they must be specified.

The File, which consists of two lines, terminating in a point, is formed like a wedge, and is borne engrailed, wavy, &c. as in the figure. It issues in general from the chief, and extends towards the base; yet there are some piles borne in bend, and issuing from other parts.
Heraldry.

The Fusil is longer than the lozenge, having its upper and lower part more acute and sharp than the other two collateral middle parts, which acuteness is occasioned by the short distance of the space between the two collateral angles; which space, if the fusil is rightly made, is always shorter than any of the four equal geometrical lines whereof it is composed. See the fig. ibid.

The R است a lozenge pierced round in the middle (see the figure). They are called by the German ruten. Menestrier gives an example of them in the arms of Lebarret in France, argent three rustres azure.

The Mascle is pretty much like a lozenge, but voided or perforated through its whole extent, showing a narrow border, as in the figure. Authors are divided about the resemblance; some taking it for the mesh of a net, and others for the spots of certain flints found about Rohan; and as no writer has given a clearer account in support of this last opinion than Coulombeau, author of La Science Heraldique, we shall transcribe it for the satisfaction of the curious.

Rohan (say he) bears Gules, nine Masclers, Or, 3 3 3. Opinions have varied very much about the original of the masclers or meshes, as being somewhat like the meshes of nets: but for my own part, having often observed that those things which are remarkable and singular in some countries, have sometimes occasioned the lords thereof to represent them in their escutcheons, and to take them for their arms, I am of opinion, that the lords of Rohan, who, I believe, are the first that bore these figures in their arms though descended from the ancient kings and princes of Bretagne, took them, because in the most ancient viscounty of Rohan, afterwards erected into a duchy, there was a abundance of small flints, which being cut in two, this figure appears on the inside of them; as also the carps, which are in the fish-ponds of that duchy, have the same mark upon their scales; which, being very extraordinary and peculiar to that country, the ancient lords of the same had good reason, upon observing that wonder, to take those figures for their arms, and to transmit them to their posterity, giving them the name of masclers, from the Latin word macula, signifying a spot; whence some of that house have taken for their motto, Sine macula macula, that is, A mascle without a spot.

Papillone is an expression used for a field or charge that is covered with figures like the scales of a fish. Mons. Baron gives as an example of it the arms of Monti, Gueules Papallone d'Argent. The proper term for it in English would be scallop work.

Diapering is said of a field or charge shadowed with flourishings or foliage with a colour a little darker than that on which it is wrought. The Germans frequently use it; but it does not enter into the blazoning or description of an arms, it only serves to embellish the coat.

If the fore-mentioned ordinaries have any attributes, that is, if they are engrafted, indented, wavy, &c. they must be distinctly specified, after the same manner as the honourable ordinaries.

See examples of subordinaries, &c. fig. xii. 1. "Guels,"
HERALDRY.

Chap. III.

14. "Azure, a Pile wavy bendways Or;" borne by the name of Hulse, and borne by Sir Edward Hulse, Bart.

15. "Or, three Piles in Bend, each point ensigned with a Fleur-de-lis Sable;" borne by the name of Norton.

16. "Argent, three Piles meeting near the point of the base Azure;" borne by the name of Bryan.

17. "Party per Pale and per Bend Or and Azure counterchanged;" borne by the name of Johnson.

18. "Party per Pale and per Chevron Argent and Gules counterchanged;" borne by the name of Lavider.

SECT. III. Of Common Charges borne in Cooks of arms.

It has been already observed, that in all ages men have made use of the representation of living creatures, and other symbolical signs, to distinguish themselves in war; and that these marks, which were promiscuously used for hieroglyphics, emblems, and personal devices, gave the first notion of heraldry. But nothing shows the extent of human wit more than the great variety of these marks of distinction, since they are composed of all sorts of figures, some natural, others artificial, and many chimerical; in allusion, it is to be supposed, to the state, quality, or inclination of the bearer.

Hence it is, that the sun, moon, stars, comets, meteors, &c. have been introduced to denote glory, grandeur, power, &c. Lions, leopards, tygers, serpents, stags, &c. have been employed to signify courage, strength, prudence, swiftness, &c.

The application to certain exercises, such as war, hunting, music, &c. has furnished lances, swords, pikes, arms, ladders, &c.; architecture, columns, chevron, &c.; and the other arts several things that relate to them.

Human bodies, or distinct parts of them, also clothes, and ornaments, have, for some particular intention, found place in armor; trees, plants, fruits, and flowers, have likewise been admitted to denote the rarities, advantages, and singularities, of different countries.

The relation of some creatures, figures, &c. to particular names, has been likewise a very fruitful source of variety in arms. Thus the family of Coningsby bears three cones; of Arundel, six swallow; of Upton, a bear; of Lucie, three pikes; in Latin tres lucos pices; of Starkey, a stork; of Castleman, a castle triple-towered; of Shuttleworth, three weavers shuttles, &c.

Besides these natural and artificial figures, there are chimerical or imaginary ones used in heraldry, the result of fancy and caprice; such as centaurs, hydra, phoenixes, griffins, dragons, &c. Which great variety of figures shows the impossibility of comprehending all common
common charges in a work of this nature; therefore such only shall be treated of as are most frequently borne in coats-of-arms.

Among the multitude of natural things which are used in coats-of-arms, those most usually borne are, for the sake of brevity as well as perspicuity, distributed into the following classes, viz.

**Celestial figures;** as, the sun, moon, stars, &c. and their parts.

**Ephics of men, women, &c. and their parts.**

**Beasts;** as, lions, tigers, foxes, boars, &c. and their parts.

**Birds;** as, eagles, swans, storks, pelicans, &c. and their parts.

**Fishes;** as dolphins, whales, sturgeons, trouts, &c. and their parts.

**Reptiles and insects;** as, tortoises, serpents, grasshoppers, &c. and their parts.

**Vegetables;** as trees, plants, flowers, herbs, &c. and their parts.

**Stones;** as diamonds, rubies, pebbles, rocks, &c.

These charges have, as well as ordinaries, divers attributes or epithets, which express their qualities, positions, and dispositions. Thus the sun is said to be in his glory, eclipsed, &c.; the moon, in her complement, crescent, &c. Animals are said to be rampant, passant, &c. Birds have also their denominations such as close, displayed, &c. Fishes are described to be haurient, naiant, &c.

I. Examples of Celestial Figures.

1. "Azure, a Sun in his Glory;" borne by the name of St. Ciers, and is found in the first and fourth quarters of the coat-of-arms of the most noble William-John Ker, marquis of Lothian, &c. It is needless to express the colour of the sun, nothing being capable to denote it but gold.

2. "Azure, one Ray of the Sun, bendways Gules, between six Beams of that Luminous Argent;" borne by the name of Aldan. There is no mention made of their issuing out of the dexter-corner of the escutcheon; for this is implied in the term bendways, for the reason mentioned before.

3. "Argent, five rays of the Sun issuing out of the sinister corner Gules;" borne by the name of Methshider, a family of distinction in France.

4. "Or, a Sun eclipsed." This bearing is seldom to be met with, except in emblematic or hieroglyphic figures; and might be expressed Sable, because that hue is accidental and not natural.

5. "Gules, the Moon in her complement Or, illustrated with all her light proper." This is sufficient without naming the colour, which is Argent.

6. "Azure, a Moon decrecent proper;" borne by the name of Delaluna.

7. "Gules, a Moon increcent Or;" borne by the name of Dascus.

8. "Argent, a Moon in her detriment, Sable." This word is used in heraldry to denote her being eclipsed.

9. "Azure, a Crescent Argent;" borne by the name of Lucy. This bearing is also used as a difference, it being assigned to the second son, as before-mentioned.

10. "Gules, three Crescents Argent;" borne by Oliphant, Lord Oliphant (at present dormant). Amongst the ancestors of this noble family was David de Oliphant, one of those barons who, in 1142, accompanied King David I. into England with an army, to assist his niece Matilda, against King Stephen; but after raising the siege of Winchester, the said King David was so closely pursued, that had it not been for the singular conduct of this brave person, the king would have been taken prisoner.

11. "Azure, a Crescent between three Mullets Argent;" borne by Arbuthnot, Viscount and Baron Arbuthnot. In the year 1105, the first of this family marrying a daughter of the family of Olibarth, sheriff of the county of Kincardine, with her he had the lands of Arbuthnot in that county, from whence he took his surname. Robert Arbuthnot was the first of this family who, for his loyalty to King Charles I. was, Nov. 16, 1641, dignified with the title of Baron and Viscount Arbuthnot.

12. "Gules, a Star issuing from between the Horns of a Crescent Argent."

13. "Azure, a Star of 16 points Argent;" borne by the name of Hutton.

14. "Argent, three Mullets pierced Sable;" borne by the name of Wallaston.

15. "Azure, six Mullets, 3, 2, 1, Or;" borne by the name of Welsh.

16. "Ermine, a Mullet of six points Gules, pierced;" borne by the name of Hoppers—When a mullet has more than five points, their number must, in blazoning, be always named.

17. "Argent, a Rainbow with a Cloud at each end proper." This is part of the crest to the earl of Hope ton's coat-of-arms, which is inserted in fig. ix. No. 13. The whole of it is a globe split on the top, and above it is the rainbow, &c.

18. "Party per Fess crenelle Gules and Azure, three Suns proper;" borne by the name of Pierson.

19. "Gules, a Mullet between three Crescents Argent;" borne by the name of Oliver.

20. "Gules, a Chief Argent, on the lower part thereof a Cloud, the Sun's resplendent rays issuing throughout proper;" borne by the name of Lescow.

II. Examples of Effigies of Men, &c. and their Parts.

1. "Azure, the Virgin Mary crowned, with her Fig. 14. Babe in her right arm and a sceptre in her left, all Or;" the coat-of-arms of the bishoprick of Salisbury.

2. "Azure, a Fresbyter sitting on a Tomb-stone, with a Crown on his head and a Glory Or, his right hand extended, and holding in his left an open Book Argent, with a sword cross his mouth Gules;" the coat-of-arms of the bishoprick of Chichester.

3. "Azure, a Bishop habited in his pontificial sitting on a chair of state, and leaning on the sinister side thereof, holding in his left hand a Crozier, his right hand extended towards the dexter chief of the escutcheon, all Or, and resting his feet on a cushion Gules, tasseled of the second;" the coat-of-arms of the bishoprick of Clogher in Ireland.

4. "Azure, a Bishop habited in his pontifical, holding before him, in a Pale, a Crucifix proper;"
HERALDRY.

Chap. III.

III. Examples of the different Positions of Lions, &c., in Coats-of-Arms.

1. "Or, a Lion rampant Gules;" quartered by Fig. 15.
   Percy, duke of Northumberland, &c.

2. "Azure, a Lion rampant-guardant Or;" borne by the name of Fitz-Hammond.

3. "Gules, a Lion rampant-reguardant Or;" quartered by Cadogan, Lord Cadogan, &c.

4. "Ermine, a Lion salient Gules;" borne by the name of Worley.

5. "Azure, a Lion statant-guardant Or;" borne by the name of Bromfield.

6. "Or, a Lion passant Gules;" borne by the name of Games.

7. "Argent, a Lion passant guardant Gules crowned Or;" quartered by the right honourable James Orlivy, earl of Findlater, &c.

8. "Gules, a Lion sejant Argent;" borne by the name of Carter.

9. "Or, a Lion rampant double-headed Azure;" borne by the name of Mason.

10. "Sable, two Lions rampant-combatant Or, armed and langued Gules;" borne by the name of Carter.

11. "Azure, two Lions rampant-adorsée Or;" This coat-of-arms is said to have been borne by Achilles at the siege of Troy.

12. "Sable, two Lioncels counter-passant Argent, the uppermost towards the sinister side of the escutcheon, both collared Gules;" borne by the name of Glegg.—It is the natural disposition of the lion not to bear a rival in the field: therefore two lions cannot be borne in one coat-of-arms, but must be supposed to be lion's whelps, called lioncels; except when they are parted by an ordinary, as in fig. viii. No 17. or so disposed as that they seem to be distinctly separated from each other, as in fig. xv. No 20. In the two foregoing examples they are called lions, because in the 10th they seem to be striving for the sovereignty of the field, which they would not do unless they were of full growth; and in the 11th they are supposed to represent two valiant men, whose dispute being accommodated by the prince, are leaving the field, their pride not suffering them to go both one way.

13. "Argent, a Demi-lion rampant Sable;" borne by the name of Meruin.

14. "Gules, a Lion couchant between six Cross-croisées, three in Chief, and as many in Base, Argent;" for the name of Tynte; and is the first and fourth quarter of the arms of Sir Charles-Kenys Tynte, Bart.

15. "Azure, a Lion dormant Or;" borne by Fines, Viscount and Baron Saye and Sele.

16. "Or, out of the midst of a Fess Sable, a Lion rampant-naisant Gules;" borne by the name of Emme. This form of blazon is peculiar to all living things that shall be found issuing out of the midst of some ordinary or other charge.

17. "Azure, three Lioncels rampant Or;" borne by Fines, Viscount and Baron Saye and Sele.

18. "Gules, a tricorporated Lion issuing from three parts of the Escutcheon, all meeting under one Head in the Fess-point Or, langued and armed Azure;" borne
Sir William Skeffington, knight, made so by King Henry VII.

9. "Argent, two Foxes counter-salient, the dexter surmounted of the sinister Gules;" for the name of Kadrod Harb, an ancient British family, from which is descended Sir Wynn, Bart. who bears this quartered, second and third, in his coat-of-arms.

10. "Argent, three Bulls passant Sable, armed and unguled Or;" for Ashley, and quartered by the right honourable Anthony Ashley Cooper, Earl of Shaftesbury, &c. This noble earl is descended from Richard Cooper, who flourished in the reign of King Henry VIII, and purchased the manor of Paulet in the county of Somerset, of which the family are still proprietors. But his ancestor who makes the greatest figure in history is Sir Anthony Ashley Cooper, who was created Baron Ashley of Winbourn, April 20, 1661, and afterwards Earl of Shaftesbury April 23, 1672.

11. "Ermine, three Cats passant in Pale Argent;" for the name of Adams.

12. "Gules, two Grizzly-bears rampant Or, respecting each other;" borne by the name of Doggett.

13. "Or, an Ass's Head erased Sable;" borne by the name of Hackwood.

14. "Gules, three Lions gambols erased Argent;" for the name of Newdigate.

15. "Argent, three Lions Tails erect and erased Gules;" borne by the name of Cork.

16. "Azure, a Buck's Head cabossed Argent;" borne by Legge, Earl of Dartmouth, &c. This noble family is descended from Signior de Lega, an Italian nobleman, who flourished in Italy in the year 1297. What time the family came into England is uncertain; but it appears they were settled at Legge-place, near Tunbridge in Kent, for many generations; and Thomas, one of their ancestors, was twice Lord-Mayor of London, viz. in 1346 and 1353.

17. "Argent, two Squirrels sejant adossées Gules, for the name of Sommerville.

18. "Gules, a Goat passant Argent;" borne by the name of Baker.

19. "Sable, a Stag standing at gaze Argent;" borne by the name of Jones, of Monmouthshire.

20. "Azure, three Holy Lambs Or;" borne by the name of Row.

V. Examples of Birds, Fishes, Reptiles, &c.

1. "Ermine, an Eagle displayed Sable;" borne by the name of Beddington.

2. "Gules, a Swan close proper;" borne by the name of Leatham.

3. "Argent, a Stork Sable, membered Gules;" borne by the name of Starkey.

4. "Gules, a Pelican in her nest with wings elevated, feeding her young ones Or; vulned proper;" borne by the name of Coare.

5. "Argent, three Peacocks in their pride proper;" borne by the name of Pawne.

6. "Sable, a Goshawk Argent, perching upon a stock in the Base-point of the Escutcheon of the second, armed, jessed, and belled Or;" borne by the name of White.
HERALDRY.

Chap. III.

7. "Or, a Raven proper;" borne by the name of

9. "Sable, a Dolphin naiant embossed Or;" borne

10. "Argent, three Whales Heads erect and erased

11. "Gules, three Escallops Argent;" borne by

12. "Azure, three Trouts frettets in Triangle Argent;" borne by the name of Troutbeck.

13. "Vert, a Grasshopper passant Or;"

14. "Azure, three Bees two and one volant in pale Argent;" borne by the name of Bye.

15. "Vert, a Tortoise passant Argent;" borne by the name of Gaudy.

16. "Gules, an Adder noded Or;" borne by the name of Nathley. Adders, snakes, and serpents, are said to represent many things, which being according to the fancy of the ancients, and a few modern authors who have adopted their opinions, it is needless to enlarge upon. It is certain they often occur in armorial: but the noblest is that of the ducy of Milan, viz. "Argent, a Serpent gliding in Pale Azure, crowned Or, vorant an Infant issuing Gules." The occasion of this bearing was this: Otho, first viscount of Milan, going to the Holy Land with Godfrey of Bouillon, defeated and slew in single combat the great giant Volucx, a man of extraordinary stature and strength, who had challenged the bravest of the Christian army. The viscount having killed him, took his armour, and among it his helmet, the crest whereof was a serpent swallowing an infant, worn by him to strike terror into those who should be so bold as to engage him.

17. "Ermine, a Rose Gules barbed and seeded proper;" borne by Boscowen Viscount Falmouth, &c. This family is descended from Richard Boscowen, of the town of Boscowen, in the county of Cornwall, who flourished in the reign of King Edward VI. Hugh, the first peer of this ancient family, was created baron of Boscowen Rose, and Viscount Falmouth, on the 13th of June 1730, 6th of George I.

18. "Azure, three Laurel leaves slipped Or;" borne by the name of Lewson, and quartered by the right honorable Granville-Lesveson Gower, earl of Gower, &c.

19. "Azure, three Garbs Or;" borne by the name of Cuming. These are sheaves of wheat; but though they were barley, rye, or any other corn whatsoever, it is sufficient, in blazoning, to call them Garbs, telling the tincture they are of.

20. "Gules, three Cinquefoils Argent;" borne by Lambart, baron of Cavan, &c. In Ireland. Of this ancient family, which is of French extraction, was Sir Oliver, who in the reign of Queen Elizabeth, attending the earl of Essex to Spain, was there knighted by him, and afterwards returning with that earl into Ireland, was, for his singular service in the north against O'Neal earl of Tyrone, made camp-master-general, and president of Connacht; and February 17, 1617, was created Lord Lambart and baron of Cavan by King James I.

It must be observed, that trees and plants are sometimes said to be trunked, eradicated, frustrated, or regulated, according as they are represented in arms.

ART. 2. OF ARTIFICIAL FIGURES borne in COATS-OF-ARMS.

After the various productions of nature, artificial figures, the objects of arts and mechanics, claim the next rank. They may be distributed into the following classes, viz.:

1. Worked instruments; as swords, arrows, battering-rams, gauntlets, spears, pole-axes, &c.

2. Ornaments used in royal and religious ceremonies; as crowns, coronets, mitres, wethers, croisiers, &c.

3. Architecture; as towers, castles, arches, columns, plinmets, battlements, churches, portcullises, &c.

4. Navigation; as ships, anchors, rudders, pendents, sails, oars, mast, flags, galley, lighters, &c.

All these bearings have different epithets, serving either to express their position, disposition, or make: viz. swords are said to be erect, pommelled, hilted, &c.; arrows, armed, feathered, &c.; towers, covered, embattled, &c.; and so on of all others, as will appear by the following examples.

1. "Sable, three Swords, their points meeting in Fig. 13, the Base Argent, pommelled and hilted Or, a Crescent in chief of the second for difference;" borne by Powlet, Duke of Bolton, &c. This noble duke is descended from Hercules, lord of Tournon in Picardy, who came over to England with Jeffrey Placentaginet earl of Anjou, third son of King Henry II. and among other lands had the lordship of Powlet in Somersetshire conferred on him. William Powlet, the first peer of this illustrious and loyal family, was treasurer of the household to King Henry VIII. and by him created Baron St John of Basing, in the county of Southampton, March 9, 1538.

2. "Argent, three Battering-rams barren in Pale, headed Azure and hooped Or, an Annulet for difference;" borne by Bertie, earl of Abington, &c. The first of the family of Bertie that bore the title of earl of Abington was James Bertie Lord Norris of Ryecote, being created earl, Nov. 30, 1683, by Charles II.

3. "Azure, three left-hand Gauntlets with their backs forward Or;" borne by Fane, earl of Westmorland, &c. This noble earl is descended from the Fanes, an
Chap. III. HERALDRY. 419

Artificial Figures.

an ancient family which resided at Badal in Kent, from which descended Francis Fane, son and heir of Sir Thomas Fane, knight, by Mary his wife, sole daughter and heiress to Henry Novil Lord Abergaveny, afterwards created Baroness Denys. The said Francis was a knight of the Bath; and in the reign of King James I. was created Baron Burghersh and earl of Westmoreland Dec. 29. 1514.

4. "Azure, three Arrows their points in base Or;" borne by Archer, Lord Archer, &c. This noble lord is descended from John de Archer, who came over from Normandy with William the Conqueror; and this family is one of the most ancient in Warwickshire, being settled at Umberslade in that county ever since the reign of Henry II. His lordship is the first peer; and was created Lord Archer and baron of Umberslade by King George II. July 14. 1747.

5. "Gules, two Helmets in chief proper, garnished Or, in a Base of a Garb of the third;" borne by Cholmondeley, earl of Cholmondeley, &c. This noble earl is descended from the ancient family of Egerton in Cheshire, which flourished in the time of the Conquest, from whom also the duke of Bridgewater was descended. The first English peer of this branch was Hugh Viscount Cholmondeley of Kells, in Ireland, who, joining with those who opposed the arbitrary measures of King James II. was on the accession of King William and Queen Mary created Lord Cholmondeley of Nantwich, in the county of Chester.

6. "Argent, a ship with its sails furled up Sable;" quartered by Hamilton, earl of Abercorn, &c. The descent of this noble family is from that of the duke of Hamilton: for James, the fourth Lord Hamilton and second earl of Arran, marrying Lady Margaret Douglas daughter of James the third earl of Morton, by her having four sons, James, John, Claud, and David: whereas Claud was progenitor of the lord we are now speaking of; and in consideration of his merit and loyalty to Mary queen of Scots, James VI. created him Lord Paisley in 1601, as also earl of Abercorn, baron of Hamilton, &c. July 10. 1606.

7. "Or, an Anchor in pale Gules;" quartered by most noble George Johnston, marquis of Annandale, &c. The Johnston are an ancient and warlike family, and derive their surname from the barony of Johnston in Annandale.

8. "Sable, three Spears heads erect Argent, imbrued Gules, on a chief Or, as many Pole-axes Azure;" borne by King, Lord King, &c. Peter King Esq. the first lord of this ancient family, was chosen recorder of the city of London, July 27. 1708, and on the 12th of September following had the honour of knighthood conferred on him. He was constituted lord-chief-justice of the common pleas in the first year of King George I. 1714; and on the 5th of April following was sworn of his majesty’s most honourable privy-council, and on May 19. 1723 was created a peer of this kingdom by the title of Lord King, baron of Ockham.

9. "Gules, three Clarions Or;" quartered by Carteret, earl of Granville, &c. This ancient family derives its pedigree from Offray de Carteret, who attended William the Conqueror in his descent upon England, and contributed to the victory he obtained over King Harold, at Hastings in Sussex, 1066: he had manors and lands in England conferred on him by that prince, as a reward for his eminent services. George the first earl was, in consideration of his own merit and the services of his ancestors, created a peer of Great Britain, October 10. 1681.

10. "Argent, a Maunch Sable;" borne by Hastings, earl of Huntingdon, &c. This family is descended from Hugh de Hastings, a younger son of the ancient and noble family of the Hastings, earl of Pembroke, of which family was William de Hastings, steward of the household to King Henry I.—William, the first Lord Hastings, was created a baron on July 6. 1461, by King Edward IV.

11. "Azure, a circular Wreath Argent and Sable, with four Hawks Bells joined thereto in quadrature Or;" borne by Jocelyn, Viscount Jocelyn, &c. This noble family is of great antiquity; for, after the Romans had been masters of Britain 500 years, wearied with the wars, they took their final farewell of it, and carried away with them a great many of their brave old British soldiers, who had served them in their wars both at home and abroad, to whom they gave Armoric in France, for their former services, which country was from them afterwards called Little Britain. It is supposed that there were some of this family amongst them; and that they gave the name of Jocelyn to a town in this country, which still preserves that name; and it is thought probable that they returned with William the Conqueror: for we find, in 1066, mention made of Sir Gilbert Jocelyn. The first lord of the family, was created Baron Newport, of Newport in Ireland, on Nov. 29. 1743, and viscount in Nov. 1751.

12. "Gules, three Towers Argent;" quartered by Fowler, Viscount Ashbrook, &c. William Fowler, Esq. was advanced to the peerage by King George II. and created Baron of Castle Durrow in the county of Kilkenny, Oct. 27. 1733; and his son was created Viscount Ashbrook, of Ashbrook in Ireland, on September 30. 1751; now extinct.

14. "Gules, two Swords in Saltier Argent, pomeleed and hilted Or;" the arms of the bishopric of London.

15. "Sable, a Key in Bend, surmounted by a Crozier in Bend-sinister, both Or;" the arms of the bishopric of St. Asaph.

16. "Gules, two Keys adossée in Bend, the uppermost Argent, the other Or; a Sword interposed between them in Bend-sinister of the second, pomeleed, and hilted of the third;" the arms of the bishopric of Winchester.

17. "Gules, three Mitres with their pendants Or;" the arms of the bishopric of Chester.

18. "Sable, three Ducal Coronets paleways Or;" the arms of the bishopric of Bristol.

19. "Gules, a Sword erect in Pale Argent, pomeleed and hilted Or, surmounted by two Keys in Saltier of the last;" the arms of the bishopric of Exeter.

20. "Gules, three Ducal Coronets, Or;" the arms of the bishopric of Ely.
ART. 3. Of Chimerical Figures.

The last and the oddest kind of bearings in coats-of-arms is comprehended under the name of chimerical figures; that is to say, such as have no real existence, but are mere fabulous and fantastical inventions. These charges, griffins, martlets, and unicorns excepted, are so uncommon in British coats, that in order to make up the same number of examples hitherto contained in each collection, several foreign bearings are introduced here; which, however, as they are conform to the laws of heraldry, will also contribute both to entertain and instruct the reader. Those most in use are the following, viz.

Angels, Cherubims, Tritons, Centaurs, Martlets, Griffins, Unicorns, Dragons, Mermaids, Satyrs, Wivers, Harpies, Cockatriccs, Phoenixes.

These, like the foregoing charges, are subject to various positions and dispositions, which, from the principles already laid down, will be plainly understood from the following examples.

Fig. 19.

1. Gules, an Angel standing affrontée, with his hands conjoined and elevated upon his breast, habited in a long robe close girt Argent, his Wings displayed Or;" borne by the name of Brangor de Cerbessi, a foreign prelate, who assisted at the council of Constance, 1412. This example is quoted by Guillim, Sect. III. Chap. I.

2. Sable, a Cheveron between three Cherubim Or;" borne by the name of Chaloner, of Yorkshire and Cheshire.

3. Azure, a Fess indented between three Cherubim Argent." These arms were granted to John Ayde, Esq. of Doddington in Kent, by Sir William Segar, garter.

4. Gules, a Cherub having three pair of Wings, the uppermost and lowermost counter-crossed Saltierways, and the middlemost displayed Argent;" borne by the name of Buocasoco, a foreign prelate. This example is copied from Menestrier's Methode du Blason, p. 120. No. viii.

5. Azure, a Griffon segreant Or, armed and langued Gules, between three Crescents Argent, quartered by Bligh, Lord Clifton, &c. The ancestor of this noble family, who lived in London, going over to Ireland in the time of Oliver Cromwell, as an agent to the adventurers there, acquired a good estate, and laid the foundation for the grandeur of this family.

6. Gules, three Martlets Or;" borne by the name of Maegill. Guilin observes, that this bird, which is represented without feet, is given for a difference to younger brothers, to put them in mind, that, in order to raise themselves, they are to trust to their wings of virtue and merit, and not to their legs, having but little land to set their feet on.

7. Azure, three Mulletts Argent within a double Treasure counter-floury Or, in the centre a Martlet of the last;" borne by Murray, Lord Elibank. Sir Gideon Murray, knighted by King James VI. by whom he was made treasurer-depute, was third son of Sir Andrew Murray of Blackbarony. His son Patrick, in respect of his loyalty to Charles I. was on May 16, 1628 made a baronet, and in 1643 created Lord Elibank.
Chap. IV: Heraldry.

Crown.

Among the Greeks, the crowns given to those who carried the prize at the Isthmian games, were of pine; at the Olympic, of laurel; and at the Nemean, of smallage.

The Romans had various crowns to reward martial exploits and extraordinary services done to the republic; for which see the detached article Crown in this Dictionary, and Plate CLXIV.

Examples of some of these crowns are frequently met with in modern achievements, viz. 1. The mural crown in that of Lord Montfort, which was conferred on Sir John Bromley, one of his lordship’s ancestors, as an augmentation to his arms, for his great courage at the battle of Le Croby. Part of the crest of Lord Archer is also a mural crown. And there are no less than ten English baronets, whose arms are ornamented with the same crown. 2. The naval or rostral crown is still used with coats-of-arms, as may be seen in those of Sir William Burnaby, Bart. now admiral of the red squadron, and of John Clerk, Esq. as part of their crests. 3. Of the castrense or vallary crown, we have instances in the coats-of-arms of Sir Reginald Graham, and of Isaac Ackerman, Esq. The crest of Grace Blackney, Esq. is ornamented with a circlet of a crown. 4. The radiated crown, according to J. Yorke, was placed over the arms of the kings of England, till the time of Edward III. It is still used as a crest on the arms of some private families; those, for example, borne by the name of Whitfield, are ornamented with it. The celestial crown is formed like the radiated, with the addition of a star on each ray; and is only used upon tombs, monuments, and the like. Others of the ancient crowns are still borne, as crests, by several families.

But modern crowns are only used as an ornament, which emperors, kings, and independent princes set on their heads, in great solemnities, both to denote their sovereign authority, and to render themselves more awful to their subjects. These are the most in use in heraldry, and are as follows:

Fig. 20.

The imperial crown (No. 1.) is made of a circle of gold, adorned with precious stones and pearls, heightened with fleurs-de-lis, bordered and seeded with pearls, raised in the form of a cap, and deprived of the cap like a crescent. From the middle of this cap rises an arched fillet enriched with pearls, and surmounted of a mound, whereon is a cross of pearls.

The crown of the kings of Great Britain (2.) is a circle of gold, bordered with ermine, enriched with pearls and precious stones, and heightened up with four crosses patee, and four large fleurs-de-lis alternately; from these rise four arched diadems adorned with pearls, which close under a mound, surmounted of a cross like those at bottom. Mr Sandford, in his Genealogical History, p. 381. remarks, that Edward IV. is the first king of England that in his seal, or on his coin, is crowned with an arched diadem.

The crown of the kings in France (3.) is a circle enamelled, adorned with precious stones, and heightened up with eight arched diadems, rising from as many fleurs-de-lis, that coadjoint at the top under a double fleur-de-lis, all of gold.

The crowns of Spain, Portugal, and Poland, are all three of the same form, and are, amongst others, thus described by Colonel Parsons, in his Genealogical Corone.

Tables of Europe, viz. A ducal corone, heightened up with eight arched diadems that support a mound, ensignified with a plain cross. Those of Denmark and Sweden are both of the same form, and consist of eight arched diadems, rising from a marquis’s corone, which conjoin at the top under a mound ensignified with a cross-bottony.

The crowns of most other kings are circles of gold, adorned with precious stones, and heightened up with large trefoils, and closed by four, six, or eight diadems, supporting a mound, surmounted of a cross.

The Great Turk (4.) bears over his arms a turban, enriched with pearls and diamonds, under two coronets, the first of which is made of pyramidal points heightened up with large pearls, and the uppermost is surmounted with crescents.

The Pope, or bishop of Rome, appropriates to himself a Tiara (No. 5.), or long cap of golden cloth, from which hang two pendants embroidered and fringed at the ends, semée of crosses of gold. This cap is enclosed by three marquises coronets; and has on its top a mound of gold, whereon is a cross of the same, which cross is sometimes represented by engravers and painters pommeled, recrossed, flowered, or plain. — It is a difficult matter to ascertain the time when the popes assumed the three forementioned coronets. A patched-up succession of the holy pontiffs, engraved and published some years ago by order of Pope Clement XIII. for the edification of his good subjects in Great Britain and Ireland, represents Marcellus, who was chosen bishop of Rome anno 310, and all his successors, adorned with such a cap: but it appears, from very good authority, that Boniface VIII., who was elected into the see of Rome anno 1227, first compassed his cap with a corone; Benedict XII. in 1335, added a second to it; and John XXIII. in 1411, a third; with a view to indicate by them, that the Pope is the sovereign priest, the supreme judge, and the sole legislator amongst Christians.

Sect. II. Of Coronets.

The coronet of the prince of Wales, or eldest son of the king of Great Britain (No. 6.), was anciently a circle of gold set round with four crosses patee, and as many fleurs-de-lis alternately; but since the Restoration, it has been closed with one arch only, adorned with pearls, and surmounted of a mound and cross, and bordered with ermine like the king’s.

Besides the aforesaid coronet, his royal highness the prince of Wales has another distinguishing mark of honour, peculiar to himself, called by the vulgar the prince’s arms, viz. A plume of three ostrich-feathers, with an ancient corone of a prince of Wales. Under it, in a scroll, is the motto, Ich Dien, which in the German or old Saxon language signifies, “I serve;” (see No. 6.). This device was at first taken by Edward prince of Wales, commonly called the Black Prince, after the famous battle of Crecy, in 1346, where having with his own hand killed John king of Bohemia, he took from his head such a plume, and put it on his own.

The coronet of all the immediate sons and brothers of the kings of Great Britain, is a circle of gold, bordered.
This ornament, with other masquerade garments, is still worn by all the archbishops and bishops of the church of Rome, whenever they officiate with solemnity; but it is never used in England, otherwise than on coats-of-arms, as before mentioned.

Sect. IV. Of Helmets.

The Helmet was formerly worn as a defensive weapon, to cover the bearer's head, and is now placed over a coat-of-arms as its chief ornament, and the true mark of gentility. There are several sorts, distinguished, 1st, by the matter they are made of; 2dly, by their form; and, 3dly, by their position.

1st. As to the matter they are, or rather were, made of: The helmets of sovereigns were of burnished gold damasked; those of princes and lords, of silver figured with gold; those of knights, of steel adorned with silver, and those of private gentlemen of polished steel.

2dly. As to their form: Those of the king and the royal family, and noblemen of Great Britain, are open-faced and grated, and the number of bars serves to distinguish the bearer's quality; that is, the helmet appropriated to the dukes and marquises is different from the king's, by having a bar exactly in the middle, and two on each side, making but five bars in all, (see fig. 21. No. 1.) whereas the king's helmet has six bars, viz. three on each side, (ibid. No. 7.) The other grated helmet with four bars is common to all degrees of peerage under a marquis. The open-faced helmet without bars denotes baronets and knights. The close helmet is for all esquires and gentlemen.

3dly. Their position is also looked upon as a mark of distinction. The grated helmet in front belongs to sovereign princes. The grated helmet in profile is common to all degrees of peerage. The helmet standing direct without bars, and the beaver a little open, denotes baronets and knights. Lastly, the side-standing helmet, with the beaver close, is the way of wearing it amongst esquires and gentlemen. See No. 5, 3, 3, 4, and 7, inserted in fig. 21. Ornaments.

Sect. V. Of Mantlings.

Mantlings are pieces of cloth jagged or cut into flowers and leaves, which now-a-days serve as an ornament for escutcheons. They were the ancient coverings of helmets, to preserve them, or the bearer, from the injuries of the weather, as also to prevent the ill consequences of their too much dazzling the eye in action. But Guilielm very judiciously observes, that their shape must have undergone a great alteration since they have been out of use, and therefore might more properly be termed填写文字段落 missing。
more honourable they were accounted; as our colours in time of war are the more esteemed for having been shot through in many places.

Sometimes skins of beasts, as lions, bears, &c. were thus borne, to make the bearer look more terrible, and that gave occasion to the doubling of mantlings with furs.

Sect. VI. Of Chapeaux.

A Chapeau is an ancient hat, or rather cap, of dignity worn by dukes, generally scarlet-coloured velvet on the outside, lined and turned up with fur; of late frequently to be met with above an helmet, instead of a wreath, under gentlemen’s and noblemen’s crests. Heretofore they were seldom to be found, as of right appertaining to private families; but by the grants of Robert Cooke, Clarenceux, and other succeeding heralds, these, together with ducal coronets, are now frequently to be met with in families, who yet claim not above the degree of gentlemen. See the representation of the chapeau, No. 5. fig. 21.

Sect. VII. Of Wreaths.

The Wreath is a kind of roll made of two skains of silk of different colours twisted together, which ancient knights wore as a head-dress when equipped for tournaments. The colours of the silk are always taken from the principal metal and colour contained in the coat-of-arms of the bearer. They are still accounted as one of the lesser ornaments of escutcheons, and are placed between the helmet and the crest: (see fig. 21. No. 6.). In the time of Henry I. and long after, no man, who was under the degree of a knight, had his crest set on a wreath; but this, like other prerogatives, has been infringed so far, that every body now a-days wears a wreath.

Sect. VIII. Of Crests.

The Crest is the highest part of the ornaments of a coat-of-arms. It is called crest, from the Latin word creta, which signifies comb or tuft, such as many birds have upon their heads, as the peacock, peahen, &c. in allusion to the place on which it is fixed.

Crests were formerly great marks of honour, because they were only worn by heroes of great valour, or by such as were advanced to some superior military command, in order that they might be the better distinguished is an engagement, and thereby rally their men if dispersed; but they are at present considered as a mere ornament. The crest is frequently a part either of the supporters, or of the charge borne in the escutcheon. Thus the crest of the royal achievement of Great Britain is a “Lion guardant crowned,” as may be seen in fig. 21. No. 7. The crest of France is a double Fleur-de-luces. Out of the many crests borrowed from supporters, are the following, viz. the duke of Montagu’s, “A Griffin’s head coup’d Or, back’d and wing’d Sable;” the marquis of Rockingham’s, “A Griffin’s head argent, gorg’d with a ducal coronet;” the earl of Westmoreland’s, “A Bull’s head Argent, py’d Sable, armed Or;” and Lord Archer’s, which is, “Out of a mural crown Or, a Wyvern’s head The Scroll Argent.” There are several instances of crests that are relative to alliances, employments, or names; and which on that account have been changed.

Sect. IX. Of the Scroll.

The Scroll is the ornament placed above the crest, containing a motto, or short sentence, alluding thereto, or to the bearings; or to the bearer’s name, as in the two following instances. The motto of the noble earl of Cholmondeley is, Cassis tuitissima virtus; i.e. “Virtue is the safest helmet;” on account of the helmet in the coat-of-arms. The motto of the right honourable Lord Fortescue is, Forte scutum solus ducum; i.e. “A strong shield is the safety of the commanders;” alluding to the name of that ancient family. Sometimes it has reference to neither, but expresses something divine or heroic; as that of the earl of Scarborough, which is, Manus armis consciscitia sana; i.e. “A good conscience is a wall of brass.” Others are enigmatical; as that of the royal achievement, which is, Dieu et mon Droit, i.e. “God and my right,” introduced by Edward III. in 1340, when he assumed the arms and title of king of France, and began to prosecute his claim, which occasioned long and bloody wars, fatal by turns to both kingdoms; or that of the prince of Wales, which is, Ich diem, “I serve,” the origin of which has been already mentioned. Mottoes, though hereditary in the families that first took them up, have been changed on some particular occasions, and others appropriated in their stead, instances of which are sometimes met with in the history of families.

Sect. X. Of Supporters.

Supporters are figures standing on the scroll, and placed at the side of the escutcheon; they are so called, because they seem to support or hold up the shield. The rise of supporters is, by F. Menestrier, traced up to ancient tournaments, wherein the knights caused their shields to be carried by servants or pages under the disguise of lions, bears, griffins, blackamoors, &c. who also held and guarded the escutcheons, which the knights were obliged to expose to public view for some time before the lists were opened. Sir George Mackenzie, who dissents from this opinion, says, in his Treatise on the Science of Heraldry, chap. xxxi. p. 93. “That the first origin and use of them was from the custom which ever was, and is, of leading such as are invested with any great honour to the prince who confers it: thus, when any man is created a duke, marquis, or knight of the Garter, or any other order, he is supported by, and led to the prince, betwixt two of the quality, and so receives from him the symbols of that honour; and in remembrance of that solemnity, his arms are thereafter supported by any two creatures he chooses.” Supporters have formerly been taken from such animals or birds as are borne in the shields, and sometimes they have been chosen as bearing some allusion to the names of those whose arms they are made to support. The supporters of the arms of Great Britain, since King James the First’s accession
Heraldry. Chap. IV.

Supporters. — Accession to the throne, are a Lion rampant guardant crowned Or, on the dexter side, and an Unicorn Argent, crowned, armed, unguled, maimed and gorged with an antique Crown, to which a chain is affixed, all Or, on the sinister; as it appears by fig. 21. No. 7.

This last figure represents the coat-of-arms of the king of Great Britain, or the royal achievement, as it has been marshalled since the accession of King George I. in 1714, and is blazoned as follows, viz.

ARMS. Quarterly, in the first grand quarter Gules, three Lions rampant guardant in pale Or, the imperial ensigns of England; impaled with Or, a Lion rampant, with a double tressure floriated and counter-floriated Gules, the royal arms of Scotland. The second is Azure, three Fleurs-de-lis Or, the arms of France. The third is Azure, a Harp Or, stringed Argent, the ensign of Ireland. The fourth grand quarter is Gules, two Lions passant guardant in pale Or, for Brunswick; impaled with Or some of Hearts Proper, a Lion rampant Azure, for Lunenburg; with graffed in base Gules a Horse current Argent, for ancient Saxony; and in a shield quartered Gules, the Crown of Charlemagne Or, as arch-treasurer of the empire; the whole within a Garter, inscribed with this motto, Honi soit qui mal y pense, as sovereign of that noble order, given by the founder King Edward III.

CREST. — On a Helmet full-faced, grated and surmounted of a Crown, a Lion guardant crowned; the mantlings of the last, and lining, Ermine.

Supporters. — On the Dexter side a Lion rampant guardant Or, crowned as the Crest. On the Sinister side an Unicorn Argent, crowned, armed, unguled, maimed, and unguled, gorged with an antique Crown; a Chain attached thereto, reflecting over the back, and passing over the hind legs of the last, both standing on a Scroll inscribed with this motto, Dieu et mon droit, from which issue the two Royal Badges of his Majesty's chief Dominions, viz. on the Dexter side a Rose party pale Argent and Gules, stalked and leaved proper, for England; and on the Sinister side a Thistle proper, for Scotland; being so adorned by King James I. upon his succeeding to the crown of England. As king of Scotland, he bore two unicorns, as above, for his supporters; but upon the union of that kingdom with England, 1603, he introduced one of the above supporters on the sinister side of the royal achievement, and which continues to this day.

It is to be observed, that bearing coats-of-arms supported, is, according to the heraldical rules of England, the prerogative, 1st, Of those called nobles maiores, viz. dukes, marquises, earls, viscounts, and barons; 2d. Of all knights of the Garter, though they should be under the degree of barons; 3d. Of knights of the Bath, who both receive on their creation a grant of supporters. And, lastly, of such grants as the king chooses to bestow this honour upon; as in the instance of Sir Andrew Fountain, who was knighted by Philip earl of Pembroke, when lord lieutenant of Ireland, Fountain being then his secretary; and on his return to England, King William granted him supporters to his arms, viz. two Griffin's Gules and Or. In Scotland, all the chiefs of clan or names have the privilege of claiming supporters; also the baronets. But by act of parliament, 10th September 1672, none are allowed to use either arms or supporters, under a penalty and confiscation of all moveables wherein arms are put, without the Lord Lyon's authority.

Chap. V. Of the Rules or Laws of Heraldry.

The several escutcheons, tinctures, charges, and ornaments of coats-of-arms, and their various properties, being now explained; it may not be improper to sub-join such rules for blazoning the same, as the ancient usage and laws of heraldry have established amongst us.

I. The first and most general rule is, to express one's self in proper terms, so as not to omit any thing that ought to be specified, and at the same time to be clear and concise without tautology; as in Ex. XIV. Chap. III. art. 1. and also in Ex. II. art. 7. wherein these expressions of the field, or of the First, prevent the repetition of the forementioned tincture.

II. One must begin with the tincture of the field, and then proceed to the principal charges which possess the most honourable place in the shield, such as Fess, Chevron, &c. always naming that charge first which lies next and immediately upon the field; as in Ex. 15. Chap. III. art. 5.

III. After naming the tincture of the field, the honourable ordinaries, or other principal figures, you must specify their attributes, and afterwards their metal or colour, as in Ex. 16. Examples of Effigies, &c.

IV. When an honourable ordinary, or some one figure, is placed upon another, whether it be a Fess, Chevron, Cross, &c. it is always to be named after the ordinary or figure over which it is placed, with one of these expressions, sur tout, or over all, as in Ex. 20. Chap. III. art. 1.

V. In the blazoning of such ordinaries as are plain, the bare mention of them is sufficient; but if an ordinary should be made of any of the crooked lines mentioned above, its form must be specified; that is, whether it be Engrailed, Wavy, &c. as in Ex. I. 2. 3. Chap. III. art. 1.

VI. When a principal figure possesses the centre of the field, its position is not to be expressed; or (which amounts to the same thing) when a bearing is named, without specifying the point where it is placed, then it is understood to possess the middle of the shield; as in Ex. 15. Examples of other Quadrupeds, &c.

VII. The number of the points of mullets or stars must be specified when more than five; and also if a mullet or any other charge be pierced, it must be mentioned as such, to distinguish it from what is plain; as in Ex. 13. 14. Examples of Celestial Figures.

VIII. When a ray of the sun, or other single figure, is borne in any other part of the escutcheon than the centre, the point it issues from must be named; as in Ex. 3. Examples of Celestial Figures.

IX. The natural colour of trees, plants, fruits, birds, &c. is no otherwise to be expressed in blazoning but by the word proper, as in Ex. 2. 7. Examples of Birds, &c.; but if discoloured, that is, if they differ from their natural colour, it must be particularized; as in Ex. 1. 2. Examples of other Quadrupeds, &c.

X. When three figures are in a field, and their position
D. D. chaplain in ordinary to his majesty, prebendary of Durham, canon of Windsor, &c. impaled with that of F. Walker, his spouse.

If a widow marry again, his late and present wife's arms are, according to G. Leigh, "to be both placed on the sinister side in the escutcheon with his own, and parted per Pale. The first wife's coat shall stand on the Chief, and the second on the Base; or he may set them both in Pale with his own, the first wife's coat next to himself, and his second outermost. If he should marry a third wife, then the first two matches shall stand on the Chief, and the third shall have the whole Base. And if he take a fourth wife, she must participate one half of the Base with the third wife, and so will they seem to be so many coats quartered." But it must be observed, that these forms of impaling are meant of hereditary coats, whereby the husband stands in expectation of having the hereditary possessions of his wife united to his patrimony.

II. In the arms of femens joined to the paternal coat of the baron, the proper differences by which they were borne by the fathers of such women must be inserted.

III. If a coat-of-arms that has a Bordure be impaled with another, as by marriage, then the Bordure must be wholly omitted in the side of the arms next the centre.

IV. The person that marries an heiress, instead of impaling his arms with those of his wife, is to bear them in an escutcheon placed in the centre of his shield, after the same manner as the baronet's badge is marshalled in N° 3...and which, on account of its showing forth his pretension to her estate, is called an escutcheon of pretence, and is blazoned surmount, i.e. over-all, as in the escutcheon borne in the fourth quarter of the royal achievement. But the children are to bear the hereditary coat-of-arms of their father and mother quarterly, which denotes a fixed inheritance, and to transmit them to posterity. The first and fourth quarters generally contain the father's arms, and the second and third mother's; except the heirs should derive not only their estate, but also their title and dignity, from their mother.

V. If a maiden or dowager lady of quality marry a commoner, or a nobleman inferior to her rank, their coats-of-arms may be set aside of another in two separate escutcheons, upon one mantle or drapery, and the lady's arms ornamented according to her title; see N° 4, and 6, which represent the coats-of-arms of Gen. C. Montagu, and Lady Elizabeth Villiers Viscountess Grandison.

VI. Archbishops and bishops impale the arms differently from the fore-mentioned coats, in giving the place of honour, that is, the dexter side, to the arms of their dignity, as it is expressed in N° 6, which represents the coat-of-arms of Dr Philip Yonge, Lord bishop of Norwich. It may be observed of the above prelates, that they thus bear their arms parted per Pale, to denote their being joined to their cathedral church in a sort of spiritual marriage.

With respect to such armorial ensigns as the sovereign thinks fit to augment a coat-of-arms with, they may be marshalled various ways, as may be seen by the arms of his grace the duke of Rutland, inserted in...
HERALDRY.

Of Escutcheons.

Of Escutcheons.

426

fig. 8. No. 19. and the example contained in fig. 11.

No. 11.

To those augmentations may be added, 1st, The baronet’s mark of distinction, or the arms of the province of Ulster in Ireland, granted and made hereditary in the male line by King James I. who erected this dignity on the 22d of May 1611, in the 9th year of his reign, in order to propagate a plantation in the fore-mentioned province. This mark is Argent, a sinister Hand couped at the Wrist, and erected Gules; which may be borne either in a canton, or in an escutcheon, as will best suit the figures of the arms. See fig. 23. No. 3. which represents the coat-of-arms of Sir William Lorrain, of Kirk-harle, Northumberland, and are thus blazoned: Quarterly, Sable and Argent, a plain Cross counter-quartered of the Field. The Crest,—A Laurel-tree couped, two branches sprouting out proper, and fixed to the lower part thereof with a Bella Gules, edged and buckled Or. This, according to tradition in the family, was granted for some worthy action in the field.

2dly, The ancient and respectable badge of the most noble order of the Garter, instituted by King Edward III. 1349, in the 27th year of his reign; and which, ever since its institution, has been looked upon as a great honour bestowed on the noblest persons of this nation and other countries. This honourable augmentation is made to surround, as with a gar- ter, the arms of such knights, and is inscribed with this motto, Honi soit qui mal y pense: see No. 7, which represents the coat-of-arms of his grace the duke of Montagu, earl of Cardigan, Baron Bromden of Stan- ton-Welf, constable and lieutenant of Windsor-caste- le, knight of the most noble order of the Garter, and baronet, president of St Luke’s Hospital, and P.R.S.

This nobleman, whose arms were Argent, a Chev- ron Gules between three Mortons proper, has, since the decease of John duke of Montagu, taken the name and arms of Montagu, on account of his being married to Lady Mary Montagu, youngest daughter, and one of the co-heiresses of his grace.

So far the causes for marshalling divers arms in one shield, &c. are manifest. As to such as are called ob- scure, that is, when coats-of-arms are marshalled in such a manner, that no probable reason can be given why they are so conjoined, they must be left to heralds to explain, as being the properest persons to unfold these and other mysteries of this science.

CHAP. VII. Of Funeral Escutcheons.

After having treated of the essential parts of the coats-of-arms, of the various charges and ornaments usually borne therewith, of their attributes and dispositions, and of the rules for blazoning and marshalling them, we shall next describe the several funeral escute- cheons, usually called hatchments; whereby may be known, after any person’s decease, what rank either he or she held when living; and if it be a gentleman’s hatchment, whether he was a bachelor, married man, or widower, with the like distinctions for gentle- women.

The hatchment, fig. 24. No. 1, represents such as are affixed to the fronts of houses, when any of the nobility and gentry dies; the arms therein being those of a pri- vate gentleman and his wife parted per pale; the dexter side, which is Gules, three Bars Or, for the hus- band; having the ground without the escutcheon black, denotes the man to be dead; and the ground on the sinister side being white, signifies that the wife is living, which is also demonstrated by the small hatchment, No. 2, which is here depicted without mantling, helmet, and crest, for perspicuity’s sake only.

When a married gentlewoman dies first, the hatch- ment is distinguished by a contrary colour from the former; that is, the arms on the sinister side have the ground without the escutcheon black; whereas those on the dexter side, for her surviving husband, are upon a white ground: the hatchment of a gentlewoman is, moreover, differentiated by a cherub over the arms instead of a crest. See No. 3.

When a bachelor dies, his arms may be depicted single or quartered, with a crest over them, but never impaled as the two first are, and all the ground without the escutcheon is also black. See No. 4.

When a maid dies, her arms, which are placed in a lozenge, may be single or quartered, as those of a bachelor; but, instead of a crest, have a cherub over them, and all the ground without the escutcheon is also black. See No. 5.

When a widow dies, his arms are represented impaled with those of his deceased wife, having a helmet, mantling, and crest over them, and all the ground without the escutcheon is also black. See No. 6.

When a widow dies, her arms are also represented impaled with those of her deceased husband, but enclosed in a lozenge, and, instead of a crest, a cherub is placed over them; all the ground without the escutcheon is also black. See No. 7.

If a widow or bachelor should happen to be the last of his family, the hatchment is depicted as in No. 6, and that of a maid or widow, whose family is extinct by her death, is depicted as in No. 7. With this difference only, that a death-head is generally annexed to each hatchment, to denote, that death has encompassed all.

By the fore-mentioned rules, which are sometimes neglected through the ignorance of illiterate people, may be known, upon the sight of any hatchment, what branch of the family is dead; and by the helmet or coronet, what title and degree the deceased person was of.

The same rules are observed with respect to the es- cutcheon placed on the hearses and horses used in pompous funerals, except that they are not surmounted with any crest, as in the foregoing examples of hatchments, but are always plain. It is necessary, however, to en- sign those of peers with coronets, and that of a maiden lady with a knot of ribbons.

In Scotland, a funeral escutcheon not only shows forth the arms and condition of the defunct, but is also a proof of the gentility of his descent; and such persons for whom this species of escutcheon can be made out, are legally entitled to the character of gentleman of blood, which is the highest species of gentility. The English hatchment above described exhibits no more than a right to a coat-of-arms which may be acquired by purchase, and is only the first step towards establishing gentility in a family.

Chap. VII.

HERALD

HERALDUS, DESIDERIUS, in French Herault, a councillor of the parliament of Paris, has given good proofs of uncommon learning by very different works. His Adversaria appeared in 1599; which little book, if the Scaligeriana may be credited, he repeated the having published. His notes on Tertullian's Apology, on Minutius Felix, and on Arnobius, have been esteemed. He also wrote notes on Martial's Epigrams. He disguised himself under the name of David Liebreccerus, to write a political dissertation on the independence of kings, some time after the death of Henry IV. He had a controversy with Salmantius, De jure Attico ac Romano; but did not live to finish what he had written on that subject. What he had done, however, was printed in 1650. He died in June 1649. Guy Patin says, that he "was looked upon as a very learned man, both in the civil law and in polite literature, and wrote with great facility on any subject he pitched on." Gaille, speaking of such Protestant writers as condemned the executing of Charles I. king of England, quotes the Pacifique Royal en deuit, by Herault. This author, son to our Desiderius Heraltus, was minister in Normandy, when he was called to the service of the Wallon-church of London under Charles I. and he was so zealous a royalist, that he was forced to fly to France, to escape the fury of the commonwealth. He returned to England after the Restoration, and resumed his ancient employment in the Wallon-church at London; some time after which he obtained a canonry in the cathedral of Canterbury, and enjoyed it till his death.

HERB, in Botany, a name by which Linnaeus designates that portion of every vegetable which arises from the root, and is terminated by the fructification. It comprehends, 1. The trunk, stalk, or stem. 2. The leaves. 3. Those minute external parts called by the same author the fulcro or supports of plants. 4. The buds, or, as he also terms them, the winter-quarters of the future vegetable.

HERB-Christopher. See Actea, Botany Index.

HERB-Robert, a species of Geranium. See Geranium, Botany Index.

HERBACEOUS PLANTS, are those which have succulent stems or stalks that die down to the ground every year. Of herbaceous plants, those are annual which perish stem and root and all every year; biennial, which subsist by the roots two years; perennial which are perpetuated by their roots for a series of years, a new stem being produced every spring.

HERBAGE, in Law, signifies the pasture provided by nature for the food of cattle; also the liberty to feed cattle in the forest, or in another person's ground.

HERBAL, signifies a book that treats of the classes, genera, species, and virtues of plants.

HERBAL, is sometimes also used for what is sometimes called Hortus siccus, or a collection of dried plants.

HERBELOT, BARTHOLOMEW D', a French writer, eminent for his oriental learning, was born at Paris in 1625. He travelled several times into Italy, where he obtained the esteem of some of the most learned men of the age. Ferdinand II. grand duke of Tuscany, gave him many marks of his favour; a library being exposed to sale at Florence, the duke desired him to examine the manuscripts in the oriental languages, to select the best of them, and to mark the price; which being done, the generous prince purchased them, and made him a present of them. M. Colbert being at length informed of Herbelot's merit, recalled him to Paris, and obtained a pension for him of 1500 livres: he afterwards became secretary and interpreter of the oriental languages, and royal professor of the Syriac tongue. He died at Paris in 1693. His principal work is entitled Bibliothecae Orientales, which he first wrote in Arabic, and afterwards translated into French. It is greatly esteemed. M. Herbelot's modesty was equal to his erudition; and his uncommon abilities were accompanied with the utmost probity, piety, and charity, which he practised through the whole course of his life.

HERBERT, MARY, countess of Pembroke, sister of the famous Sir Philip Sidney, and wife of Henry earl of Pembroke. She was not only a lover of the muses, but a great encourager of polite literature; a character not very common among ladies. Her brother dedicated his incomparable romance Arcadia to her, from which circumstance it hath been called The Countess of Pembroke's Arcadia. She translated a dra...
mantic piece from the French, entitled Antonius, a tragedy; though it is said she was assisted by her lord's chaplain, Dr Babington, afterwards bishop of Exeter. She also turned the Psalm of David into English metre; but it is doubtful whether these works were ever printed. She died in 1621; and an exalted character of her is to be found in Francis Osborne's Memoirs of King James I.

HERBERT, Edward, Lord Herbert of Cherbury in Shropshire, an eminent English writer, was born in 1581, and educated at Oxford, after which he travelled, and at his return was made knight of the Bath. James I. sent him ambassador to Louis XIII. in behalf of the Protestants who were besieged in several cities of France; and continued in this station till he was recalled, on account of a dispute between him and the constable of Luines. In 1625 he was advanced to the dignity of a baron in the kingdom of Ireland, by the title of Lord Herbert of Castle Island; and in 1631 to that of Lord Herbert of Cherbury in Shropshire. After the breaking out of the civil wars, he adhered to the parliament; and in 1644 obtained a pension, on account of his having been plundered by the king's forces. He wrote a History of the Life and Reign of Henry VIII. which was greatly admired; a treatise De veritate; and several other works. He died at London in 1648.

"Lord Herbert (says Mr Granger), stands in the first rank of the public ministers, historians, and philosophers of his age. It is hard to say whether his person, his understanding, or his courage, was the most extraordinary; as the fair, the learned, and the brave, held him in equal admiration. But the same man was wise and capricious; redressed wrongs, and quarrelled for punctilios; hated bigotry in religion, and was himself a bigot to philosophy. He exposed himself to such dangers as other men of courage would have carefully declined: and called in question the fundamentals of a religion which none had the hardness to dispute besides himself."

HERBERT, William, earl of Pembroke, was born at Wilton in Wiltshire, 1580; and admitted to New-college in Oxford in 1592, where he continued about two years. In 1601 he succeeded to his father's honours and estate; was made K. G. in 1604; and governor of Portsmouth six years after. In 1626, he was elected chancellor of the university of Oxford; and about the same time made lord steward of the king's household. He died suddenly at his house called Beynard's castle, in London, April 10. 1630; according to the calculation of his nativity, says Wood, made several years before by Mr Thomas Allen of Gloucesterhall. Clarendon relates concerning this calculation, that some considerable persons connected with Lord Pembroke being met at Maidenhead, one of them at supper drank a health to the lord steward; upon which another said, that he believed his lordship was at that time very merry; for he had now outlived the day, which it had been prognosticated upon his nativity he would not outlive; but he had outlived it now, for that was his birth day, which had completed his age to 50 years. The next morning, however, they received the news of his death. Whether the noble historian really believed this and other accounts relating to astrology, apparitions, providential interpositions, &c. which he has inserted in his history, we do not presume to say: he delivers them, however, as if he did not actually disbelieve them. Lord Pembroke was not only a great favourer of learned and ingenionous men, but was himself learned, and endowed with a considerable share of poetic genius. All that are extant of his productions in this way were published with this title: "Poems written by William Earl of Pembroke, &c. many of which are answered by way of repartee by Sir Benjamin Rudyerd, with other poems written by them occasionally and apart," 1660, 8vo.

HERBERT, Sir Thomas, an eminent gentleman of the Pembroke family, was born at York, where his father was an alderman. William earl of Pembroke sent him to travel at his expense in 1626, and he spent four years in visiting Asia and Africa: his expectations of preferment ending with the death of the earl, he went aboard again, and travelled over several parts of Europe. In 1634, he published, in folio, a Relation of some Years Travel into Africa and the Great Asia, especially the Territories of the Persian monarchy, and some parts of the Oriental Indies and isles adjacent. On the breaking out of the civil war, he adhered to the Parliament; and at Pembroke, on the removal of the king's servants, by the desire of the commissioners from the parliament, he and James Harrington were detained as grooms of his bed-chamber, and attended him even to the block. At the Restoration he was created a baronet by Charles II. for his faithful services to his father during his two last years. In 1678 he wrote Thesmodia Carolina, containing an account of the two last years of the life of Charles I. and he assisted Sir William Dugdale in compiling the third volume of his Monasticon Anglicanum. He died at York in 1682, leaving several MSS. to the public library at Oxford, and others to that of the cathedral at York.

HERBIVOROUS ANIMALS, those which feed only on vegetables.

HERCULANEUM is the name of an ancient city of Campania in Italy, which was destroyed by an eruption of Vesuvius in the first year of the emperor Titus, or the 79th of the Christian era, and lately rendered famous on account of the curious monuments of antiquity discovered in its ruins; an account of which has been published by order of the king of Naples, in a work of six volumes folio.—The epocha of the foundation of Herculaneum is unknown. Dionysius Halicarnassensis conjectures that it may be referred to 65 years before the war of Troy, or about 1342 years before Christ; and therefore that it lasted about 1400 years.

The thickness of the heap of lava and ashes by which the city was overwhelmed, has been much increased by fiery streams vomited since that catastrophe; and now forms a mass 24 feet deep, of dark gray stone, which is easily broken to pieces. By its non-adhesion to foreign bodies, marbles and bronzes are preserved in it as in a case made to fit them; and exact moulds of the faces and limbs of statues are frequently found in this substance. The precise situation of this subterraneous city was not known till the year 1713, when it was accidentally discovered by some labourers, who, in digging a well, struck upon a statue on the bench of the theatre. Many others were afterwards dug out and sent to France by the prince of Elbeuf.

But
But little progress was made in the excavations till Charles the infant of Spain ascended the Neapolitan throne; by whose unwearied efforts and liberality a very considerable part of Herculaneum has been explored, and such treasures of antiquity drawn out as form the most curious museum in the world. It being too arduous a task to attempt removing the covering, the king contented himself with cutting galleries to the principal buildings, and causing the extent of one or two of them to be cleared. Of these the theatre is the most considerable. On a balustrade which divided the orchestra from the stage was found a row of statues; and, on each side of the pulpitum, the equestrian figure of a person of the Nonix family. They are now placed under porticoes of the palace; and from the great rarity of equestrian statues in marble would be very valuable objects, were their workmanship even less excellent than it is: one of them in particular is a very fine piece of sculpture. Since the king of Spain left Naples, the digging has been continued, but with less spirit and expenditure: indeed the collection of curiosities brought out of Herculaneum and Pompeii is already so considerable, that a relaxation of zeal and activity becomes excusable. They are now arranged in a wing of the palace; and consist not only of statues, busts, altars, inscriptions, and other ornamental appendages of opulence and luxury; but also comprehend an entire assortment of the domestic, musical, and chirurgical instruments used by the ancients; tripods of elegant form and exquisite execution, lamps in endless variety, vases and basons of noble dimensions, chandeliers of the most beautiful shapes, pateras and other appurtenances of sacrifice, looking-glasses of polished metal, coloured glass, so hard, clear, and well stained, as to appear emeralds, sapphires, and other precious stones; a kitchen completely fitted up with copper-panns lined with silver, kettles, cisterns for heating water, and every utensil necessary for culinary purposes; specimens of various sorts of combustibles, retaining their form though burnt to a cinder; corn, bread, fish, oil, wine, and flour; a lady's toilet, fully furnished with combs, thimbles, rings, pins, paint, ear-rings, &c. Among the statues, which are numerous, connoisseurs allow the greatest share of merit to a Mercury and a sleeping faun: the busts fill several rooms; but very few of the originals whom they were meant to imitate are known. The floors are paved with ancient mosaic. Few rare medals have been found in these ruins; the most curious is a gold medallion of Augustus struck in Sicily in the 15th year of his reign. The fresco paintings, which, for the sake of preservation, have been torn off the walls and framed and glazed, are to be seen in another part of the palace. "The elegance of the attitudes, and the infinite variety of the subjects (Mr. Svinborne observes), stamp them as performances worthy of the attention of artists and antiquarians; but no pictures yet found are masterly enough to prove that the Greeks carried the art of painting to as great a height of perfection as they did that of statuary. Yet can we suppose those authors incapable of appreciating the merits of an Apelles or a Zeuxis, who with so much critical discernment have pointed out the beauties of the works of a Phidias or a Praxiteles, beauties that we have still an opportunity of contemplating? would they have bestowed equal praises upon both kinds of performances if either of them had been much inferior to the other? I think it is not probable; and we must presume, that the capital productions of the ancient painters, being of more perishable materials than busts and statues, have been destroyed in the fatal disasters that have so often afflicted both Greece and Italy. Herculaneum and Pompeii were but towns of the second order, and not likely to possess the masterpieces of the great artists, which were usually destined to adorn the more celebrated temples, or the palaces of kings and emperors." A more valuable acquisition than bronzes and pictures was thought to be made, when a large parcel of manuscripts was found among the ruins. Hopes were entertained that many works of the classics, which time has deprived of us, were now going to be restored to light, and that a new mine of science was on the point of being opened. But the difficulty of unrolling the burnt parchment, of pasting the fragments on a flat surface, and of deciphering the obscure letters, have proved such obstacles, that very little progress has been made in the work. A priest invented the method of proceeding; but it was found not to answer. A great many other processes have since been tried, but none has been entirely successful. And the value of the writings which has been unrolled has by no means corresponded to the public expectation. See Herculaneum, Supplement.

HERCULES, in fabulous history, a most renowned Grecian hero, who after death was ranked among the gods, and received divine honours. According to the ancients, there were many persons of the same name. Diodorus mentions three, Cicero six, and some authors extend the number to no less than forty-three. Of all these, one generally called the Theban Hercules, is the most celebrated; and to him, as may easily be imagined, the actions of the others have been attributed. He is reported to have been the son of Jupiter by Alcmena (wife to Amphitryon king of Argos), whom Jupiter enjoyed in the shape of her husband while he was absent; and in order to add the greater strength to the child, made it to that amorous night as long as three. Amphitryon having soon after accidentally killed his uncle and father-in-law Electryon, was obliged to fly to Thebes, where Hercules was born. The jealousy of Juno, on account of her husband's amour with Alcmena, prompted her to destroy the infant. For this purpose she sent two serpents to kill him in the cradle, but young Hercules strangled them both. He was early instructed in the liberal arts, and Castor the son of Tyndarus taught him bow to fight, Eurytus how to shoot with a bow and arrows, Autolycus to drive a chariot, Linus to play on the lyre, and Eumolpus to sing. He, like the rest of his illustrious contemporaries, soon after became the pupil of the centaur Chiron, and under him he perfected and rendered himself the most valiant and accomplished of the age. In the 18th year of his age he resolved to deliver the neighbourhood of Mount Citheron from a huge lion which preyed on the flocks of Amphitryon his supposed father, and which laid waste the adjacent country. He went to the court of Theseus king of Thespis, who shared in the general calamity; and he received here a tender treatment, and was entertained during 30 days. The 50 daughters of the king became mothers by Hercules during
Hercules during his stay at Thebes, and some say that it was effected in one night. After he had destroyed the lion of Mount Citharon, he delivered his country from the annual tribute of 100 oxen which it paid to Erginos. Such public services became universally known; and Creon, who then sat on the throne of Thebes, rewarded the patriotic deeds of Hercules by giving him his daughter in marriage, and entrusting him with the government of his kingdom.

Euristheus, the son of Amphitrion, having succeeded his father, soon became jealous of Hercules; and fearing lest he might by him be deprived of his crown, left no means untiring to get rid of him. Of this Hercules was not insensible, because he was perpetually engaging him on some desperate expedition; and therefore went to consult the oracle. But being answered that it was the pleasure of the gods that he should serve Euristheus 12 years, he fell into a deep melancholy, which at last ended in a furious madness; during which, among other desperate actions, he put away his wife Megara, and murdered all the children he had by her. As an expiation of this crime, the king imposed upon him these twelve labours, assuming the power of all other mortals to accomplish, which nevertheless our hero performed with great ease. The favours of the gods had indeed completely armed him when he undertook his labours. He had received a coat of armour and helmet from Minerva, a sword from Mercury, a horse from Neptune, a shield from Jupiter, a bow and arrows from Apollo, and from Vesta a golden cuirass and brazen buskin, with a celebrated club of brass according to the opinion of some writers.

The first labour imposed upon him was the killing of a lion in Nemea, a wood of Achaia; whose hide was proof against any weapon, so that he was forced to seize him by the throat and strangle him. He carried the dead beast on his shoulders to Mycenae, and even after clothed himself with the skin. Euristheus was so astonished at the sight of this beast, and at the courage of Hercules, that he ordered him never to enter the gates of the city when he returned from his expeditions, but to wait for his orders without the walls. He even made himself a brazen vessel into which he retired whenever Hercules returned.—The second labour was to destroy the Lernean hydra, which had seven heads according to Apollodor, 50 according to Simonides, and 100 according to Diodorus. This celebrated monster he first attacked with his arrows; but soon after he came to a close engagement, and by means of his heavy club he destroyed the heads of his enemy. This, however, was productive of no advantage; for as soon as one head was beaten to pieces by the club, immediately two sprang up; and the labour of Hercules would have remained unfinished, had not he commanded his friend Iolas to burn with a hot iron the root of the head which he had crushed to pieces. This succeeded; and Hercules became victorious, opened the belly of the monster, and dipped his arrows in the gall to render the wounds which he gave fatal and incurable.—He was ordered in his third labour to bring alive and unharmed into the presence of Euristheus a stag, famous for its incredible swiftness, its golden horns, and brazen feet. This celebrated animal frequented the neighbourhood of Oeneus; and Hercules was employed for a whole year in continually pursuing it; at last he caught it in a trap, or when tired, or, according to others, by slightly wounding it and lessening its swiftness.—The fourth labour was to bring alive to Euristheus a wild boar which ravaged the neighbourhood of Erymanthus. In this expedition he destroyed the centaurs, and caught the boar by closely pursuing him through the deep snow. Euristheus was so frightened at the sight of the boar, that, according to Diodorus, he bid himself in his brazen vessel for some days.—In his fifth labour Hercules was ordered to clean the stables of Augean, where 3000 oxen had been confined for many years.—For his sixth labour he was ordered to kill the carnivorous birds which ravaged the country near the lake Stymphalis in Arcadia.—In his seventh labour he brought alive into Peloponnesus a prodigious wild bull which laid waste the island of Crete.—In his eighth labour he was employed in obtaining the mares of Diomedes, which fed upon human flesh. He killed Diomedes, and gave him to be eaten by his mares, which he brought to Euristheus. They were sent to Mount Olympus by the king of Mycenae, where they were devoured by the wild beasts; or, according to others, they were consecrated to Jupiter, and their breed still existed in the age of Alexander the Great.—For his ninth labour, he was commanded to obtain the girdle of the queen of the Amazons.—In his tenth labour he killed the monster Geryon king of Gades, and brought to Argos his numerous flocks which fed upon human flesh. This was in Iberia or Spain; in the furthest parts of which he erected his two pillars, as the utmost limits of the then known world. These ten labours he achieved, as the fable says, in about eight years. In this last expedition he is likewise affirmed to have killed Anteus, a famous giant of a monstrous size, who, when weary with wrestling or labour, was immediately refreshed by touching the earth. Hercules overcame him in wrestling, and slew him; and after him the tyrant Buatir, in his way through Egypt. This bloody man used to sacrifice all his guests and strangers upon his altar; and designing to have done the same by Hercules, was slain by him, together with all his attendants.—His eleventh labour was the carrying away the Hesperian golden apples kept by a dragon: (See HERCULI).

—The twelfth and last, and most dangerous of his labours, was to bring upon earth the three-headed dog Cerberus. Descending into hell by a cave on Mount Tenerum, he was permitted by Pluto to carry away his friends Theseus and Pirithous, who were condemned to punishment in hell, and Cerberus also was granted to his prayers, provided he made use of no arms but only force to drag them away. Hercules, as some report, carried him back to hell after he had brought him before Euristheus.

Many other exploits are said to have been performed by Hercules; in particular, he accompanied the Argonauts to Colchis before he delivered himself up to the king of Mycenae. He assisted the gods in their wars against the giants, and it was through him alone that Jupiter obtained a victory. He conquered Laomedon, and pillaged Troy. When Iole, the daughter of Enyrtus, king of Oechalia, of whom he was deeply enamoured, was refused to his entertain, he became the prey of a second fit of insanity, and he murdered Iphitus,
Hercules, Iphitus, the only one of the sons of Eurytus who favoured his addresses to Iole. He was some time after purged of the murder, and his insanity ceased; but the gods persecuted him, and he was visited by a disorder which obliged him to apply to the oracle of Delphi for relief. The coldness with which the Pythia received him irritated him, and he resolved to plunder Apollo's temple and carry away the sacred tripod. Apollo opposed him, and a severe conflict was begun, which nothing but the interference of Jupiter with his thunderbolts could have prevented. He was upon this told by the oracle that he must be sold as a slave, and remain three years in the most abject servitude to recover from his disorder. He complied; and Mercury, by order of Jupiter, conducted him to Omphale, queen of Lydia, to whom he was sold as a slave. Here he cleared all the country from robbers; and Omphale, who was astonished at the greatness of his exploits, married him. Hercules had Agelaus and Lamon by Omphale, from whom Creses, king of Lydia was descended. He became also enamoured of one of Omphe's female servants, by whom he had Alceus. After he had completed the years of his slavery, he returned to Peloponnesus, where he re-established on the throne of Sparta Tyndarus, who had been expelled by Hippocoon. He became one of Dejanira's suitors, and married her after he had overcome all his rivals. He was obliged to leave Calydon his father-in-law's kingdom, because he had inadvertently killed a man with a blow of his fist, and it was on account of this expiatory act that he was not present at the hunting of the Calydonian boar. From Calydon he retired to the court of Ceryx king of Thrace. The king received him and his wife with great marks of friendship, and purified him of the murder which he had committed at Calydon. Hercules was still mindful that he had once been refused the hand of Iole; he therefore made war against his father Eurytus, and killed him with three of his sons. Iole fell into the hands of her father's murderer, and found that she was loved by Hercules as much as before. She accompanied him to Mount Oeta, where he was going to raise an altar and offer a solemn sacrifice to Jupiter. As he had not then the shirt and tunic in which he arrayed himself to offer a sacrifice, he sent Ichnos to Thracia to his wife Dejanira, in order to provide himself a proper dress. Dejanira had some time before been attempted by the Centaur Nessus, as he was ferrying her over the river Euneus; and Hercules beholding it from the shore, had given him a mortal wound with an arrow. The monster finding himself dying, advised her to mix some oil with the blood which flowed from his wound, and to anoint her husband's shirt with it, pretending that it would infallibly secure him from loving any other woman; and she, too well apprised of his inconstancy, had actually prepared the poisoned ointment accordingly. Ichnos coming to her for the garments, unfortunately acquainted her with his having brought away Iole; upon which she, in a fit of jealousy, anointed his shirt with the fatal mixture. This had no sooner touched his body, than he felt the poison diffuse itself through all his veins; the violent pain of which caused him to disband his army, and to return to Thracia. His torment still increasing, he sent to consult the oracle for a cure; and was answered, that he should cause himself to be conveyed to Mount Oeta, and there rear up a great pile of wood, and leave the rest to Jupiter. By the time he had obeyed the oracle, his pains being become intolerable, he dressed himself in his martial habit, flung himself upon the pile, and desired the bystanders to set fire to it. Others say that he left the charge of it to his son Philoctetes; who, having performed his father's command, had his bow and arrows given him as a reward for his obedience. At the same time Jupiter, to be as good as his word, sent a flash of lightning, which consumed both the pile and the hero; insomuch that Ioleus, coming to take up his bones, found nothing but ashes: from which they concluded, that he was passed from earth to heaven, and joined to the gods. His friends showed their gratitude to his memory by raising an altar where the burning pile had stood. Menocrius the son of Actor offered him a sacrifice of a bull, a wild boar, and a goat, and enjoined the people of Opus yearly to observe the same religious ceremonies. His worship soon became as universal as his fame; and Juno, who had once persecuted him with such fury forgot her resentment, and gave him her daughter Hebe in marriage. Hercules has received many surnames and epithets, either from the place where his worship was established, or from the labours which he achieved. His temples were numerous and magnificent, and his divinity revered. No dogs or flies ever entered his temple at Rome; and that of Gades, according to Strabo, was always forbidden to women and pigs. The Phocianians offered quails on his altars; and as it was supposed that he provided over dreams, the sick and infirm were sent to sleep in his temples, that they might receive in their dreams the agreeable presages of their approaching recovery. The white poplar was particularly dedicated to his service.

It is observed, that there are none even of the twelve great gods of antiquity that have so many ancient monuments relating to them as Hercules. The famous statue of Hercules, in the Farnese palace at Rome, is well known to the connoisseurs: this represents him resting after the last of his twelve labours above recited, leaning on his club, and holding the apples of the Hesperides in his hand. In this statue, as in all the other figures of him, he is formed, by the breadth of his shoulders, the spaciousness of his chest, the largeness of his size, and the firmness of his muscles, to express strength and a capacity of enduring great fatigue, which constituted the chief idea of virtue among the ancient heathens. His other attributes are his lion's skin, his club, and his bow. —Hercules is represented by the ancients as an exemplar of virtue: however, the Hercules Bibas, or drunken Hercules, is no uncommon figure; and his amours are described both by the poets and artists. Thus, the Cupids are made to take away his club, and his bow is exhibited in the posture of bending under a little boy; by which actions we perceive, that he who conquered all difficulties was a slave to love. His children are as numerous as the labours and difficulties which he underwent; and indeed they became so powerful soon after his death, that they alone had the courage to invade all Peloponnesus. See HERACLIDE.
The apotheosis of Hercules, or the establishment of his altars in the principal cities of Greece, is fixed by Thrasybulus 29 years before the taking of Troy.

Hercules has been particularly honoured by the Greeks under the name of Μουσάτης, the conductor of the Muses, and at Rome under that of Hercules Musarum. He is represented on medals with a lyre in his hand; and the reverse is marked with the figure of the nine Muses, with their proper symbols.

Hercules, in Astronomy, one of the constellations of the northern hemisphere. — The stars in the constellation Hercules in Ptolemy’s catalogue are 29; in Tycho’s, 28; in the Britannic catalogue, 113.

Hercules’s Pillars, in antiquity, a name given to two lofty mountains, one situated on the most southern extremity of Spain, and the other on the opposite part of Africa. They were called by the ancients 

Abys and Colpe. They were reckoned the boundaries of the labours of Hercules; and according to ancient tradition, they were joined together till they were severed by the arm of the hero, and a communication opened between the Mediterranean and Atlantic seas.

Hercynia Silva, in Ancient Geography, the largest of forests. Its breadth was a journey of nine days to the best traveller. Taking its rise at the limits of the Helvetii, Nemetes, and Rauraci, it ran along the Danube to the borders of the Daci and Anartes, a length of 60 days journey, according to Caesar, who appears to have been well acquainted with its true breadth, seeing it occupied all Lower Germany. It may therefore be considered as covering the whole of Germany; and most of the other forests may be considered as parts of it, though distinguished by particular names: consequently the Harz, in the duchy of Brunswick, which gave name to the whole, may be considered as one of its parts. The name Harz denotes “resinous,” or “pine-tree.” By the Greeks it is called Orkynia, as a name common to all the forests in Germany; in the same manner as Hercynia was the name given by the Romans; and both from the German Harz.

Herd, among hunters, an assemblage of black or fallow beasts in contradistinction to flock. See Flock.

—In the hunting language there are various terms used for companies of the divers kinds of game. We say a herd of harts or bucks, a bevy of roes, a rout of wolves, a reichness of martens, &c.

Hereditaments, whatever moveable things a person may have to himself and his heirs by way of inheritance; and which, if not otherwise bequeathed, descend to him who is next heir, and not to the executor as chattels do.

Hereditary, an appellation given to whatever belongs to a family by right of succession from heir to heir.

Hereditary is also figuratively applied to good or ill qualities supposed to be transmitted from father to son: thus we say virtue and piety are hereditary qualities in such a family; and that in Italy the hatred of families is hereditary. And indeed the gout, king’s evil, madness, &c. may really be hereditary diseases.

Hereditary Right, in the British constitution. The grand fundamental maxim upon which the jux coronae, or right of succession to the throne of Britain depends, Sir William Blackstone takes to be this: That the crown is, by common law and constitutional custom, hereditary, and this in a manner peculiar to itself: but hereditary that the right of inheritance may from time to time be changed or limited by act of parliament; under which limitations the crown still continues hereditary.

1. The crown is in general hereditary, or descendible to the next heir, on the death or demise of the last proprietor. All regal governments must be either hereditary or elective: and as there is no instance where the crown of England has ever been asserted to be elective, except by the regicides at the infamous and unparalleled trial of King Charles I.; it must of consequence be hereditary. Yet in thus asserting an hereditary right, a jux divino title to the throne is by no means intended. Such a title may be allowed to have subsisted under the theocratical establishments of the children of Israel in Palestine; but it never yet subsisted in any other country; save only so far as kingdoms, like other human fabrics, are subject to the general and ordinary dispensations of Providence. Nor indeed have a jux divino and an hereditary right any necessary connection with each other; as some have very weakly imagined. The titles of David and Jehu were equally jux divino as those of either Solomon or Ahab; and yet David slew the sons of his predecessor, and Jehu his predecessor himself. And when our kings have the same warrant as they had, whether it be to sit upon the throne of their fathers, or to destroy the house of the preceding sovereign, they will then, and not before, possess the crown of England by a right like theirs, immediately derived from heaven. The hereditary right, which the laws of England acknowledge, owes its origin to the founders of our constitution, and to them only. It has no relation to, nor depends upon, the civil laws of the Jews, the Greeks, the Romans, or any other nation upon earth; the municipal laws of one society having no connection with, or influence upon, the fundamental polity of another. The founders of our English monarchy might perhaps, if they had thought proper, have made it an elective monarchy; but they rather chose, and upon good reason, to establish originally a succession by inheritance. This has been acquiesced in by general consent, and ripened by degrees into common law; the very same title that every private man has to his own estate. Lands are not naturally descendible, any more than thrones: but the law has thought proper, for the benefit and peace of the public, to establish hereditary succession in the one as well as the other.

It must be owned, an elective monarchy seems to be the most obvious, and best suited of any to the rational principles of government, and the freedom of human nature; and accordingly we find from history, that, in the infancy and first rudiments of almost every state, the leader, chief magistrate, or prince, hath usually been elective. And, if the individuals who compose that state could always continue true to first principles, uninfluenced by passion or prejudice, unassailed by corruption, and unawed by violence, elective succession were as much to be desired in a kingdom as in other inferior communities. The best, the wisest, and the bravest man, would then be sure of receiving that crown which his endowments have merited; and the sense of an unbiased majority would be dutifully acquiesced in by the few who were of different opinions. But history and observation will inform us, that elections of every kind
the lineal descendants of any person deceased stand in the same place as their ancestor, if living, would have done. Thus Richard II. succeeded his grandfather Edward III. in right of his father the Black Prince; to the exclusion of all his uncles, his grandfather's younger children. Lastly, on failure of lineal descendants, the crown goes to the next collateral relations of the late king; provided they are lineally descended from the blood-royal, that is, from that royal stock which originally acquired the crown. Thus Henry I. succeeded to William II. John to Richard I. and James I. to Elizabeth; being all derived from the Conqueror, who was then the only regal stock. But herein there is no objection (as in the case of common descents) to the succession of a brother, an uncle, or other collateral relation, of the half-blood; that is, where the relationship proceeds not from the same couple of ancestors (which constitutes a kinsman of the whole blood), but from a single ancestor only; as when two persons are derived from the same father, and not from the same mother, or vice versa: provided only, that the one ancestor, from whom both are descended, be that from whose veins the blood-royal is communicated to each. Thus Mary I. inherited to Edward VI. and Elizabeth inherited to Mary; all born of the same father, King Henry VIII. but all by different mothers. See the articles Consanguinity, Descent, and Succession.

3. The doctrine of hereditary right does by no means imply an indefeasible right to the throne. No man will assert this, who has considered our laws, constitution, and history, without prejudice, and with any degree of attention. It is unquestionably in the hand of the supreme legislative authority of this kingdom, the king and both houses of parliament, to defeat this hereditary right; and by particular entails, limitations, and provisions, to exclude the immediate heir, and vest the inheritance in any one else. This is strictly consonant to our laws and constitution; as may be gathered from the expression so frequently used in our statute-book, of “the king's majesty, his heirs, and successors.” In which we may observe, that as the word heirs necessarily implies an inheritance or hereditary right generally subsisting in the royal person; so the word successors, distinctly taken, must imply that the inheritance may sometimes be broken through; or, that there may be a successor, without being the heir of the king. And this is so extremely reasonable, that without such a power, lodged somewhere, our polity would be very defective. For, let us barely suppose so melancholy a case, as that the heir-apparent should be a lunatic, an idiot, or otherwise incapable of reigning; how miserable would the condition of the nation be, if he were also incapable of being succeeded?

It is therefore necessary that this power should be lodged somewhere; and yet the inheritance and regal dignity would be very precarious indeed, if this power were expressly and avowedly lodged in the hands of the subject only, to be exerted whenever prejudice, caprice, or discontent, should happen to take the lead. Consequently it can nowhere be so properly lodged as in the two houses of parliament, by and with the consent of the reigning king; who, it is not to be supposed, will agree to any thing improperly prejudicial to the rights of his own descendants. And therefore in
the king, lords, and commons, and parliament assembled, our laws have expressly lodged it.

4. But, fourthly, however the crown may be limited or transferred, it still retains its descendible quality, and becomes hereditary in the wearer of it. And hence in our law the king is said never to die in his political capacity; though in common with other men, he is subject to mortality in his natural: because immediately upon the natural death of Henry, William, or Edward, the king survives in his successor. For the right of the crown vesta co instanti, upon his heir; either the heres naturae, if the course of descent remains unimpeached, or the heres factus, if the inheritance be under any particular settlement. So that there can be no interregnum; but, as Sir Matthew Hale observes, the right of sovereignty is fully invested in the successor by the very descent of the crown. And therefore, however acquired, it becomes in him absolutely hereditary, unless by the rules of the limitation it is otherwise ordered and determined: In the same manner as landed estates, to continue our former comparison, are by the law hereditary, or descendible to the heirs of the owner; but still there exists a power, by which the property of those lands may be transferred to another person. If this transfer be made simply and absolutely, the lands will be hereditary in the new owner, and descend to his heir at law: but if the transfer be clogged with any limitations, conditions, or entails, the lands must descend in that channel, so limited and prescribed, and no other. See Succession.

HEREDITAS JACENS, in Scots Law. An estate is said to be in hereditate jacentes, after the proprietor's death, till the heir's entry.

HEREFORD, which in Saxon signifies the ford of the army, the capital of Herefordshire in England, situated in W. Long. 2° 35'. N. Lat. 52° 6'. It is supposed to have risen out of the ruins of Kenchester, in its neighbourhood, which Camden believes to have been the Ariconium of Antoninus. It is very pleasantly situated among meadows and corn fields, and is almost encompassed with rivers. It stands on a hill, or at least its increase, to the building and dedicating a church there to Ethelbert king of the East Angles, who was murdered in the neighbour- hood, and afterwards taken into the catalogue of martyrs; soon after it became a bishop's see, and in consequence of that a considerable place. In 1055 it was sacked, the cathedral destroyed, and its bishop Leo sheep carried away captive by Gryffin prince of South-Wales, and Algar, an Englishman, who had rebelled against Edward the Confessor. Harold fortified it with a broad and high rampart; and it appears by Doumont's book, that there were no more than 300 men within and without the wall. A very large and strong castle was built by the Normans along the Wye, and the city walled round. The present stately cathedral was founded in the reign of Henry I. by Bishop Reineim, but enlarged and beautified by his successors. It suffered much in the barons wars; and was often taken and retaken in the war between King Charles I. and the parliament. This city is pretty large, and had once six churches; but two were destroyed in the civil wars. It is not very populous nor well built, many of the houses being old. Its manufactures are gloves and other leathern goods; and its corporation consists of a mayor, six aldermen, a high steward, deputy-steward, and town-clerk; who have a sword-bearer and four sergeants at mace. Each of the companies enjoys distinct laws and privileges by their charter, and each has its ball. The cathedral, which was built in 1050, and destroyed by the Welsh in 1060, but rebuilt in the reign of the Conqueror, or, as some say, in that of Henry I. is a beautiful and magnificent structure, but being greatly decayed, part of it was destroyed by the fall of the tower in September 1786, and the spire on another tower was taken down to be rebuilt at the same time. Here is a hospital well endowed for 16 poor people; and two charity-schools, one for 60 boys, the other for 40 girls. The chapter-house, which was once a very elegant building, built about the year 1279, is now in ruins. Here were formerly two or three priories. Almost the only drink here is cider, which is both cheap and good, the very hedges in the country being planted with apple-trees. The city gave the title of earl to the noble family of the Bohuns; then of duke to Henry of Lancaster, afterwards Henry IV. king of England; after him, of earl to Stafford earl of Buckingham; then of viscount to Devereux earl of Essex, which a collateral branch of his family still enjoys, and is thereby the premier viscount of England.

HEREFORDSHIRE, a county of England nearly of a circular form, bounded on the east by Worcestershire and Gloucester, on the south by Monmouthshire, on the west by Radnorshire and Brecknockshire, and on the north by Shropshire. Its length from north to south is 46 miles, its breadth from east to west 40. It contains 6 market towns, 87 vicarages, 776 parishes, and 397 villages. This county contains, according to the returns made to the house of commons, in 1811, 12,926 houses, occupied by 20,081 families; and the whole number of inhabitants was 94,773: of this number 46,404 were males, and 47,669 females. The number of families supported by agriculture was 12,559, by trade and manufactures 5044, the number of others 2438. The marriages in the preceding year were 669, the baptisms 2636. It is divided into 14 hundreds, and consists of eight members of parliament; namely, two knights for the shire, and two for each of the following towns, Hereford, Lemplaster or Leominster, and Weobly.

The air of this country is allowed to be as pleasant, sweet, and wholesome, as that of any other in England, there being nothing either in the soil or situation to render it otherwise. The soil throughout is excellent, and inferior to none, either for grain, fruit, or pasture, supplying the inhabitants plentifully with all the necessaries of life: but that by which it is distinguished from most others, is its fruit, especially apples, of which it produces such quantities, that the cider made of them is not only sufficient for their own consumption, though it is their ordinary drink, but also in a great measure for that of London and other parts. That in particular which is made from the apple called red-streak, is much admired, and has a body almost equal to that of white-wine. The county is well supplied with wood and water; for, besides lesser streams, there are the rivers Frome, Lodon, Log, Wye, Wadul, Arro, Dare, and Monow; the last of which is large, and all of them are well stored with fish, particularly the Wye, which breeds salmon. It lies in the diocese of Hereford, and Oxford circuit. See HEREFORDSHIRE, SUPPLEMENT.
HEREUSAEN, a palace of Germany near Hanover, formerly belonging to the king of Great Britain. Here are lodgings for all the court; and a garden of vast extent, in which are fine waterworks, a labyrinth, and many other curiosities worthy the observation of a traveller.

HERENTHALS, a town of Brabant in the Netherlands, in the quarter of Antwerp; seated on the river Nethe, in E. Long. 4°. 54′. N. Lat. 51°. 13′.

HEResy, in Law, an offence against Christianity, consisting in a denial of some of its essential doctrines, publicly and obstinately avowed; being defined sententia rerum divinarum humanae sensus excogitata, posita docta et pertinaciter defensa. And here it must be acknowledged that particular modes of belief, or unbelief, not tending to overturn Christianity itself, or to sap the foundations of morality, are by no means the object of coercion by the civil magistrate. What doctrines shall therefore be adjudged heresy, was left by our old constitution to the determination of the ecclesiastical judge; who had herein a most arbitrary latitude allowed him. For the general definition of an heretic given by Lyndewode, extends to the smallest deviations from the doctrines of the holy church: haereticus est qui dubitatus de fide catholica, et qui negotiis servavit ea, quae Romana ecclesia statuit, esse vero decreteverat. Or, as the statute 2 Hen. IV. c. 15, expresses it in English, "teachers of erroneous opinions contrary to the faith and blessed determinations of the holy church." Very contrary this to the usage of the first general councils, which defined all heretical doctrines with the utmost precision and exactness. And what ought to have alleviated the punishment, the uncertainty of the crime, seems to have enhanced it in those days of blind zeal and pious cruelty. It is true, that the sanctimonious hypocrisy of the canonists went at first no farther than enjoining penance, excommunication, and ecclesiastical deprivation, for heresy; though afterwards they proceeded boldly to imprisonment by the ordinary, and confiscation of goods in pias suas. But in the mean time they had prevailed upon the weakness of bigotted princes to make the civil power subservient to their purposes, by making heresy not only a temporal, but even a capital, offence: the Roman ecclesiastics determining, without appeal, whatever they pleased to be heresy, and shifting off to the secular arm the odium and drudgery of executions; with which they themselves were too tender and delicate to intermeddle. Nay, they pretended to intercede and pray, on behalf of the convicted heretic, ut cirea mortis periculoa sententia circa eum moderetur: well knowing that at the same time they were delivering the unhappy victim to certain death. Hence the capital punishments inflicted on the ancient Donatists and Manicheans by the emperors Theodosius and Justinian: hence also the constitution of the emperor Frederick mentioned by Lyndewode, adjudging all persons without distinction to be burnt at fire who were convicted of heresy by the ecclesiastical judge. The same emperor, in another constitution, ordained, that if any temporal lord, when admonished by the church, should neglect to clear his territories of heretics within a year, it should be lawful for good Catholics to seize and occupy the lands, and utterly to extirpate the heretical possessors. And upon this foundation was built that arbitrary power, so long claimed and so fatally exerted by the pope, of disposing even of the kingdoms of refractory princes to more dutiful sons of the church. The immediate event of this constitution was something singular, and may serve to illustrate at once the gratitude of the holy see, and the just punishment of the royal bigot; for, upon the authority of this very constitution, the pope afterwards expelled this very emperor Frederic from his kingdom of Sicily, and gave it to Charles of Anjou.

Christianity being thus deformed by the demon of persecution upon the continent, we cannot expect that our own island should be entirely free from the same scourge. And therefore we find among our ancient precedents a writ de haereticocomburendo, which is thought by some to be as ancient as the common law itself. However, it appears from thence, that the conviction of heresy by the common law was not in any petty ecclesiastical court, but before the archbishop himself in a provincial synod; and that the delinquent was delivered over to the king to do as he should please with him; so that the crown had a control over the spiritual power, and might pardon the convict by issuing no process against him; the writ de haereticocomburendo being not a writ of course, but issuing only by the special direction of the king in council.

But in the reign of Henry IV., when the eyes of the Christian world began to open, and the seeds of the Protestant religion (though under the opprobrious name of lollardy) took root in this kingdom; the clergy, taking advantage from the king's dubious title to demand an increase of their own power, obtained an act of parliament, which sharpened the edge of persecution to its utmost keenness. For, by that statute, the diocesan alone, without the intervention of a synod, might convict of heretical tenets; and unless the convict abjured his opinions, or if after abjuration he relapsed, the sheriff was bound ex officio, if required by the bishop, to commit the unhappy victim to the flames, without waiting for the consent of the crown. By the statute 2 Hen. V. c. 7, lollardy was also made a temporal offence, and indictable in the king's courts; which did not thereby gain an exclusive, but only a concurrent, jurisdiction with the bishop's consistory.

Afterwards, when the final reformation of religion began to advance, the power of the ecclesiastics was somewhat moderated; for though what heresy is, was not then precisely defined, yet we are told in some points what it is not: the statute 25 Hen. VIII. c. 14, declaring, that offences against the see of Rome are not heresy; and the ordinary being thereby restrained from proceeding in any case upon mere suspicion; that is, unless the party be accused by two credible witnesses, or an indictment of heresy be first previously found in the king's courts of common law. And yet the spirit of persecution was not yet abated, but only diverted into a lay channel. For in six years afterwards, by statute 31 Hen. VIII. c. 14, the bloody law of the six articles was made, which set forth the six most contested points of heresy, transubstantiation, communion in one kind, the celibacy of the clergy, mystic, monastic vows, the sacrifice of the mass, and auricular confession; which points were "determined and resolved by the most godly study, pain, and travail of his majesty: for which his most humble and obedient subjects, the lords..."
HERETIC and temporal and the commons, in parliament assembled, did not only render and give unto his highness their most high and hearty thanks; but did also exact and declare all oppressive laws of the first to be revocable, and to be burnt with fire; and of the fifth last to be felonies, and to suffer death. The same statute established a new and mixed jurisdiction of clergy and laity for the trial and conviction of heretics; the reigning prince being then equally intent on destroying the supremacy of the bishops of Rome, and establishing all other their corruptions of the Christian Religion.

Without perplexing this detail with the various repeals and revivals of these sanguinary laws in the two succeeding reigns, let us proceed to the reign of Queen Elizabeth; when the reformation was finally established with temper and decency, unsullied with party-rancour, or personal caprice and resentment. By statute 1 Eliz. c. 5, all former statutes belonging to heresies are repealed, which leaves the jurisdiction of heresy as it stood at common law; viz. as to the infliction of common censures in the ecclesiastical courts; and in case of burning the heretic, in the provincial synod only. Sir Matthew Hale is indeed of a different opinion, and holds that such power resided in the diocesan also; though he agrees that in either case the writ de hereticis comburendo was not demandable of common right, but grantable or otherwise merely at the king’s discretion. But the principal point now gained was, that by this statute a boundary is for the first time set to what shall be accounted heresy; nothing for the future being to be so determined, but only such tenets as have been heretofore so declared, 1. By the words of the holy scriptures; or, 2. By the first four general councils, or such others as have only used the words of the holy scriptures; or, 3. Which shall hereafter be so declared by the parliament, with the assent of the clergy in convocation. Thus was heresy reduced to a greater certainty than before; though it might not have been the worse to have defined it in terms still more precise and particular: as a man continued still liable to be burnt, for what perhaps he did not understand to be heresy, till the ecclesiastical judge so interpreted the words of the canonical scriptures.

For the writ de hereticis comburendo remained still in force; and we have instances of its being put in execution upon two Anabaptists in the 17th of Elizabeth, and two Arians in the 9th of James I. But it was totally abolished, and heresy again subjected only to ecclesiastical correction, pro salute animæ, by virtue of the statute 23 Car. II. c. 9. For, in one and the same reign, our lands were delivered from the slavery of military tenures; our bodies from arbitrary imprisonment by the habeas corpus act; and our minds from the tyranny of superstitious bigotry, by demolishing this last badge of persecution in the English law.

Every thing is now as it should be, with respect to the spiritual cognizance, and spiritual punishment of heresy: unless perhaps that the crime ought to be more strictly defined, and no persecution permitted, even in the ecclesiastical courts, till the tenets in question are by proper authority previously declared to be heretical. Under these restrictions, it seems necessary for the support of the national religion, that the officers of the church should have power to censure heretics; yet not to harass them with temporal penalties, much less to exterminate or destroy them. The legislature hath indeed thought it proper, that the civil magistrate should again interpose, with regard to one species of heresy prevalent in modern times, by status 24 and 25 W. III. c. 32. If any person educated in the Christian religion, or professing the same, shall by writing, printing, teaching, or advising speaking, deny any one of the persons in the Holy Trinity to be God, or maintain that there are more gods than one, he shall undergo the same penalties and incapacities which were just now mentioned to be inflicted on apostasy by the same statute.

HERETIC, a general name for all such persons under any religion, but especially the Christian, as profess or teach religious opinions contrary to the established faith, or to what is made the standard of orthodoxy. See HERESY.

HERETOCHS, among our Saxon ancestors, signified the same with dukes or duces, denoting the commanders or leaders of their armies.

It appears, from Edward the Confessor’s laws, that the military force of this kingdom was in the hands of the dukes or heretoachs, who were constituted through every province and county in the kingdom, being selected out of the principal nobility, and such as were most remarkable for being soperientes, fideles, et animosus. Their duty was to lead and regulate the English armies, with a very unlimited power; and because of their great power, they were elected by the people in their full assembly, or folk-mote, in the same manner as sheriffs were elected.

HERFORDEN, or HERWARDEN, a free and imperial town of Germany, in the circle of Westphalia, and capital of the county of Ravensberg. Here is a famous nunnery belonging to the Protestants of the congregation of Augsburg, whose abbess is a princess of the empire, and has a voice and place in the diet. It is seated on the river An. E. Long. 8. 25. N. Lat. 52. 12.

HERGRUNDT, a town of Upper Hungary, remarkable for its rich mines of vitriol. Those who work in the mines have built a subterranean town, which has a great number of inhabitants. E. Long. 18. 15. N. Lat. 48. 30.

HERIOT, in Law, a customary tribute of goods and chattels, payable to the lord of the fee on the decease of the owner of the land. See TENURE.

Heriot is of two sorts—viz. 1. Heriot-custom, where heriots have been paid time out of mind by custom, after the death of a tenant for life. In some places, there is a customary composition in money, as 10 or 20 shillings in lieu of a heriot, by which the lord and tenant are both bound, if it be an indisputably ancient custom; but a new composition of this sort will not bind the representatives of either party. 2. Heriot-service, when a tenant holds by such service to pay heriot at the time of his death; which service is expressed in the deed of seisin.—For this latter the lord shall distress; and for the other he shall seize, and not distress. If the lord purchase part of the tenancy, heriot-service is extinguished; but it is not so of heriot-custom.

HERISSON, in Fortification, a beam armed with a great number of iron spikes with their points outward, and supported by a pivot on which it turns. These serve as a barrier to block up any passage, and are frequently placed before the gates, and more especially when those
HERITABLE RIGHTS, in Scots Law, signify all rights affecting lands, houses, &c. or any immovable subject.

HERITAGE, in Scots Law, lands, houses, or any immovable subject, in contradistinction to moveables or movable subjects. It also sometimes signifies such immovable property as a person succeeds to as heir to another, in contradistinction to that which he himself purchases or acquires in any other manner, called conquest.

HERMEA, in antiquity, ancient Greek festivals in honour of the god Hermes or Mercury. One of these was celebrated by the Pheneatians in Arcadia; a second by the Cylleneans in Elis; and a third by the Tanagrans, where Mercury was represented with a ram upon his shoulder, because he was said to have walked through the city in that posture in time of a plague, and to have cured the sick; in memory of which, it was customary at this festival for one of the most beautiful youths in the city to walk round the walls with a ram upon his shoulder. A fourth festival of the same name was observed in Crete, when it was usual for the servants to sit down at the table while their masters waited; a custom which was also observed at the Roman Saturnalia.

HERMANN, Paul, a celebrated botanist, was born at Halle in Saxony, and practised physic in the island of Ceylon, and the Cape of Good Hope, after which (in 1679) he was chosen professor of botany at Leyden, and superintendent of the botanical garden, in which science he obtained the highest reputation, and died in the year 1695. His first publication, in 1687, was a catalogue of plants in the garden of the university—a garden which, in seven years he had so much enriched with plants from the East and West Indies, that it nearly rivaled the very first in Europe. His method of botanical classification is contained in his Flora Lugduno Batavae Fiores, published in 1690. His Paraditus Batavus &c. was published after his decease, by William Sherard, which contains many rare, and some entirely new species, delineated in a very elegant manner. The rest of Hermann's works are, Materia Indicii Catalogus, continens variarum exotica animalium, insecta, vegetabilia, mineralis; Lapis Lydius Medicae, in which last his new characters of plants are made use of to illustrate their medical properties. At his death he left behind him 450 fine drawings, and a numerous collection of dried plants, which served for the basis of the Flora Ceylonica of Linneus, and also a catalogue of plants of the Cape of Good Hope. Dr Hannes addressed to him a beautiful Latin ode, which is still preserved; but many of the treasures of his industrious life were strangely neglected, and allowed to be dispersed.

HERMANNIA, a genus of plants belonging to the monodelphie class, and in the natural method ranking under the 37th order, Colummifera.

HERMANNSTADT, a handsome, populous, and strong town of Hungary, capital of Transylvania, with a bishop's see. It is the residence of the governor of the province; and is seated on the river Ceben, in E. Long. 23. 50. N. Lat. 46. 0.

HERMAPHRODITE, is generally understood to signify a human creature possessed of both sexes, or who has the parts of generation both of male and female. The term however is applied also to other animals, and even to plants. The word is formed of the Greek Ἐρμαφρόδιτος, a compound of Ἑρμης, Mercury, and Ἀφρόδιτα, Venus; q. d. a mixture of Mercury and Venus, i.e., of male and female. For it is to be observed, Hermaphroditus was originally a proper name applied by the heathen mythologists to a fabulous deity, whom some represent as a son of Hermes, Mercury, and Aphrodite, Venus; and who, being desperately in love with the nymph Salmis, obtained of the god to have his body and hers united into one. Others say, that the god Hermaphroditus was conceived as a composition of Mercury and Venus; to exhibit the union between eloquence, or rather commerce, whereof Mercury was god, with pleasure, whereof Venus was the proper deity. Lastly, others think this junction intended to show that Venus (pleasure) was of both sexes; as, in effect, the poet Calvus calls Venus a god.

Pollentemque Deum Venerem.

As also Virgil, Æneid, lib. ii.

Discendo, ac ducente Deus flamman inter et hostes

Expeditur.

M. Spon observes, Hesychius calls Venus Aphroditos: and Theophrastus affirms, that Aphroditos, or Venus, is Hermaphroditus; and that in the island of Cyprus she has a statue, which represents her with a beard like a man. The Greeks also call hermaphroditus, androgyno, androgyni, q. d. men-women. See the article ANDROGYNES.

In a treatise by Mr Hunter, in the 6th volume of the Philosophical Transactions, hermaphrodites are divided into natural and unnatural or monstrous. The first belongs to the more simple orders of animals, of which there are a much greater number than of the more perfect. The unnatural takes place in every tribe of animals, having distinct sexes, but is more common in some than in others. The human species, our author imagines, has the fewest; never having seen them in that species, nor in dogs; but in the horse, sheep, and black cattle, they are very frequent.

From Mr Hunter's account, however, it does not appear that such a creature as a perfect hermaphrodite has ever existed. All the hermaphrodites which he had the opportunity of seeing had the appearance of females, and were generally saved as such. In the horse they are very frequent; and in the most perfect of this kind he ever saw, the testicles had come down out of the abdomen into the place where the udder should have been, and appeared like an udder, not so pendulous as the scrotum in the male of such animals. There were also two nipples, of which horses have no perfect form; being blended in them with the sheath or prepuce, of which there was none here. The external female parts were exactly similar to those of a perfect female; but instead of a common-sized clitoris, there was one about five or six inches long: which when erect, stood almost directly backwards.

A foal as very similar to the above was killed, and the following appearances were observed on dissection. The testicles were not come down as in the former, possibly.
Of these creatures Mr Hunter dissected three, and the following appearances were observed in the most perfect of them.—The external parts were rather smaller than in the cow. The vagina passed on as in the cow to the opening of the urethra, and then it began to contract into a small canal, which passed on to the division of the uterus into the two horns; each horn passing along the edge of the broad ligament laterally towards the ovaries. At the termination of these horns were placed both the ovaries and testicles, both of which were nearly about the size of a small nutshell. No Fallopian tubes could be found. To the testicles were vasa deferentia, but imperfect. The left one did not come near the testicle; the right only came close to it, but did not terminate in the body called epididymis. They were both pervious, and opened into the vagina near the opening of the urethra.—On the posterior surface of the bladder, or between the uterus and bladder, were the two bags called the vesiculae seminales in the male, but much smaller than what they are in the bull: the ducts opened along with the vasa deferentia.

Concerning hermaphrodites of the human species, much has been written, and many laws enacted about them in different nations; but the existence of them is still disputed. Dr Parsons has given us a treatise on the subject, in which he endeavours to explode the notion as a vulgar error. According to him, all the hermaphrodites that have appeared, were only women whose clitoris from some cause or other was overgrown; and, in particular, that this was the case with an Anglian woman shown at London as a hermaphrodite some time ago.

Among the reptile tribe, indeed, such as worms, snails, leeches, &c. hermaphrodites are very frequent. In the memoirs of the French academy, we have an account of this very extraordinary kind of hermaphrodites, which not only have both sexes, but do the office of both at the same time. Such are earth-worms, round-tailed worms found in the intestines of men and horses, land-snares, and those of fresh-waters, and all the sorts of leeches. And, as all these are reptiles, and without bones, M. Poupart concludes it probable, that all other insects which have these two characters are also hermaphrodites.

The method of coupling practised in this class of hermaphrodites, may be illustrated in the instance of earth-worms. These little creatures creep, two by two, out of holes proper to receive them, where they dispose their bodies in such a manner, that the head of the one is turned to the tail of the other. Being thus stretched lengthwise, a little conical button or papilla is thrust forth by each, and received into an aperture of the other. These animals, being male in one part of the body, and female in another, and the body flexible withal, M. Homberg does not think it impossible but that an earth-worm may couple with itself, and be both father and mother of its young; an observation which, to some, appears highly extravagant.

Among the insects of the soft or boneless kind, there are great numbers indeed, which are so far from being hermaphrodites, that they are of no sex at all. Of this kind are all the caterpillars, maggots, and worms, produced of the eggs of flies of all kinds: but the reason...
HERMAPOCRATES, or HERMAPHROCRATES, in antiquity, a deity, or figure of a deity, composed of Mercury, and Harpocrates the god of Silence.

M. Spon gives us a hermaphrocrates in his Rech. Cor. de l'Antiquité, p. 98. fig. 15, having wings on his feet like Mercury, and laying his finger on his mouth like Harpocrates. It is probable they might mean, by this combination, that silence is sometimes eloquent.
HERMIANI, or HERMIATITAE, a sect of heretics in the second century, thus called from their leader Hermias. They were also denominated Seleuciastes.

One of their distinguishing tenets was, that God is corporeal. Another, that Jesus Christ did not ascend into heaven with his body, but left it in the sun.

HERMIONE, in Ancient Geography, a considerable city of Argolis. It was in ruins (except a few temples) in the time of Pausanias; who says that the new city was at the distance of four stadia from the promontory on which the temple of Neptune stood. It gave name to the Sicus Hermionicus, a part of the Sinus Argolicus.

HERMIT, or EREMIT, Eremita, a devout person retired into solitude, to be more at leisure for prayer and contemplation, and to disencumber himself of the affairs of this world. The word is formed from the Greek ἑρμητικός, desert or wilderness; and according to the etymology, should rather be wrote Eremit.

Paul surnamed the Hermit, is usually reckoned the first hermit; though St Jerome at the beginning of the life of that saint says, it is not known who was the first. Some go back to John the Baptist, others to Elias; others make St Anthony the founder of the eremitical life; but others think that he only rekindled and heightened the fervour thereof, and hold that the discipules of that saint owned St Paul of Thebes for the first that practised it. The persecutions of Decius and Valerian are supposed to have been the occasion

Several of the ancient hermits, as St Anthony, &c. though they lived in deserts, had yet numbers of religious accompanying them.

There are also various orders and congregations of religious distinguished by the title of hermits; as, hermits of St Augustine, of St John Baptist, of St Jerome, of St Paul, &c.

HERMIT, the Peter Gautier, a French officer of Amiens in Picardy, who quitted the military profession, and commenced hermit and pilgrim. He travelled to the Holy Land about the year 1093; and making a melancholy recital of the deplorable situation of a few Christians in that country to Pope Urban II. and at the same time enthusiastically lamenting that Infidels should be in possession of the famous city where the Author of Christianity first promulgated his sacred doctrines, Urban gave him a fatal commission to excite all Christian princes to a general war against the Turks and Saracens the possessors of the Holy Land. See CRUSADE.

HERMITAGE properly signifies a little hut or habitation, in some desert place, where a hermit dwells.

Hermitage is also popularly attributed to any religious cell, built and endowed in a private and recluse place, and thus annexed to some large abbey, of which the superior was called hermit.

HERMODACTYL, in the Materia Medica, a root brought from Turkey. It is of the shape of a heart flatted, of a white colour, compact, yet easy to be cut or powdered; of a viscous sweetish taste, with a light degree of acrimony. Hermodactyls were of great reputation among the ancients as a cathartic; but those we now meet with in the shops have very little purgative virtue; Neumann declares he never found them to have any effect at all. The hermodactyl is the root of the colchicum variegatum, according to some; others suppose it to be the root of the iris tuberosa.

HERMOGENES, the first and most celebrated architect of antiquity, was, according to Vitruvius, born at Alabanda, a city in Caria. He built a temple of Diana at Magnesia; another of Bacchus at Tros; and was the inventor of several parts of architecture. He composed a book on the subject, which is lost.

HERMOGENES Tarsensis, a rhetorician and orator, and who was in every respect a prodigy. At 17 years of age he published his system of rhetoric; and at 20 his philosophic ideas; but at 25 he forgot every thing he had known. It is said that his body being opened after his death, his heart was found of an extraordinary size, and all over hairy. He died about 158 B. C.

HERMOGENIANS, a sect of ancient heretics, denominated from their leader Hermogenes, who lived towards the close of the second century. Hermogenes established matter as his first principle; and regarding matter as the fountain of all evil, he maintained that the world, and every thing contained in it, as also the souls of men and other spirits, were formed by the Deity from an uncreated and eternal mass of corrupt matter. The opinions of Hermogenes, with regard to the origin of the world and the nature of the soul, were warmly opposed by Tertullian.

The Hermogenians were divided into several branches under their respective chiefains, viz. Hermiani, Seleuciasts, Materiari, &c.

HERMON, or AERMON, in Ancient Geography, a mountain of the Amorites, called Senior by the Phenicians, and Senior or Senir by the Amorites, on the east of Jordan. It is also called Sinai, (Moses); but must not be confounded with the Sion of Jerusalem. By the Sidonians it was called Sciron; in the vulgar, it is called Sarion. Joshua informs us, that it was the dominion of Og king of Bashan; which must be understood of its south side. It is never particularly mentioned by profane writers; being comprised under the appellation Libanus, or Antilibanus, with which mountain it is joined to the east. It is also called Hermonia, pluralis, Psalm xiii. 6. because it was extensive, and contained several mountains.

HERMOPOLIS, in Ancient Geography, the name of several cities in Egypt, dedicated, as the name imports, to Hermes or Mercury. Near one of these cities, probably Hermopolis Magna, was situated a most magnificent temple, of which the portico only now remains. It was visited by Denon, who accompanied the French army in their expedition to Egypt, in 1799. and he describes it as a most beautiful monument of ancient architecture, and a splendid relic of the highest antiquity. Among the hillocks within 300 or 400 yards of the portico, enormous blocks of stone are seen buried in sand, and regular architecture beneath them, which appear to form an edifice containing columns of granite, just rising above the present level of the soil. Every part of this edifice is covered with hieroglyphics. Connected with the scattered fragments of the great temple, a mosque has been built, in which is a number of columns of cipoline marble. Near this is the village of Achmusin, which contains 5000 inhabitants.

HERMUS, in Ancient Geography, a river of Jonia; which
HERNANDRIA, JACK-IN-A-BOX-TREE; a genus of plants belonging to the monoeccia class; and in the natural method ranking under the 38th order, Tricocce. See Botany Index.

HERNE, a town of Kent, six miles from Canterbury, 12 from Margate, and 14 from Faversham. The church is a large ancient structure, with a tower of flint, and has six stalls of the cathedral kind, with divisions of the choir from the nave by a carved screen of oak. The church is 113 feet long. The stone front is very ancient. Here the great Dr. Ridley, the English martyr, was vicar. Here is a commodious bay, frequented by gilbearers.

HERNiARIA, in Medicine and Surgery, a descent of the intestines or omentum out of their natural place; or rather, the tumour formed by that descent, popularly called a rupture. The word is Latin, hernia, and originally signifies the same with tumor scroti, called also romex. Priscian observes, that the ancient Marsi gave the appellation hernia to rocks: whence some will have hernias thus called propter duritiam, on account of their hardiness. Scaliger chooses rather to derive the word from the Greek ischem, romas, branch. See Surgery Index.

HERNIARIA, RUPTURE-WORT, a genus of plants belonging to the pentandria class; and in the natural method ranking under the 11th order, Sarmentaceae. See Botany Index.

HERO, in Pagan mythology, a great and illustrious person, of a mortal nature, though supposed by the populace to partake of immortality, and after his death to be placed among the number of the gods. The term is formed of the Latin heroes, and that of the Greek is, semi-deva, "semi-god."—The Greeks erected columns and other monuments over the tombs of their heroes, and established a kind of worship in honour of the manes both of their heroes and heroines. The Romans also raised statues in honour of their heroes; but there were six of their heroes of a superior order, and who were supposed to be admitted into the community of the twelve great gods: these were Hercules, Bacchus, Enceladus, Romulus, Castor, and Pollux. Writers have distinguished between the worship which the ancients paid to their heroes and that offered to their gods. The latter, it is said, consisted of sacrifices and libations; the former was only a kind of funeral honour, in which they celebrated their exploits, concluding the religious with feasts.

Hero is also used in a more extensive sense, for a great, illustrious, and extraordinary personage: particularly in respect of virtues. F. Bouhorts makes this distinction between a great man and a hero, that the latter is more daring, fierce, and enterprising; and the former more prudent, thoughtful, and reserved. In this sense we properly say, Alexander was a hero, Julius Caesar a great man.

Hero of a poem or romance, is the principal personage, or he who has the chief part in it. Thus the Vol. X. Part II.

HERO, in fabulous history, a famous priestess of Venus, lived at Abydos, in a tower situated on the banks of the Hellespont. She being beloved by Leander, who lived at Sestus on the other side of the strait, he every night swam over to visit her, being directed by a light fixed on the tower. But the light being put out in a stormy night, the youth missed his way and was drowned; on which Hero threw herself into the sea, and perished.

Hero, the name of two celebrated Greek mathematicians; the one called the old, and the other the young, Hero. The younger was a disciple of Cononius. They are known by two works, translated into Latin by Barocbus: Spiraurn liber, by Hero senior; and Tractat. arct. et machin. militar. by Hero junior. They flourished about 130 and 100 B.C.

HEROD, surnamed the Great, was born about 71 years before the commencement of the Christian era. When about 25 years of age, his father Antipater made him governor of Galilee, where he distinguished himself by suppressing a band of robbers, and executing their ringleader. For this action, as it was performed by his own authority, and without trial of the criminals, he was ordered to appear before the sanhedrim; but by the influence of his party and the favour of the high priest, he escaped judgment. During the civil war between the republican and Cezarian parties, Herod joined Cassius, and was made governor of Cæsaria. He caused Malchus to be assassinated for having poisoned his father, and ingratiated himself with Mark Antony. After being an exile for some time in Egypt, he found means to arrive at Rome, where Antony received him with great kindness, and elected him a senator and made choice of him to the crown of Judea, about five years before the birth of Christ. It was in the possession of Antigonus at that time, and he had consequently to fight his way to it. He was finally victorious, Antigonus was taken prisoner, and Herod succeeded to the regal dignity in the year 37 before Christ. In filling his empty coffers he was guilty of many cruel extortions, and in it is but justice to add, that he performed many acts of clemency. He sent for the aged high priest Hyrcanus, who had been deposed, and treated him with the greatest kindness, and raised Aristobulus, the brother of his beloved Mariamne, to the pontifical dignity. Soon after, indeed, from a fit of jealousy, he caused him to be drowned in a bath. He was accused to Antony by his mother-in-law, and he appointed his uncle Joseph to govern in his absence, charging him to put the queen to death, if her trial should prove fatal to him, as he could not support the idea of her falling into the possession of another.

Herod received a visit from Cleopatra, who is reported to have had amorous intentions with regard to him, which he prudently disappointed, for fear of the vengeance of Antony; but he fully satisfied her avarice with the most ample donations. When hostilities commenced between Antony and Octavian, he raised an army to join the former, but had first to contend with

3 K

Malchus,
Malchus, king of part of Arabia, whom he defeated, and compelled to sue for peace. After the battle of Actium, he resolved to make terms with the victor, to prepare for which he put the aged Hyrcan to death, and embarked for Rhodes, where Augustus at that time was. He appeared before the emperor in all the insignia of royalty except his diadem, boldly relating all the services he had performed to his benefactor Antony, and observed that he was willing to transfer the same gratitude to a new patron, from whom he might hold his crown and kingdom.

Augustus was struck with the magnanimity of this defence, and replaced the diadem on his head. When Augustus passed through Syria in his way to and from Egypt, he was magnificently entertained by Herod, for which he restored him the whole of his dominions, and even enlarged them. Before his interview with Augustus, Herod had given a second order respecting the murder of Mariamne; and growing jealous of Soherab, her last guardian, he soon after had her condemned and executed, in spite of the solemn protestations of her innocence. His remorse on this occasion was dreadful, and no scenes of riot or debauchery could banish her from his mind. He would frequently call aloud upon her name, and order his attendants to bring her into his presence, as if unwilling to forget that she was no more. He built a theatre and amphitheatre at Jerusalem, for the purpose of celebrating games in honour of Augustus, which exasperated the Jews to such a degree, that a conspiracy was formed against him, and on the detection of it, the principal contrivers were punished with a merciless severity.

He built several strong fortresses in different parts of Judea, for his own security, one of which, in honour of the emperor, was denominatCesarea. To supply in some measure the loss of Mariamne, he married another lady of the same name, the beautiful daughter of a priest, whom he raised to the supreme pontificate. He was in such favour with Augustus, that he was appointed imperial procurator of Syria, and obtained a tetrarchy for his brother. To conciliate the favour of the Jews, he undertook the vast work of rebuilding the temple of Jerusalem, and by constantly employing a whole army of workmen for a year and a half, this magnificent edifice was completed. In the course of another visit to the emperor, Herod obtained new favours, particularly a grant of half the produce of the mines of Cyprus, and the overseership of the rest. After this he dedicated his new city of Cesarea, when he exhibited so much profuse magnificence, that Augustus said, his soul was too great for his kingdom. He procured the condemnation and death of his two sons by the first Mariamne, for which he has been bitterly accused; but when we recollect that he took the greatest care of the two sons whom each left behind him, we much conclude that there was no more reason for their punishment than some are willing to allow. The charge brought against him was an unnatural conspiracy against his life and crown, and it seems to have been fairly substantiated. His ungrateful brother Pheroras, and his favoured son Antipater conspired against him. Soon after the discovery of it the former died, and the latter went to Rome.

The birth of Christ happened in the 33d year of his reign, which is said to have been soon followed by that act of barbarous cruelty, the massacre of the children of Bethlehem, instigated by jealousy of this king of the Jews in a spiritual sense, of whose birth he obtained information from the magi. It is to be observed that the account of this deed is no where to be met with but in St Matthew's gospel, for while Josephus seems to dwell with studied minuteness on the cruelties of Herod, he gives not a single hint respecting this massacre. As Antipater was returning from Rome, he was arrested by his father's orders, tried and condemned for treasonable practices. These calamities, joined to a shattered constitution, threw Herod into a loathsome distemper, accompanied with remarkable symptoms, which has sometimes been considered as a judgment from heaven. He ordered the sentence against Antipater to be put in execution, and appointed his son Archelaus to succeed him on the throne. According to Josephus, he collected together at Jericho the chief persons among the Jews, where he ordered them to be shot up in the circus, giving strict orders to his sister Salome to have them all massacred as soon as he breathed his last. This order was never executed, but we very much doubt the veracity of Josephus whether it was ever given. The most bloody monster that ever existed, was chiefly pleased with such acts of cruelty as he could either perform in person, witness by the agency of his slaves, or know to be done during his lifetime; but this supposed posthumous cruelty of Herod is wholly unaccountable. If it was actually the case, we can account for it upon no principles of human depravity, and it is wholly unique in the annals of tyranny.

His remains were interred with great pomp and magnificence; and although his memory has been consigned to detestation and abhorrence, his great talents and the glories of his reign, conspire to assign him a distinguished place in the list of sovereigns.

HERODIAN, an eminent Greek historian, who spent the greatest part of his life at Rome, flourished in the third century, in the reigns of Severus, Caracalla, Heliogabalus, Alexander, and Maximin. His history begins from the death of Marcus Aurelius the Philosopher; and ends with the death of Balbibus and Maximin, and the beginning of the reign of Gordian. It is written in very elegant Greek; and there is an excellent translation of it into Latin, by Angelus Politianus. Herodian has been published by Henry Stephens in 4to, in 1581; by Boecker, at Strasburg, in 1662, 8vo; and by Hudson, at Oxford, in 1699, 8vo.

HERODIANS, a sect among the Jews at the time of our Saviour: mentioned Matt. xxii. 16. Mark iii. 6.

The critics and commentators are very much divided with regard to the Herodians. St Jerome, in his Dialogue, against the Luciferians, takes the name to have been given to such as owned Herod for the Messiah; and Tertullian and Epiphanius are of the same opinion. But the same Jerome, in his Commentary on St Matthew, treats his opinion as ridiculous; and maintains, that the Pharisees gave this appellation by way of ridicule to Herod's soldiers who paid tribute to the Romans; agreeable to which the Syrian interpreters render the word by the domestics of Herod, i.e. "his courtiers." M. Simon, in his notes on the 22d chapter of Matthew, advances a more probable opinion. The
HERODOTUS, an ancient Greek historian of Halicarnassus in Caria, son of Lyzus and Dryo, was born in the first year of the 74th Olympiad, that is, about 483 B.C. The city of Halicarnassus being at that time under the tyranny of Lygdamis grandson of Artemisia queen of Caria, Herodotus quitted his country and retired to Samos, from whence he travelled over Egypt, Greece, Italy, &c. and in his travels acquired the knowledge of the history and origin of many nations. He then began to digest the materials he had collected into order, and composed that history which has preserved his name among men ever since. He wrote it in the isle of Samos, according to the general opinion. — Lucian informs us, that when Herodotus left Caria to go into Greece, he began to consider with himself

What he should do to be for ever known, and make the age to come his own, in the most expeditious way, and with as little trouble as possible. His history, he presumed, would easily procure him fame, and raise his name among the Greeks in whose favour it was written; but then he foresaw that it would be very tedious to go through the several cities of Greece, and recite it to each respective city; to the Athenians, Corinthians, Argives, Lacedaemonians, &c. He thought it most proper therefore to take the opportunity of their assembling all together, and accordingly recited his work at the Olympic games, which rendered him more famous than even those who had obtained the prizes. None were ignorant of his name, nor was there a single person in Greece who had not seen him at the Olympic games, or heard those speak of him who had seen him there.

His work is divided into nine books; which according to the computation of Dionysius Halicarnassensis, contain the most remarkable occurrences within a period of 240 years; from the reign of Cyrus the first king of Persia, to that of Xerxes when the historian was living. These nine books are called after the names of the nine muses, each book being distinguished by the name of a muse; and this has given birth to two disquisitions among the learned: 1. Whether they were so called by Herodotus himself; and, 2. For what reason they were so called. As to the first, it is generally agreed that Herodotus did not impose these names himself; but it is not agreed why they were imposed by others. Lucian tells us, that these names were given them by the Grecians at the Olympic games, when they were first recited, as the best compliment that could be paid the man who had taken pains to do them so much honour. Others have thought that the names of the muses have been fixed upon them by way of reproach; and were designed to intimate, that Herodotus, instead of true history, had written a great deal of fable. But, be this as it will, it is certain, that with regard to the truth of his history, he is accused by several authors; and, on the other hand, he has not wanted persons to defend him. Aldus Manutius, Joachim Camerarius, and Henry Stephens, have written apologies for him; and, among other things, have very justly observed, that he seldom relates any thing of doubtful credit without producing the authority on which his narration is founded; and, if he has no certain authority to fix it upon, uses always the terms ut dixit, ut ego audivi, &c.

There is ascribed also to Herodotus, but falsely, a Life of Homer, which is usually printed at the end of his work. — He wrote in the Ionic dialect, and his style and manner have ever been admired by all people of taste. There have been several editions of the works of this historian; two by Bernard Stephens, one in 1573, and the other in 1592; one by Gale at London in 1679; and one by Gronovius at Leyden in 1715, which is the last and best, though not the best printed.

HEROIC, something belonging to a hero, or heroine. Thus we say, heroic actions, heroic virtues, heroic style, heroic verse, heroic poet, heroic age, &c.

Heroic Age, is that age or period of the world wherein the heroes, or those called by the poets the children of the gods, are supposed to have lived. — The heroic age coincides with the fabulous age.

Heroic Poem, is that which undertakes to describe some extraordinary action or enterprise. Homer, Virgil, Statius, Lucan, Tasso, Camoens, Milton, and Voltaire, have composed heroic poems. In this sense, heroic poem coincides with epic poem.

Heroic Verse, is that wherein heroic poems are usually composed; or, it is that proper for such poems. In the Greek and Latin, hexameter verses are peculiarly denominated heroic verses, as being alone used by Homer, Virgil, &c. Alexandrine verses, of 12 syllables, were formerly called heroic verses, as being supposed the only verse proper for heroic poetry; but later writers use verses of ten syllables.

HEROINE, HEROINA, or Herois, a woman that has the qualities and virtues of a hero, or that has done some heroic action.

HERON. See Ardea, Ornithology Index.

This bird is a very great devourer of fish, and will do more mischief to a pond than even an otter. Some say that an heron will destroy more fish in a week than an otter will in three months; but that seems carrying the matter too far. People who have kept herons, have had the curiosity to number out the fish they fed them with into a tub of water; and counting them again afterwards, it has been found that a heron will eat 50 moderate-sized dace and roaches in a day. It has been found, that in carp-ponds visited by this bird, one heron will eat up 1000 store carp in a year, and...
HERPES, in Medicine, a bilious pustule, which breaking out in different manners upon the skin, accordingly receives different denominations. See Medical Index.

HERRERA Tordesillas, Anthony, a Spanish historian, the son of Roderic de Tordesillas and Agnes de Herrera, it being the custom of that country to bear the mother's name, was born in 1565. He was secretary to Vespasian de Gonzaga, viceroy of Navarre and Valen¬tia, and afterwards appointed royal historiographer for the Indies by Philip II. to which a liberal pension was attached. While he held this office, he wrote his general history of the Indies in 4 vols folio, comprehending the whole of the Spanish transactions there, from 1492 to 1554. The celebrated Scottish historian Dr. Robertson, says of it, that it 'furnishes the fullest and most accurate information concerning the conquest of Mexico, as well as every other transaction of America. The industry and attention with which he consulted not only the books, but the original and public records were so great, and he usually judges of the evidence before him with so much impartiality and candour, that his decades may be ranked among the most judicious and useful historical collections.' Herrera likewise composed a general history of his own time, from 1554 to 1598, which is not so much admired. His death, which happened in 1625, prevented him from enjoying the office of secretary of state, which Phillip IV. designed for him on the very first vacancy.

HERRERA, Ferdinand de, a Spanish poet of the 16th century, was a native of Seville. In the year 1582, he published a collection of poems of the lyric and heroic species, which were reprinted in 1619. By these he obtained a considerable reputation as a favourite of the muses, and made him be regarded as the first lyric poet belonging to Spain. As to his style, it is generally allowed to be neat, elegant, copious, and correct. He likewise published an edition of Garcilasso de la Vega, with notes; a narrative of the war with Cyprus, and of the battle of Lepanto.

HERRING, in Ichthyology, a species of Clupea. The name herring is derived from the German her, an army, which expresses their number, when they migrate into our seas. Herrings are found in great plenty from the highest northern latitudes as low as the northern coasts of France. They are also met with in vast shoals on the coast of America, as low as Carolina: they are found also in the seas of Kamtschatka, and possibly reach Japan: but their winter rendezvous is within the arctic circle, whither they retire after spawning, and where they are provided with plenty of insect food. For an account of the remarkable migration of herrings, and the history of the fishery, &c. see Clupea and Herring-Fishery.

Herings, in Herring. They are in full roe at the end of June, and continue in perfection till the beginning of winter, when they begin to deposit their spawn.

There are different names given to preserved herrings, according to the different manners wherein they are ordered: as, 1. Sea-sticks; which are such as are caught all the fishing season, and are but once packed. A barrel of these holds six or eight hundred; eight barrels go to the ton by law; a hundred of herrings is to be a hundred and twenty; a last is ten thousand, and they commonly reckon fourteen barrels to the last. 2. These are others, repacked on shore, called repacked herrings; seventeen barrels of sea-sticks commonly make from twelve to fourteen of repacked herrings. The manner of repacking them is, to take out the herrings, wash them out in their own pickle, and lay them orderly in a fresh barrel; these have no salt put to them, but are close packed, and headed up by a sworn cooper, with pickle, when the barrel is half full. The pickle is brine; so strong as that the herring will swim in it. 3. Summers, are such as the Dutch chasers or divers catch from June to the 15th of July. These are sold away in sea-sticks, to be spent presently, in regard of their fatness; because they will not endure repacking. They go one with another, full and shotten; but the repacked herrings are sorted, the full herrings by themselves. 4. The shotten and sick herrings by themselves; the barrel whereof is to be marked distinctly. 5. Cross herrings; which are such as are caught after the 14th of September. These are cured with that kind of salt called salt upon salt, and are carefully sorted out, all full herrings, and used in the repacking. 6. Cowed herrings. These serve to make red herrings, being such as are taken in the Yarmouth seas, from the end of August to the middle of October; provided they can be carried ashore within a week, more or less, after they are taken. These are never gipped but rowed in salt, for the better preserving of them, till they can be brought on shore; and such as are kept to make red herrings, are washed in great vats in fresh water, before they are hung up in the herring-hangs or red-herring houses.

As for the manner of salting herrings. The nets being haled on board, the fishes are taken out, and put into the warbacks, which stand on one side of the vessel. When all the nets are thus unloaded, one sixt of the gippers baskets. The gippers cut their throats, take out their guts, and fling out the full herrings into one basket, and the shotten into another. One man takes the full basket when they are gipped, and carries them to the rower-back, wherein there is salt. One boy rows and stirs them about in the salt, and another takes them; thus rowed, and carries them in baskets to the packers. Four men pack the herrings into one barrel, and lay them, one by one, straight and even; and another man, when the barrel is full, takes it from the packers. It is left to stand a day, or more, open to settle, that the salt may melt and dissolve to pickle; after which it is filled up, and the barrel headed. The pickle is to be strong enough to sustain a herring; otherwise the fish decay in it.

HERRING, Thomas, archbishop of Canterbury, memorable for his attachment to civil and religious liberty, was the son of a clergyman, and born in the year 1693. He received his grammar-school education at Wisbech.
Herring was in the isle of Ely; and at the age of 17 was sent to Jesus college in the university of Cambridge, at which place he was made B.A. in 1742, and the title or degree of A.M. was conferred upon him about three years afterwards. In the year 1748, he was appointed chaplain to Dr Fleetwood, bishop of Ely, who gave him two rectories; and in 1756 he was nominated preacher to the honourable society of Lincoln’s Inn. He was chosen chaplain in ordinary to his majesty about the same period, and obtained from Cambridge the degree of D.D. in the year 1752. Bishop Fleetwood, his worthy patron, declared to his friends, that he never heard a sermon from Dr Herring which he would not have been proud to be the author of himself. In 1731, he was chosen rector of Blechingley in Surrey; the same year appointed dean of Rochester, and the king promoted him to the see of Bangor in the year 1737. He was appointed archbishop of York in 1743; and it was peculiarly fortunate for the country at that critical juncture, that a man of his principles and public spirit was raised to such an exalted rank. The rebellion in Scotland was so artfully concealed by its friends in England, that it was scarcely believed the Highlanders were in arms, till the royalists were defeated at the battle of Prestonpans. Amidst the universal consternation which this event occasioned, Archbishop Herring roused the people to a sense of their danger, contributed to remove the panic, and encouraged them to unite with firmness and vigour in the defence of their country. A meeting of the nobility, gentry, and clergy, was held at York, where the archbishop addressed them in a very able and animated speech, requesting them to unite as one man in averting the present danger, to preserve their happy constitution, and contribute to a subscription for raising troops in defence of the country. The whole assembly entered warmly into his views, and immediately subscribed about 40,000l. for the important purpose recommended by his grace. On the death of Archbishop Potter, which happened in 1747, Dr Herring was translated to the see of Canterbury. In 1753 he was seized with a violent fever, which brought him to the verge of the grave; and although he so far recovered that he languished for a few years, yet his strength and spirits were very much exhausted, and he expired in 1755, in the 63d year of his age. He was buried, according to his own desire, without any pomp or parade, and no monument was erected to his memory.

We are informed by Mr Duncombe, that the archbishop’s person was tall and comely; his constitution, from his tenderest youth, weak and delicate; his address easy, engaging, and polite. He was generous without prodigality, magnificent without profusion, and humble without meanness. In his life-time he could never be prevailed upon to publish any of his sermons; but after his death Mr Duncombe published seven sermons on public occasions, in one volume octavo, giving in the preface some account of the author’s life. In the Monthly Review he was termed “a prelate of uncommon virtues, a man of extraordinary accomplishments, a candid divine, a polite scholar, a warm lover of his country, a true friend to liberty, religious as well as civil, and of course, a most sincere hater of persecution.”

Herrnhut, or Herrnuth, the first and most considerable settlement of the United Brethren, commonly called Moravians, situated in upper Lusatia, upon an estate belonging to the family of Nicholas Louis Count Zinzendorf, about 50 miles east of Dresden. See the article United Brethren.

The building of this place was begun in 1727 by some emigrants from Moravia, who forsook their possessions on account of the persecution they suffered as Protestants from the Roman Catholics; and being well received by Count Zinzendorf, cleared a spot of ground allotted to them by him upon the rise of an hill called the Huthberg, or Watch-hill, from which they took occasion to call the new settlement Herrn hut, or the Watch of the Lord. More emigrants taking refuge with them, and many other persons joining their congregation, the buildings increased considerably; and at present Herrn hut is a regular and well-built village, containing about 1300 inhabitants, all members of the Church of the United Brethren. Besides the minister and his assistants, a warden is appointed, who presides in the vestry, and superintends the temporal concerns of the settlement. The Brethren distinguish themselves by a plain and uniform dress, the women having retained the dress of the countries from which the first emigrants proceeded, not from any superstitious attachment to old forms, but from a desire to preclude vanity and useless expense. As most of the settlements of this community resemble each other, both in the disposition of their buildings and in their internal regulations, we will give a short sketch of Herrn hut, as the pattern from which the rest were copied, though there are others in which the buildings are more regularly planned. The chapel, which is situated in a large square, is a spacious and neat building, furnished with a good organ and movable forms, but no pews. The men sit on one side, and the women on the other, entering at separate doors. Besides the usual Sunday’s service, the congregation meets here every evening and the children every morning. The dwelling of the minister and warden of the congregation form one, and a school-house the other, wing to the chapel. From the chapel an avenue of trees leads to the burying ground, which is a large square field on the declivity of the Huthberg, and at some distance from the village. Several walks bordered by trees, and furnished with seats, surround and intersect it. The grave-stones and graves are all of equal size, and placed in regular rows; only the vault of Count Zinzendorf, as lord of the manor, is larger than the rest. Burials are performed with great solemnity, but no mourning dresses used. On one side of the square, in which the chapel stands, is a large building, inhabited by the single men, with workshops, out-houses, and gardens, exclusive of the dwelling rooms. The main building contains a neat chapel, in which a short morning and evening service is performed for the inhabitants; a dining-hall; and a dormitory, in which each has a separate bed. The latter is a lofty room, furnished with large windows and ventilators, so as to admit and preserve a pure air. For the sick, apartments are allotted, and sick waiters appointed. The number of inhabitants in one room is proportioned to its size, but there are many who have rooms to themselves. No one lives here by compulsion. Each inhabitant pays for rent and board a moderate sum, fixed.
Herrnhut. by a committee of overseers, in which the warden of the house presides; whose business it is to maintain good order, attend to the external welfare of the house and its inhabitants, and by his advice and activity to prevent every evil arising from external sources. Besides the warden, an unmarried clergyman resides in the house, appointed to attend to the moral conduct and spiritual concerns of all the single men belonging to the congregation. He hears their complaints, assists them with good advice, and uses all his influence for their benefit, and for the prevention of any evil that would undermine their spiritual happiness. — On the other side of the square is another large building, inhabited by single women; with a chapel, dining hall, dormitory, and a large garden. The internal regulations are exactly the same with those of the house of the single men. There are likewise houses for widowers and widows, who find in them an agreeable retreat, with board and lodging. The poor are cared for and maintained; for which purpose several charitable institutions exist in the congregation. — The manor-house, the house of Count Reuss, the shop and linen warehouse, are the most considerable buildings in Herrnhut; the family houses are built in regular streets opening into the square. Both the streets and houses are kept clean; and besides a watchman at night, an officer is appointed to attend to good order in the day. All strangers are treated with civility; but neither drunken nor disorderly visitors nor beggars are suffered to infest the streets. The latter receive an alms, and are then desired to proceed. The principal trade carried on at Herrnhut is in linen; besides which the work done there by tailors, glovers, shoemakers, cabinet-makers, silversmiths, and other artisans, is well known for its good quality. They have their first prices, and never make any abatement. Every workman receives his wages; no community of goods existing among the brethren, as is falsely supposed; and the contributions towards the support of the establishment at large, the missions, and other charitable institutions, are voluntary. The building and increase of this settlement occasioned no small surprise in the adjacent country; and both in 1732, 1736, and 1737, commissioners were appointed to examine into the doctrines and proceedings of the brethren at Herrnhut. The commissioners made a favourable report; and ever since both Herrnhut and other settlements of the United Brethren in Saxony have been protected, and even several immunities offered them by the court, but not accepted. Herrnhut was visited in 1766 by the late emperor Joseph II. after his return from Dresden, by the present king of Prussia, and by several other royal personages, who expressed their satisfaction in examining its peculiar regulations. The united Brethren have settlements in Saxony, Silesia, and other parts of Germany; in Holland, Denmark, England, Ireland, and America. In England, their principal settlements are at Fulneck near Leeds, and Fairfield near Manchester. In Greenland, North and South America, the West Indies and Russia, they have missions for the propagation of Christianity among the heathen; and in many parts have had considerable success. See Buschings Account of the Rise and Progress of the Church of the Brethren, Halle 1791; and Crantz's History of the Brethren, London 1782.

Herrnhut, New, the first mission settlement of the United Brethren, in the island of St Thomas in the West Indies, under the Danish government, begun in 1739; their missionaries having endeavoured to propagate Christianity among the negro slaves ever since 1731, and suffered many hardships and persecutions, from which their converts were not exempted. Many of the planters finding in process of time that the Christian slaves were more tractable, moral, and industrious, than the heathen, not only countenanced but encouraged their endeavours. These were also greatly facilitated by the protection of the king of Denmark. The settlement consists of a spacious negro church, a dwelling-house for the missionaries, negro-huts, out-houses, and gardens. From this place the islands of St Croix and St Jan were at first supplied with missionaries; and the Brethren have now two settlements in each. The negro converts belonging to their church amount in those three islands to near eight thousand souls.

Herrnhut, New, is also the name of the oldest mission settlement of the United Brethren in Greenland. It is situated on Balls River, a few miles from the sea, near Davis's Straits, on the western coast of Greenland, not far from the Danish colony Godthaab. The two first missionaries were sent from Herrnhut in the year 1733, and their laudable intentions were favoured by the king of Denmark. They had to struggle in this uncultivated, frozen, and savage country, with inconceivable hardships, and found at first great difficulty in acquiring the language of the natives. However, after six years labour and perseverance, they had the satisfaction to baptize four persons, all of one family: and from that time the mission began to prosper, so that in the succeeding years two other settlements were begun, called Lichtensels and Lichtenauf: All of them continue in prosperity. About 1300 of the natives have been christianized since the beginning of this mission. See Crantz's History of Greenland, London, 1777.

Herschel, the name by which the French, and most other European nations, call the planet discovered by Dr H. of Hevel in the year 1781. The Italians call it Uranus, and the British Georgium Sidus.

Herse, in Fortification, a lattice, or portcullis, in form of a harrow, beset with iron spikes. The word herse is French, and literally signifies "harrow; being formed of the Latin herpes or irpes, which denotes the same. It is usually hung by a rope fastened to a moulinet; to be cut, in case of surprise, or when the first gate is broken with a petard, that the herse may fall, and stop up the passage of the gate or other entrance of a fortress.

The herse is otherwise called a serrain, or cataract; and when it consists of straight stakes, without any cross-pieces, it is called orgues.

Herse, is also a harrow, which the besieged, for want of chevaux de frise, lay in the way, or in breaches, with the points up, to incommodate the march as well of the horse as of the infantry.

Hersillon, in the military art, a sort of plank or beam, ten or twelve feet long, whose two sides are driven full of spikes or nails, to incommodate the march of the infantry or cavalry. The word is a diminutive of herse; the hersillon doing the office of a little herse. See Herse.

Herford.
HERTFORD. See HARTFORD.—In the account given of this county under the latter name, it was omitted to mention that the East India Company had established a college in it, where persons are to be properly qualified for filling places of trust and importance in the government of India. It is composed of a school, into which boys may be admitted at an early age, and a school for students, 15 years old, in which they are to continue till they have completed their 18th year, or till the directors send them to their particular destinations. In the school, the chief intention is to qualify them for public business, and the first departments of commercial life. The students of the college are to hear public lectures, similar to those which are delivered in the universities. The means of instructing them in the elements of oriental literature will also be attended to, for which purpose they will be taught the rudiments of the Asiatic, Arabic, and Persian languages, and the history, customs, and manners of the eastern nations, as well as the political and commercial relations subsisting between Great Britain and India.

The college is to be under the authority of a principal and seven professors, besides a French master, a drawing-master, a fencing-master, and other suitable instructors.

The principal is required to preach in the college chapel, in rotation with such of the professors as are in holy orders, and to hear his part in performing the other functions of religious worship.

The lectures of the professors are to be arranged under the following heads; viz. oriental literature; mathematics and natural philosophy; classical and general literature; law, history, and political economy.

It is proposed to divide the college year into two terms of 20 weeks each, and the last week of each term is to be dedicated to the examination of the students. A list of their names who are found to have made the greatest proficiency, will be transmitted to the court of directors, who will reward merit in such a manner as may be agreed upon by the college committee. The utmost attention will be paid to their moral and religious instruction, comprehending an account of the evidences, doctrines, and duties of divine revelation.

The college and school were opened on the 3d of Feb. 1806, for the reception of students and pupils. The master of the school is to receive 70 guineas annually, without any additional charge, and students are to pay 50 guineas to the company at the commencement of each term, for which they will receive every accommodation except a few articles of private convenience. Every kind of extravagant expense is to be discouraged.

HERTHA, or HERTHUS, in Mythology, a deity worshipped by the ancient Germans. This is mentioned by Tacitus, in his book De Moribus Germanorum, cap. 40. Vossius conjectures, that this goddess was Cybele: but she was more probably Terra or the Earth; because the Germans still use the word her for the earth, whence also the English earth.

HERTZBERG, a considerable town of Germany, in the electorate of Saxony, and on the confines of Lusatia. E. Long. 13. 37. N. Lat. 51. 42.

HERVEY, James, a pious and ingenious divine of the church of England in the 18th century, a writer of very great popularity among people of the Calvinistic persuasion, was born at Hardingshorne in the year 1714. He was educated at the free grammar-school of Northampton, where he acquired a competent knowledge of the Greek and Latin languages; and in 1731 he was sent to the university of Oxford. The first two or three years of his residence at that seminary were spent, we are told, without much application to study, and therefore without making much improvement; but afterwards becoming acquainted with those who zealously studied what they called primitive Christianity, afterwards termed Methodists, he became strongly attached both to piety and learning. Independent of his other studies, he learned anatomy from Dr. Keil, and natural philosophy from Dr. Derham's Physico and Astrotheology; and by the perusal of Mr. Spence's essay on Pope's Odyssey he improved his style. He attempted the Hebrew language without a teacher, and after relinquishing the study of it in despair, he resumed his labours, and became a tolerable proficient in that forbidding language.

In the year 1749 he was curate of Biddeford in Devonshire, where he had only 50l. a year, including a stated collection made by his friends. On the death of the rector he was dismissed by the new incumbent, contrary to the earnest expostulation of the parishioners, who offered to maintain him independent of the rector. In 1743 he became curate to his father, who held the living of Weston-Favell in Northamptonshire, and continued in that station till 1750, when his health was rapidly declining, from his intense application to study, and a constitution naturally delicate. Having been artfully decoyed to London for a change of air, he continued about two years in that metropolis, and was soon recalled to Weston-Favell to succeed his father. He got both the livings of Weston and Collingtree in the same neighbourhood, and in 1752 was made M. A. He attended to the duties of both parishes alternately with a curate, in the discharge of which he was fervent and indefatigable. He seldom made use of notes in the pulpit, and constantly catechised the children of his parishioners, nor did he neglect his pastoral visitations at their own houses. So great were his exertions, that he brought on a decline, accompanied with an incessant cough and acute pains, all which he supported, not only with fortitude, but without a single expression of penitiveness.

He died without a groan on the 25th of December 1758, about 44 years of age. His piety was ardent and sincere, although in the estimation of good judges he was rather enthusiastic. He was unquestionably a man of the most unblemished moral deportment; his temper was disinterested, and he was truly humble without affectation. To society he was just and punctual, and candid to people of every description. This solemn which he received for his Meditations, were applied to the relief of the indigent and distressed. He was such a rigid Calvinist, that he was almost an Antinomian, whenever he spoke of imputed righteousness. His erudition was respectable, but not such as to place him among scholars of the first rank, although he seems to have been master of the classics. Many have admired the style of his writings, but a judge must certainly pronounce it by far too diffuse to be termed elegant, for it is neither chaste, manly, nor nervous.

Besides...
Besides his Meditations, he published remarks on Lord Bolingbroke's letters on the use and study of history, so far as they relate to the history of the Old Testament; Theron and Aspasio; Aspasio Vindicated, and Sermons on the Trinity, &c. published from his own MSS. after his death.

Hesiodic island, one of the South Sea islands discovered by Capt. Cook, September 23, 1773, who gave it that name in honour of the earl of Bristol. It is a low island, situated in W. Long. 158. 54. S. Lat. 19. 8.

HESBON, Ezechon, or Hesbon, in Ancient Geography, the royal city of the Amorites, in the tribe of Reuben, according to Moses: Thus in Joshua xxi. 39. where it is reckoned among the Levitical cities, it is put in the tribe of Gad; which argues its situation to be on the confines of both.

HESIOD, a very ancient Greek poet; but whether cotemporary with Homer, or a little older or younger than him, is not yet agreed among the learned; nor is there light enough in antiquity to settle the matter exactly. His father, as he tells us in his Opera et Dies, was an inhabitant of Cyme, one of the Eolian isles, now called Taio Nova; and removed from thence to Ascrya, a little village of Boeotia, at the foot of Mount Helicon, where Hesiod was probably born, and called, as he often is, Ascryeus, from it. Of what quality his father was, is nowhere said; but that he was driven by his misfortunes from Cyme to Ascrya, Hesiod himself informs us. His father seems to have prospered better at Ascrya than he did in his own country; yet Hesiod could arrive at no higher fortune than keeping sheep on the top of Mount Helicon. Here the muses met with him, and entered into him their service:

Erewhile as they the shepherd swain behold,
Feeding beneath the sacred mount his fold,
With love of charming song his breast they fill'd;
There me the heavenly muses first inspir'd;
There, when the maids of Jove the silence broke,
To Hesiod thus, the shepherd swain, they spake, &c.

To this account, which is to be found in the beginning of his Generatio Deorum, Ovid alludes in these two lines:

Nec nisi sunt visa Clio, Clitumque sores,
Servanti precesque solittus Astra tuis.
Nor Clio nor her sisters have I seen,
As Hesiod saw them in the Ascryan green.

On the death of the father, an estate was left, which ought to have been equally divided between the two brothers Hesiod and Perseus; but Perseus defrauded him in the division, by corrupting the judges. Hesiod was so far from resenting this injustice, that he expresses a concern for those mistaken mortals who place their happiness in riches only, even at the expense of their virtue. He lets us know, that he was not only above want, but capable of assisting his brother in time of need; which he often did though he had been so ill used by him. The last circumstance he mentions relating to himself is his conquest in a poetical contention. Archimamus, king of Nubia, had instituted funeral games in honour of his own memory, which his sons afterwards took care to have performed. Here Hesiod was a competitor for the prize in poetry; and won a tripod, which he consecrated to the muses. Hesiod having entered himself in the service of the muses, left off the pastoral life, and applied himself to the study of arts and learning. When he was grown old, for it is agreed by all that he lived to a very great age, he removed to Locris, a town about the same distance from Mount Parnassus as Ascrya was from Helicon. His death was tragic. The man with whom he lived at Locris, a Milezan born, ravished a maid in the same house; and though Hesiod was entirely ignorant of the fact, yet being maliciously accused by her brothers as an accomplice, he was injuriously slain with the ravisher, and thrown into the sea. The Theogony, and Works and Days, are the only undoubted pieces of this poet now extant: though it is supposed that these poems have not descended perfect and finished to the present time. A good edition of Hesiod's works was published by Mr. Le Clerc at Amsterdam in 1701.

HESPERUS, in Astronomy, the evening star, as a Venusian planet, to some sets when she falls or sets after the sun. This word is formed of the Greek Ἑσπερός, and is supposed to have been originally the proper name of a man, brother of Atlas, and father of the Hesperides.

Diodorus, lib. iii., relates, that Hesperus having ascended to the top of Mount Atlas, the better to observe and contemplate the stars, never returned more; and that hence he was fabled to have been changed into this star.

HESPERIA, an ancient name of Italy; so called by the Greeks from its western situation. Hesperia was also an appellation of Spain; but with the epithet ultima (Horace), to distinguish it from Italy, which is called Hesperia magna (Virgil), from its extent of empire.

HESPERI CORMUS, called the Great Bay by the author of Hanno's Periplus; but most interpreters, following Mela, understand a promontory; some Cape Verd, others Palmas Cape: Vossius takes it to be the former, since Hanno did not proceed so far as the latter cape.

HESPERIDEÆ, in Botany (from the Hesperides); golden or precious fruit: the name of the 39th order in Linnaeus's Fragments of a Natural Method. See BOTANY.

HESPERIDES, in the ancient mythology, were the daughters of Hesperus or Hesperus, the brother of Atlas. According to Diodorus, Hesperus and Atlas were two brothers who possessed great riches in the western parts of Africa. Hesperus had a daughter called Hesperia, who married her uncle Atlas, and from this marriage proceeded seven daughters, called Hesperides from the name of their mother, and Atlantides from that of their father. According to the poets, the Hesperides were three in number, Ægle, Arthemis, and Hesperthus. Hesiod, in his Theogony, makes them the daughters of Nox, Night, and sets them in the same place with the Gorgons; viz. at the extremities of the west, near Mount Atlas: it is on that account he makes them the daughters of Night, because the sun sets there. The Hesperides are represented by the ancients as having the keeping of certain golden apples, on the other side the ocean. And the poets gave them a dragon to watch the garden where the fruit grows; and this dragon they tell us Hercules slew, and carried off the
Hesperides

Pliny and Solinus will have the dragon to be no other than an arm of the sea, whereby the garden was encompassed, and which defended the entrance thereof. And Varro supposes, that the golden apples were nothing but sheep. Others, with more probability, say they were oranges.

The Gardens of the Hesperides are placed by some authors at Larache, a city of Fes; by others at Berenich a city of Barca, which tallies better with the fable. Others take the province of Sasa in Morocco for the island wherein the garden was seated. And, lastly, Rudbeck places the Fortunate Islands, and the gardens of the Hesperides, in his own country Sweden.

HESPERIDUM INSulaE, in Ancient Geography, islands near the Hesperian Corn; but the accounts of them are so much involved in fable, that nothing certain can be affirmed of them.

Hesperis, Rocket, Dame’s Violet, or Queen’s Gilliflower; a genus of plants belonging to the tetradynamia class; and in the natural method ranking under the 39th order, Siliqueae. See Botany Index.

Hesperus, in fabulous history, son of Cephalus by Aurora, as fair as Venus, was changed into a star, called Lucifer in the morning, and Hesperus in the evening. See Hesper.

Hesse, a country of Germany, is in the circle of the Upper Rhine; bounded on the south by Baden and Bavaria; on the east by the principalities of Saxe Meiningen, Saxe Weimar, and the Prussian states; on the north by Brunswick and the Prussian states; and on the west by the same states and Nassau. In the above limits, the county of Katzenellenbogen and some other territories are not included. The whole country, in its utmost length, is near 100 miles, and in some places about 60 in breadth. The air is cold, but wholesome; and the soil fruitful in corn, wine, wood, and pasture. The country abounds also in cattle, fish, and game; salt springs, baths, and mineral waters. The hills, which are many, yield silver, copper, lead, iron, alum, vitriol, pit-coal, sulphur, boles, a porcelain earth, marble, and alabaster. In the Eder, gold is sometimes found; and at Frankenberg a gold mine was formerly worked. Besides many lesser streams, Hesse is watered by the following rivers, viz. the Lahn, the Fulda, the Eder or Schwalm, the Werra or Weser, and Diemel. The Mayne passes through the county of Katzenellenbogen. This country, like most others in Germany, has its states, consisting of the prelates, as they are called, the nobility, and the towns. The diets are divided into general and particular, and the latter into the greater and smaller committees. The house of Hesse is divided into two principal branches, viz. Cassel and Darmstadt, of which Philippsdalen, Rhinfeld, and Homburg, are collateral branches; the two first of Hesse-Cassel, and the last of Hesse-Darmstadt. Their rights and privileges are very considerable. In particular, they have votes at the diet of Frankfort. The princes of Hesse-Cassel are not of age till they are 25, but those of Hesse-Darmstadt are so at 18. The right of primogeniture hath been established in both houses. The revenues of Darmstadt are said to amount to 370,000l. a-year, and those of Hesse-Cassel to near 380,000l. The small county of Schauenberg alone yields a revenue of 10,000l. and that of Katzenellenbogen, with the forests of Richarstown, it is said, was farmed near 200 years ago at 12,000l. In 1818 Hesse Darmstadt contained 619,500 inhabitants, and Hesse Cassel 540,000.

The troops that the former hires out have often brought him in large sums, especially from Great Britain. He keeps a standing army of 13,000 men. This family is allied to most if not all of the Protestant princes in Europe. The branches of Cassel, Homburg, and Philippsdale, are Calvinists; that of Darmstadt, Lutherans, and that of Rhinfelda, Roman Catholics. The prince of Hesse-Cassel, in the year 1749, embraced the Roman Catholic religion; but in 1754 drew up, and confirmed by oath, an instrument, of which all the Protestant princes are guarantors, declaring that the established religion of his dominions should continue in every respect as before, and that his children should be brought up and instructed therein. Here, as in the other Protestant Lutheran countries of Germany, are consistory, superintendents, and inspectors of the church. In the whole landgrave state are three universities, besides Latin schools and gymnasium, for the education of youth. The manufactures of Hesse are linen cloth, hats, stockings, gloves, paper, goldsmiths' wares; and at Cassel a beautiful porcelain is made. They have also the finest wool in Germany; but are reproached with want of industry, in exporting instead of manufacturing it themselves. This is supposed to have been the country of the ancient Catti, mentioned by Tacitus, &c. who in after ages, were called Chatti, Chazii, Hassi, and Hessi. The two chief branches of Cassel and Darmstadt have many rights and privileges in common, which we have not room to specify. Both of them have a seat and vote in the diet of the empire. In 1806, the greater part of Hesse Cassel was incorporated with the kingdom of Westphalia, erected by Bonaparte in favour of his brother Jerome. But in 1813 it was restored to the hereditary prince. Both Hesse Cassel and Hesse Darmstadt have received considerable additions of territory since the year 1800.

Hessian Flt, a very mischievous insect which lately made its appearance in North America; and whose depredations threaten in time to destroy the crops of wheat in that country entirely. It is, in its perfect state, a small winged insect; but the mischief it does is while in the form of a caterpillar; and the difficulty of destroying it is increased by its being as yet unknown where it deposits its eggs to be hatched, before the first appearance of the caterpillars. These mischievous insects begin their depredations in autumn, as soon as the wheat begins to shoot up through the ground. They devour the tender leaf and stem with great voracity, and continue to do so till stopped by the frost; but no sooner is this obstacle removed by the warmth of the spring, but the fly appears again, laying its eggs now, as has been supposed, upon the stems of the wheat just beginning to sprout. The caterpillars, hatched from these eggs, perforate the stems of the remaining plants at the joints, and lodge themselves in the hollow within the corn, which shows the design of disease till the ears begin to turn heavy. Then the stem breaks; and being no longer able to perform their office in supporting and supplying the ears with nourishment, the corn perishes about the time that it goes into a milky state. These insects attack also rye, barley, and
and timothy-grass, though they seem to prefer wheat. The destruction occasioned by them is described in the American Museum (a magazine published at Philadelphia) for February 1787, in the following words: "It is well known that all the crops of wheat in all the land over which it has extended, have fallen before it, and that the farmers beyond it dread its approach; the prospect is, that unless means are discovered to prevent its progress, the whole continent will be overrun—a calamity more to be dreaded than the ravages of war." This terrible insect appeared first in Long Island during the American war, and was supposed to have been brought from Germany by the Hessians; whence it had the name of the Hessian fly. From thence it has proceeded inland at the rate of about 15 or 20 miles annually; and by the year 1789 had reached 200 miles from the place where it was first observed. At that time it continued to proceed with unabating increase; being apparently stopped neither by rivers nor mountains. In the fly state it is likewise exceedingly troublesome; by getting into houses in swarms, falling into victuals and drink; filling the windows, and flying perpetually into the candles. It still continued to infest Long Island as much as ever; and in many places the culture of wheat was entirely abandoned.

The American States are likewise infested with another mischievous insect, named the Virginian wheat-fly. This, however, has not yet passed the river Delaware; though there is danger of its being gradually inveterate colder climates so as to extend its depredations to the northern colonies also. But it is by no means the same with the Hessian fly. The wheat fly is the same with that whose ravages in the Angoumois in France are recorded by M. Du Hamel; it eats the grain, and is a moth in its perfect state. On the other hand, the Hessian fly has hitherto been unknown to naturalists; it eats only the leaf and stalk; and, in its perfect state, is probably a tenthreda, like the black negro-fly of the turnip. As of late years great quantities of wheat were imported from America into Britain, it became an object worthy of the attention of government to consider how far it was proper to allow of such importation, lest this destructive insect might be brought along with the grain. The matter, therefore, was fully canvassed before the privy council; and the following is the substance of the information relative to it; and in consequence of this, the importation of American wheat was forbid by proclamation.

1. By a letter, dated 23d April 1788, Mr Bond, consul at Philadelphia, informed the marquis of Caernarthen, that there was a design to export wheat from thence to England; that the fly had made great depredations; and that there might be danger of its thus being conveyed across the Atlantic. He added, that it was not known where the eggs of the insect were deposited, though it was supposed to be in the grain. Steeping the seed in elder juice he recommended as an effectual remedy and preservative of the crop.

2. In consequence of this information, his Lordship wrote to Sir Joseph Banks, president of the royal society, desiring him to enquire as much as possible concerning the insect, both with regard to its natural history, and the method of preventing its ravages. In this research, however, that learned gentleman mistook the insect called the flying weevil for the Hessian fly. Of this insect he gives a description; but in a little time, being sensible of his mistake, he observed to the council, that his report to the marquis of Caernarthen applied not to the Hessian fly, but to a different insect, viz. the flying weevil; that the danger of importing this insect was much greater than that of the Hessian fly. The corn already brought from America, he was of opinion, might easily be examined, and a discovery made whether the fly had been there. Among other methods which might be used for this purpose, that of putting the corn among water was one, when infected grains would rise to the top, and might then be opened and examined. Some slight trials of this kind he had already made; and found manifest signs of the fly in some grains which he had opened.

3. A farther account of the insect was given by Dr Mitchel, in consequence of the above-mentioned letter from the marquis of Caernarthen. According to him it was first discovered in the year 1776, on Staten Island, and the west end of Long Island; since that time it proceeded regularly through the southern district of the state of New York, part of Connecticut; and at the time of giving the account, July 1788, had got into New Jersey. As it appeared about the time that the Hessian troops arrived, an opinion had gone abroad that they brought it along with them; but the Doctor was of opinion that it is a native animal, nourished by some indigenous plant, but which then, for the first time, came among the wheat, and found it proper food. He had seen the caterpillar, chrysalis, and fly, but never could find the egg, or discover where it is deposited. The caterpillar appears, as has already been said, in autumn, and, after having devoured the tender stalk, soon becomes a chrysalis, coloured like a flax-seed; which, being fixed between the leaf and the stalk, injures the plant by its mechanical pressure; from this proceeds the fly, which is either able of itself to sustain the intense winter frosts, or lays eggs capable of doing it. Early in the spring the caterpillar appears again, even when the heat is scarce sufficient to make the wheat grow; its ravages, therefore, are at this period particularly destructive; and it passes through its metamorphoses with such speed, as to produce a third generation while the wheat is yet tender and juicy; however, as the corn has by this time grown considerably, the third generation is not so destructive as the second. It hurts chiefly by rendering the straw weak, and liable to break down when loaded afterwards by the weight of a full ear; " and sometimes (says the Doctor) it will be infested by the fourth swarm before harvest."

4. In another communication, Sir Joseph Banks, dated July 24. 1788, he makes some general observations on the nature of those caterpillars from which flying insects proceed; and to which class both the flying weevil and Hessian fly belong. Nature, he observes, has provided against the kinds of danger these tender insects are most likely to meet with. Thus, in climates where the winters are severe, the eggs of the most tender insects resist the force of the usual frost; in seasons of remarkable severity, indeed, some are destroyed;
The young caterpillar, if hatch-
ed before its proper food be ready, will survive even weeks before it perishes for want of nourishment; and in some few instances where it is hatched in the autumn, it is directed by instinct to spin a web, in which it remains torpid and without food during the whole winter. The chrysis, though deprived of locomotion, is capable of resisting various dangers, arising from cold, heat, wet, &c.; and the length of time which the animal remains in that state is capable of very considerable extension. The complete animal, tender as it appears, and intended to exist no longer than is necessary to fulfill the business of propagation, which, in some species, is gone through in a few days, nevertheless is capable, in some instances, of enduring the utmost variation of climate; and if by accidental circumstances, the sexes are prevented from meeting, its short life is extended to many times the amount of its usual duration.

The observations on the fly made by Sir Joseph in this paper, are not different from those already related; only he dissent from the opinion of Mr. Bond, that the eggs are laid on the grain; thinking it more probable from analogy, that they are deposited on the straw; and being shaken off from thence by the strokes of the flail in thrashing, are mixed with the corn; from whence it must be very difficult to separate them. Hence he concluded, that there was an apparent and very great risk of importing the eggs along with the corn; and there was no doubt, that when one had got a footing, they would establish themselves in Britain as well as in America. It must be observed, however, that none of the grain which was examined showed any signs of this fly, its eggs, or caterpillars; such insects as were found in some diseased specimens being only the weevils common in England as well as in other countries; though some which were inspected in the month of August this year contained the chrysis of some insects, which Sir Joseph Banks was of opinion might be the flying weevil; and as he did not know whether these would revive or not, he gave it as his opinion, that the cargo in which they were found ought not to be suffered to come into the kingdom.

5. In order to procure all the intelligence that could be had concerning these insects, the duke of Dorset addressed a letter to the Royal Society of Agriculture in France, to know whether any of them exists in that country. The report of the society was accompanied with a drawing of two insects; one of which was supposed to be the caterpillar of the Hessian fly, from its attacking the wheat only, when in the herbage stage; and beginning its ravages in autumn, reappearing in the spring, and undergoing the metamorphoses already mentioned.

That insect (say the society), whose havoc has been well known in America only since 1776, does not appear to differ from it, as well as we can judge from a very short description of those which have been observed in the north, and of which the history is contained in the different volumes of the academy of sciences of Stockholm. We know that there exist in France caterpillars whose manner of living resembles that of those insects; but the mischief which they do to corn having never been considerable enough to attract the attention of government, and not having been ourselves engaged in following in detail the history of that species of caterpillar, we regret not being able to say anything particular upon that subject. The rest of the report contains an account of the flying weevil.

6. Further recourse was now had to America for information. The marquis of Caernarvon wrote to Sir John Temple at New York, the British consul general, and this gentleman applied to Colonel Morgan, who had been more curious with respect to this insect than any other person with whom he was acquainted. His account was, that the Hessian fly was first introduced into America by means of some straw made use of in package, or otherwise landed on Long Island at an early period of the late war; and its first appearance was in the neighbourhood of Sir William Howe's debarkation, and at Flat Bush. From thence it spread in every direction, but at first very slowly; and it was not till the year 1786 that they reached Mr. Morgan's farm, situated not quite 50 miles from New York. No damage was done the first season, and very little the second; but in 1788 they were materially damaged, and in some places totally destroyed all round. "The name of Hessian fly (says Mr. Morgan) was given to this insect by myself and a friend early after its appearance on Long Island." In a letter to General Washington, dated July 31st 1788, Mr. Morgan treats particularly of the insect itself, and mentions several experiments made by himself to oppose its depredations. The result of these was, that good culture of strong soil, or well-manured lands, may sometimes produce a crop of wheat or barley, when that sowed on poor or middling soil, without the other advantages, will be totally destroyed. "But (says he) as the insect lives in its aurelia state in straw and litter through the winter, I find that unmixed barn-yard manure spread on the land in the spring multiplies the fly to an astonishing degree; hence the farmer will see the necessity of mixing his yard with earth and marl in heaps; adding, where he can do it, a quantity of lime, and changing the heaps, after they have undergone the necessary fermentation, that their parts may be well incorporated, and a new digestion brought on, which will effectually destroy the insects. Rolling of wheat just before the first frosts in autumn, and soon after the last in spring, or before the wheat begins to pipe or spindel, has also a good effect. In the first place, it is a part of good culture; and, secondly, the roller crushes and destroys a great proportion of the insects. Top-dressings of lime, or of live ashes, are useful as manures, and may (when applied about the times I have mentioned as proper for rolling) be offensive to the insect; but if used in sufficient quantity to destroy them, would, I believe, destroy the wheat also. In the year 1782, a particular species of wheat was introduced on Long Island, which is found to resist the fly, and to yield a crop when all other wheats in the same neighbourhood are destroyed by it. But as this wheat has been incautiously sowed in field with other kinds, it has generally become so mixed by the farmers, as to suffer in its character in proportion to this mixture; insomuch, that some farmers, from inattention to this circumstance, have condemned it altogether. Fortunately, however, some crops have been preserved from this degeneration; and I was so lucky as to procure the whole of my last year's seed of the purest kind: the
the consequence of which has been a good crop, whilst
my neighbours fields, sowed with other kinds of wheat,
have been either totally destroyed or materially injur-
ed. I have satisfied myself that this species of wheat
was brought to New York in 1782; that a cargo of
it was then sent to Messrs. Underhill's mill to be
manufactured into flour; and that from seed saved out
of this parcel, the yellow-bearded wheat was propa-
gated. It is a generally received opinion, that the ca-
cacity of the yellow-bearded wheat to resist the attacks
of the fly is owing to the hardness or solidity of the
straw; but when we reflect that other wheats are some-
times wholly cut off in the fall of the year, and some-
times early in the spring, before the season of its run-
in to straw, we shall be induced to assign some other
cause. I cannot point out more than two distinctions
of this from other wheats. The first is in the ear,
at or after harvest. The obvious difference, then, is in
the colour of the chaff. The second can only be ob-
served by the miller, who says, "this grain requires
to be more aired and dried than any other wheat before
grinding, or it will not yield its flour so kindly, as it
is of a more oily nature; but when thus aired and
dried, the quality and quantity of its flour are equal to
that of the best white wheat."

7. In a letter to Mr. Wadsworth, dated 22d Au-
gust 1788, we are informed that the experiments
made with elder juice, recommended as a preventive
of this evil by Mr Bond, were fallacious, and had fail-
ed in every instance in 1785; but the efficacy of the
yellow-bearded wheat in resisting the attacks of the fly
is confirmed. The progress of the fly northward is
likewise confirmed; but we are told that it has disap-
peared in many places near New York, where it form-
erly abounded.

8. In consequence of the correspondence between
the marquis of Caernarvon and Mr Bond, the latter
made very particular inquiry concerning this mischie-
vous insect, and has given a better account of it than
any of the above. He says the Hessian fly (says he)
small dark fly, with thin, long, black legs; clear trans-
parent wings, extending far beyond the body of the
trunk; with small, though perceptible, horns or feelers
projecting from the snout. These I have seen appear
in size and shape like a little fly which attacks cheese
in this country, and which is very closely watched by
the keepers of dairies here, as productive of the worm
or skippers which destroy cheese; and it is remark-
able, that the worm produced from the egg of the
Hessian fly, though rather thinner and longer, bears a
strong resemblance to the worm in cheese. The horns
which evidently appear on the Hessian fly may be
provided by nature as feelers to enable them to perfo-
rerate hard grain, as well as grain in a softer state;
though I have not yet seen any person who has perceived
the egg, worm, or fly, in the grain of the wheat, or who
has found any nut, mucus, or even dust, in the dry straw,
in ricks or barns, to induce a belief that the egg is
there deposited after the harvest. One publication,
signed a Landholder, goes so far as to favour the idea
that the fly even penetrates the seed, and deposits its
eggs therein. His ideas have been condemned, as
sending to mislead others; but by no means confuted
either by reason or experiment. An observation I
made myself, gave me some cause to apprehend that the
idea mentioned in the paper signed a Landholder was
founded in fact: Upon examining a barn, in a country
wherein the fly had not been known to injure the har-
vest (though it has now certainly made its appearance
there within a few weeks), I observed in the flaws and
apertures where the wood was decayed, over which
cobwebs were woven, several of these flies entangled
in the webs, many of them dead, but some alive, and
struggling to disengage themselves; from hence I con-
cluded that there was a propensity in the fly to get in
to the mow; but whether with a purpose of mere shel-
ter and nurture, or with a view to deposit its eggs, I
am at a loss to decide."

9. Mr Bond then refers to some observations by a
Mr Potts and Mr Cleaver, which, with several other
papers on the subject, he had inclosed in his letter to
the marquis. The former was a farmer in the county
of Chester, who stacked his wheat in autumn 1788, at
a time when the fly had not been seen in or near that
county. About six or seven weeks after the harvest
he had occasion to thresh some of his wheat; and with
a view to prevent its scattering and waste, he threw
the sheaves from the rick upon a large sheet. On tak-
ing up the sheaves to carry them to the threshing-
floor, he perceived a great number of flies, answering
precisely the description of the Hessian fly, lying upon
the sheet, some dead, and others in a torpid state;
from whence he concluded that the fly had got a
footing in his rick; but from any examination either
of the straw or grain, no trace of the eggs being de-
posited was discovered. Mr Cleaver, a farmer in the
same county, apprehending that the fly might ap-
proach his neighbourhood, sowed some wheat in his
garden, which grew so as to appear above ground in
less than a fortnight, when a violent north-east wind
came on; and immediately after he perceived small
clouds of flies over and about the wheat he had sown.
He examined the grain in a few days; and found that
numbers of the flies had deposited their eggs in the
nucellus of the main stalks; the young worm then hatching
on the ground where the wheat was sown, and near it.
Many of the eggs were found in the stalk; and
some small white worms produced from other eggs
were lately discovered in the stalk very near the root
of the wheat. Wherever these worms were found,
the whole of the individual stalk was perceptibly
changed in point of colour, tending to a yellowish cast;
the top hanging down quite shrunk and wither-
ed. In some of the wheat which was carefully ex-
amined, the eggs were found within the stalk, of a
very minute size and whitish colour, with something
of a yellow tinge. In those where the worm was
formed, it was carefully wrapped up, surrounded by
different coats of the shoot in which it lay, as if it
had been skilfully and tenderly rolled up for its pre-
servation; around it the stalk was plainly eaten away,
some nearly through. The worm strongly resembles
the skimmer in cheese, somewhat thinner, and rather
longer, of a whitish cast. The ground on which this
wheat was sown was rich garden ground, high and
dry; the natural soil a strong red clay; a few of the
shots of which there were many in one cluster, in
proportion to their number, were burnt by the fly.
This was imputed to the strength of the soil, which
producing a robust powerful growth, resisted, in a
great degree, the attack of the fly, though the weak shoots suffered generally.

10. A similar account of the Hessian fly is given by Mr. Jacobs, an experienced farmer in the county of Montgomery. From his observations the egg is usually deposited in the funnel or sheath, a little above the first joint. When the eggs are laid in the autumn or spring, they are utterly destructive of the growth of the wheat; but when they are deposited shortly before the harvest, the grain or even the stalk is scarcely affected, especially in rich ground. The egg, he says, is at first very minute; it grows rapidly, becomes full and large, and turns to a brown hue, in size and colour very like a flax seed. A material difference was also perceived between rich and poor ground with respect to the ravages of the fly; but none between moist and dry soils. He is also of opinion that the yellow-bearded wheat will resist the attacks of the fly; and that rolling and feeding the wheat will be of great service.

11. A farmer in Jersey, who dates his letter from Hunterdon, Jan. 30, 1787, observes, that though the fly is supposed to advance about 15 miles annually, and neither waters nor mountains obstruct its passage, yet when disturbed, he never saw them take a flight of above five or six feet; nevertheless they are so active, that it is very difficult to catch them. They first appear towards the end of September; and soon after their eggs appear hatched, in colour and size like a flax seed; they are very low at the joints; some even in the ground; and here they harbour all winter. On their first appearance in any district, their numbers being small they seldom cut off the crop in this state, which is often the case the second or third year. In the spring, after warm weather, they again appear as a small worm, and destroy the crop. The remedies proposed by this farmer are, sowing upon rich ground, elder, and rolling. A gentleman whose account was dated on the first of November 1786, says, that their eggs resemble what is commonly called the fly-blown on meat, being very small, and only one in a place. Soon after, the other blades of wheat proceeding from the same kernel incline the first, the egg is covered, and agreeable to the usual progress of insects arrives at the state of a worm, and descends towards the root, where it consumes the tender blade, sometimes destroying the whole crop in the fall; but if, by reason of the fertility of the soil, and other concurrent circumstances, the vegetation is so rapid as to haflice their efforts, some of the latter-laid eggs, when at the worm state, entrench themselves in the ground to the depth of an inch or more, where lie had found them after severe frosts changed from a white to a greenish colour, and almost transparent; from this they proceed to the aurinal state, and thus continue probably in the ground till the spring, when the fly is again produced, which again lay eggs, and so on. As the work begins in the fall, to the total destruction of the crop. Another piece of intelligence he gives, but not from his own observation, that by feeding the wheat very close in the winter and spring, if the land is rich, it will again spring up, and the worms do not much injure the second growth. By another correspondent we are informed, that maritime places are less liable to be infested with the fly than the interior parts of the country; and therefore recommends as an experiment, that fine salt should be sprinkled on the wheat just before, or very soon after, the appearance of the fly. By others, elder has been much recommended, as well as rolling, &c., though the bearded wheat already mentioned seems to be the only effectual remedy.

12. By another communication from Mr. Morgan to the Philadelphia Society for promoting Agriculture, he informs us, that he had made himself acquainted with the fly by breeding a number of them from the chrysalis into the perfect state. The fly is at first of a white body with long black legs and whiskers, so small and motionless as not to be easily perceived by the naked eye, though very discernible with a microscope; but they soon become black and very nimble, both on the wing and feet, being about the size of a small ant. During the height of the brood in June, when 50 or 100 of the nits have been deposited on one stalk of wheat, he has sometimes discovered, even with the naked eye, some of them to twist and move on being disturbed: this is while they are white; but they do not then travel from one stalk to another, nor to different parts of the same stalk. The usual time of their spring-hatching from the chrysalis is in May.

"Those (says he) who are doubtful whether the fly is in their neighbourhood, or cannot find their eggs or nits in the wheat, may satisfy themselves by opening their windows at night and burning a candle in the room. The fly will enter in proportion to their numbers abroad. The first night after the commencement of wheat bearest, this season, they filled my dining-room in such numbers as to be exceedingly troublesome in the eating and drinking vessels. Without exaggeration I may say, that a glass tumbler from which beer had been just drunk at dinner, had 100 flies in it in a few minutes. The windows are filled with them when they desire to make their escape. They are very distinguishable from every other fly by their horns or whiskers."

With regard to the cure, it seems to be confirmed that the sowing of that called the yellow-bearded wheat can only be depended upon. The fly indeed will reside in fields of this wheat, and lay its eggs upon the stalks; but no injury was ever known to happen, except in one single instance, where it was sown in a field along with the common sort, and that in a very small proportion to it. By another account, however, we are told that the yellow-bearded wheat is equally liable to be destroyed in the autumn with the common kind; so that the only method of securing the crop is by sowing it late in the season, when the fly is mostly over.

13. The utmost pains were taken by the British government to find out whether this destructive insect exists in Germany or any of the northern countries of Europe; but from the accounts received, it appears that it has not hitherto been observed, or at least if it exists, the damage done by it is too inconsiderable to attract notice.

14. From the whole correspondence on this subject, which from the abridgment just now given of it is evidently somewhat discordant, Sir Joseph Banks drew up a report for the privy council, dated March 2, 1780, in which he states the following particulars: 1. The appearance of the fly in Long Island was first observed in 1779. We must suppose this to be meant, that
that its destructive effects became then first perceivable; for it seems undoubtedly to have been known in the year 1776. 2. The opinion of Colonel Morgan, that it was imported by the Hessians, seems to be erroneous, as no such insect can be found to exist in Germany or any other part of Europe. 3. Since its first appearance in Long Island it has advanced at the rate of 15 or 20 miles a year, and neither waters nor mountains have impeded its progress. It was seen crossing the Delaware like a cloud, from the Fall's Township to Makefield; had reached Saratoga 200 miles from its first appearance, infesting the counties of Middlesex, Somerset, Huntington, Morris, Sussex, the neighbourhood of Philadelphia, all the wheat counties of Connecticut, &c. committing the most dreadful ravages; attacking wheat, rye, barley, and timothy-grass. 4. The Americans who have suffered by this insect, speak of it in terms of the greatest horror. In Colonel Morgan's letter to Sir John Temple, he uses the following expressions. "Were it to reach Great Britain, it would be the greatest scourge that island ever experienced; as it multiplies from heat and moisture, and the most intense frosts have no effect on the egg or aurelia. Were a single straw, containing the insect, egg, or aurelia, to be carried and safely deposited in the centre of Norfolk in England, it would multiply in a few years, so as to destroy all the wheat and barley crops of the whole kingdom. There cannot exist such an atrocious villain as to commit such an act intentionally. 5. No satisfactory account of the mode in which this insect is propagated has hitherto been obtained. Those which say that the eggs are deposited on the stalk from six or eight to 50, and by their growth compress and hinder the stalk from growing, are evidently erroneous, and the authors of them have plainly mistaken the animal itself for its eggs. It is sufficient to remember, that eggs do not grow or increase in bulk, to prove that what they observed was not eggs. 6. The landholder's opinion, that the eggs are deposited on the ripe grains of wheat, though contradicted by Colonel Morgan, is not disproved, as the colonel advances no argument against it. 7. A letter dated New York, September 1, 1786, says, that the eggs are deposited on the young blade, resembling what we call a fly-blown in meat; very small, and but one in a place: but this, though the only natural mode of accounting for the appearance of the insect, had it been true, must undoubtedly have been confirmed by numbers of observations. 8. Even though this should be found hereafter to be the case, there will still remain a danger of the aurelias being beaten off by the flail from the straw in threshing the wheat, and imported into Britain along with it; the presence of these flies in barns having been fully proved by the observations of Messrs Potts and Bond. 9. None of the remedies proposed against this destructive insect have been in any degree effectual, excepting that of sowing the yellow-bearded wheat; the straw of which is sufficiently strong to resist the impression of the insect, and even if its eggs are deposited upon it, receives little injury in point of produce in grain: this provides, however, no remedy for the loss of the barley crop, or for that which must be incurred by sowing the yellow-bearded wheat on lands better suited by nature for the produce of other kinds: it appears also that this very kind is liable to degenerate, and probably from a different cause than that proposed by Colonel Morgan, viz. the mixture with common wheat. 9. Though the Agricultural Society at Philadelphia, as well as Colonel Morgan, have declared their opinions decisively, that no danger can arise from wheat imported into Britain, as the insect has no immediate connection with the grain; yet with nearly, if not exactly the same materials before him which these gentlemen were furnished with, Sir Joseph Banks could not avoid drawing a conclusion directly contrary; and he concludes his report with the words of Mr Bond in a letter to the marquis of Caermarthan. "Satisfactory as it would be to my feelings to be able to say with precision, that I apprehend no danger of extending the mischief by seed, my duty urges me to declare, that I have not heard nor seen any conclusive fact by which I could decide on a matter of such importance; and till that test occurs, the wisdom of guarding against so grievous a calamity is obvious." On the 27th of April the same year, another paper, by way of appendix to the foregoing, was given in by Sir Joseph Banks. In this he again observes, that none of the descriptions of any European insect hitherto published answer exactly to the Hessian fly. In a letter from Mr Bond to the marquis of Caermarthan, he mentions another kind of insect in the state of Maryland, called by way of eminence the fly; and which in some things resembles the Hessian fly, though it cannot be accounted the same. It makes its way into the mow, and bites the end of the grain perceptibly, and no doubt deposits its eggs in the grain itself; since it has been observed, that wheat recently threshed, and laid in a warm dry place, will soon be covered with an extreme clammy crust, which binds the wheat on the surface together in such a way as to admit its being lifted in lumps; but the wheat beneath will not be hurt to any considerable depth. Such is the quality of this fly, that if the hand be inserted into the heap, affected by it, the fingers are immediately raised; and the farmers and slaves, riding upon bags of this infected wheat, never fail to be severely blistered thereby. "This insect (says he) is called in Maryland the Revolution fly, by the friends of the British government; but from all I can learn it is not the same insect which originated on Long Island, and is called the Hessian fly (by way of opprobrium) by those who favoured the revolution. All the papers I have read on the Hessian fly are very inaccurate, not to say contradictory; and I am convinced it is by no means a settled point at this moment, in what manner and place the eggs of these insects are deposited. The policy which induced government to open the ports being founded on an appearance of a scarcity of corn, that evil may be remedied by the admission of flour instead of grain; and though the countries from whence the flour is carried will have the advantage of the manufacture, still that cannot be reckoned as an object, when opposed in the scale to an evil of such immense magnitude as the introduction of so destructive an insect may occasion. The ravages there are beyond ruinous. Many farmers have had their crops so completely cut off as to be left without bread-corn or even seed-corn. If the measure of confining the importation to flour alone should be adopted, great attention
attention should be paid to the quality of the flour admitted into the British ports. An infinite deal of the wheat of the last harvest is of a very wretched quality; and stratagems will be practised to give an extensive vent to so essential a staple of the middle states of America.

In another letter to the same nobleman, Mr Bond expresses himself to the following purpose. "I have not been able to collect any decided information which fixes the essential point, how far the insect may be communicated by seed. It is a matter at this time quite undecided here; nor have I heard or observed any very conclusive reason to suppose that the fly makes its way generally into barns and stacks. A very intelligent farmer in the county of Bucks, informed me that it was the prevailing opinion there, and so I found it, that the fly did not, either in the field or in the mound, affect the grain of the wheat: a neighbour of his, in threshing the little wheat he had saved last harvest, observed the fly rise from the straw in great numbers wherever it was struck by the flail; but though it was at first presumed that the fly had insinuated itself into the mow for the purpose of depositing its eggs in the grain or in the straw, no trace of the egg could be discovered from the appearance of any mucus or dust, either in the grain or in the straw; hence it was inferred that all the mischief was done in the field."

HESYCHIUS, the most celebrated of all the ancient Greek grammarians whose works are now extant, was a Christian; and, according to some, the same with Hesychius patriarch of Jerusalem, who died in 659. He wrote a Greek lexicon; which, in the opinion of Casaubon, is the most learned and useful work of that kind produced by the ancients. Schrevelius published a good edition of it in 1669, in 4to, with notes; but the best is that of John Alberti, printed at Leyden in 1746, in two volumes.

HETEIARCH, HETEIARCHA, in antiquity, an officer in the Greek empire, whereof there were two species; the one called simply hetiarch, and the other great hetiarch, who had the direction of the former.

The word is Greek, ἱτείραρχος, formed of ἱτείρας, socius, "companion, ally," and αρχή, imperium, "command." Their principal function was to command the troops of the allies; besides which, they had some other duties in the emperor's court, described by Codin, De Officiis, cap. 5. No 30, 31, 32, 37.

HETEROCLITE, HETEROCLITON, in Grammar, an irregular or anomalous word, which either in declension, conjugation, or regimen, deviates from the ordinary rules of grammar. The word is Greek, ἱτείραρχος; formed of ἱτείρας, alter, "another, different," and αρχή, "command.

Heterocliton is more peculiarly applied to nouns which vary or are irregular in point of declension; having fewer cases, numbers, &c. than ordinary; or that are of one declension in one number, and another in another: as Hoc cas, casis; hoc casum, pasum.

HETEROLOGY, in Political Theology, something that is contrary to the faith or doctrine established in the true church. The word is formed of the Greek ἱτείραρχος; a compound of ἱτείρας, "alter," and αρχή, "opinion." Thus, we say a heterodox opinion, a heterodox or Heterodox divine, &c. The word stands in opposition to orthodos.

HETEROGENEITY, in Physics, the quality or disposition which denominates a thing heterogeneous. The word is also used for the heterogeneous parts themselves: in which sense, the heterogeneities of a body are the same thing with the impurities thereof.

HETEROGENEOUS, or HETEROGENEAL, literally imports something of a different nature, or that consists of parts of different or dissimilar kinds; in opposition to homogenous. The word is Greek; formed of ἑτερός, alter, "different," and γένος, genus, "kind;" q. d. composed of different kinds of parts.

Heterogeneous Light, is by Sir Isaac Newton said to be that which consists of rays of different degrees of refrangibility. Thus the common light of the sun or clouds is heterogeneous, being a mixture of all sorts of rays.

HETEROGENEOUS Nouns, one of the three variations in irregular nouns; or such as are of one gender in the singular number, and of another in the plural.—Heterogenous, under which are comprehended mixed nouns, are sixfold. 1. Those which are of the masculine gender in the singular number, and neuter in the plural; as, hic taraxus, haec tartara. 2. Those which are masculine in the singular number, but masculine and neuter in the plural; as, hic locus, hic loci et haec loca. 3. Such as are feminine in the singular number, but neuter in the plural; as, haec carbasus, et haec carbasus. 4. Such nouns as are neuter in the singular number, but masculine in the plural; as, hoc caelestum, hi caeli. 5. Such as are neuter in the singular, but neuter and masculine in the plural; as, hoc rastrum, hi rastris, et haec rastra. 6. Such as are neuter in the singular, but feminine in the plural number; as hoc epulum, haec epula.

Heterogeneous Quantities, are those which are of such different kind and consideration, as that one of them, taken any number of times, never equals or exceeds the other.

Heterogeneous Surds, are such as have different radical signs; as $\sqrt{a}$, and $\sqrt{b}$; $\sqrt[3]{a}$, and $\sqrt[3]{b}$.

HETEROSCIO, in Geography, a term of relation, denoting such inhabitants of the earth as have their shadows falling but one way, as those who live between the tropics and polar circles; whose shadows at noon in north latitude are always to the northward, and in south latitude to the southward.

HETH, the father of the Hittites, was the eldest son of Canaan (Gen. x. 15.), and dwelt southward of the promised land, at Hebron or thereabouts. Ephron, an inhabitant of Hebron, was of the race of Heth, and this whole city in Abraham's time was peopled by the children of Heth. There are some who maintain that there was a city called Heth, but we find no footsteps of it in the Scripture.

HETURIA, or ETRURIA, a celebrated country of Italy, to the west of the Tyber. It originally contained 12 different nations, which had each their respective monarch. Their names were Veientes, Cluci, Perusini, Cortonesini, Arretini, Vetulini, Volaterrani, Rusellani, Volscini, Tarquinii, Faliscii, and Cameretani. The inhabitants were particularly famous for their superstition and strict confidence in omens, dreams, auguries.
Hewson, William, a very ingenious anatomist, was born in 1739. He became assistant to Dr Hunter, and was afterwards in partnership with him; but on their disagreement, read anatomical lectures at his own house (in which he was seconded by Mr Falconer).
HEXASTYLE, in Architecture, a building with six columns in front.

HEXHAM, a town of Northumberland, situated near the conflux of the north and south Tyne. It is commonly supposed to be the Alecudunnum of the Romans, where the first cohort of the Spaniards were in garrison. It was made a bishop’s see by Ecdeldreda, wife of King Egfred, in the year 675. Its first bishop St Wilfred built here a most magnificent cathedral and monastery, and it was possessed by seven bishops successively; but being very much infested by the Danes, the see was removed to York. The town and priory were destroyed by the Scots in 1296, and pillaged again in 1346. There was a remarkable and bloody battle fought near this town between the houses of Lancaster and York, wherein the former were defeated, chiefly by the extraordinary bravery and conduct of John Nevil, Lord Montague, who was for that reason created earl of Northumberland. The present town is more populous, and the streets are narrow, with ill built houses. The market-place near the centre of the town is a spacious square, and is supplied by a fountain with water. Among the remains of ancient structures is a gateway of ancient architecture, leading to the priory, but of a much older date. There are two ancient towers in the town, one of which is used as a sessions-house, and was formerly an exploratory tower; the other is on the top of a hill towards the Tyne, of remarkable architecture, which has been much higher than at present, and has two dungeons within it, besides several chambers with very little narrow windows. The town has a charity or grammar-school. It was in 1571 annexed to the county of Cumberland: but only in civil matters; for in its ecclesiastical jurisdiction it is still a peculiar belonging to the archbishop of York; and the common people still call the neighbouring county Hexhamshire. It is a corporation governed by a bailiff, and contained 3518 inhabitants in 1811.

HEYDON, a small well-built town in the east riding of Yorkshire, in that part called Holderness, seated on a river that falls into the Humber. It has now but one church, though there are the remains of two more; and had formerly a considerable trade, which is now lost, on account of its being so near Hull. It sends two members to parliament. Population 780 in 1811. W. Long. o. 55. N. Lat. 53° 46'.

HEYDON, John, who sometimes assumed the name of Eugenius Theodidactus, was a great pretender to skill in the Rosicrucian philosophy and the celestial signs, in the reign of King Charles I.; and wrote a considerable number of chemical and astrological works, with very singular titles. This ridiculous author was much resorted to by the duke of Buckingham, who was infatuated with judicial astrology. He employed him to calculate the king’s and his own nativity, and was assured that his stars had promised him great things. The duke also employed Heydon in some treasonable and seditious practices, for which he was sent to the Tower. He lost much of his former reputation by telling Richard Cromwell and Thurloe, who went to him disguised like cavaliers, that Oliver would infallibly be hawked by a certain time; this period, however, he outlived several years.

HELIN, Dr PETER, an eminent English writer,
HEYWOOD was born at Burford, in Oxfordshire, in 1600. He studied at Hart Hall, Oxford; where he took his degrees in arts and divinity, and became an able geographer and historian. He was appointed one of the chaplains in ordinary to King Charles I.; was presented to the rectory of Hemingford in Huntingdonshire, made a prebendary of Westminster, and obtained several other livings: but of these he was deprived by the parliament, who also sequestered his estate; by which means he and his family were reduced to great necessity. However, upon the Restoration, he was restored to his spiritualities; but never rose higher than to be subdean of Westminster. He died in 1662; and was interred in St. Peter's church in Westminster, where he had a neat monument erected to his memory. His writings are very numerous: the principal of which are, 1. Microcosmus, or a description of the Great World. 2. Cosmographia. 3. The history of St. George. 4. Ecclesia Vindicata, or the church of England Justified. 5. Historical and Miscellaneous Tracts, &c.

HEYNE, CHRISTIAN GOTOZ, a late eminent German classical scholar. See SUPPLEMENT.

HEYWOOD, JOHN, an English dramatic poet, was born at North-Mims, near St. Alban's in Hertfordshire, and educated at Oxford. From thence he retired to the place of his nativity; where he had the good fortune to become acquainted with Sir Thomas More, who, it seems, had a seat in that neighbourhood. This patron of genius introduced our comic poet to the princess Mary, and afterwards to her father Henry, who, we are told, was much delighted with his wit and skill in music, and by whom he was frequently rewarded. When his former patroness, Queen Mary, came to the crown, Heywood became a favourite at court, and continued often to entertain her majesty, exercising his fancy before her, even to the time that she lay languishing on her deathbed. On the accession of Elizabeth, being a zealous Papist, he thought fit to decamp, with other favourites of her deceased majesty. He settled at Mechlin in Flanders, where he died in the year 1565—John Heywood was a man of great genius; and it was his poetical talents by any means extraordinary; but he possessed talents of more importance in the times in which he lived, namely, the talents of a jester. He wrote several plays; 500 epigrams; A Dialogue in Verse concerning English Proverbs; and The Spider and Fly, a Parable, a thick 4to. Before the title of this last work is a whole length wooden print of the author; who is also represented at the head of every chapter in the book, of which there are 77. He left two sons, who both became Jesuits and eminent men: viz. Ellis Heywood, who continued some time at Florence under the patronage of Cardinal Polo, and became so good a master of the Italian tongue, as to write a treatise in that language, entitled Il Moro; he died at Louvain about the year 1572. His other son was Jasper Heywood, who was obliged to resign a fellowship at Oxford on account of his immorality; he translated three tragedies of Seneca, and wrote various poems and devotions. He died at Naples in 1597.

Heywood, Ellis, a voluminous novel writer; of whose name more is known than that her father was a tradesman, and that she was born about the year 1696. In the early part of her life, her pen, whether to gratify her own disposition or the prevailing taste, dealt chiefly in licentious tales, and memoirs of personal scandal: the celebrated Atlantia of Mrs. Manley served her for a model; and The Court of Carinonia, The new Utopia, with some other pieces of a like nature, were the copies her genius produced. She also attempted dramatic writing and performance, but did not succeed in either. Whatever it was that provoked the resentment of Pope, he gave full scope to it by distinguishing her as one of the prizes to be gained in the games introduced in honour of Dullness, in his Dunciad. Nevertheless, it seems undeniable, that there is much spirit, and much ingenuity, in her manner of treating subjects, which the friends of virtue may perhaps wish she had never meddled with at all. But, whatever offence she may have given to delicacy or morality in her early works, she appears to have been soon convinced of, and endeavoured to atone for in the latter part of her life; as no author then appeared a greater advocate for virtue. Among her riper productions may be specified. The Female Spectator, 5 vols.; Th. History of Miss Betty Thoughtless, 4 vols.; Jenny and Jenny Jessamy, 3 vols.; The Invisible Spy, 3 vols.; with a pamphlet, entitled A Present for a Servant Maid. She died in 1759.

HIAMEN, or Emouy. See Emouy.

HIATUS, properly signifies an opening, chasm, or gap; but it is particularly applied to those verses where one word ends with a vowel, and the following word begins with one, and thereby occasions the mouth to be more open, and the sound to be very harsh.

The term hiatus is also used in speaking of manuscripts, to denote their defects, or the parts that have been lost or effaced.

HIBISCUS, SYRIAN MALLOW, a genus of plants belonging to the monodelphus class, and in the natural method ranking under the 37th order, Columnifera. See BOTANY INDEX.

HICETAS of Syracuse, an ancient philosopher and astronomer, who taught that the sun and stars were without characters, and that the earth moved round them. This is mentioned by Cicero, and probably gave the first hint of the true system to Copernicus. He flourished 344 B.C.

HICKES, GEORGE, an English divine of extraordinary parts and learning, was born in 1642. In 1681 he was made king's chaplain, and two years after dean of Worcester. The death of Charles II. stopped his farther preferment; for though his church principles were very high, he manifested too much zeal against Popery to be any favourite with James II. On the revolution, he with many others was deprived for refusing to take the oaths to King William and Queen Mary; and soon after, Archbishop Sancroft and his colleagues considering how to maintain episcopal succession among those who adhered to them, Dr. Hickes carried over a list of the deprived clergy to King James; and with his sanction a private consecration was performed, at which it is said Lord Clarendon was present. Among others, Dr. Hickes was consecrated suffragan bishop of Thetford, and died in 1715. He wrote, 1. Institutiones Grammaticae Anglo-Saxonicae, et Musico-Criticæ. 2. Antiqua literature septentrionalis. 3. Two treatises, one of the Christian priesthood, the other of the dignity of the
HID [459]

Hickes

Hidalgo

Hickup, or Hicough, a spasmodic affection of the stomach, oesophagus, and muscles subervient to deglutition, arising sometimes from some particular injury done to the stomach, oesophagus, diaphragm, &c. and sometimes from a general affection of the nervous system. See Medicine Index.

HIDAGE (Hidalgum), was an extraordinary tax payable to the kings of England for every hide of land. This taxation was levied not only in money, but in provision, armour, &c. and when the Danes landed in Sandwich in 994, King Ethelred taxed all his lands by hides; so that every 310 hides found one ship furnished, and every eight hides furnished one jack and one saddle, to arm for the defence of the kingdom, &c. Sometimes the word hidage was used for the being quit of that tax; which was also called hidage; and interpreted, from the Saxon, "a price or ransom paid to save one's skin or hide from beating."

HIDALGO, in modern history, a title given in Spain to all who are of a noble family.

The Hidalgos claim a descent from those valiant soldiers who retired into Castile, and the mountains of Asturias, and other remote parts of Spain, on the invasion of the Moors, where having fortified themselves, they successively descended into the plains, in proportion to the success of their arms; from the notoriety of their persons, or the lands they became possessed of, they acquired the appellation of Hidalgos notables. Hidalgo de solar conocido, or de casa solariega. Of these, according to Hernando Mexia, there are three sorts; the first being lords of places, villages, towns, or castles, from whence they took their surnames, as the Guzmanas, Mendoza, Laras, Guivras, and others; the second, who recovered any fortress from the Moors, as the Ponces de Leon, and others; and the third sort from the places where they resided, or held jurisdiction, as Rodrigo de Navarez was called of Antequara, from being alcaide there. But this definition is not considered as exact or conclusive by Otalora, another civilian, who says that the true meaning of Hidalgo de solar conocido is explained by the laws of Castile to be a well known mansion or possession, the nature of which is particularly explained in the laws of Fardilas, lib. v. tit. 35. which describe three sorts of tenures, called Devita, Solariega, and Behetría. By the first, lands are devised by the ancestor; solar is a tenure upon another person's manor, and obliges the owner to receive the lord of the fee when necessity obliges him to travel; and Behetría is in the nature of an alodium. In proportion as these Aborigines gained ground on the Moors, and increased in their numbers, many private persons distinguished themselves by their valour, and obtained testimonies of their services called cartas de merced, which served them as a foundation of their birth and good descent, without which documents their posterity could not make it appear; and if from a lapse of time, or other unavoidable accidents, such proof should happen to be lost or destroyed, the law affords them a remedy under these circumstances, by a declaration importing, that such persons as are supposed to have had such certificates, may be relieved by making it appear that their ancestors, time immemorial, have always been held and reputed as Hidalgos, and enjoyed the privileges of such, form a strong presumption in their favour; the possession of land having equal force to any other document; which is fully set forth in the Pragmatica de Cordova. To these executory letters are granted, cartas executorias, expressive of their privileges; and for the better regulation of these matters, proper officers are appointed in the chancery courts, called alcaldes de los hidalgos, who ought to be hidalgos themselves, and hold jurisdiction in these cases, and no others; but even here innovations have taken place; for as these grants flow from the sovereign, who is the fountain of honour, some are declared Hidalgos de sangre, by right of descent, and others de privilegio, by office, in which the will of the sovereigns has made amends for any deficiency of blood.

There is a set of people near Segovia, at a place called Zamarramala, who are exempt from tribute on account of the care they take in sending proper persons every night to the castle of Segovia to keep sentinels; one cries out, Vela, vela, kai, and the other blows a horn, from whence they have been titled hidalgos by the horn. In Catalonia those gentlemen who are styled Hombre de Pareja, are considered the same as hidalgos in Castile, and were so called from the word parejar, to equip, this name being given as a distinction by Borela, the fourth count of Barcelonas, at the siege of that city, in 965, who sumonning all his vassals to come to his assistance against the Moors, nine hundred horsemen were mounted and equipped joined him, and with their aid he took the city; and this appellation has been given in honourable remembrance of this loyal acton.

These noble hidalgos enjoy many privileges and distinctions; of which the following are the principal:

1. The first and greatest privilege which they hold by law, is to enjoy all posts of dignity and honour in the church and state, with liberty, when churchmen, of having a plurality of benefices. They are qualified for receiving all orders of knighthood, and are to be preferred in all embassies, governments, and public commissions.

2. When they are examined as witnesses in civil and criminal cases, their depositions are to be taken in their own houses, without being obliged to quit them to go to those of others.

3. In all churches, procession, and other public acts or assemblies, they are to have the next place of honour and precedence after the officers of justice, conforming themselves to particular customs.

4. They are not obliged to accept of any challenge for combat, supposing such were allowed of, but from those who are their equals.

5. Though it is forbidden to guardians to purchase the estates of minors, this does not extend to Hidalgos, in whom the law does not suppose any fraud, and they may purchase them publicly.

6. They are permitted to be seated in courts of justice in presence of the judges, from the respect and honour due to them. They have also seats in the courts of chancery, in consideration of their birth, which gives them a right to be near the persons of princes.
7. Their persons are free from arrest for debt, nor can any attachment be laid on their dwelling-houses, furniture, apparel, arms, horses, or mules in immediate use: nor can they make a cession of their estates, nor be distressed in suits of law, farther than their circumstances will admit of, but are to be allowed a reasonable and decent maintenance for their support.

8. In cases of imprisonment for criminal matters, they are to be treated differently from others. They are generally confined to their own houses with a safe-guard, or under arrest upon their honour, or allowed the city, or town they live in, and in particular cases are sent into castles.

9. When punishments are inflicted for criminal cases they are to be less severe than to others; as they are to suffer ignominious punishments, such as public shame, whipping, gallies; nor are they to be hanged, but beheaded, excepting in cases of treason or heresy. In cases that do not imply a corporal punishment but a pecuniary one, they are treated with more rigour, and pay a larger fine than others.

10. They are not to be put to the rack or torture, excepting for such heinous crimes as are particularly specified by the laws.

11. When there are title-deeds or other writings or papers in which two or more persons have an equal right or property, and require a particular charge, they are to be given up by preference to the custody of an Hidalgo, if any of the parties are such.

12. The daughter of an Hidalgo enjoys every privilege of her birth, though married to a commoner; and a woman who is not an Hidalgo enjoys all these privileges when she is a widow, following the fortune of her husband.—But if the widow is an Hidalgo, and the late husband was a commoner, she falls into the state of her husband after his death, though she had the privileges of her birth during his life.

13. They are free from all duties, called Pechos, Pedidos, Monedas, Marteniegas, Contribuciones, as well royal as civil, and all other levies of whatever kind they may be, with a reserve for such as are for the public benefit, in which they are equally concerned, such as the repairing the highways, bridges, fountains, walls, destruction of locusts, and other vermin.

14. They are free from personal service, and from going to the wars, excepting when the king attends in person; even then they are not to be forced, but invited, and acquainted that the royal standard is displayed.

15. No persons whatever can be quartered upon, or lodged in their houses, except when the king, queen, prince or infant are on the road, as in such cases even the houses of the clergy are not exempt.

16. They cannot be compelled to accept of the office of receiver of the king's rents, or any other employment which is considered as mean and derogatory to their dignity and rank.

17. By a particular custom confirmed by royal authority, in that part of Castile beyond the Ebro, bastards succeed to their parents, and enjoy their honours, contrary to the royal and common law.

18. If a lady, who marries a commoner, should be a queen, duchess, marchioness, or countess (for they have no barons in Castile), she not only does not lose her rank, but conveys her titles to her husband, who hold them in right of his wife.

These are the general privileges which the Hidalgos enjoy; there are some others of less consequence, as well as particular grants to certain persons and families. An ancient and ridiculous custom is said to be observed by noble ladies who are widows of plebeians, in order to recover their birthright, for which purposes they carry a pack saddle on their shoulders to their husband's grave, then throwing it down and striking it three times, say, 'Villain, take thy villainy, for I will abide by my nobility.' and then they recover their privileges again.

HIDE, the skin of beasts; but the word is particularly applied to those of large cattle, as bullocks, cows, horses, &c.

Hides are either raw or green, just as taken off the carcass; salted, or seasoned with salt, alum, and salt-petre, to prevent their spoiling; or curried and tanned. See TANNING.

HIDE OF LAND; was such a quantity of land as might be ploughed with one plough within the compass of a year, or as much as would maintain a family; some call it 60, some 80, and others 100 acres.

HIDE-BOUND, a disease in the skin of horses. See FARRIERY.

HIERACIUM, HAWKWEEDE, a genus of plants belonging to the syngenesia class; and in the natural method ranking under the 49th order, Compositae. See BOTANY INDEX.

HIERACITES, in church-history, Christian heretics in the third century; so called from their leader Hierax, a philosopher of Egypt: who taught that Melchisedeck was the Holy Ghost, denied the resurrection, and condemned marriage.

HIERANOSIS, or MORBUS SACER. See MEDICINE INDEX.

HIERA PICRA. See PHARMACY INDEX.

HIERAPOLIS, in Ancient Geography, a town of Phrygia, abounding in hot springs; and having its name from the number of its temples. There are coins exhibiting figures of various gods who had temples here. Of this place was Epicetus the Stoic philosopher.—It is now called Pambouk; and is situated near the Scamander, on a portion of Mount Mavorsis, distant six miles from Laodicea.—Its site appears at a distance as a white lofty cliff; and upon arriving at it, the view which it presents is so marvellous (says Dr. Chandler), that the description of it, to bear even a faint resemblance, ought to appear romantic. Dr. Chandler's description is as follows:

"The vast slope which at a distance we had taken for chalk, was now beheld with wonder, it seeming an immense frozen cascade, the surface wavy, as of water at once fixed, or in its headlong course suddenly petrified. Round about us were many high, bare, stony ridges; and close by our tent, one with a wide basis, and a slender rill of water, clear, soft, and warm, running in a small channel on the top. A woman was washing linen in it, with a child at her back; and, beyond were cabins of the Turcomans, standing distinct, much nearer than any we had seen, each with poultry feeding, and a fence of reeds in front.

"It is an old observation, that the country about the Meander,
Hierapolis. Meander, the soil being light and friable, and full of salts generating inflammable matter, was undermined by fire and water. Hence it abounded in hot springs, which, after passing under ground from the reservoirs appeared on the mountain, or were found bubbling up in the plain or in the mud of the river; and hence it was subject to frequent earthquakes; the nitrous vapour compressed in the cavities, and subdued by heat for fermentation, bursting its prison with loud explosions, agitating the atmosphere, and shaking the earth and waters with a violence as destructive as it is destructive; and hence, moreover, the pestilential grottoes, which had subterraneous communication with each other, derived their noisome effluvia; and serving as small vents to these furnaces or hollows, were regarded as apertures of hell, as passages for deadly fumes rising up from the realms of Pluto. One or more of the mountains perhaps has burned. It may be suspected, that the surface of the country has in some places been formed from its own bowels: and in particular, it seems probable, that the hill of Luodicea was originally an eruption.

The hot waters of Hierapolis have produced most extraordinary phenomena, the cliff, which is one entire incrustation. They were anciently renowned for this species of tempestation. It is related, that they changed so easily, that being conducted about the vineyards and gardens, the channels became long fences, each a single stone. They produced the ridges by our tent. The road up to the ruins, which appears as a wide and high causeway, is a petrification; and overlooks many green spots, once vineyards and gardens, separated by partitions of the same material. The surface of the flat, above the cliff, is rough with stone and with channels, branching out in various directions, a large pool overflowing and feeding the numerous rills, some of which spread over the slope as they descend, and give to the white stony bed a humid look, resembling salt or driven snow when melting. This crust, which has no taste or smell, being an alkaline substance, will ferment with acids; and Pecorini relates, that trial of it had been made with spirit of viuval. The waters, though hot, were used in agriculture.

Tamerlane, when he invaded this country, encamped for the summer at Tanaenzik, where many of his men were destroyed by drinking of a spring which stagnated and perished. The Turkish name Pambock signifies cotton; and, it has been said, refers to the whiteness of the incrustation.

The shepherd-poet of Smyrna, after mentioning a cave in Phrygia sacred to the Nymphs, relates, that there Luna had once descended from the sky to Ennymion, while he was sleeping by his herds; that marks of their bed were then extant under the earth; and that in the thicket around it the milk of cows had been spilt, which men still beheld with admiration (for such was the appearance if you saw it very far off); but that from thence flowed clear or warm water, which in a little while concreted round about the channels, and formed a stone pavement. The writer describes the cliff of Hierapolis, if I mistake not, as in his time; and has added a local story, current when he lived. It was the genius of the people to unite fiction with truth; and, as in this and other instances, to dignify the tales of their mythology with fabulous evidence taken from the natural wonders in which their country abounded.

We ascended in the morning to the ruins, which are on a flat, passing by sepulchres with inscriptions, and entering the city from the east. We had soon the theatre on our right hand, and the pool between us and the cliff. Opposite to it, near the margin of the cliff, are the remains of an amazing structure, once perhaps baths, or, as we conjectured, a gymnasium; the huge vaults of the roof striking horror as we rode underneath. Beyond it is the mean ruin of a modern fortress; and farther on are vast edifices of buildings, several of them leaning from their perpendicular, the stones distorted, and seeming every moment ready to fall; the effects and evidences of violent and repeated earthquakes. In a recess of the mountain on the right hand is the area of a stadium. Then again sepulchres succeed, some nearly buried in the mountain side, and one, a square building, with an inscription in large letters. All these remains are plain, and of the stone created by the waters. The site has been computed about two hundred paces wide and a mile in length.

After taking a general survey, we returned to the theatre, intending to copy inscriptions, and examine more particularly as we changed our station. We found this a very large and sumptuous structure, and the least ruined of any we had seen. Part of the front is standing. In the heap which lies in confusion, are many sculptures well executed in baso relievo: with pieces of architrave inscribed, but disjointed; or so encumbered with massive marbles, that we could collect from them no information. The character is large and bold, with ligatures. The marble seats are still unremodeled. The numerous ranges are divided by a low semicircular wall, near mid way, with inscriptions on the face of it, but most illegible. I copied a short but imperfect one, in which Apollo Archegetes or The Leader is requested to be propitious. In another compartment, mention is made of the city by its name Hierapolis; and on a third is an encomium in verse, which may be thus translated, 'Hail, golden city Hierapolis, the spot to be preferred before any in wide Asia; revered for the rills of the Nymphs; adorned with splendor.' The Nymphs presided over springs and fountains.

After attentively viewing them, and considering their height, width, and manner of arrangement, I am inclined to believe, that the ancient Asiatics sat at their plays and public spectacles like the modern, with their legs crossed or gathered under them; and it is probable upon carpets.

The waters of Hierapolis, were surprisingly attempted for tinging wool, with a colour from roots rivaling the more costly purples; and were a principal source of the riches of the place. The company of dyers is mentioned in the inscription on the square building among the sepulchres. The heroum or monument was to be crowned by them with garlands or festoons of flowers. The springs flowed so copiously, that the city was full of spontaneous baths; and Apollo, the tutelar deity of the Hieropolitans, with Asclepius and Hygeia, on their medals, bear witness to the medicinal virtues which they possess. The people, in some of their inscriptions, are styled the most splendid, and the senate the most powerful.

The
The pool before the theatre has been a bath, and marble fragments are visible at the bottom of the water, which is perfectly transparent, and of a briny taste.

Hierapolis was noted, besides its hot waters, for a plutonium. This was an opening in a small brow of the adjacent mountain, capable of admitting a man, and very deep, with a square fence before it, inclining about half an acre; which space was filled with black thick mist, so that the bottom could be scarcely discerned. The air, to those who approached it, was innocent on the outside of the fence, being clear of the mist in serene weather, it remaining then within the boundary; but there death abode. Bulls, as at Nysa, dropped down, and were dragged forth without life; and some sparrows which Strabo let fly instantly fell senseless. But eunuchs, the priests of Magna Mater, or Cybele, could go in quite to the aperture, lean forward, or enter it unharmed; but they held their breath, as their visages testified, and sometimes issued in danger of suffocation. Strabo, the relation, was in doubt whether all eunuchs could do this, or only they of the temple; and whether they were preserved by Divine Providence, as in cases of enthusiasm, or were possessed of some powerful antidotes. But it is likely this mist was the condensed steam of the hot waters, made noxious by the qualities of the soil; and that the whole secret of the priests consisted in carrying their faces high in the air, as another spectator has observed they always did; and in avoiding respiration when they stooped. I had hoped the description of this spot would have enabled me to find it, but I searched about for it unsuccessfully.

We descended to our tent at the approach of evening by a steep track down the cliff, beginning beyond the pool, in which we also bathed with pleasure, on the side next the gymnasium. Our way was often rough and slippery, resembling ice, and our horses with difficulty preserved their footing. When arrived at our tent, I renewed my inquiries for the plutonium; and an old Turk, with a beard as white as snow, told me he knew the place, that it was often fatal to their goats; and accounting for the effect, said, it was believed to be the habitation of a demon or evil spirit. We ascended again early in the morning to the theatre, where he had promised to join us; and a live fowl was intended to be the martyr of experiment." But our author was interrupted by some banditti, and obliged to leave Hierapolis in haste.

Hierarchy, among divines, denotes the subordination of angels.

Some of the rabbis reckon four, others ten, orders or ranks of angels; and give different names according to their different degrees of power and knowledge.

Hierarchy, likewise denotes the subordination of the clergy, ecclesiastical polity, or the constitution and government of the Christian church considered as a society.

Hieres, the name of some small islands lying near the coast of Provence in France, opposite to the towns of Hieres and Toulon, where the English fleet lay many months in 1744, and blockaded the French and Spanish fleets in the harbour of Toulon.

Hieres, a town of Provence in France, seated on the Mediterranean sea. It is a pretty little town, and was formerly a colony of the Marsilians; and pilgrims used to embark here for the holy land. But its harbour being now choked up, it is considerable only for its salt-works. E. Long. 6. 13. N. Lat. 43. 7.

Hierocles, and II. Kings of Syracuse. See Syracuse.

Hierocles, a cruel persecutor of the Christians and a violent promoter of the persecution under Diocletian, flourished in 302. He wrote some books against the Christian religion; in which he pretends some inconsistencies in the Holy Scriptures, and compares the miracles of Apollo and Tyanaeus to those of our Saviour. He was refuted by Lactantius and Eusebius. The remains of his works were collected into one volume octavo, by Bishop Pearson; and published in 1654, with a learned dissertation prefixed to the work.

Hierocles, a Platonic philosopher of the fifth century, taught at Alexandria, and was admired for his eloquence. He wrote seven books upon Providence and Fate; and dedicated them to the philosopher Olympiodorus, who by his embassies did the Romans great service under the emperors Honorius and Theodosius the younger. But these books are lost, and we only know them by the extracts in Photius. He wrote also a commentary upon the golden verses of Pythagoras; which is still extant, and has been several times published with those verses.

Hieroglyphics, in antiquity, mystical characters, or symbols, in use among the Egyptians, and that as well in their writings as inscriptions; being the figures of various animals, the parts of human bodies, and mechanical instruments. The word is composed of the Greek ιγραφής, sacer, "holy," and γραφέω, sculpere, "to engrave;" it being the custom to have the walls, doors, &c. of their temples, obelisks, &c. engraved with such figures.

Hieroglyphics are properly emblems or signs of divine, sacred, or supernatural things; by which they are distinguished from common symbols, which are signs of sensible and natural things.

Hierocles is commonly esteemed the inventor of hieroglyphics; he first introduced them into the heathen theology, from whence they have been translated into the Jewish and Christian.

Sacred things, says Hippocrates, should only be communicated to sacred persons. Hence it was that the ancient Egyptians communicated to none but their kings and priests, and those who were to succeed to the priesthood and the crown, the secrets of nature, and the secrets of their morality and history; and this they did by a kind of cabbala, which, at the same time that it instructed them, only amused the rest of the people. Hence the use of hieroglyphics, or mystic figures, to veil their morality, politics, &c. from profane eyes. This author, it may be observed, and many others, do not keep to the precise character of a hieroglyphic, but apply it to profane as well as divine things.

Hieroglyphics are a kind of real character, which do not only denote, but in some measure express, the things. Thus, according to Clemens Alexandrinus, Strom. v. a lion is the hieroglyph of strength and ferocity; a bull, of agriculture; a horse, of liberty; a sphinx, of subtilty, &c.
Such is the opinion that has generally been embraced both by ancient and modern writers, of the origin and use of hieroglyphics. It has been almost uniformly maintained, that they were invented by the Egyptian priests in order to conceal their wisdom from the knowledge of the vulgar; but the late Bishop Warburton hath, with much ingenuity and learning, endeavoured to show that this account is erroneous.

According to this writer, the first kind of hieroglyphics were mere pictures, because the most natural way of communicating our conceptions by marks or figures was by tracing out the images of things; and this is actually verified in the case of the Mexicans, whose only method of writing their laws and history was by this picture-writing. But the hieroglyphics invented by the Egyptians were an improvement, on this rude and inconvenient essay towards writing, for they contrived to make them both pictures and characters. In order to effect the improvement, they were obliged to proceed gradually, by first making the principal circumstance of the subject stand for the whole; as in the hieroglyphics of Harapolo, which represent a battle of two armies in array by two hands, one holding a shield and the other a bow: then putting the instrument of the thing, whether real or metaphorical, for the thing itself, as an eye and sceptre to represent a monarch, a ship and pilot the governor of the universe, &c.; and finally, by making one thing stand for or represent another, where their observations of nature or traditional superstitions led them to discover or imagine any resemblance: thus, the universe was designed by a serpent in a circle, whose variegated spots denoted the stars; and a man who had nobly surmounted his misfortune was represented by the skin of the hyena, because this was supposed to furnish an invulnerable defence in battle.

The Chinese writing, he observes, was the next kind of improvement in the use of hieroglyphics. The Egyptians joined characteristic marks to images; the Chinese threw out the images and retained only the contracted marks, and from these marks proceeded letters. The general concurrence of different people in this method of recording their thoughts can never be supposed to be the effect of imitation, sinister views, or chance; but must be considered as the uniform voice of nature speaking to the rude conceptions of mankind: for not only the Chinese of the East, the Mexicans of the West, and the Egyptians of the South, but the Scythians likewise of the North, and the intermediate inhabitants of the earth, viz. the Indians, Phenicians, Ethiopians, &c. used the same way of writing by picture and hieroglyphic.

The bishop farther shows, that the several species of hieroglyphic writing took their rise from nature and most men are not from choice and artifice, by tracing at large the origin and progress of the art of speech. He proceeds to show how in process of time the Egyptian hieroglyphics came to be employed for the vehicle of mystery. They used their hieroglyphics two ways; the one more simple, by putting the part for the whole, which was the curiologic hieroglyphic; and the other more artificial, by putting one thing of resembling qualities for another, called the tropical hieroglyphic; thus the moon was sometimes represented by a half circle and sometimes by a cynocephalus. They employed their proper hieroglyphics to record openly and plainly their laws, policies, public morals, and history, and all kinds of civil matters: this is evident from their obelisks, which are full of hieroglyphic characters, designed to record singular events, memorable actions, and new inventions; and also from the celebrated inscription on the temple of Minerva, at Sais, where an infant, an old man, a hawk, a fish, and a river-horse, expressed this moral sentence: "All you who come into the world and go out of it, know this, that the gods hate impudence." However, the tropical hieroglyphics, which were employed to divulge, gradually produced symbols which were designed to secrete or conceal: thus Egypt was sometimes expressed by the crocodile, sometimes by a burning censer with a heart upon it; where the simplicity of the first representation and the abstruseness of the latter show, that the one was a tropical hieroglyphic for communication, and the other a tropical symbol invented for secrecy.

Enigmatical symbols were afterwards formed by the assemblage of different things, or of their properties that were less known; and though they might have been intelligible at first; yet when the art of writing was invented, hieroglyphics were more generally disused, the people forgot the signification of them, and the priests, retaining and cultivating the knowledge of them because they were the repositories of their learning and history, at length applied them to the purpose of preserving the secrets of their religion. Symbols were the true original of animal-worship in Egypt, as Sir John Marsham conjectures, Can. Chron. p. 58. because in these hieroglyphics was recorded the history of their greater deities, their kings, and law-givers, represented by animals and other creatures. The symbol of each god was well known and familiar to his worshippers, by means of the popular paintings and engravings on their temples and other sacred monuments; so that the symbol presenting the idea of the god, and that idea exciting sentiments of religion, it was natural for them, in their addresses to any particular god, to turn to his representative mark or symbol; especially when we consider farther, that the Egyptian priests feigned a divine original for hieroglyphic characters, in order to increase the veneration of the people for them. These would of course bring on a relative devotion to these symbolic figures, which, when it came to be paid to the living animal, would soon terminate in an ultimate worship.

Another consequence of the sacredness of the hieroglyphic characters was, that it disposed the more superstitious to engrave them on gems, and wear them as amulets or charms. This magical abuse seems not to have been much earlier than the established worship of the god Serapis, which spread itself through the Hellenic and Roman cities, and was first brought to the general knowledge of the world by certain Christian heretics and natives of Egypt, who had mixed a number of Pagan superstitions with their Christianity. These gems, called abraxas, are frequently to be met with in the cabinets of the curious, and are engraved with all kinds of hieroglyphic characters. To these abraxas succeed the talismans.

HIEROGRAMMATISTS: (Hierogrammatise), i.e. holy registers, were an order of priests among the ancient
To the hierophantes it belonged to dress and adorn Hierophan
the statues of the gods, and to bear them in processions
and solemn ceremonies.

HIEROPHYLAX, an officer in the Greek church
who was guardian or keeper of the holy utensils, vest-
ments, &c. answering to our sacrist or vestry-keeper.

HIGH, a term or relation, importing one thing's
being superior or above another: thus we say, a high
mountain, the high court of parliament, high relief,
&c.

HIGH, in Music, is sometimes used in the same
sense with loud, and sometimes in the same sense with ocul-

HIGH Dutch, is the German tongue in its greatest
purity, &c. as spoken in Misnia, &c.

HIGH Operation, in chirurgery, is a method of ex-
tracting the stone; thus called, because the stone is
taken out at the upper part of the bladder. See SUR-
GERY.

HIGH Places, were eminences on which the heathens
used to worship their gods, chosen for that purpose as
being supposed to be nearer heaven their constant resi-
dence. The Jews are frequently blamed for their at-
tachment to high places, after the manner of the Gent-
tiles; though their proscription were frequently upon
mountains with groves planted about them. Where
high-places are represented in scripture, therefore, we
should understand them as abused and prostituted to
idolatrous purposes. Before the temple was built,
there was indeed nothing in the high-places very con-
trary to the law, provided God only was adored there,
and that no incense or victims were offered to idols.
Under the judges they seem to have been tolerated;
and Samuel offered sacrifices in several places besides
the tabernacle, where the ark was not present. Even
in David's time, they sacrificed to the Lord at Shiloh,
Jerusalem, and Gibeah; but after the temple was
built, and a place prepared for the fixed settlement of
the ark, it was no more allowed of to sacrifice out of
Jerusalem. Solomon, in the beginning of his reign,
went a pilgrimage to Gibeah; but from that time we
see no lawful sacrifices offered out of the temple.

HIGH Priest. See Pontifex and Priest.

HIGH Way, a free passage for the king's subjects:
on which account it is called the king's high way,
though the freehold or the soil belonged to the owner of
the land. Those ways that lead from one town to
another, and such as are drift or cart ways, and are for
all travellers in great roads, or that communicate with
them, are high ways only; and as to their reparation,
are under the care of surveyors.

HIGH-WAY-MEN, are robbers on the high way;
for the apprehending and taking of whom, a reward
of 40l. is given by the statute of 4 and 5 W. and M. to
be paid within a month after conviction by the sherif
of the county; to which the statute 8 Geo. II. cap. 6.
superadds 10l. to be paid by the hundred indemnified
by such taking.

HIGHAM FERRERS, an ancient borough of North-
amptonshire in England, which has its name from the
family of the Ferrers, to whom it formerly belonged,
and who had a castle in the neighbourhood. It sends
one member to parliament. E. Long. i. 40. N. Lat.
52. 26.

HIGHGATE, a village five miles north of Lon-
don. It has its name from its high situation, and from
a gate set up there about 400 years ago, to receive toll for the bishop of London, when the old miry road from Gray’s-Inn lane to Barnet was turned through the bishop’s park. There was a hermitage where the chapel now stands; and one of the hermits caused a causeway to be made between Highgate and Islington, with gravel dug out of the top of the hill, where there is now a pond. Near the chapel, in 1559, lord chief baron Cholmondeley built and endowed a free school, which was enlarged in 1770 by Edwin Sandys bishop of London.—This village is a noted and miry retirement for the gentry and wealthy citizens; and is a place of good accommodation, besides it affording a delightful and pleasant prospect over the city and adjacent country.

HIGHLANDERS, a general appellation for the inhabitants of the mountainous parts of any country. In Britain, the name is appropriated to the people who inhabit the mountainous parts of Scotland, to the north and north-west, including those of the Hebrides or Western isles.—They are a branch of the ancient Celts; and undoubtedly the descendants of the first inhabitants of Britain, as appears from the many monuments of their language still retained in the most ancient names of places in all parts of the island. The Highlanders, or, as they are often termed by ancient authors, the Caledonians, were always a brave, warlike, and hardy race of people; and, in the remotest times, seem to have possessed a degree of refinement in sentiment and manners then unknown to the other nations that surrounded them. This appears not only from their own traditions and poems, but also from the testimony of many ancient authors. This civilization was probably owing in a great measure to the order of the bards, or Druids, and some other institutions peculiar to this people.

The ancient Highlanders lived in the hunting state till some time after the era of Fingal, who was one of their kings towards the close of the third century. For some ages after that, they turned their chief attention to the pastoral life, which afforded a less precarious subsistence. Till of late, agriculture in most parts of the Highlands made but little progress.

The Highlanders always enjoyed a king and government of their own, till Kenneth M’Alpine (anno 845), after having subdued the Pictish kingdom, transferred the seat of royalty. This event proved very unfavourable to the virtues of the Highlanders, which from this period began to decline. The country, no longer awed by the presence of the sovereign, fell into anarchy and confusion. The chief-tains began to extend their authority, to form factions, and to foment divisions and feuds between contending clans. The laws were either too feeble to bind them, or too remote to take notice of them. Hence sprung all those evils which long disgraced the country, and disturbed the peace of its inhabitants. Robbery or plunder, providing it was committed on any one of an adverse clan or tribe, was countenanced and authorised; and their reprisals on one another were perpetual. Thus quarrels were handed down from one generation to another, and the whole clan were bound in honour to espouse the cause of every individual that belonged to it. By this means the genius of the people was greatly altered; and the Highlanders of a few ages back were almost as remarkable for their irregular and highland-disorderly way of life as their predecessors were for their civilization and virtue. It is not from attending to this distinction between the ancient Highlanders and their posterity in later times, that many have doubted the existence of those exalted virtues ascribed by their poets to the more ancient inhabitants of the country. But now that the power of the chief-tains is again abolished, law established, and property secured, the genius of the people (where it is not hindered by some other extraneous cause) begins again to show itself in its genuine colours; and many of their ancient virtues begin to shine with conspicuous lustre. Justice, generosity, honesty, friendship, peace, and love, are perhaps nowhere more cultivated than among this people. But one of the strongest features which marked the character of the Highlanders in every age, was their hospitality and benevolence to strangers. At night the traveller was always sure to find a hearty welcome in whatever house he should go to; and the host thought himself happier in giving the entertainment than the guest in receiving it. Even with regard to their enemies, the laws of hospitality were observed with the most sacred regard. They who fought against each other in the day, could in the night feast, and even sleep together, in the same house. From the same principle, they were, in most other cases, so faithful to their trust, that they rarely betrayed any confidence reposed in them. A promise they thought as binding as an oath, and held it equally inviolable and sacred.

The Caledonians in all ages have been much addicted to poetry and music. The poems of Ossian, so universally repeated, and so highly esteemed by every Highlander, are a strong proof of the early proficiency of this people in the poetical art. Even to this day, notwithstanding the many disadvantages they labour under, the most illiterate of either sex discover frequently a genius for poetry, which often breaks forth in the most natural and simple strains, when, love, grief, joy, or any other subject of song, demands it. Wherever their circumstances are so easy as to allow them any respite from toil, or any cheerfulness of spirits, a good portion of their time, especially of the winter nights, is still devoted to the song and tale. This last species of composition is chiefly of the novel-kind, and is handed down by tradition like their poems. It was the work of the bards; and proved, while they existed, no contemptible entertainment. But since the extinction of that order, both the Gaelic poems and tales are in a great measure either lost or adulterated.

The genius and character of the Gaelic poetry is well known. It is tender, simple, beautiful, and sublime.

Among the ancient Highlanders, the harp was the chief instrument of music. It suited the mildness of their manners, and was well adapted to the peace and quiet which they enjoyed under their own kings. In a later period, however, when the constant quarrels of their chiefs, and the endless feuds of contending clans, turned all their thoughts to war, it was forced to give place to the bag-pipe, an instrument altogether of the martial kind, and therefore well suited to the state of the country at that time. But ever since the cause which has brought this instrument in vogue had ceased.
to operate, the attention to it has been on the decline; so that the harp, with very little encouragement, might again resume the seat from which it was once expelled.

The most, and especially the oldest of the Highland music, having been composed to the harp, is of a soft, tender, and elegiac cast, as best suited to the genius of that instrument. These pieces are generally expressive of the passions of love and grief. Other pieces, which were composed in their state of war, and adapted to a different instrument, are altogether bold and martial. And many are of a sprightly and cheerful cast, the offspring of mirth, and the sport of fancy in the season of festivity. Many of these last are of the chorus kind: and are sung in almost all the exercises in which a number of people are engaged, such as rowing, reaping, fulling, &c. The time of these pieces is adapted to the exercises to which they are respectively sung. They greatly forward the work, and alleviate the labour. The particular music which is generally used by the Highlanders in their dances is well known by the name of Strathspey reels.

The language of the Highlanders is still the Gaelic; which, with many of its customs and manners, has been secured to them by their mountains and fastnesses, amidst the many revolutions which the rest of the island has undergone in so long a course of ages. The Gaelic seems to be the oldest and purest dialect which remains of the Celtic, as appears from its approaching the nearest to the names of places, &c. which that language left in most countries where it prevailed, and from its most obvious affinity to those tongues, ancient or modern, which have been in any measure derived from the old Celtic. The Gaelic has all the marks of an original and primitive language. Most of the words are expressive of some property or quality of the objects which they denote. This, together with the variety of its sounds (many of which, especially of those that express the soft and mournful passions, are peculiar to itself), renders it highly adapted for poetry. It is generally allowed to have been the language of court, in Scotland, till the reign of Malcolm Canmore. The Gaelic epithet of Com-mor, or "large head," by which this king is distinguished, seems to intimate so much. In some particular parishes at least, it was spoken much later, as in that held by Robert the Bruce at Ardochattan. That it has been formerly a good deal cultivated, appears from the style and complexity of its poems and tales, and from several ancient MSS. that have come down to the present time.

To strangers the Gaelic has a forbidding aspect, on account of the number of its quiescent consonants (which are retained to mark the derivation of words and their variation in case and tense), but its sound is abundantly musical and harmonious; and its genius strong and masculine. Its alphabet consists of 18 letters, of which one is an aspirate, 12 are consonants, and 5 are vowels. The Highlanders are beginning to late to apply to learning, agriculture, and especially to commerce, for which their country, everywhere indented with arms of the sea, is peculiarly favourable. Cattle is the chief staple of the country; but it produces more grain than would supply its inhabitants, if so much of it were not consumed in whisky. The natives are beginning to avail themselves of their mines, woods, wool, and fisheries; and by a vigorous application, with the due encouragement of government, may become a prosperous and useful people.

The Highlanders are of a quick and penetrating genius, strongly tintured with a curiosity or thirst of knowledge, which disposes them to learn anything very readily. They are active and industrious, where oppression does not discourage them by excluding even the hope of thriving. They are remarkably bold and adventurous, which qualifies them for being excellent seamen and soldiers. They are generally of a middle size, rather above it than otherwise; their eyes are quick and lively, their features distinctly marked, and their persons tight and well made. Their countenance is open and ingenious, and their temper frank and communicative.

HIGHMORE, JOS. Esq. an eminent painter, was born in the parish of St James's, Garlickhythe, London, June 13. 1693, being the third son of Mr Edward Highmore, a coal merchant in Thames-street.

Having such an early and strong inclination to painting, that he could think of nothing else with pleasure, his father endeavoured to gratify him in a proposal to his uncle, who was serjeant-painter to King William, and with whom Mr (afterwards Sir James) Thornhill had served his apprenticeship. But this was afterwards for good reasons declined, and he was articled as clerk to an attorney, July 18th 1707; but so much against his own declared inclination, that in about three years he began to form resolutions of indulging his natural disposition to his favourite art, having continually employed his leisure hours in designing, and in the study of geometry, perspective, architecture, and anatomy, but without any instructors except books. He had afterwards an opportunity of improving himself in anatomy, by attending the lectures of Mr Cheselden, besides entering himself at the painters academy in Great Queen-street, where he drew 10 years, and had the honour to be particularly noticed by Sir Godfrey Kneller, who distinguished him by the name of "The Young Lawyer." On June 17th, 1714, his clerkship expired; and on March 26th 1715, he began painting as a profession, and settled in the city. In the same year Dr Brook Taylor published his "Linear Perspective: or, a new method of representing justly all manner of objects as they appear to the eye in all situations." On this complete and universal theory our artist grounded his subsequent practice; and it has been generally allowed, that few, if any, of the profession at that time were so thorough masters of that excellent but intricate system. In 1716, he married Miss Susanna Hiller, daughter and heiress of Mr Anthony Hiller of Effingham in Surry; a young lady in every respect worthy of his choice. For Mr Cheselden's "Anatomy of the Human Body," published in 1722, he made drawings from the real subjects at the time of dissection, two of which were engraved for that work, and appear, but without his name, in tables xii. and xiii. In the same year, on the exhibition of "The Conscious Lovers," written by Sir Richard Steele, Mr Highmore addressed a letter to the author on the limits of filial obedience, pointing out a material defect in the character of J. Bevil, with that clearness and precision for which, in conversation and writing, he was always remarkable, as the pencil by so
Higmore. means engrossed his whole attention. His reputation and business increasing, he took a more conspicuous station, by removing to a house in Lincoln's-Inn-Fields, in March 1723-4, and an opportunity soon offered of introducing him advantageously to the nobility, &c. by his being desired, by Mr. Pine the engraver, to make the drawings for his prints of the knights of the Bath, on the revival of that order in 1725. In consequence, several of the knights had their portraits also by the same hand, some of them whole lengths; and the duke of Richmond, in particular, was attended by his three esquires, with a perspective view of King Henry VIIth's chapel. This capital picture is now at Godwood. And our artist was sent for to St James's by George I. to draw the late duke of Cumberland, from which Smith scraped a mezzotinto.

In 1732, Mr. Hawkins Browne, then of Lincoln's-Inn, who had ever a just sense of his talents and abilities, addressed to him a poetical epistle "On Design and Beauty," and some years after, an elegant Latin Ode, both now collected in his poems. In the summer of 1732, Mr. Higmore visited the continent, in company with Dr. Pemberton, Mr. Benjamin Robins, and two other friends, chiefly with a view of seeing the gallery of pictures belonging to the elector Palatine at Dusseldorf, collected by Rubens, and supposed the best in Europe. At Antwerp also he had peculiar pleasure in contemplating the works of his favourite master. In their return they visited the principal towns in Holland. In 1734, he made a like excursion, but alone, to Paris, where he received great civilities from his countrymen then there, particularly the duke of Kingston, Dr. Hickman (his tutor), Robert Knight, Esq. (the late cashier), &c. Here he had the satisfaction of being shown, by Cardinal de Polignac, his famous group of antique statues, the court of Lycomedes, then just brought from Rome, and since purchased by the king of Prussia, and destroyed at Charlottenbourg in 1760 by the Russians. In 1742, he had the honour to paint the late prince and princess of Wales for the duke of Saxe Gotha; as he did some years after the late queen of Denmark for that court. The publication of "Pamela," in 1744, gave rise to a set of paintings by Mr. Higmore, which were engraved by two French engravers, and published by subscription in 1745. In the same year he painted the only original of the late General Wolfe, then about 18. His Pamela introduced him to the acquaintance and friendship of the excellent author whose picture he drew, and for whom he painted the only original of Dr. Young. In 1750 he had the misfortune to lose his wife. On the first institution of the academy of painting, sculpture, &c. in 1753, he was elected one of the professors; an honour which, on account of his many avocations, he desired to decline. In 1754 he published "A critical examination of those two Paintings [by Rubens] on the Ceiling of the Banqueting-house at Whitehall, in which Architecture is introduced, so far as relates to Perspective; together with the Discussion of a Question which has been the Subject of Debate among Painters!" printed in 4to. In the solution of this question, he proved that Rubens and several other great painters were mistaken in the practice, and Mr. Kirby and several other authors in the theory. And in the 2nd volume of the "Monthly Review," he animadverted (anonymously) on Mr. Kirby's unwarrantable treatment of Mr. Ware, and detected and exposed his errors, even when he exults in his own superior science. Of the many portraits which Mr. Higmore painted, in a large practice of 46 years (of which several have been engraved), it is impossible and useless to discuss particulars. Some of the most capital in the historical branch, which was then much less cultivated than it is at present, shall only be mentioned, viz. "Hagar and Ishmael," a present to the Foundling-hospital; "The good Samaritan," painted for Mr. Shepherd of Campsea Ash: "The finding of Moses," purchased at his sale by Colonel (now General) Lister: "The Harlowe family, as described in Clarissa," now in the possession of Thomas Watkinson Payler, Esq. at Heden in Kent: "Clarissa," the portrait mentioned in that work: "The Graces unveiling Nature," drawn by memory from Rubens: "The Confession of Grandison, and the queen mother of Edward IV. with her younger son, &c. in Westminster-abbey," the three last in the possession of his son.

In 1761, on the marriage of his daughter to the reverend Mr. Duncombe, son to one of his oldest friends, he took a resolution of retiring from business, and disposing of his collection of pictures, which he did by auction, in March 1762, and soon after removed to his son-in-law's at Canterbury, where he passed the remainder of his life without ever revisiting the metropolis. But though he had laid down the pencil, he never wanted employment: so active and vigorous was his mind, that, with a constitutional flow of spirits, and a relish for instructive society, he was never less "alone when alone;" and besides, his professional pursuits above mentioned, to philosophy, both natural and moral, and also to divinity, he landedly dedicated his time and attention. No man had more clearness and precision of ideas, or a more ardent desire to know the truth; and, when known, conscientiously to pursue it. With strong passions, ever guided by the strictest virtue, he had a tender, susceptible heart, always open to the distress of his fellow-creatures, and always ready to relieve them. His capital work of the literary kind was his "Practice of Perspective, on the principles of Dr. Brook Taylor," &c. written many years before, but not published till 1763, when it was printed for Nourse, in one vol. 4to. This not only evinced his scientific knowledge of the subject, but removed, by its perspicuity, the only objection, that can be made to the system of Dr. Taylor. It accordingly received, from his friends and the intelligent public, the applause it deserved. In 1765 he published (without his name) Observations on a Pamphlet entitled, "Christianity not founded on Argument," in which, after showing that it is a continued irony, and lamenting that so ample a field should be offered the author of it for the display of his sophistry; he gives up creeds, articles, and catechisms, as out-works raised by fallible men, and, confining himself to the defence of the gospel, or citadel, shows, that pure primitive Christianity, though assaulted by infidels, will ever remain impregnable. His opinion of Rubens may be seen.
HIG [ 468 ] HIL

seen in the Gentleman's Magazine for 1766, p. 313, under the title of "Remarks on some passages in Mr Webb's inquiry into the Beauties of Painting." &c. In the same year he published, with only his initials, "J. H." two small volumes of "Essays, moral, religious, and miscellaneous; with a Translation in prose of Mr Brown's Latin Fable on the Immortality of the Soul," selected from a large number written at his leisure, at different periods of life. "As such (says Dr Hawkesworth) they do the author great credit. They are not excursions of fancy, but efforts of thought, and indubitable indications of a vigorous and active mind." In the Gentleman's Magazine for 1769, p. 287, he communicated "A natural and obvious Manner of constructing Sun-dials, deduced from the Situation and Motion of the Earth with respect to the Sun," explained by a scheme. And in that for 1778, p. 526, his remarks on colouring, suggested by way of a note on the "Epistle to an eminent Painter," will show that his talents were by no means impaired at the age of 86. Indeed he retained them to the last, and had even strength and spirits sufficient to enable him to ride out daily on horseback the summer before he died. A strong constitution, habitual temperance, and constant attention to his health in youth as well as in age, prolonged his life, and preserved his faculties to his 88th year, when he gradually ceased to breathe, and, as it were, fell asleep on March 3, 1780. He was interred in the south aisle of Canterbury cathedral, leaving one son, Anthony, educated in his own profession; and a daughter, Susanna, mentioned above.

His abilities as a painter appear in his works, which will not only be admired by his contemporaries, but by their posterity; as his tints, like those of Rubens and Van Dyck, instead of being impaired, are improved by time, which some of them have now withstood above 60 years. His idea of beauty, when he indulged his fancy, was of the highest kind; and his knowledge of perspective gave him great advantages in family-pieces, of which he painted more than any one of his time. He could take a likeness by memory as well as by a sitting, as appears by his picture of the duke of Lorraine (the late emperor), which Faber engraved; and those of King George II. (in York assembly-room), Queen Caroline, the two Miss Cunnings, &c. Like many other great painters, he had "a poet for his friend," in the late Mr Browne; to which may be added a poem addressed to him in 1726, by the reverend Mr Bunce, at that time of Trinity-hall, Cambridge, who succeeded Mr Higginson, and in 1780 was vicar of St Stephen's near Canterbury.

HIGNESS, a quality or title of honour given to princes. The kings of England and Spain had formerly no other title but that of Highness; the first till the time of James I. and the second till that of Charles V. The petty princes of Italy began first to be complimented with the title of highness in the year 1630. The duke of Orleans assumed the title of royal highness in the year 1631, to distinguish himself from the other princes of France.

The duke of Savoy, afterwards king of Sardinia, bore the title of royal highness, on account of his pretensions to the kingdom of Cyprus. It is said that duke only took the title of royal highness, to put himself above the duke of Florence, who was called great duke; but the great duke afterwards assumed the title of royal highness, to put himself on a level with the duke of Savoy.

The prince of Condé first took the title of most serene highness, leaving that of simple highness to the natural prince.

HILARIA, in antiquity, feasts celebrated every year by the Romans on the 8th of the kalends of April, or the 25th of March, in honour of Cybele the mother of the gods.

The festival were solemnized with great pomp and rejoicing. Every person dressed himself as he pleased, and took the marks or badges of whatever dignity or quality he had a fancy for. The statue of the goddess was carried in procession through the streets of the city, accompanied by multitudes in the most splendid attire. The day before the festival was spent in tears and mourning. Cybele represented the earth, which at this time of the year begins to feel the kindly warmth of the spring; so that this sudden transition from sorrow to joy was an emblem of the vicissitude of the seasons, which succeed one another.

The Romans took this feast originally from the Greeks, who called it anthest, q. d. ascensus; the eve of that day they spent in tears and lamentations, and thence denominated it anthest, ascensus.

Afterwards, the Greeks took the name hile from the Romans; as appears from Ptolemy, in his extract of the life of the philosopher Isidorus.

Casaubon maintains, that beside this particular signification, the word hila was also a general name for any joyful or festival day, whether public or private and domestic. But Salmiasi does not allow of this.

Tristan, tom. i. p. 482. distinguishes between hila and hiliaris. The former, according to him, were public rejoicings; and the latter, prayers made in consequence thereof; or even of any private feast or rejoicing, as a marriage, &c. The public lasted several days; during which, all mourning and funeral ceremonies were suspended.

HILARIUS, an ancient father of the Christian church, who flourished in the 4th century. He was born, as St Jerome informs us, at Poictiers, of a good family; who gave him a liberal education in the pagan religion, and which he did not forsake till he was arrived at maturity. He was advanced to the bishopric of Poictiers in the year 355, according to Baronius: and became a most zealous champion for the orthodox faith, particularly against the Arians, who were at that time gaining ground in France. He assembled several councils there, in which the determinations of the synods of Rimini and Seleucia were condemned. He wrote a treatise concerning synods; and a famous work in 12 books on the Trinity, which is much admired by the orthodox believers. He died in the latter end of the year 367. His works have been many times published; but the last and best edition of them was given by the Benedictines at Paris in 1692.

HILARODI, in the ancient music and poetry, a sort of poets among the Greeks, who went about singing little gay poems or songs, somewhat graver than the Ionic pieces, accompanied with some instrument. From the streets they were at last introduced into the theatre,
tragedy, as the masques were into comedy. They appeared dressed in white, and were crowned with gold. At first they wore shoes; but afterwards they assumed the crepida, being only a sole tied on with a strap.

HILARY-TERM. See Term.

HILDESHEIM, a small district of Germany, in the circle of Lower Saxony. It lies between the duchies of Luneburg and Brunswick; and may be about 25 miles from east to west, and 36 from north to south. It is watered by the rivers Leine and Innerste. The soil is fertile; and its principal places are Feine, Sarsted, Broggen, and Alved. Hildesheim, from whence it takes its name, was formerly an imperial city. It is now subject to Hanover.

HILDESHEIM, a strong city of Germany, in Lower Saxony, with a Roman Catholic bishop's see. It was a free imperial city, though in some things independent on the king, but now subject to its privileges. It is a large town, well built and fortified. It is divided into the Old Town and the New, which have each separate council. It is seated on the river Innerst, in E. Long. 10. 0. N. Lat. 52. 17.

HILL, a term denoting any considerable eminence on the earth's surface. It is sometimes synonymous with the word mountain; though generally it denotes only the lower eminences, the word mountain being particularly applied to the very largest. See MOUNTAIN, GEOLOGY, Index.

HILL, Aenon, a poet of considerable eminence, the son of a gentleman of Malmsbury-abbey in Wiltshire, was born in 1685. His father's imprudence having cut off his paternal inheritance, he left Westminster school at 14 years of age; and embarked for Constantinople, to visit Lord Paget the English ambassador there, who was his distant relation. Lord Paget received him with surprise and pleasure, provided him a tutor, and sent him to travel: by which opportunity he saw Egypt, Palestine, and a great part of the east; and returning home with his new views, visited some of the courts of Europe. About the year 1700, he published his first poem entitled Camillus, in honour of the earl of Peterborough who had been general in Spain; and being the same year made master of Drury-lane theatre, he wrote his first tragedy Elfred, or the Fair Inconstant. In 1710, he became master of the opera-house in the Hay-market; when he wrote an opera called Rinaldo, which met with great success, being the first that Mr Handel set to music after he came to England. Unfortunately for Mr Hill, he was a projector as well as poet, and in 1715 obtained a patent for extracting oil from beechnuts; which undertaking, whether good or bad, miscarried after engaging three years of his attention. He was also concerned in the first attempt to settle the colony of Georgia; from which he never reaped any advantage; and in 1725 he made a journey into the Highlands of Scotland, on a scheme of applying the woods there to ship-building; in which he also lost his labour. Mr Hill seems to have lived in perfect harmony with all the writers of his time, except Mr Pope, with whom he had a short paper-war, occasioned by that gentleman's introducing him in the Dunciad, as one of the competitors for the prize offered by the goddess of Dulness, in the following lines:

This, though far the gentlest piece of satire in the whole poem, and conveying at the same time an oblique compliment, roused Mr Hill to some notice of it; which he did by a poem written during his pilgrimage in the north, entitled, "The Progress of Wit, a Vestal for the use of an eminent writer," in which he begins with the following eight lines, in which Mr Pope's too well known disposition is elegantly, yet very severely characterized:

The sneakingly approves, in the last couplet, Mr Pope was much affected by; and indeed through their whole controversy afterwards, in which it was generally thought that Mr Hill had much the advantage, Mr Pope seems rather to express his repentance by denying the offence, than to vindicate himself supposing it to have been given. Besides the above poems, Mr Hill, among many others, wrote one, called The northern star, upon the actions of Czar Peter the Great; for which he was several years afterwards complimented with a gold medal from the empress Catharine, according to the Czar's desire before his death. He likewise altered some of Shakespeare's plays, and translated some of Voltaire's. His last production was Merope; which was brought upon the stage in Drury-lane by Mr Garrick. He died on the 8th of February 1749, as it is said, in the very moment when the prompter; and after his decease four volumes of his works in prose and verse were published in octavo, and his dramatic works in two volumes.

HILL, Sir John, a voluminous writer, was originally bred an apothecary; but his marrying early, and without a fortune, made him very soon look around for other resources than his profession. Having, therefore, in his apprenticeship, attended the botanical lectures of the company, and being possessed of quick natural parts, he soon made himself acquainted with the theoretical as well as practical parts of botany: from whence being recommended to the late duke of Richmond and Lord Petre, he was by them employed in the inspection and arrangement of their botanic gardens. Assisted by the liberality of these noblemen, he executed a scheme of travelling over the kingdom, to collect the most rare and uncommon plants; which he afterward published by subscription: but after great researches and uncommon industry, this undertaking turned out by no means adequate to his expectation. The stage next presented itself, as a soil in which genius might stand a chance of flourishing: but after two or three unsuccessful attempts, it was found he had no pretensions either to the sock or drama: which once more reduced him to his botanical pursuits, and his business.
HILL, the nasi, or prince, another learned Jew, the grandson of Judas Hakkodesh, or the Saint, the author of the Mishna, lived in the fourth century. He composed a cycle; and was one of the principal doc-
 tors of the Gamara. The greatest number of the Jewish writers attribute to him the correct edition of the Hebrew text which bears the name of Hillel, which we have already mentioned in the preceding article. There have been several other Jewish writers of the same name.

HILLIA, a genus of plants belonging to the hexandria class; and in the natural method ranking with those of which the order is doubtful. See Botany Index.

HILLSBOROUGH, a borough, fair, and post-town, in the county of Down, and province of Ulster, 69 miles from Dublin. Here is a fine seat of the earl of Hillsborough. The town is pleasantly situated and almost new built, in view of Lisburn, Belfast, and Carrickfergus bay; the church is magnificent, having an elegant spire, as lofty as that of St Patrick's in Dublin, and seven painted windows. This place gives title of earl to the family of Hillsborough. N. Lat. 54° 30'. W. Long. 5° 56'.

HILUM, among botanists, denotes the eye of a bean.

HIMALEH, a very high chain of mountains in Asia. See Supplement.

HIMERA, in Ancient Geography, the name of two rivers in Sicily; one running northwards into the Tuscan sea, now called Fiume de Termini; and the other southwards into the Libyan; dividing Sicily into two parts, being the boundary between the Syracusans to the east and Carthaginians to the west; not rising from the same, but from different springs.

HIMERA, in Ancient Geography, a town of Sicily, at the mouth of the Himera, which ran northwards, on its left or west side: A colony of Zancle: afterwards destroyed by the Carthaginians (Diodorus Siculus).

HIMERENSES THERME, in Ancient Geography, a town of Sicily, on the east side of that Himera which runs to the north. After the destruction of the town of Himera by the Carthaginians, such of the inhabitants as remained, settled in the same territory, not far from the ancient town. Now Termini. Made a Roman colony by Augustus.

HIN, a Hebrew measure of capacity for things liquid, containing the sixth part of an ephah, or one gallon two pints English measure.

HINCKLEY, a market-town of Leicestershire, built on a rising ground, nearly on the borders of Leicestershire, from which it is separated by the Roman Watling-street road. It is distant from Coventry and Leicester 15 miles each, and 102 from London. It has been much larger than it is at present, the back lanes between the orchards having evidently been streets originally, and the traces of the town-wall and ditch are in many places yet visible. There are vestiges of two Roman works, viz. the moat near the river, and the ruins of a bath near St Nicholas church, where tessellated pavements have been dug up. The Jewry wall is said to have been the temple of Janus. The castle was inhabited by John of Gaunt; but is now no more, the scite being converted into garden-ground, the castle-hill considerably lowered, and a gentleman's house erected on the spot in 1770. The steeple of the present church was built with some of the stones of the castle. The town is now divided into the borough, and
AND the bond without the liberties. It has a good market on Mondays, and a fair in August. The chief manufacture is stockings and fustian. The town contained 6,049 inhabitants in 1811. There are two churches, one chapel, and a place of worship for the Roman Catholics, besides four meeting-houses. The church is a neat large old structure with a modern tower and a spire, the body of it was built in the 13th century, and near it are three mineral springs. This town is said to be the middle and highest ground in England; and from it 50 churches may be seen, besides gentlemen's seats. It received great damage by a fire September 5. 1728.

HIND, a female stag in the third year of its age.

See CERVUS, MAMMALIA Index.

HINDON, a small town of Wiltshire in England, which sends two members to parliament. It is situated in E. Long. 2. 14. N. Lat. 51. 12.

HINDOOS, or GENTOOs, the inhabitants of that part of India known by the name of Hindostan or the Mogul's empire, who profess the religion of the Brahmans, supposed to be the same with that of the ancient Gymnosophists of Ethiopia.

From the earliest period of history these people seem to have maintained the same religion, laws, and customs, which they do at this day: and indeed they and the Chinese are examples of perseverance in these respects altogether unknown in the western world. In the time of Diocletian, Sibyllus they are said to have been divided into seven casts or tribes; but the intercourse between Europe and India was in his time so small, that we may well suppose the historian to have been mistaken, and that the same tenacity for which they are so remarkable in other respects has manifested itself also in this. At present they are divided only into four tribes; 1. The Bramin; 2. The Khattri; 3. The Bhyse; and, 4. The Sooders. All these have distinct and separate offices, and cannot, according to their laws, intermingle with each other; but for certain offences they are subject to the loss of their cast, which is reckoned the highest punishment they can suffer; and hence is formed a kind of fifth cast named Pariars on the coast of Coromandel, but in the Sian or sacred language Chandals. These are esteemed the dregs of the people, and are never employed but in the meanest offices. There is besides a general division which pervades the four casts indiscriminately, and which is taken from the worship of their gods Vishnou and Shrewh; the worshippers of the former being named Vishnou-bukht; of the latter Shrewh-bukht.

Of these four casts the Bramins are accounted the foremost in every respect; and all the laws have such an evident partiality towards them, as cannot but induce us to suppose that they have had the principal band in framing them. They are not, however, allowed to assume the sovereignty; the religious ceremonies and the instruction of the people being their peculiar province. They alone are allowed to read the Vedas or sacred books; the Khattrics, or cast next in dignity, being only allowed to hear them read; while the other two can only read the Sastras or commentaries upon them. As for the poor Chandals, they dare not enter a temple, or be present at any religious ceremony.

In point of precedence the Brahmans claim a superiority even to the princes; the latter being chosen of the Khattri or second cast. A rajah will receive with respect the food that is prepared by a Brahm, but the latter will eat nothing that has been prepared by any member of an inferior cast. The punishment of a Brahm for any crime is much milder than if he had belonged to another tribe; and the greatest crime that can be committed is the murder of a Brahm. No magistrate must desire the death of one of these sacred persons, or cut off one of their limbs. They must be readily admitted into the presence even of princes whenever they please: when passengers in a boat, they must be the first to enter and to go out; and the waterman must besides carry them for nothing; every one who meets them on the road being likewise obliged to give place to them.

All the priests are chosen from among this order, such as are not admitted to the sacerdotal function being employed as secretaries and accountants. These can never afterwards become priests, but continue to be greatly revered by the other castes.

The Khattri or second cast are those from among whom the sovereigns are chosen.—The Bhyse or Braniens, who constitute the third cast, have the charge of commercial affairs; and the Sooders, or fourth cast, the most numerous of all, comprehend the labourers and artisans. These last are divided into as many classes as there are followers of different arts; all the children being invariably brought up to the professions of their fathers, and it being absolutely unlawful for them ever to alter it afterwards.

No Hindoos is allowed to quit the cast in which he was born upon any account. All of them are very scrupulous with regard to their diet; but the Brahmans much more so than any of the rest. They eat no flesh, nor shed blood; which we are informed by Porphyry and Clemens Alexandrinus was the case in their time. Their ordinary food is rice and other vegetables, dressed with ghee (a kind of butter melted and refined so as to be capable of being kept for a long time), and seasoned with ginger and other spices. The food which they most esteem, however, is milk, as coming from the cow; an animal for which they have the most extravagant veneration, insomuch that it is enacted in the code of Gentoo laws, that any one who exacts labour from a bullock that is hungry or thirsty, or that shall oblige him to labour when fatigued or out of season, is liable to be fined by the magistrates. The other casts, though less rigid, abstain very religiously from what is forbidden them; nor will they eat any thing provided by a person of an inferior cast, or by one of a different religion. Though they may eat some kinds of flesh and fish, yet it is counted a virtue to abstain from them all. None of them are allowed to taste intoxicating liquor of any kind. Quintus Curtius indeed mentions a sort of wine made use of by the Indians in his time; but this is supposed to have been no other than toddy, or the unfermented juice of the cocoa nut. This when fermented affords a spirit of a very unwholesome quality; but it is drunk only by the Chandals and the lower class of Europeans in the country. So exceedingly bigotted and superstition, are they in their absurd maxims with regard to meat and drink, that some seacpoys in a British ship having been served,
Hindoo. expended all the water appropriated to their use, would have suffered themselves to perish for thirst rather than taste a drop of that which was used by the ship's company.

Of the religion of the Hindoo. The religion of the Hindoos, by which these maxims are inculcated, and by which they are made to differ so much from other nations, is contained in certain books named Vedas, Vedams, or Bada, written in a language called Shasandit, which is now known only to the learned among them. The books are supposed to have been the work not of the supreme God himself, but of an inferior deity named Brimba. They inform us, that Brama, or Brahms, the supreme God, having created the world by the word of his mouth, formed a female deity named Bavauney, who in the enthusiasm of joy and praise brought forth three eggs. From these were produced three male deities, named Brimha, Vishnoo, and Sheevah. Brimha was endowed with the power of creating the things of this world, Vishnoo with that of cherishing them, and Sheevah with that of restraining and correcting them. Thus Brimha became the creator of man; and in this character he formed the four casts from different parts of his own body, the Bramins from his mouth, the Khatri from his arms, the Banians from his belly and thighs, and the Soodera from his feet. Hence, say they, these four different casts derive the different offices assigned them; the Bramins to teach; the Khatri to defend and govern; the Banians to enrich by commerce and agriculture; and the Soodera to labour, serve, and obey. Brama himself endowed mankind with passions, and understanding to regulate them; while Brimha, having created the inferior beings, proceeded to write the Vedans, and delivered them to be read and explained by the Bramins.

The religion of the Hindoos, though involved in superstition and idolatry, seems to be originally pure; inculcating the belief of an eternal and omnipotent being; their subordinate deities Brimha, Vishnoo, and Sheevah, being only representatives of the wisdom, goodness, and power, of the supreme God Brama. All created things suppose to be types of the attributes of Brama, whom they call the principle of truth, the spirit of wisdom, and the supreme being; so that it is probable that all their idols were at first only designated to represent these attributes.

There are a variety of sects among the Hindoos; two great classes we have mentioned already, viz. the worshippers of Vishnoo, and those of Sheevah; and these distinguish themselves, the former by painting their faces with an horizontal line, the latter by a perpendicular one. There is, however, very little difference in point of religion between these or any other Hindoo sects. All of them believe in the immortality of the soul, a state of future rewards and punishments, and transmigration. Charity and hospitality are inculcated in the strongest manner, and exist among them not only in theory but in practice. "Hospitality (say they) is commanded to be exercised even towards an enemy, or when he cometh into thine house; the tree doth not withdraw its shade even from the wood-cutter. Good men extend their charity even to the vilest animals. The moon doth not withhold her light even from the Chandala." These pure doctrines, however, are intermixed with some of the vilest and most absurd superstitions; and along with the true God they worship a number of inferior ones, of whom the principal are:

1. Bavauney, the mother of the gods, already mentioned, and superior to all but Brama himself; but all the other goddesses are reckoned inferior to their gods or lords.

2. Brimha, in the Shasandit language said to mean the wisdom of God, and who is supposed to fly on the wings of the house or flamingo; an image of which is constantly kept near that of the god in the temple where he is worshipped. He has a crown on his head, and is represented with four hands. In one of these he holds a sceptre, in another the sacred books or Vedams, in the third a ring or circle as the emblem of eternity, supposed to be employed in assisting and protecting his works.

3. Serawatoj, the goddess or wife of Brimha, presides over music, harmony, eloquence, and invention. She is also said to be the inventress of the letters called Devanagary, by which the divine will was first promulgated among mankind. In the argument of an hymn addressed to this goddess, she is supposed to have a number of inferior deities acting in subordination to her. These are called Ragas, and preside over each mode, and likewise over each of the seasons. These seasons in Hindostan are six in number; viz. 1. The Sesur, or dewy season. 2. Hemat, or the cold season. 3. Vasuti, the mild season or spring. 4. Gressha, or the hot season. 5. Varca, the rainy season. 6. Sarrat, the breaking up end of the rains.

The Raga, in their musical capacity, are accompanied each with five Ragins, a kind of female deities or nympha of harmony. Each of these has eight sons or genii; and a distinct season is appointed for the music of each rag, during which only it can be sung or played; and this at distinct or stated hours of the day or night. A seventh mode of music belonging to Deipea, or Cupti the inflamer, is said once to have existed, but now to be lost; and a musician, who attempted to restore it, to have been consumed with fire from heaven.

4. Vishnoo, the most celebrated of all the Indian deities, is supposed to fly or ride on the garoona, a kind of large brown kite, which is found in plenty in the neighbourhood; and on which Vishnoo is sometimes represented as sitting; though at others he is represented on a serpent with a great number of different heads. At some of his temples the Bramins accustom all the birds they can find, of the species above mentioned, to come and be fed; calling them by striking upon a brass plate. This deity is said to have had ten different incarnations to destroy the giants with which the earth was infested; and in these he is represented in as many different figures, all of which are to the last degree fantastic and monstrous. His common form is that of a man with four arms, and a number of heads set round in a circle, supposed to be emblems of omniscience and omnipotence. In his first incarnation he is represented as coming out of the mouth of a fish, with several hands containing swords, &c. In another he has the head of a boar with monstrous tusks, bearing a city in the air, and stands upon a vanquished giant with horns on his head. In-eaters of his incarnations, he has the head of a horse or other animals,
In some parts of his character this deity is represented not as a destroyer, but a preserver of mankind; and he is then distinguished by the name of Hory. Bishop Wilkins describes an image of him in this character at a place named Jehan-guery, a small rocky island of the Ganges in the province of Babar. This image is of a gigantic size, recumbent on a coiled serpent, whose numerous heads are twisted by the artist into a kind of canopy over the sleeping god, and from each of its mouths issues a forked tongue, as threatening destruction to those who should dare to approach.

5. Sheeva is represented under a human form, though frequently varied, as is also his name; but he is most frequently called Sheevah and Mahadev. In his destroying character he is represented as a man with a fierce look, and with a snake twisted round his neck. He is thought to preside over good and evil fortune, in token of which he is represented with a crescent on his head. He rides upon an ox.

6. Vikrama, the god of victory, is said to have had a particular kind of sacrifice offered to him, somewhat like the scape-goat of the Jews, viz. by letting a horse loose in the forest, and not employing him again.

7. Yam Rajah, or Daroram Rajah, is represented as the judge of the dead, and ruler of the infernal regions, in a manner similar to the Minos and Pluto of the ancient Greeks. He is the son of Sour, "the sun," by Bīvēsakama daughter of the great architect of the heavenly mansions, and patron of artificers. He rides upon a buffalo, with a sceptre in his hand, having two assistants, Chiter and Goṭi; the former of whom reports the good, and the latter the bad actions of men. These are attended by two genii, who watch every individual of the human race; Chiter's spy being on the right, and Goṭi's on the left. The souls of deceased persons are carried by the Jambouts or messengers of death into the presence of Daroram, where their actions are instantly proclaimed, and sentence passed accordingly. The infernal mansions are named by the Hindoos Narekha, and are divided into a great number of places, according to the degrees of punishment to be endured by the criminal; but eternal punishment for any offence is supposed to be inconsistent with the goodness of God. Instead of this, the Hindoos suppose that after the souls of the wicked have been punished long enough in Narekha, they are sent back into the world to animate other bodies either of men or beasts, according to circumstances. Those who have lived a life partly good and partly bad, are likewise sent back to this world; and these trials and migrations are repeated till they be thoroughly purged of all inclination to sin. But as for those holy men who have spent their lives in piety and devotion, they are instantly conveyed by the genii to the mansions of celestial bliss, where they are absorbed into the universal spirit; a state, according to every idea we can form, equivalent to annihilation.

8. Kishen and the nine Goṣia, among the Hindoos, correspond with Apollo and the nine muses of the Greeks. This deity is represented as a young man sometimes playing on a flute. He has a variety of names, and is supposed to be of a very amorous complexion, having once resided in a district named Birge,

where he embraced almost all the women in the country. From his residence here, or from these amorous exploits, he is sometimes called Birge-pat.

9. Kames-deva, the god of love, is said to be the son of Mäya, or the general attractive power, married to Retty, or Affection. He is represented as a beautiful youth, sometimes conversing with his mother or consort in his temples or gardens; at other times riding on a parrot by moonlight: And Mr Forster informs us, that on the taking of Tanjore by the English, a curious picture was found, representing him riding on an elephant, the body of which was composed of seven young women twisted together in such a manner as to represent that enormous animal. This is supposed to be a device of a similar nature with that of the Greeks, who placed their Eros upon a lion; thus intimating, that love is capable of taming the fiercest of animals. The bow of this deity is said to be of sugar-cane, or of flowers, and the string of bees: he has five arrows, each of them tipped with an Indian blossom of a burning nature. His ensign is a fish on a red ground, carried by the foremost of his attendant nymphae or dancing girls.

10. Lingam, corresponding to the Priapus or Phallus of the ancients, is worshipped by the Hindoos in order to obtain fecundity. This deity is adored the more fervently, as they depend on their children for performing certain ceremonies to their manses, which they imagine will mitigate their punishment in the next world. The devotees of the god go naked, but are supposed to be such sanctified persons, that women may approach them without any danger. They vow perpetual chastity; and death is the consequence of a breach of their vow. Husbands whose wives are barren invite them to their houses, where certain ceremonies, generally thought to be effectual, are performed.

Besides these, there is a number of other gods whose character is less eminent; though it seems not to be ascertained distinctly, even by the Hindoos themselves, what particular rank each deity holds with respect to another. Some of these deities are, 11. Nared, the son of Brintha, and inventor of a fretted instrument named Vene. 12. Leechmy, the goddess of plenty, and wife of Vishnu. 13. Goutry, Kaly, from Kali, "time," the wife of Sheevah, and goddess of destruction. 14. Varooma, the god of the seas and waters, riding on a crocodile. 15. Vepoo, the god of the winds, riding on an antelope with a subre in his hand. 16. Agnee, the god of fire, riding on a ram. 17. Vasuokha, a goddess representing the earth. 18. Pakrecht, or nature, represented by a beautiful young woman. 19. Sour or Shan, the sun; called also the king of the stars and planets, represented as sitting in a chariot drawn by one horse, sometimes with seven and sometimes with twelve heads. 20. Sangia, the mother of the river Jumna, and wife of the sun. 21. Chandava, the moon, in a chariot drawn by antelopes, and holding a rabbit in her right hand. 22. Vreekaspaty, the god of learning; attended by beautiful young nymphs, named Veeryadhares, or professors of science. 23. Ganes, the god of prudence and policy, worshipped before the undertaking of any thing of consequence. 24. Fane, represented by a serpent with a great number of tongues; and known by several names.
Hindoos. 25. Darma-deva, the god of virtue, sometimes represented by a white bull. 26. Visvarupa or Cobbair, the god of riches, represented by a man riding on a white horse. 27. Dharm-cuntry, the god of medicine.

Their deities. Besides the supreme deities the Hindoos have a number of demigods, who are supposed to inhabit the air, the earth, and the waters, and in short the whole world; so that every mountain, river, wood, town, village, &c. has one of these tutelar deities, as was the case among the western heathens. By nature these demigods are subject to death, but are supposed to obtain immortality by the use of a certain drink named Amrut. Their exploits in many instances resemble those of Bacchus, Hercules, Theseus, &c. and in a beautiful epic poem named Ranyak, we have an account of the wars of Ram, one of the demigods, with Ravana tyrant of Ceylon.

Manner of worship. All these deities are worshipped, as in other countries, by going to their temples, fasting, prayers, and the performance of ceremonies to their honour. They pray thrice a day, at morning, noon, and evening, turning their faces towards the east. They use many ablations, and, like the Pharisees of old, they always wash before meals. Running water is always preferred for this purpose to such as stagnates. Fruits, flowers, incense, and money, are offered in sacrifice to their idols; but for the dead they offer a kind of cake named Penda; and offerings of this kind always take place on the day of the full moon. Nothing singular is known in the worship of the Hindoos at present, though there is a tradition that it was formerly of this kind; nay, that even human sacrifices were made use of: but if such a custom ever did exist, it must have been at a very distant period. Their sacred writings indeed make mention of bloody sacrifices of various kinds, not excepting even those of the human race; but so many peculiarities are mentioned with regard to the proper victims, that it is almost impossible to find them. The only instance of bloody sacrifices we find on record among the Hindoos is that of the buffalo to Bawaney, the mother of the gods.

Among the Hindoos there are two kinds of worship, distinguished by the name of the worship of the invisible God and of idols. The worshipers of the invisible God are, strictly speaking, deists: the idolaters perform many absurd and unmeaning ceremonies, too tedious to mention, all of which are conducted by a bramin; and during the performance of these rites, the dancing women occasionally perform in the court, singing the praises of the deity in concert with various instruments. All the Hindoos seem to worship the fire; at least they certainly pay a great veneration to it. Bishop Wilkins informs us, that they are enjoined to light up a fire at certain times, which must be produced by the friction of two pieces of wood of a particular kind; and the fire thus produced is made use of for consuming their sacrifices, burning the dead, and in the ceremonies of marriage.

Great numbers of devotees are to be met with everywhere through Hindostan. Every cast is allowed to assume this way of life excepting the Chandalas, who are excluded. Those held most in esteem are named Sersises and Jogees. The former are allowed no other clothing but what suffices for covering their nakedness, nor have they any worldly goods besides a pitcher and staff; but though they are strictly enjoined to meditate on the truths contained in the sacred writings, they are expressly forbidden to argue about them. They must fast but once a day, and that very sparingly, of rice or other vegetables; they must also show the most perfect indifference about hunger, thirst, heat, cold, or any thing whatever relative to this world; looking forward with continual desire to the separation of the soul from the body. Should any of them fail in this extravagant self-denial, he is rendered so much more criminal by the attempt, as he neglected the duties of ordinary life for those of another which he was not able to accomplish. The Jogees are bound to much the same rules, and both subject themselves to the most extravagant penances. Some will keep their arms constantly stretched over their heads till they become quite withered and incapable of motion; others keep them crossed over their breast during life; while others, by keeping their hands constantly shut, have them quite pierced through by the growth of their nails. Some chain themselves to trees or particular spots of ground, which they never quit; others resolve never to lie down, but sleep leaning against a tree: but the most curious penance perhaps on record is that of a Jogee, who measured the distance between Benares and Juggernaut with the length of his body, lying down and rising alternately. Many of these enthusiasts will throw themselves in the way of the chariots of Vishnou or Sheevah, which are sometimes brought forth in procession to celebrate the feast of a temple and drawn by several hundreds of men. Thus the wretched devotees are in an instant crushed to pieces. Others devote themselves to the flames, in order to show their regard to some of their idols, or to appease the wrath of one whom they suppose to be offended.

A certain set of devotees are named Pandarama; and another on the coast of Coromandel are named Carya-Patra Pandarama. The former rub themselves all over with cow-dung, running about the country singing the praises of the god Sheevah whom they worship. The latter go about asking charity at doors by striking their hands together, for they never speak. They accept of nothing but rice; and when they have got as much as will satisfy their hunger, never give themselves any trouble about more, but pass the rest of the day in the shade, in a state of such supine indolence as scarcely to look at any object whatever. The Tadunas are another set of mendicants, who sing the incantations of Vishnou. They have hollow brass rings round their ankles, which they fill with pebbles; so that they make a considerable noise as they walk; they beat likewise a kind of tabour.

The greatest singularity in the Hindoo religion, however, is, that so far from persecuting those of another contrary persuasion, which is too often the case with religions, other professors, they absolutely refuse even to admit of a proselyte. They believe all religions to be equally acceptable to the Supreme Being; assigning as a reason, that if the Author of the universe preferred one to another, it would have been impossible for any other to have prevailed than that which he approved. Every religion,
Hindoos. religion, therefore, they conclude to be adapted to the country where it is established; and that all in their original purity are equally acceptable.

Among the Hindoos, marriage is considered as a religious duty; and parents are strictly commanded to marry their children by the time they arrive at eleven years of age at farthest. Polygamy is allowed; but this licence is seldom made use of unless there should be no children by the first wife. In case the second wife also proves barren, they commonly adopt a son from among their relations.

The Hindoos receive no dowry with their wives; but, on the contrary, the intended husband makes a present to the father of his bride. Nevertheless, in many cases, a rich man will choose a poor relation for his daughter; in which case the bride's father is at the expense of the wedding, receives his son-in-law into his house, or gives him a part of his fortune. The bridegroom then quits the dwelling of his parents with certain ceremonies, and lives with his father-in-law. Many formalities take place between the parties even after the match is fully agreed upon; and the celebration of the marriage is attended with much expense; magnificent processions are made, the bride and bridegroom sitting in the same palankeen, attended by their friends and relations; some riding in palankeens, some on horses, and others on elephants. So great is their vanity indeed on this occasion, that they will borrow or hire numbers of these expensive animals to do honour to the ceremony. The rejoicing lasts several days; during the evenings of which, fire-works and illuminations are displayed, and dancing-women perform their feats; the whole concluding with alms to the poor, and presents to the bramins and principal guests, generally consisting of shawls, pieces of muslin, and other cloths. A number of other ceremonies are performed when the parties come of age, and are allowed to cohabit together. The same are repeated when the young wife becomes pregnant; when she passes the seventh month without any accident; and when she is delivered of her child. The relations assemble on the tenth day after the birth, to assist at the ceremony of naming the child; but if the bramin be of opinion that the aspect of the planets is at that time unfavourable, the ceremony is delayed, and prayers offered up to avert the misfortune. When the lucky moment is discovered, they fill as many pots with water as there are planets, and offer a sacrifice to them; afterwards they sprinkle the head of the child with water, and the bramin gives it such a name as he thinks best adapted to the time and circumstances; and the ceremony concludes with prayers, presents to the bramins, and alms to the poor. Mothers are obliged to suckle their own children; nor can this duty be dispensed with except in case of sickness. New ceremonies, with presents to the bramins, take place, when a boy comes of age to receive the string which the three first casts wear round their waist.

Boys are taught to read and write by the bramins, who keep schools for that purpose throughout the country. They use leaves instead of books, and write with a pointed iron instrument. The leaves are generally chosen of the palm-tree, which being smooth and hard, and having a thick substance, may be kept for almost any length of time, and the letters are not subject to grow faint or be effaced. The leaves are cut into slips about an inch broad, and their books consist of a number of these tied together by means of a hole in one end. Sometimes the letters are rubbed over with a black powder, to render them more legible. When they write upon paper, they make use of a small reed. Sometimes they are initiated in writing by making letters upon sand strewed on the floor; and they are taught arithmetic by means of a number of small pebbles. The education of the girls is much more limited; seldom extending farther than the articles of their religion.

Among these people the custom of burning the dead prevails universally; and the horrid practice of burning themselves along with their deceased husbands was formerly very common, though now much less so. At present it is totally prohibited in the British dominions; and even the Mohammedans endeavour to discountenance a practice so barbarous, though many of their governors are accused of conniving at it through motives of avarice. At present it is most common in the country of the Rajahs, and among women of high rank.

This piece of barbarity is not enjoined by any law existing among the Hindoos; it is only said to be proper, and rewards are promised in the next world to those who do so. But though a wife chooses to outlive her husband, she is in no case whatever permitted to marry again, even though the marriage with the former had never been completed. It is unlawful for a woman to burn herself if she be with child at the time of her husband's decease, or if he died at a distance from her. In the latter case, however, she may do so if she can procure his girdle or turban to be put on the funeral pile along with her. These miserable enthusiasts, who devote themselves to this dreadful death, suffer with the greatest constancy; and Mr Holwel gives an account of one who, being told of the pain she must suffer (with a view to dissuade her), put her finger into the fire and kept it there for a considerable time; after which she put fire on the palm of her hand, with incease upon it, and fumigated the bramins who were present. Sometimes a chapel is erected on the place where one of those sacrifices has been performed; sometimes it is inclosed, flowers planted upon it, and images set up. In some few places the Hindoos bury their dead; and some women have been known to suffer themselves to be buried alive with their deceased husbands: but the instances of this are still more rare than those of burning. No woman is allowed any inheritance among the Hindoos; so that if a man dies without male issue, his estate goes to his adopted son or to his nearest relation.

The Hindoos, though naturally mild and timid, will instances on many occasions meet death with the most heroic intrepidity. An Hindoo who lies at the point of death, will talk of his decease with the utmost composure; and if near the river Ganges, will desire to be carried out, that he may expire on its banks. Such is the excessive veneration they have for their religion and customs, that no person will infringe them even to preserve his own life. An Hindoo, we are told, being ill of a putrid fever, was prevailed upon to ascend, by a European physician, who prescribed him the bark in wine; but this was refused with the greatest obstinacy even
Hindus.

Hindus, to the very last, though the governor himself joined in his solicitations, and in other matters had a considerable influence over him. In many instances these people, both in ancient and modern times, have been known, when closely besieged by an enemy whom they could not resist, to kill their wives and children, set fire to their houses, and then violently rush upon their adversaries till every one was destroyed. Some sepoys, in the British service, having been concerned in a mutiny, were condemned to be blown away from the mouths of cannon. Of these some were grenadiers, who cried out, that as they had all along had the post of honour, they saw no reason why they should be denied it now; and therefore desired that they might be blown away first. This being granted, they walked forward to the guns with composure, begged that they might be spared the indignity of being tied, and, placing their breasts close to the muzzles, were shot away. The commanding officer was so much affected with this instance of heroism, that he pardoned all the rest.

In ordinary life the Hindus are cheerful and lively; fond of conversation and amusement, particularly dancing. They do not, however, learn or practise dancing themselves, but have women taught for the purpose; and in beholding these they will spend whole nights. They disapprove of many parts of the education of European ladies, as supposing that they engage the attention too much, and draw away a woman's affection from her husband and children. Hence there are few women in Hindostan who can either read or write. In general they are finely shaped, gentle in their manners, and have sweet and even musical voices. The women of Kashmir, according to Mr. Forster, have a bright olive complexion, fine features, and delicate shape; a pleasing freedom in their manners, without any tendency to immodesty.

Dress of the women.

The dress of the modest women in Hindostan consists of a close jacket, which covers their breasts, but perfectly shows their form. The sleeves are tight, and reach half way to the elbows, with a narrow border painted or embroidered all round the edges. Instead of a petticoat, they have a piece of white cotton cloth wrapped round the loins, and reaching near the ankle on one side, but not quite so low on the other. A wide piece of muslin is thrown over the right shoulder; which, passing under the left arm, is crossed round the middle, and hangs down to the feet. The hair is usually rolled up into a knot or bunch towards the back part of the head; and some have curls hanging before and behind the ears. They wear bracelets on their arms, rings in their ears, and on their fingers, toes, and ankles; with sometimes a small one in their nostril.

The dress of the dancing women, who are likewise votaries of Venus, is very various. Sometimes they wear a jaun, or long robe of wrought muslin, or gold and silver tissue; the hair plaits and hanging behind with spiral curls on each side of the face. They are taught every accomplishment which can be supposed to captivate the other sex; form a class entirely different from the rest of the people, and live by their own rules. Their clothes, jewels, and lodgings, are considered as implements of their trade, and must be allowed them in cases of confiscation for debt: They may drink spirituous liquors, and eat any kind of meat except beef: Their dances are said to resemble pretty exactly those of the ancient Bacchanalians represented in some of the ancient paintings and bas reliefs. In some of their dances they attach gold and silver bells to the rings of the same metals they wear on their ankles.

The men generally shave their heads and beards, and of leaving only a pair of small whiskers and a lock on the back part of their head, which they take great care to preserve. In Kashmir and some other places, they let their beards grow to the length of two inches. They wear turbans on their heads; but the Brahmins who officiate in the temples commonly go with their heads uncovered, and the upper part of the body naked: round their shoulder they hang the sacred string called Zennar, made of a kind of perennial cotton, and composed of a certain number of threads of a determined length. The Khatries wear also a string of this kind, but composed of fewer threads; the Bihys have one with still fewer threads, but the Sooderas are not allowed to wear any string. The other dress of the Brahmins consists of a piece of white cotton cloth wrapped about the loins, descending below the knee, but lower on the left than on the right side. In cold weather they sometimes put a red cap on their heads, and wrap a shawl round their bodies. The Khatries, and most other of the inhabitants of this country, wear also pieces of cotton cloth wrapped round them, but which cover the upper as well as the lower part of the body. Ear-rings and bracelets are worn by the men as well as women: and they are fond of ornamenting themselves with diamonds, rubies, and other precious stones, when they can procure them. They wear slippers on their feet of fine woollen cloth or velvet, frequently embroidered with gold and silver; those of princes sometimes adorned with precious stones. The lower classes wear sandals or slippers of coarse woollen cloth, or leather. These slippers are always put off on going into any apartment, being left at the door, or given to an attendant; nevertheless the Hindus make no complaints of the Europeans for not putting off their shoes when they come into their houses, which must certainly appear very uncouth to them.

Hindoo families are always governed by the eldest male, to whom great respect is shewn. Filial veneration is carried to such a height among them, that a son will not sit down in the presence of his father until ordered to do so; and Mr. Forster observes, that during the whole time of his residence in India, he never saw a direct instance of undutifulness to parents; and the same is related by other writers.

The houses of the Hindus make a worse appearance than could be supposed from their ingenuity in other respects. In the southern parts of the country, the houses are only of one story. On each side of the door, towards the street, is a narrow gallery covered by the slope of the roof which projects over it, and which, as far as the gallery extends, is supported by pillars of brick or wood. The floor of this gallery is raised about 20 inches above the level of the street; and the porters, or bearers of palankees, with the foot soldiers named Peons, who commonly hire themselves to noblemen, often lie down in this place. This entrance leads into a court, which is also surrounded by a gallery like the former. On one side of the court is a large room, on a level with the floor of the gallery; open in front, and
spread with mats and carpets covered with white cotton cloth, where the master of the house receives visits and transacts business. From this court there are entrances by very small doors to the private apartments. In the northern parts, houses of two or three stories are commonly met with. Over all the country also we meet with the ruins of palaces, which evidently show the magnificence of former times.

Learning of the Bramins.

The Brahmans of India were anciently much celebrated for their learning, though they now make a very inconsiderable figure in comparison with the Europeans. According to Philostratus, the Gymnosophists of Ethiopia, were a colony of Brahmans, who being obliged to leave India on account of the murder of their king near the banks of the Ganges, migrated into that country. The ancient Brahmans, however, may justly be supposed to have cultivated science with much greater success than their descendants can boast of, considering the ruinous wars and revolutions to which the country has been subjected. Metaphysics, as well as moral and natural philosophy, appear to have been well understood among them; but at present all the Hindoo knowledge is confined to those whom they call Pandits, “doctors or learned men.” These only understand the language called Sanscrit or Sacrist, (from two words signifying perfection); in which the ancient books were written.

The metaphysics of the Brahmans is much the same with that of some ancient Greek philosophers. They believe the human soul to be an emanation from the Deity, as light and heat from the sun. Goutama, an ancient metaphysician, distinguishes two kinds of souls, the divine and vital. The former resembles the eternal spirit from which it came, is immaterial, indivisible, and without passions; the vital soul is a subtle element which pervades all things, distinct from organized matter, and which is the origin of all our desires. The external senses, according to this author, are representations of external things to the mind, by which it is furnished with materials for its various operations; but unless the mind act in conjunction with the senses, the operation is lost, as in that absence of mind which takes place in deep contemplation. He treats likewise of reason, memory, perception, and other abstract subjects. He is of opinion, that the world could not exist without a first cause; chance being nothing but the effect of an unknown cause: he is of opinion, however, that it is folly to make any conjectures concerning the beginning or duration of the world. In treating of providence, he denies any immediate interposition of the Deity; maintaining, that the Supreme Being having created the system of nature, allowed it to proceed according to the laws originally impressed upon it, and man to follow the impulse of his own desires, restrained and conducted by his reason. His doctrine concerning a future state is not different from what we have already stated as the belief of the Hindoos in general. According to Bishop Wilkins, many of them believe that this world is a state of rewards and punishments as well as of probation; and that good or bad fortune are the effects of good or evil actions committed in a former state.

The science for which the Brahmans, however, were most remarkable, is that of astronomy; and in their progress was so great, as even yet to furnish matter of admiration to the moderns.—The Europeans first became acquainted with the Indian astronomy in 1687, from a Siamese MS. containing rules for calculating the places of the sun and moon, brought home by M. Loubrere the French ambassador at Siam. The principles on which the tables in this MS. were founded, however, proved to be so obscure, that it required the genius of Cassini to investigate them. The missionaries afterwards sent over two other sets of tables from Hindostan; but no attention was paid to them till M. le Gentil returned from observing the transit of Venus in 1769. During the time of his stay in Hindostan, the Brahmans had been much more familiar with him on account of his astronomical knowledge, than they usually were with Europeans; and he thus had an opportunity of obtaining considerable insight into their methods of calculation. In consequence of this instruction he published tables and rules, according to the Indian method, in the academy of sciences for 1772; and in the explanation of these M. Bailly has employed a whole volume. The objects of this astronomy, according to Mr Playfair, are 1. Tables and rules for calculating the places of the sun and moon. 2. Of the planets. 3. For determining the phases of eclipses. They divide the Zodiac into 27 constellations, probably from the motion of the moon through it in 27 days; and to this lunar motion the Professor ascribes the general division of time into weeks, which has prevailed so universally throughout the world. The days of the week were dedicated to the planets, as by the ancient heathens of the west, and in precisely the same order. The ephemeris is divided into signs, degrees, and minutes, as with us: and indeed their calculations are entirely sexagesimal, the day and night being divided into 60 hours; so that each of their hours is only 24 of our minutes, and each of their minutes 24 of our seconds.

The requisites for calculating by the Indian tables are, 1. An observation of the celestial body in some past moment of time, which is commonly called the Epoch of the tables. 2. The mean rate of the planet's motion. 3. The correction on account of the irregular motion of the body, to be added or subtracted from the mean place, according to circumstances. They calculate the places of the sun and moon, not from the time of their entrance into the signs, but into the movable Zodiac. Thus the beginning of the year is continually advancing with regard to the sessions; and in 24,000 years will have made the complete round. The mean place of the sun for any time is deduced on the supposition that 800 years contain 292,207 days; from whence, by various calculations, the length of the year comes out only 1° 53' greater than that of De la Caille; which is more accurate than any of our ancient astronomical tables. In the equation of the sun's centre, however, they commit an error of no less than 56°: But Mr Playfair is of opinion that this cannot be ascribed wholly to their inaccuracy, as there was a time when their calculation approached very near the truth; and even at present the error is less than it appears to be.

The motions of the moon are deduced from a cycle of 19 years; during which she makes nearly 235 revolutions; and which period constitutes the famous cycle supposed to have been invented by Meton the Athenian astronomer, and from him called the Metonic Cycle. They are likewise surprisingly exact in calculating.
Hindoo. ting the moon's apogee and some of the inequalities of her motion; they know the apparent motion of the fixed stars eastward, and the Siamese tables make it only four seconds too quick; which still shows a great accuracy of calculation, as Ptolemy the celebrated astronomer made an error of no less than 14 seconds in calculating the same thing. M. Cassini, however, informs us, that these tables are not calculated for the meridian of Siam, but for a place 19° 15' to the westward of it, which brings us very near the meridian of Benares, the ancient seat of Indian learning. This likewise agrees with what the Hindoos call their first meridian, which passes through Ceylon, and the banks of the river Remanur. It must be observed, however, that the geography of the Hindoos is much more inaccurate than their astronomy.

The date of the Siamese tables is not very ancient; and that of the table above mentioned sent from Hindostan by the missionaries is still more modern. These, however, are written in such an enigmatical manner, that the missionary who sent them was unable to tell their meaning; and Mr Playfair supposes that even the Brahmins themselves were ignorant of it. Nevertheless they were deciphered by M. le Gentil; who thinks that they have the appearance of being copied from inscriptions on stones. The minutes and seconds are not ranged in vertical columns, but in rows under one another, and without any title to point out their meaning or connexion.

The tables of Trivalore are among the most remarkable of all we are yet acquainted with. Their date, according to Mr Playfair, corresponds with the year 3102 B. C.; thus running up to the year of the world 902, when Adam was still in life. This era is famous in Hindostan, under the name of Calyougham: and as this extraordinary antiquity cannot but create some suspicion, Mr Playfair has been at some pains to determine whether it is real or fictitious, i.e. whether it has been determined by actual observation, or derived by calculation from tables of more modern date. The result of his labours is, that we are to account the Calyougham as determined by observation; and that had it been otherwise, we must have been furnished with infallible methods of detecting the fallacy. His reasons for this opinion are,

1. The task would have been too difficult, even for modern astronomers, to make the necessary calculations without taking into account the disturbances arising from the action of the heavenly bodies upon one another, and with which we cannot suppose the ancient astronomers to have been equally well acquainted with the moderns. By reason of these variations, as well as from the small errors unavoidable in every calculation, any set of astronomical tables will be found prodigiously inaccurate when applied to any period very far distant from the time of observation. Hence, says our author, “it may be established as a maxim, that if there be given a system of astronomical tables, founded on observations of an unknown date, that date may be found by taking the time when the tables represent the celestial motions most exactly.” This indeed might be done, provided we were furnished with any set of perfectly accurate tables with which we could compare the suspected ones; and Mr Playfair thinks it a very reasonable postulatum, that our modern astronomical tables, though not perfectly accurate, are yet capable of determining the places of the celestial bodies without any sensible error for a longer period than that of the Calyougham.

2. By calculation from our modern tables, it appears that the place of the star Aldebaran, at the commencement of the Calyougham, differs only 53' from what the Indian tables make it. He thinks this coincidence the more remarkable, as the Brahmins, by reason of the inaccuracy of their own date, would have erred by four or five degrees, had they calculated from their most modern tables dated in 1451.

3. At the commencement of this epoch (which according to M. Bailly, happened at midnight between the 17th and 18th of February 3102 B.C.), the sun was in 10° 30' 13' 13'' by the Indian tables. But the mean longitude of the sun, according to the tables of M. de la Caille, for the same time, comes out to be only 10° 1° 5' 57"; supposing the precession of the equinoxes to have been the same at that time as now. M. de la Grange, however, has demonstrated, that, in former ages, the precession of the equinoxes was less than at present; whence there arises an equation of 1° 45' 22" to be added to the sun's place already mentioned: and thus it will differ only 47 from the radical place in the tables of Trivalore. Notwithstanding this reasoning, however, Mr Playfair thinks that no stress is to be laid upon this argument, as it depends on the truth of a conjecture of M. Bailly that the place of the sun above mentioned was not the mean but the true one.

4. The mean place of the moon at Benares, calculated from Mr Mayer's tables, for the 18th of February 3102 B.C., will be 10° 00' 16''; provided her motion had all that time been equable: but the same astronomer informs us, that the motion of the moon is subject to a small but uniform acceleration, about 20'' in 100 years; which, in an interval of 4800 years, must have amounted to 5° 45' 44''; which added to the preceding, gives 10° 46' 27'' for the true place of the moon at the commencement of the Calyougham. Now the place of this luminary, at that time, by the tables of Trivalore, is 10° 6'; the difference is less than two-thirds of a degree, which, for so remote a period, and considering the acceleration of the moon's motion, for which no allowance could be made in an Indian calculation, is a degree of accuracy that nothing but actual observation could have produced.——This conclusion is confirmed by a computation of the moon's place from all the tables to which the Indians could have had any access, and of which the enormous errors would instantly show the deception. Thus, by the tables of Ptolemy, the place of the sun would be 10° 21' 13'' greater; and that of the moon 11° 52' 1'' greater than has just been found from the Indian tables. By those of Ulugh Beg, the place of the sun would be 1° 30', and that of the moon 6'', different from what it is by the Indian tables; and in like manner our author shows that the Indian calculations could not be derived from any other set of tables extant. In like manner, he shows that, with regard to the mean place of the moon, there is a coincidence for a period of more than 4000 years between the tables of Mayer and those of India named Chriembouram; which, though they bear a more modern date than those of Trivalore, are thus probably more ancient.

"From
...from this remarkable coincidence (says Mr Playfair), we may conclude, with the highest probability, that at least one set of these observations on which the tables are founded, is not less ancient than the era of the Calyougham: and though the possibility of their being some ages later than that epoch is not absolutely excluded, yet it may, by strict mathematical reasoning, be inferred, that they cannot have been later than 2000 years before the Christian era.

5. Since the time that M. Baillie wrote, every argument respecting the acceleration of the moon's motion has become more worthy of attention, and more conclusive. For that acceleration is no longer a mere empirical equation introduced to reconcile the ancient observations with the modern, nor a fact that can only be accounted for by hypothetical causes, such as the resistance of the ether, or the time necessary for the transmission of gravity; but a phenomenon which M. de la Place has with great ability deduced from the principle of universal gravitation, and shown to be necessarily connected with the changes of eccentricity in the earth's orbit discovered by M. de la Grange: so that the action of the moon is indirectly produced by the action of the planets, which alternately increasing and diminishing this eccentricity, subjects the moon to different degrees of that force by which the sun disturbs the time of her revolution round the earth. It is therefore a periodical inequality, by which the moon's motion, in the course of ages, will be as much retarded as accelerated; but its changes are so slow, that her motion has been constantly accelerated, even for a much longer period than that to which the observations of India extend.---To M. de la Grange also we are indebted for one of the most beautiful discoveries in physical astronomy, viz. That all the variations in our system are periodical; so that, though every thing, almost without exception, be subject to change, it will, after a certain interval, return to the same state in which it is at present, and leave no room for the introduction of disorder, or of any irregularity that might constantly increase. Many of these periods, however, are of vast duration. A great number of ages, for instance, must elapse, before the year be exactly of the same length, or the sun's equation be of the same magnitude, as at present. An astronomy, therefore, which professes to be so ancient as the Indian, ought to differ considerably from ours in many of its elements. If, indeed, these differences are irregular, they are the effects of chance, and must be accounted errors; but if they observe the laws which theory informs us they do, they must be held as the most undoubted marks of authenticity.

6. Neither these tables of Trivalore, nor the more ancient ones of Chrisnabouram, are those of the greatest antiquity in India. The Bramins constantly refer to an astronomy at Benares, which they emphatically style the ancient; and which, they say, is not now understood by them, though they believe it to be much more accurate than that by which they calculate.

From these and other similar arguments, Mr Playfair draws the following conclusions with respect to Indian astronomy. 1. The observations on which it is founded, were made more than 2000 years before the Christian era; and, in particular, the places of the sun and moon, at the beginning of the Calyougham, were determined by actual observation. 2. Though the astronomy now in the hands of the Bramins is so ancient in its origin, yet it contains many rules and tables that are of later construction. 3. The basis of their four systems of astronomical tables is evidently the same. 4. The construction of these tables implies a great knowledge of geometry, arithmetic, and even the theoretical part of astronomy. All this, however, we find controverted, or at least rendered somewhat doubtful, by William Marsden, Esq. who has written a paper on the chronology of the Hindoos, in the Philosophical Transactions for 1750. "The Kules Yogy (says he), or principal chronological era, began in the year 3102 B.C. according to the common method of computation, or in 3101 according to the astronomical method, on the 18th of February, at sunrise; or at midnight, according to different accounts, under their first meridian of Louka. At that period it is said to have been asserted by their astronomers, that the sun, moon, and all the planets, were in conjunction according to their mean places. The reality of this fact, but with considerable modification, has received a respectable sanction from the writings of an ingenious and celebrated member of the French academy of sciences, who concludes that the actual observation of this rare phenomenon, by the Hindoos of that day, was the occasion of its establishment as an astronomical epoch. Although M. Baillie has supported this opinion with his usual powers of reasoning, and although abundant circumstances tend to prove their early skill in this science, and some parts of the mathematics connected with it; yet we are constrained to question the verity or possibility of the observation, and to conclude rather that the supposed conjunction was, at a later period, sought for as an epoch, and calculated retrospectively. That it was widely miscalculated too, is sufficiently evident from the computation which M. Baillie himself has given of the longitudes of the planets at that time, when there was a difference of no less than 73° between the places of Mercury and Venus. But fifteen days after, when the sun and moon were in opposition, and the planets far enough from the sun to be visible, he computes that all, except Venus, were comprehended within a space of 15°; and on this he grounds his supposition of an actual observation.

"In their current transactions the inhabitants of the peninsula employ a mode of computation of a different nature, which, though not unknown in other parts of the world, is confined to these people among the Hindoos. This is a cycle, or revolving period, of 60 solar years, which has no farther correspondence with their other eras than that of their years respectively commencing on the same day. Those that constitute the cycle, instead of being numerically counted, are distinguished from each other by appropriate names, which in their epistles, bills, and the like, are inserted as dates, with the months, and perhaps the age of the moon annexed; but in their writings of importance and record, the year of Salabau (often called the Saka year) is superadded; and this is the more essential, as I do not find it customary to number the cycles by any progressive reckoning. In their astronomical calculations we observe, that they sometimes give the number of their cycles by multiplying the number of cycles elapsed, and adding the complement of the cycle in which it commenced,
Hindoos, menced, as well as the years of the present cycle; but from hence we are led to no satisfactory conclusion concerning this popular mode of estimating time. The presumption is in favour of its being more ancient than their historical epochs. The present cycle, of which 43 complete years expired in April 1790, began in 1747, with the year of Salaban 1669, and of the grand era 4848. M. le Gentil, to whom Europe is chiefly indebted for what is known of Hindoo astronomy, has fallen into an unaccountable error with regard to the years of this cycle, and their correspondence with those of the Kalee Yoog, as appears by the comparative table he has given of them, and other passages of his work. He seems to have taken it for granted, without due examination, that the years 3600 of the latter must have been produced by the multiplication of the cycle of 60 into itself; and consequently that the first year of this grand era must likewise have been the first of the cycle. But this is totally inconsistent with the fact; the Kalee Yoog began the 13th year of the cycle of 60; and all the reasoning founded on the self-production and harmony of these periods must fall to the ground."

From what Mr. Marsden here sets forth, it is plain that we must make very considerable abatements in our confidence of the extreme antiquity of the Hindoos observations. Indeed we can scarcely conceive a possibility of reconciling such extravagant antiquity with the authentic histories of which we are possessed, or with those of Scripture. The want of an ancient history of Hindostan leaves us indeed in the dark, and gives room for ingenious and speculative men to indulge themselves in marvellous reveries concerning their antiquity. But the flood, we know, which if it existed at all, could not be but general over the whole earth*, must have destroyed every monument of art and science; and it is surely more reasonable to believe, that M. le Gentil, or the most learned man in the present age, has been mistaken (even though we should not be able to determine the particular manner in which at once to deny the authenticity of all history both sacred and profane), and attempt to evade evidence which no power of reasoning can ever set aside.

It is, however, undeniable, that the progress of the Hindoos in geometry as well as astronomy has been very great in ancient times. Of this a most remarkable instance is given by Mr. Playfair, in their finding out the proportion of the circumference of a circle to its diameter to a great degree of accuracy. This is determined, in the Ayen Akbery, to be as 3927 to 1250, and which, to do it arithmetically in the simplest manner possible, would require the inscription of a polygon of 768 sides; an operation which cannot be performed without the knowledge of some very curious properties of the circle, and at least nine extractions of the square root, each as far as ten places of decimals. This proportion of 1250 to 3927 is the same with that of 1 to 3.1416; and differs very little from that of 113 to 355 discovered by Metrus. He and Vieta were the first who surpassed the accuracy of Archimedes in the solution of this problem; and it is remarkable that these two mathematicians flourished at the very time that the Ayen Akbery was composed among the Hindoos. In geography, however, they are much deficient; and it is very difficult to find out the true situation of the merridians mentioned by their authors from what they have said concerning them.

The art of painting among the Hindoos is in an imperfect state; nor are there any remains of antiquity which evince its ever being more perfect than it is just now. Their principal defect is in drawing, and they seem to be almost totally ignorant of the rules of perspective. They are much better skilled in colouring, and some of their pictures are finished with great nicety. Their sculptures are likewise rude, and greatly resemble those of the Egyptians. They seem to follow no regular rules in architecture: their temples indeed are filled with innumerable columns, but most of them without any just shape or proportion. They are principally remarkable for their immense size, which gives them an air of majesty and grandeur.

The music of the Hindoos is but little known to Europeans; and the art seems to have made but little progress among them in comparison with what it has done in the western countries; though some of the Indian airs are said to be very melodious. Their musical instruments are very numerous: in war they use a kind of great kettle-drum named nagar, carried by a camel, and sometimes by an elephant. The doli is a long narrow drum slung round the neck; and the tam-tam is a flat kind of drum resembling a tabor, but larger and louder. They use also the cymbal, which they name talan; and they have various sorts of trumpets, particularly a great one named tary, which emits a most doleful sound, and is always used at funerals, and sometimes to announce the death of persons of distinction.

The jugglers among the Hindoos are so expert, that jugglers many of the missionaries have ascribed their tricks to supernatual power; and even so late a traveller as Mr. Grose seems to be of a very different opinion. Like the Egyptians, they seem to have the power of disarming serpents of their poison, and there are many strollers who go about with numbers of these animals in bags, having along with them a small bagpipe called magouty, which they pretend is useful to bring them from their lurking places. They take the serpents, though of the most poisonous kinds, out of the bags with their naked hands, and throw them on the ground, where they are taught to rear and move about to the sound of their music. They say that this is accomplished by means of certain incantations.

The use of fire-arms appears to have been of great antiquity in India. They are prohibited by the code of fire-arms of Gentoo laws, which is certainly of a very ancient date. The phrase by which they are denominated is agnecaster, or weapons of fire; and there is also mention mode of shet-ognee, or the weapon that kills an hundred men at once. It is impossible to guess at the time when those weapons were invented among the Hindoos; but we are certain, that in many places of the east, which have neither been frequented by Mohammedans nor Europeans, rockets are almost universally made use of as weapons of war. The Hindoo books themselves ascribe the invention of fire-arms to Baeshkokerma, who formed all the weapons made use of in a war between the good and evil spirits. Fire-balls, or blue lights, employed in besieged places in the night-time, to observe the motions of the besiegers, are met with everywhere through Hindostan, and are constructed
Hindoo. 

Fireworks also are met with in great perfection, and, from the earliest ages, have constituted a principal article of amusement among the Hindoos. Gunpowder, or a composition somewhat resembling it, has been found in many other places of the east, particularly China, Pegu, and Siam; but there is reason to believe that the invention came originally from Hindostan. Poisoned weapons of all kinds are forbidden in this country.

The Hindoos are remarkable for their ingenuity in all kinds of handicraft; but their utensils are simple, and in many respects inconvenient, so that incredible labour and patience are necessary for the accomplishment of any piece of work; and for this the Hindoos are very remarkable. Lacquering and gilding are used all over the country, and must have been used in very early ages; though in some places the lacquering is brought to much greater perfection than in others.

The principal article of food throughout all Hindostan is rice, and of consequence the cultivation of it forms the principal object of agriculture. In this the most important requisite is plenty of water; and when there happens to be a scarcity in this respect, a famine must be the consequence. To prevent this as far as possible, a vast number of tanks and water-courses are to be met with throughout the country, though in some places these are too much neglected, and gradually going to decay. After the rice is grown a certain length, it is pulled up, and transplanted into fields of about 100 yards square, separated from each other by ridges of earth; which are daily supplied with water let in upon them from the neighbouring tanks. When the water happens to fall below the level of the channels made to receive it, it is raised by a simple machine named picoci, the construction of which is as follows. A piece of timber is fixed upright in the ground, and forked so as to admit another piece to move transversely in it by means of a strong pin. The transverse timber is flat on one side, and has pieces of wood across it in the manner of steps. At one end of this timber there is a large bucket, at the other a weight. A man walking down the steps throws the bucket into the well or tank; by going up, and by means of the weight, he raises it; and another person standing below empties it into a channel made to convey the water into the fields. The man who moves the machine may support himself by long bamboo that are fixed in the way of a railing from the top of the piece of upright timber towards the wall.

A number of other kinds of grain are to be met with in Hindostan, but wheat is not cultivated farther south than 18° latitude. It is imported, however, to every part of the country by the Banjaries. These are a set of people belonging to no particular cast, who live in tents, and travel in separate bodies, each of which is governed by its own particular regulations. They frequently visit towns on the sea-coast, with bullocks loaded with wheat and other articles; carrying away in exchange spices, cloths, but especially salt, which they carry into the inland parts of the country. Some of their parties have several thousand of oxen belonging to them. They are rarely molested, even in time of war, otherwise than by being sometimes pressed into the service of an army to carry baggage or provisions; but for this they are paid, and dismissed as soon as the service is over. The Hindoos themselves are prohibited from going out of the country, under the severest of all penalties, that of losing their cast.—Notwithstanding this, however, it is certain that they do settle in foreign parts in the character of merchants and bankers. Perhaps these may have a toleration from the principal Brahmin, or there may be an exemption for people of their profession; but this is not known. At any rate, wherever they go, they appear inviolably attached to their religious ceremonies, and refuse to eat what is prohibited to them in their own country. The Ryots, or people who cultivate the ground, are in many places in the most miserable situation; their only food being some coarse rice and pepper, for which they are obliged to endure all the inclemencies of a burning sun, and the inconveniences which attend alternately wading in water and walking with their bare feet on the ground heated intensely by the solar rays; by which they are frequently blistered in a miserable manner. All this, however, they submit to with the utmost patience, and without making any complaint, expecting to be released from their sufferings by death; though even then their religion teaches them to hope for nothing more than what they call absorption into the essence of the Deity; a state almost synonymous with what we call annihilation.

HINDOSTAN, a celebrated and extensive country of Asia, bounded on the north by Great and Little Tibet; on the south, by the bither peninsula of India, part of the Indian sea, and bay of Bengal; on the west, by Persia; and on the east, by Tibet, and the farther peninsula. It is situated between 24° and 25° of east longitude, and between 21° and 36° of north latitude; being in length about 1204 miles, and in breadth 560; though in some places much less.

This country was in early times distinguished among the Greeks by the name of India, the most probable of the derivation of which is from Hind, the Persian name, for Hindostan. We are assured by Mr Wilkins, that no such words as Hindoo or Hindostan exist in the Sanscrit or learned language of the country; in which it is named Bharata, a word totally unknown to Europeans. The first accounts we have of Hindostan are from Herodotus, who lived 113 years before the expedition of Alexander the Great. His accounts, however, convey very inadequate information, as he appears only to have heard of the western part of the country, and that on account of its being tributary to Persia. He informs us, that Darius Hystaspes, about 508 B.C. had sent Scylax of Caryanda to explore the river Indus. He set sail from Caspatyrus, a town near the source of the Indus, and the territories of Pactya (which Major Rennel supposes to be the modern Pehickly), and continued his course eastward to the sea; then altering his course to the west, he arrived at that place where the Phcenicians had formerly sailed round the continent of Africa; after which Darius subdued the Indians, and became master of that sea. The northern inhabitants of India, he says, resembled the Bactrians in their manners, and were more valiant than the rest; those far to the southward were as black as the Ethiopians, killed no animals, but lived chiefly upon rice; and clothed themselves with cotton. By the expedition of Alexander,
Hindostan, the Greeks acquired a little more knowledge of the country of Hindostan, though he did little else than march over the tracts described by Herodotus. He was informed of the existence of the river Ganges, which had not been known to Herodotus; and the story of his supposing that he had discovered the source of the Nile, when near the head of the Indus, is well known, as well as his surprise and consternation when he arrived at the mouth of that river, on account of the high tides. Major Renel is of opinion that both these stories are falsehoods. He thinks it is impossible that Alexander could have been ignorant of the writings of Herodotus, who gave an account of the discoveries of Soylex; and with regard to the other circumstance he expresses himself as follows: "The story of Alexander’s supprise at seeing the tides in the Indus, appears to me equally improbable; seeing that the same Herodotus, book iii. speaks very particularly of the tides in the Red sea, and describes them as being not only strong, but ebbing and flowing every day. (That most intelligent and ingenious traveller Mr. Volney informs us, that the tide tides and flows three feet, and a half at Suez.) Arrian takes no notice of the tides until Alexander’s fleet had arrived near the mouth of the river. It is true, the tide of the Indus does not go up as high as in other rivers of equal bulk, and that run so small a descent; but nevertheless, as the tide is perceptible at 50 or 60 miles above the river’s mouth, we may conclude, that it could hardly escape the notice of Alexander and his people in their voyage from Patalla to the sea, supposing they had not been apprised of the circumstance. Besides, Arrian’s account of the tides which did so much mischiefe to the fleet, is descriptive of the bore, or sudden influx of the tide, in a body of water elevated above the common surface of the sea; such as occurs in the Ganges, &c. He says, those ships which lay upon the sand were swept away by the fury of the tide; while those that stuck in the mud were set about again without any damage. To the generality of readers no reason will appear why the circumstances of the ships should be different in the mud and on the sand: the fact is, that the bottoms of channels in great rivers are muddy, while their shallows are formed of sand; and it is the nature of the bore to take the shortest cut up a river, instead of following the windings of the channel; consequently it must cross the sand banks it meets in its way, and will also prove more destructive to whatever it meets with aground than what is aloft." For an account of the exploits of Alexander in Hindostan, see the article Macedon.

The Grecian expedition into India soon excited a general curiosity in the Europeans to become acquainted with a country so wealthy and so remote. Megasthenes, the ambassador of Seleucus, resided long at Palieschra the capital of an Indian nation, and from him the ancient writers learned most of what they knew concerning that part of the world. He lived about 300 years before the Christian era, and kept a journal during the time he resided in India.

For some short time the western provinces of India continued subject to the Syrian empire founded by Seleucus; but he quickly ceded those distant countries to one Sandroctus, who gave him only 500 elephants in exchange. Soon after this the province of Bactria likewise became independent; and thus the connection between India and the western parts of the world was entirely dissolved, and we are almost entirely ignorant of the transactions of that country till the time of the Mohammedan conquest. That extensive country we now call Hindostan was divided among many different nations, we have no reason to doubt; but Major Renel is of opinion, that however this might be the case, there was generally a large empire or kingdom, which occupied the principal part of that immense valley through which the Ganges takes its course; the capital of which has fluctuated between Delhi and Patna, as the limits of the empire have varied. This was named the kingdom of the Pusaj or Gangaride in the times of Alexander and Megasthenes. Major Renel is of opinion that it extended westward to the Punjab country; and he also thinks it probable that the capital named Palieschra stood on the same spot which is now occupied by the city of Patna. The kingdom, according to this supposition, would occupy part of Bengal; and he thinks that it could not be less than that of France. It was on the borders of this kingdom that Alexander’s army mutinied and refused to proceed any farther. Arrian informs us, that the people were rich, excellent soldiers, and good husbandmen; that they were governed by nobility, and that their rulers imposed nothing harsh upon them.

The Hindoos themselves pretend to an extraordinary ancient antiquity; but we are informed by Major Renel, that there is no known history of Hindostan (that rests on the foundation of Hindoo materials or records) extant before the period of the Mohammedan conquests; for either the Hindoos kept no regular histories, or they were all destroyed, or excluded from common eyes by the Pundits. We may judge of their traditions by that existing concerning Alexander’s expedition; which is, that he fought a great battle with the emperor of Hindostan near Delhi, and though victorious, retired to Persia across the northern mountains; so that the remarkable circumstance of his sailing down the Indus, in which he employed many months, is sunk altogether. And yet, perhaps, few events of ancient times rest on better foundations than this part of the history of Alexander, as appears by its being so highly celebrated, not only by contemporaries, but by several of the most eminent authors for some centuries following. The only traces of Indian history we meet with are in the Persian historians. In the beginning of the 17th century, Mohammed Ferishta composed a history of Hindostan, most of which was given in that of Colonel Dow, published upwards of 30 years ago; but with regard to the early part of it, Major Renel is of opinion that it cannot at all be depended upon.
Hindostan, had projected the conquest of the western part of India; but dying before he could put his design in execution, Mahmud took upon himself the conduct of the expedition; but previous to his invasion of India, he strengthened himself by the conquest of the whole of the ancient Bactria. His first invasion took place in the year 1000; during which he made no farther progress than the province of Moulton. That part of the country was inhabited by the Kuttity and Rajafoot tribe, the Ghiliz and Cuthers of Alexander, who still retained their ancient spirit, and made a strong resistance to the armory of that furious enthusiast. As he was prompted to this undertaking no less by a desire of exterminating the Hindoo religion than by that of conquest, a league was at last formed against him among all the Indian princes from the banks of the Ganges to the Nerbudda. Their allied forces, however, were defeated, and the year 1008 was marked by a revolution from the famous temple of Nagra-cut in the Panjub country. Having satiated himself with plunder on this occasion, Mahmud returned to his own country; but in 1011 invaded Hindostan once more, destroying Tanur a city in the west of Delhi, and a more celebrated place of worship than Nagra-cut itself. Delhi was reduced on this occasion; and in seven years after Canoge was taken; the temple of Matra or Methura, the Meeth of Fluct, a city of great antiquity, and remarkable for a place of worship near Agra, were likewise demolished; but he failed in his attempts on the Rajpoats of Agimer, either through the natural force of their strength. His twelfth expedition took place in the year 1024, when he destroyed the celebrated temple of Somanaut in the peninsula of Guzerat; adjoining to the city of Bittam on the sea-coast, and not far from the island of Bimb, now in the hands of the Portuguese. In this expedition he proved very successful, reducing the whole peninsula of Guzerat, with many cities, the temples of which he constantly destroyed; and indeed seemed no less pleased with the overthrow of the Hindoo religion than with the conquest of the country. At his death, which happened in 1028, he was possessed of the eastern part of Persea, and nominally of all the provinces from the western part of the Ganges to the peninsula of Guzerat; as well as those lying between the Indus and the mountains of Agimer; but the Rajpoats in that country still preserved their independency, which they have done all along, even to the present time.

In the year 1158 the empire of Cazna fell to pieces from the same causes by which other large and unwieldy states have been destroyed. The western part of the largest part, which still retained the name of Cazna, was seized upon by the family of Gaurides, so named from Gaur or Ghor, a province beyond the Indian Caucasus; while those contiguous to both shores of the Indus were allowed to remain in the possession of Chusero or Casroor, whose capital was fixed at Lahore. In 1124 the posterity of this prince were driven out of their territories by the Gaurides; by which means the Mohammedans became neighbours to the Hindoos, and in a short time began to extend their dominions to the eastward. In 1204 Mohammed Gori penetrated into Hindostan as far as Benares, and repeated the same scenes of devastation which had formerly taken place under Mahmud Gazni. At this period Major Kennel is of opinion, that the purity of the language of Hindostan began to decline, and continued to do so till it became what it is at present; the original dialect being what is called the Sanscrit, and which is now a dead language. Mohammed Gori also reduced the southern part of the province of Agimer, and the territory to the south of the river Jumna, taking possession of the strong fortress of Culpur. After his death in 1205, the empire of Cazna was again divided; and the Patan or Afghani empire was founded by Cuttub, who had the Indian part; the Persian remaining to Eldoza. Cuttub fixed his imperial residence at Delhi; and in 1210 the greatest part of Hindostan Proper was conquered by the emperor Altmnun, the successor of Cuttub. After his time the government of Bengal was always bestowed upon one of the reigning emperor's sons; and during his reign the bloody conqueror Jenghiz Khan put an end to the other branch of the Caznian empire, known by the name of Khurassan; of which revolution an account is given under the article Cazna; but Hindostan was at that time left undisturbed. In 1242 the Moguls began to make incursions into Hindostan; but did not at this time make any permanent conquest. The country was now in much the same state in which it had been before the invasion of the Mohammedans, viz. divided into a great number of states tributary to the emperor, but in a great measure independent; and which did not fail to revolt whenever a favourable opportunity offered. The kingdom of Malwa, which had been reduced by Cuttub in 1205, shook off the yoke in the year 1265, and the Rajpoats were on every occasion ready to revolt, notwithstanding that their country lay in the neighbourhood of the capital.

The most dreadful massacres, rebellions, and confusion, now took place, which, from that period almost to the time that the British government commenced, made up the history of Hindostan. The empire being parcelled out among as set of rapacious governors, the people were reduced to the last degree of misery, and were at last so far misled as to imagine that it was their interest to take up arms, in order to render these governors independent. Had the emperors of Hindostan consulted their true interest, they would have given up the provinces which lay beyond the upper part of the Indus and the deserts of Agimer; as these formed a barrier which could not easily be passed by any invader. By neglecting this precaution, however, they at last gave an opportunity to the Moguls to penetrate into their country; and these, after several invasions, became at last so formidable, that they were permitted by the emperor, in the year 1292, to settle in the country. At this time the reigning emperor was Ferose I., of the tribe of Chiligi or Killi, so named from Kiblak near the mountains of Causas; and in 1293 this emperor projected the conquest of the Deccan; by which means was meant at that time all the territory lying to the southward of the Nerbudda and Mahanada and Cattack rivers; an extent of dominion almost equal to all that he already possessed in Hindostan. Ferose was incited to attempt this by the riches of one of the princes of Deccan; and the person who proposed it was one Alla, governor of Gurrah, a country nearly bordering upon that which he was about to invade.
Hindostan Alla, having accomplished his undertaking, during which he amased an incredible quantity of treasure, deposed and murdered the emperor, assuming to himself the sovereignty of Hindostan. He then began a new plan of conquest; and the first instance of his success was the reduction of Guzerat, a strong fortress, which had hitherto remained independent, and, while it continued so, was a strong obstacle to his designs upon the Deccan. He next reduced Rantapour and Cheitore, two of the strongest forts in the Rajput country. In 1303 the city of Warangole, capital of a kingdom of the Deccan named Tellingana, was reduced; but in the midst of these conquests the Moguls invaded the country from an opposite quarter, and plundered the suburbs of Delhi. Notwithstanding this check the emperor resumed his plan of conquest; the remainder of Malwa was subdued; and in 1305 the conquest of the Deccan was again undertaken. The conduct of the war was now committed to Caffoor, who not only carried his army into Dowlatabad, but, in 1310, penetrated into the Carnatic also. The extent of his conquests in that country is not known; and indeed his expeditions seem to have been made with a view rather to plunder than to achieve any permanent conquest. The quantity of riches he amassed was so great, that the soldiers are said to have carried away only the gold, leaving silver behind them as too cumbersome. As the treasure carried off on this occasion had been accumulating for a number of ages, it is probable that the country had long remained in a state of tranquility.

Caffoor still proceeding in his conquests, ravaged a second time the northern part of the Deccan, and obliged the inhabitants of Tellingana and the Carnatic to become tributary to him. Revolutions took place in 1322; but the country was again reduced in 1326, and the whole Carnatic ravaged from one sea to the other. This year Alla died, and his successors, not being possessed of his abilities, were unable to retain the dominions he had left. Under the emperor Mohammed III., the people of the Deccan again revolted, and drove the Mohammedans so completely out of these countries, that nothing remained to them but the fortress of Dowlatabad. In 1344 the city of Bijapur, properly Bidinagar, was founded by Belaldeo, the king of Deccan, who had headed the inhabitants in their late revolt. Mohammed in the mean time attempted to extend his dominions towards the east; but while he employed himself in this, many provinces were lost by rebellions in Bengal, Guzerat, and the Panjib. His successor Ferose III., who ascended the throne in 1351, seemed more desirous of improving the remains of his empire than of extending it; and, during his reign, which continued for 37 years, agriculture and the arts were the favourite objects of his pursuit. After his death, in 1388, a rebellion and civil war took place, and continued for several years; and matters were brought to a crisis in the time of Mahmud III., who succeeded to the throne in 1393; and, during this time, the empire of Hindostan exhibited the singular circumstance of two emperors residing in the same capital, and in arms against each other. While matters remained in this situation, Tamerlane, after having subdued all the western part of Tartary and Asia, turned his arms against Hindostan in the year 1398. His conquest was easy, and his behaviour such as rendered him worthy of the name by which he is yet known in Hindostan, "the destroying prince." After having brought into captivity a vast number of the poor inhabitants, he caused a general massacre to be commenced lest they should join the enemy in case of any sudden emergency; and in consequence of this cruel order, upwards of 100,000 were put to death in one hour. In the beginning of the year 1399 he was met by the Indian army, whom he defeated with great slaughter, and soon after made himself master of the imperial city of Delhi. At this time the capital consisted of three cities, named Old Delhi, Seyri, and Jehan Penah. Seyri was surrounded with a wall in the form of a circle; and Old Delhi was the same; but much larger, lying to the south-west of the other. These two were joined on each side by a wall: and the third, which was larger than the other two, lay between them. As the city made no resistance, there could not be a pretence for using the inhabitants with any cruelty; and thus matters passed on quietly till the 22nd of January, when the Tartar soldiers insulted some of the inhabitants and one of the doctors. The Emirs were ordered to put a stop to these disorders, which had become impossible. The Sultan, having a curiosity to see the rarities of Delhi, and particularly a famous palace adorned with 1000 pillars built by an ancient king, went in with all the court; and the gate being thus left open for every body, above 15,000 soldiers got in unperceived. But there was a far larger number of troops in a place between the cities above mentioned, who committed such disorders, that an insurrection commenced; some of the inhabitants attacking them, while others, in despair, set fire to their houses, and burnt themselves with their wives and children. The soldiers, taking advantage of this confusion, pillaged the houses; while the disorder was augmented by the admission of more troops, who seized the inhabitants of the neighbouring cities that had fled to Delhi for shelter. The Emirs caused the gates to be shut; but they were quickly opened by the soldiers, who rose in arms against their officers; so that, by the morning of the next day, the whole army had entered, and the city was totally destroyed. Some soldiers carried off no fewer than 150 slaves, men, women, and children; and some of their boys had 20 slaves a-piece to their share. The other spoils in jewels, plate, and manufactures, were immense; for the Indian women and girls were all adorned with precious stones, and had bracelets and rings on their hands, feet, and even toes, so that the soldiers were loaded with them. On the 15th the Indians attempted to defend themselves in the great mosque of Old Delhi; but being attacked by the Tartars, they were all slaughtered, and towers erected. A dreadful carnage now ensued throughout the whole city, though several days elapsed before the inhabitants could be forced to quit it entirely; and as they went, the Emirs took many of them into their service. The artisans were also distributed among the princes and commanders, all but the masons, who were reserved for the emperor, in order to build him a large stone mosque at Samarqand.

After this terrible devastation, Tamerlane marched into the different provinces of Hindostan, everywhere defeating the Indians who opposed him, and slaughter-
Hindostan being the Chebra or worshippers of fire. On the 25th of March he retired, and thus set the miserable inhabitants free from the most bloody conqueror that had ever invaded them. He did not, however, disturb the succession to the throne, but left Mahmud in quiet possession of it, reserving to himself only that of the Punjab country. The death of Mahmud, which happened in 1413, put an end to what is called the Patan dynasty, founded by Cottub in 1205. He was succeed by Chizer, who derived his pedigree from the impostor Mohamed, and his posterity continued to enjoy it till the year 1450; when Belloli, an Afghan of the tribe of Lodi, took possession of it, the reigning prince Ali II. having abdicated the government. Under him all Hindostan was divided into separate states; and a prince, whose title was the king of the east, who resided at Jionpour in the province of Allahabad, became so formidable, that the king of Delhi had only a shadow of authority remaining to him. A considerable part of the empire, however, was recovered by the son of Belloli; who, in the year 1501, fixed his royal residence at Agra. During his reign the Portuguese first accomplished the passage to India by the Cape of Good Hope, but they had no connection with any other part of Hindostan than some maritime places in the Deccan which had always been independent of the court of Delhi. In 1501, during the reign of Ibrahim II. matters fell into such confusion that Sultan Baber, a descendant of Tamerlane, found means to conquer a very considerable part of the empire. His first expedition took place in the year 1518; and the year 1525 he made himself master of Delhi. In his last invasion he is said to have brought with him only 10,000 horse; having been furnished with the rest by the disaffected subjects of the emperor. During the five years that he reigned, his chief employment was the reduction of some of the eastern provinces; but he had not time to compose the disturbances which took place throughout the whole of his dominions. On his death the seeds of rebellion, which Baber had not been able to exterminate, produced so many revolts and insurrections, that his son Humain, though a prince of great abilities and virtue, was driven from the throne, and obliged to take shelter among the Rajpoot princes of Agimere, where he lived in great distress. During the time of his exile his son Acbar was born, whom Mr Rennell looks upon to be one of the greatest princes that ever sat on the throne of Hindostan. The sovereignty was held in the mean time by an usurper, named Sheerkan, who in 1545 was killed at the siege of Cheitore, and buried in a magnificent mausoleum, of which Mr Hodges has exhibited a drawing in this country. His territories, at the time of his death, extended from the Indus to Bengal; but so unsettled was the government, that after his decease no fewer than five sovereigns appeared in the space of nine years. This induced a strong party in Hindostan to recall Humain; but he lived only one year after his return. In 1555, Humain was succeeded by his son Acbar, at that time only 14 years of age. During his long reign of 51 years, he established the empire on a more sure foundation than it had probably ever been before; though even at this time Mr Rennell is of opinion, that all the tranquility enjoyed by the people was merely that there was no actual rebellion. The first Hindostan years of his reign were spent in reducing the provinces which had revolted from Agimere to Bengal; and the obedience of these he took care to secure as well as possible by a careful choice of governors; particularly by an unlimited toleration in religious matters, and an attention to the rights and privileges of the people. In 1585, he resolved to invade the Deccan, which had hitherto resisted the power of the Mogul princes. The war continued for 20 years; during all which time no farther progress was made than the reduction of the western part of Berar, Candeish, Tellingana (a division of Golconda), and the northern part of Amednagor; the capital of which, named also Amedinagor, was taken in 1601, after a long and bloody siege, and an unsuccessful attempt of the princes of the Deccan to relieve it. Under his successor Jehan Guire, the project was but had con- fidently carried on; the empire was disturbed by the rebel- lion of Shah Jehan the emperor's son; and the influ- ence of Noor Jehan his mistress perplexed the councils of the nation. In this prince's reign Sir Thomas Roe, the first English ambassador, arrived at the court of Hin- dostan. The Portuguese had now acquired considerable possessions in Guzerat and Bengal, but only those in the former provinces attracted the attention of the court; so that the Persian historian takes no notice of those in Bengal. In the reign of Shah Jehan, who succeeded his father Jehan Guire in 1627, the conquest of the Deccan was more vigorously pushed than before; and the war was carried on in such a destructive manner, that most of the princes in those parts were fain to make submission to the emperor. During this reign a war took place with the Portuguese, which ended in the ex- pulsion of the latter from Hoogly on the Ganges. In his private character Shah Jehan was a very debauched and wicked prince, which gave occasion to one of his sons named Aureng-zib, or Aureng-zeibe, to dethrone him. This prince attained his end by a train of deep hypo- crisisy and dissimulation; covering his ambition with a pretence of religion, and under that pretence committed the greatest crimes. He engaged in a war with two of his brothers, both of whom he defeated by un-foreseen accidents, when he himself seemed to be on the brink of destruction. Having at last got them into his power, he put them both to death, and then lamented their misfortunes. One of his brothers who as-isted him, was rewarded first with imprisonment, and then with death. By the year 1660, he had attained full possession of the sovereignty, and from that time to the year 1678 there reigned a profound tranquili- ty throughout the whole empire. In the latter part of his reign he undertook the conquest of the Deccan, to which he was supposed to be incited by the resolution and growing power of Savages, the founder of the Mahratta state; and who, in that character, appeared almost as a rival to Aureng-zebe himself. Having quelled a rebellion of the Pataons, who lived beyond the Indus, he persecuted the Hindoos to such a degree, that the Rajpoot tribes in Agimere commenced a war against him. On this occasion he headed his armies also in person; but having the misfortune to be hemmed in among the mountains, he would certainly have been taken prisoner, had not the enemy thought proper to allow him to escape. They allowed also the empress to make her escape, after she had been actually taken.
In 1681, he renewed his incursions into that country, took and destroyed Chetterah, committing other devastations, and everywhere destroying the Hindu temples and objects of worship; but notwithstanding all his efforts, he was at last obliged to abandon his enterprise, and allow them to remain in peace. From the year 1678 to the time of his death in 1707, he is said to have been chiefly employed in the Deccan, the greatest part of which he reduced, and for the last five years of his life is said to have been actually employed in the field. This long absence from his capital could not but be productive of bad consequences. Rebellions broke out in various parts of the empire; and during this period, the Jats or Jauts first made their appearance in the province of Agra. They were at first only a set of banditti; but have since grown to be a very considerable state, and once were of some consequence in Upper Hindostan. After the 10th year of Aurengzebe's reign, however, we know very little of his transactions, as he would not allow any history of it to be written. At the time of his death the empire extended from the 10th to the 33rd degree of latitude, and almost as many degrees in longitude. His revenue (says Major Rennel) exceeded 35 millions of pounds sterling, in a country where the products of the earth are about four times as cheap as in England. But so weighty a sceptre could be wielded only by a hand like Aurengzebe's; and we accordingly find, that in the course of 30 years after his death, a succession of weak princes and wicked ministers reduced this astonishing empire to nothing.

Aurengzebe left four sons; Munsam, afterwards emperors, under the title of Bahader Shah; Azem, Kaum Bush, and Achar, who had been obliged to fly to Persia 30 years before, on account of his having engaged in rebellion against his father. A civil war instantly commenced between Azem and Munsam; the event of which was decided in a great battle, where 300,000 combatants were brought into the field on each side. In this battle Azem was defeated and killed; after which Munsam ascended the throne by the title of Bahader Shah. He was a prince of considerable abilities; but the disorders of the empire were already risen to so an height, that during his short reign of five years, he found it impossible to compose them. He was first engaged in war with his brother Kaum Bush, whom he also defeated and killed; after which his attention was engaged by the Seeks, a new set of religiousists; who, during the reign of Shah Jehan, had silently established themselves along the foot of the eastern mountains. They now appeared in arms in the province of Lahore, and ravaged the whole country from thence to the banks of the Jumna. The emperor marched against these adversaries in person, and with great difficulty brought them under subjection. He then took up his residence at Lahore, where he died after a short illness, without having ever visited the imperial cities of Agra or Delhi.

After the death of Bahader Shah the empire was again contested among his four sons. Of these the second, named Azem Ooshahn, took possession of the treasuries; but was opposed by his three brothers, who agreed to divide the empire among them. Azem was defeated and killed in a battle, gained chiefly by the valour and conduct of the youngest named Shah Jehan; who seemed resolved to abide by the agreement, and as Hindostan a proof of his sincerity, ordered the treasures to be divided. This was prevented by the intrigues of Zool-fecar Khan, an omrak in high trust. A new civil war commenced, in which Jehan Shah was killed. The two remaining brothers tried their fortune in a third battle, which left Jehauder, the eldest, in possession of the throne. In nine months he was dethroned by Feraksere, or Furroksere, son to the deceased Azem Oooshahn; having, during his short reign, displayed almost unparalleled meanness of spirit.

This revolution was accomplished by the assistance of two brothers, Housein Ali Khan and Abdul All Khan, who had extensive governments in the eastern provinces. The calamities of the empire were not all abated during this reign. In 1723 the Seeks appeared again in arms; and in 1716 were grown so formidable, that the emperor himself was obliged to march against them; but we are totally ignorant of the particulars of this campaign. About this time the Firmaan English East India Company obtained the famous Firmaan or grant, by which their goods of export and import were exempted from duties or customs; which was regarded as the company's commercial charter in India, while they stood in need of protection from the princes of that country.

Ferroksere was deposed; and his eyes put out, by the two brothers who had raised him to the throne; and in the course of the same year two other emperors, whom they afterwards set up, were deposed and murdered; and thus, in eleven years after the death of Aurengzebe, 11 princes of his line, who had either mounted the throne, or been competitors for it, were exterminated, while the government declined with such rapidity, that the empire seemed ready to be dismembered to a greater degree than it had even been before the invasion of Tamerlane. In 1719 the two brothers raised to the throne Mohammed Shah, the grandson of Bahader Shah; but this prince having got sufficient warning by the fate of his predecessors, took care to rid himself of these powerful subjects, though this could not be accomplished without a civil war. New enemies, however, started up. Nizam-ul-Mulk, viceroy of the Deccan, had been for some time augmenting his power by every possible method, and was evidently aspiring at independence. Having received some attentions from the two brothers, who for some time had ruled every thing with an absolute sway, he thought proper to retire to his government. In 1722 he was invited to court, and offered the place of vizier or prime minister, but declined accepting it, while the growing and formidable power of the Mahattas furnished him with a pretence for augmenting his army. At last, having by the year 1738 attained a sufficient degree of strength to accomplish his purposes, and confident of his having a large party at court, he came thither attended by a great body of armed followers. Finding, however, that the interest of the emperor was still too powerful for him, he invited the celebrated Persian usurper Nadir Shah, commonly known by the name of Invasion of Koutl Khan, to invade Hindostan. The invitation of Nadir was accepted, and Nadir entered the country without opposition. The imperial general Douran being killed in a skirmish, no decisive engagement took place; and the Persian chief, though far advanced into Hindostan, yet
Hindostan, yet looked upon matters to be so uncertain, that he offered to evacuate the country and retire for 30 lacs of rupees, about half a million sterling. The intrigues of the Nizam and his party hindered the emperor from complying with this moderate demand; instead of which he absurdly threw himself upon the usurper's mercy, who then took possession of Delhi, demanding a ransom of 30 millions sterling. At an interview with the emperor, he severely reprimanded him for his misconduct; however, he told him, that as he was of the race of Timour (Tamerlane), who had not offended the reigning family of Persia, he would not take the empire from him; only as he had put him to the trouble of coming so far to settle his affairs, he insisted that his expenses should be paid. The unfortunate emperor made no answer to this speech; but Nadir took care to enforce the latter part of it. Some time after the departure of the emperor, Nadir went to the camp to pay him a visit; where he seized upon 200 cannon, with some treasure and valuable effects, sending them off immediately to Candoor. He then marched back to Delhi, where a mob arose about the price of corn. As Nadir Shah was endeavouring to quell it, a musket was designedly fired at him, by which he narrowly escaped being killed. Exasperated at this, he commanded an indiscriminate massacre to be made, which his cruel soldiers instantly put in execution with the greatest alacrity, and 120,000, or, according to others, 150,000, of the miserable inhabitants were slaughtered without mercy. This was followed by a seizure of all the jewels, plate, and valuable articles which could be found, besides the exacting of the 30 millions, which was done with the utmost rigour; insomuch that many of the inhabitants chose rather to put an end to their own lives than to bear the torments to which they were subjected in case of inability to pay the sum imposed upon them. During these horrid scenes, Nadir caused the marriage of his son to be celebrated with a grand-daughter of Aureng-zeb; and after having extorted every thing which he demanded, at last took leave of the emperor with every mark of friendship. He put the crown upon his head with his own hands; and after having given him some solitary advice relative to the government of his empire, he set out for Delhi on the 6th of May 1739.

By this invasion the empire sustained prodigious loss. Since the arrival of Nadir in Hindostan, about 200,000 people had been destroyed, and goods and treasure carried off to the amount of 125 millions sterling. Mohammad had ceded to the usurper all the provinces of Hindostan situated to the west of the Indus. His departure left the Nizam in possession of all the remaining power of the empire, which he instantly made use of to establish himself in the sovereignty of the Deccan. The province of Bengal had already become independent under Aliverdy Cawn, in the year 1738; and not long after, it was invaded by a vast army of Maharrattas under sanction of the emperor's name; who being unable to satisfy them in the arrears of tribute he had been obliged to consent to pay, sent them into Bengal to collect for themselves. About the same time, the Rohillas, a tribe from the mountains which lie between India and Persia, erected an independent state on the east of the Ganges, within 80 miles of Delhi. The total dissolution of the empire seemed now to be fast approaching. In the confusion which took place after the murder of Nadir Shah, Abdullah, one of his generals, seized upon the eastern part of Persia, and the adjoining provinces of India, which had been ceded to Nadir by Mohammed Shah; which he formed into a kingdom still known by the name of Candoor or Abdali; of which a more particular account is given in the subsequent part of this article.

This year Mohammed Shah died, after a reign of 25 years; which, considering the fate of his immediate predecessors, and the anarchy universally prevalent throughout Hindostan, must be accounted very wonderful. He was succeeded by his son Ahmed Shah; during whose reign, which lasted about six years, the total division of the remainder of the empire took place. Nothing now remained to the family of Tamerlane but a small tract of territory round the city of Delhi, now no longer a capital, and exposed to the repeated depredations of invaders, with consequent massacres and famines. The last army which could with propriety be termed imperial, was defeated by the Rohillas in 1749; by which their independence was fully established in the eastern parts of the province of Delhi. The Jants, or Jats, a Hindu tribe, established themselves in the province of Agra; the Deccan and Bengal were seized upon by their viceroys, Nizam and Aliverdy. Oude was seized on by Seidfar Jang (father to the late Sujah Dowlah); Allahabad by Mohammad Kooli. Malwa was divided between the Poonah Maharrattas and several native princes and zamindars; Agimere reverted of course to its ancient lords, the Rajput princes; and the Maharrattas, in addition to their proper share of Malwa, possessed the greatest part of Guzerat, Berar, and Orissa; besides their ancient dominions in the Deccan. These people were now become so powerful, that they were alternately courted and employed by the contending parties, like the Swiss in Europe; with this difference, that the Swiss are paid by those who employ them, whereas the Maharrattas always take care to pay themselves. Abdullah having established his empire in the manner above related, entered Lahore and Moultan, or the Panjab, with a view to conquest. "The whole country of Hindostan was in commotion (says Major Renel) from one entrance to the other, each party fearing the machinations or attacks of the other; so that all regular government was at an end, and villany was practised in every form. Perhaps in the annals of the world it has seldom happened that the bonds of government were so suddenly dissolved, over a portion of country containing at least 60 millions of inhabitants."

In 1748 the Nizam died at the age of 104, and was succeeded by his son Nazir Jung, to the prejudice of his four sons, of eldest brother Gazi, vizier to the nominal emperor, the French and English interest in the throne of the Deccan, and nabobship of Arcot, first engaged the French and English as auxiliaries on opposite sides. This was followed by a series of hostilities, which terminated in the total expulsion of the French from Hindostan, the entire humiliation of the Mogul, and his being reduced to the state of dependence on the English East India Company; together with the subjection of a vast tract of country to the latter. These transactions have occasioned very considerable revolutions, not only in the country properly called Hindostan,
Lahore, Ahmed quitted Hindostan, and returned to his dominions, where he found everything in confusion. Timur, who during his father’s absence had been frequently disturbed by the Seiks, a tribe of Hindoos who profess deism, was in 1760 driven out by a vast army of Maharrattas commanded by Ragonaut. How the Peishwa’s brother, of whom so much mention has already been made. Next year, however, Ahmed crossed the Indus, and easily recovered his former territories; soon after which he became head of a league formed among some of the Indian princes, in order to oppose the overgrown power of the Maharrattas. In this enterprise he proved successful; and overthrew the Maharrattas in a decisive and very bloody battle, in which more than 50,000 of them were killed on the spot. The pursuit lasted several days, and their vast army was totally dispersed; Ahmed being everywhere received with acclamations as the deliverer of the faithful. In 1762 he again crossed the Indus, with a view to conquer, or rather to exterminate, the Seiks, whose incursions had become very troublesome, and even dangerous to his kingdom. Having defeated their army, and forced them to take refuge in the woods and strong holds, he set a price on the heads of all those who professed their tenets; and that with such success, that heaps of them are said to have been piled up in all the principal towns in these parts. At last, hearing that they had assembled in great numbers to celebrate an annual festival, he marched with an army to surprise them. The Seiks, however, were well provided for his reception, and an obstinate battle ensued. During the time of the engagement an eclipse of the sun happened, which, though disregarded by the Seiks, greatly dismayed the superstitious Mohammedans. Ahmed was therefore defeated; and though he frequently returned, was never able thoroughly to subdue that people. At last, having been long afflicted with an ulcer in his face, he died on the 15th of July 1773, at a place named Kohtoba, among the mountains of Candahar, to which he had retired for the sake of coolness, and was succeeded by his son Timur, who still continues to enjoy the sovereignty. The dominions of this prince extend a very considerable way to the northward of the Indus, but he possesses nothing in Hindostan besides the province of Kashmere.

2. The Seiks inhabit a country on the other side of the Indus, and making part of Hindostan properly so called. They derive their origin from a Hindoo named Nanuck of the cast of Khatri. His father, named Baba Caloo, possessed a small district in the province of Lahore named Tehandi, where Nanuck was born in the year 1470. Like other founders of new sects or nations, he is said during his infancy to have given many indications of his future superiority to the rest of mankind. He seems, however, to have received no further education than what was common to young men of his cast, viz. reading, writing, and arithmetic, and hearing the sutras or commentaries on the sacred books. In his early youth he was married to a woman of his own cast, by whom he had two sons. Being a convert to the worship of the Invisible, or deism, he accustomed himself to declaim against the folly of worshipping idols, and the impiety of paying adoration to any but the Supreme Being. At the age of 25 he left
Hindostan.

his family to visit Bengal, and the eastern parts of Hindostan; in a second journey he visited the southern, and in a third he went as far as Persia and Arabia. On his return from this last journey, he expressed a desire of remaining in his native country; and was furnished, according to his wish, with a piece of ground on the banks of the river Destiny, about 50 miles north-eastward from the city of Lahore. Here he took up his residence for the rest of his days, and choosing to be free from the cares of this world, he dwelt at a distance from his wife and children, who came occasionally to visit him. Having acquired great reputation for his piety, wisdom, and learning, he died at the age of 70; and since his death the place of his abode has obtained the name of Dihra Daira, or "the place of worship." His eldest son founded a sect of devotees named Nanuck Shait; but his second employed himself in the usual occupations of mankind. On account of the oppression of the Mohammedan governors, however, he removed from Telvandi, the estate of his ancestors, and settled at Kartapour, which his descendants still possess. They are respected by the Seiks on account of their being the posterity of Nanuck, but are not held in any veneration on a religious account.

The doctrines of Nanuck were taught by a favourite disciple of his named Lisain, but on whom he bestowed on his deathbed the appellation of Angud. By him the doctrines of the sect were collected in a work named Zayyat, or "the book;" and an history of the life of Nanuck himself was given in another name, Naima Sahay. Both these were written in a particular kind of character called Gour Moukey, and said to have been invented by Nanuck himself. Angud named for his successor another disciple named Amerdass; and this method of continuing the succession seems to have been practised as long as the disciples continued to own one supreme chief.

For many years the Seiks lived in peace, and gained the good-will of the Mohammedan governors by their quiet and inoffensive behaviour. By degrees their numbers and their power greatly increased, but in proportion to their good fortune, they seem to have lost their virtue; so that their gourous, or chiefs, who had hitherto borne the character of apostles, at last stood forth as military leaders. The first of these was named Daigh, whose successor, named Govard Sing, was the tenth and last of the gourous. He engaged in a rebellion against the government; but was at last obliged to submit, and even attended the emperor Bahader Shah in person. At last he was assassinated by a Petan soldier, not without a suspicion of the emperor himself being concerned. As he did not name a successor, his followers chose a chief for themselves named Bandal, who soon began to make depredations on his neighbours; but being at last taken prisoner, and sent to Delhi with his family and many of his counrymen, they were all put to an ignominious death. By this execution the Seiks were so much exasperated, that they swore eternal vengeance against the Mohammedans, and have ever since manifested a most implacable hatred against them. Taking advantage of the distraction of the Mogul empire by the invasion of Nadir Shah, they conquered several provinces. Wherever they came they threw down the mosques, and obliged every one to quit the country.

who refused to embrace their tenets. The war with Hindostan.

Ahmed Shah has been already mentioned. Since his death they have recovered all the territories they lost during their contest with him; and now possess the greatest part of Mooltan, as well as several districts in the province of Delhi; including in their territories the whole of that rich country named the Fanning, on account of five rivers which descend from the northern mountains, and inclose or intersect it, running afterwards into the Indus.

The Seiks, as has already been mentioned, worship one God; but without image, or believing in any mediator. They eat all kinds of meat except beef; sparing the black cattle, in all probability, on account of their utility. Pork is very generally eaten, probably on account of its being forbidden by the Mohammedans. They are commonly dressed in blue, a colour reckoned unlucky by the Hinduos. Their dress consists of blue trousers of cotton, a sort of plaid generally chequered with blue and thrown over the right shoulder, with a blue turban. Their government is lodged in an assembly of different chiefs, but who as individuals, are independent of one another, and have separate territories. They meet annually, or oftener if occasion requires, at a place called Anber, which is held in a kind of religious veneration; where there is a large tank lined with granite, and surrounded with buildings, and beautifully ornamented. Their force is very considerable, amounting to no fewer than 200,000 cavalry. However, they can seldom be brought to act in concert, unless the whole nation be threatened with some imminent danger. They are a strong hardy race of men, and capable of bearing much fatigue; and so expert in war, that of late almost all the neighbouring countries have been laid under contribution by them, several petty chiefs having consented to pay them a small annual tribute in order to avoid their incursions. When in the field, none but the principal officers have tents, and those extremely small, so that they may be struck and transported with the greater quickness and facility. In cold weather the soldiers wrap themselves during the night in a coarse blanket, which in the time of marching is folded and carried on their horse. Their country is well cultivated, populous, and abounding in cattle, particularly horses, which are reckoned the best in all Hindostan. This may probably be owing to the studs which were formerly established in different places of the province of Lahore on account of the Mogul himself. Stallions were sent thither from Persia and Arabia, and there was a fixed order to send to the studs in Lahore all such Arabian and Persian horses as by any accident should be rendered unfit for mounting. Notwithstanding their deism, the Seiks are said to have a superstitious veneration for their sword; insomuch, that before one of them will eat with a person of another religion, he draws his sword, and, passing it over the victuals, repeats some words of prayer, after which he will freely partake of them. Contrary to the practice of all the other Hinduos, they dislike the smoking of tobacco; but many of them smoke and chew bang, which sometimes produces a degree of intoxication.

3. The provinces of Delhi have, in the course of a few years, frequently changed their masters, but have
Hindostan scarce at any period during that time been under the
authority of the sovereign. Their last governor was
named Nadji Khan, under the title of generalissimo
of the emperor. He was involved in the ruin of Mo-
hammed Koully Khan, cousin to Soujah al Dowah;
after which he went to Cassim Aly Khan nabob of
Bengal; after whose expulsion he retired with a party
of horse to Bundeclund into the service of Rajah Comun
Sing. He next joined the English; and at last became
the general of Shah Allum. With a body of English
seapoy who had been put under his command, and
some other troops whom he had taken into his service,
he subdued the countries near Delhi, conquered almost
all the territories of the Jauts, reducing the cities of
Agra, Dieg, and other principal towns. These con-
quests were indeed effected in the name of the Mogul,
but he derived little benefit from them; Nadji being
the real master, and keeping possession of them till his
death, which happened in 1782: and since that time
the countries we speak of have been involved in a scene
of continual anarchy and bloodshed.

4. Next to the provinces of Delhi are the dominions
of the independent rajahs, whose dominions lie con-
tiguous to one another. The principal are those of
Joinagar, or Japor, Jodpour, or Marwar, Oudhpour
or Chitore, and Jessmire. These countries are under
a kind of feudal constitution, and every village is
obliged to furnish a certain number of horsemen at the
shortest warning. The people are brave, hardy, and
very much attached to their respective chiefs; and their
army is very formidable, amounting when collected to
about 150,000 horsemen.

5. The Jauts were a tribe who followed the occu-
pation of agriculture in the northern part of Hindo-
stan. About 40 years ago they were formed into a
nation by Tackou Sotragenmul, proprietor of an in-
considerable district. After making himself master of
all the countries dependant on Agra, of the town it-
self, and many other important places, he was killed
in battle with Nadjiul Dowlah, the Rohilla chief, in
1763. Since that time the power of this people has
been so much reduced by domestic contentions and
foreign wars, that the present rajah possesses only a
strong town named Bapthpore, with a small district
around it. The Jauts, however, it is said, are now
manifesting a martial disposition, and thus may possibly
be soon in a condition to recover their former extent
of territory.

6. The most considerable of all the Hindoo powers
are the Mahrattas, with whom the Europeans first
became acquainted in their original territories of Ma-
labar. The first of their chiefs was named Sivu, or
Sceva-jee; who is said to have been descended from the
ancient Hindoo emperors, and whose father was lord of
a small district, for which he paid tribute to the Mo-
hammedan king of Viziapour. For some reason, un-
known to us, he was at last arrested by order of that
king, and died in confinement; but his son Sceva-jee
took up arms in defence of his country, and made him-
self master of several important places, with a consider-
able tract of territory, which were afterwards ceded to
him by the queen regent, the king of Viziapour having
died soon after the commencement of the war.
Sceva-jee having thus established himself, soon became
formidable to his neighbours. Many of the Hindoo
princes put themselves under his protection, and he at Hindostan
length ventured to make war upon the emperor Aureng-
Zeebe. In this he proved unsuccessful, was taken prisoner,
and carried to Delhi. Having found means, however, to
make his escape, he quickly recommenced hostilities;
and the emperor, who was now far advanced in life,
thought proper to come to an accommodation with so
troublesome an enemy. On this occasion the Mahrattas
pretend that their prince obtained a grant of 12 per
cent. on all the revenues of the Deccan; which has
often served as a pretence to invade that country, and
levy contributions on the southern nabobs. Since that
time the Mahrattas have become so powerful, that all
the princes of Hindostan are alarmed when they put
themselves in motion. Their territories extend about
1200 miles in length and 500 in breadth; and they
are governed by a number of separate chiefs, all of
whom acknowledge the Ram Rajah as their sovereign,
and all except Moodjee Booshah acknowledge the
Paishwa as his viceroy. The capital of the sovereign
was Sattarah; but the Paishwa generally resides at
Poonah, one degree to the southward, and about 100
miles distant from Bombay. The country extends along
the coast nearly from Goa to Cambay. On the south it
borders on the territories of Tippoo Saib; on the east
it has those of the Nizam and the rajah of Berar;
and on the north those of the Mahratta chief Sin-
dia and Holkar.

7. The rajah of Berar, besides that country, has
the greatest part of Orix. His dominions extend
about 600 miles in length from east to west, and
250 from north to south. The eastern part of Orix ex-
tends along the sea-coast for about 150 English miles,
and divides the British possessions in Bengal from those
commonly called the Northern Circars. On the west
his territories border upon those of the Paishwa; on
the south, upon those of the Nizam, Mahomet Hyst a
Patan chief, Nizam Shah, and Ajid-Sing. The rajah
himself resides at Nagapour, about midway betwixt
Calcutta and Bombay.

8. Madajee Sindia, has the greatest part of the govern-
ment of Malva, together with the province of Can-
desh. The remainder is under the government of Hol-
kar; who, as well as Sindia, pretends to be descended
from the ancient kings of Malva. The principal resi-
dence of Sindia is at Ugeir near the city of Murno,
which was once the capital of these kings. Holkar re-
sides at Indoor, a town little more than 30 miles to the
westward of the former. The dominions of these, and
some other princes of smaller note, extend as far as the
river Jumna.

The two last-mentioned princes, though properly
Mahrattas, own no allegiance to the Ram Rajah, or
great chief to whom the main body are nominally sub-
ject. Some time ago the Mahrattas aimed at the con-
quest of all Hindostan, and even avowed a design of
expelling all the Mohammedan princes; but their power
was effectually checked by the British, and their dissen-
sions among themselves put an end to all schemes of that
kind. Still, however, they were ready to watch every
opportunity of invading the territories of their neigh-
bours; and their resources being so considerable, they
were deservedly accounted a very formidable enemy.
The strength of their army consists chiefly in cavalry;
and both men and horse are capable of enduring a great
dal
Hindostan. deal of fatigue. Bodies of 50 or 60,000 cavalry have
been known to travel 50 miles a day for many days
together; which, considering the excessive heat of the
country, must certainly appear very surprising. The
country abounds very much in horses, and there is one
kind named the Blue-eyed, which is greatly
esteemed, and sold at a very high price. The com-
mon horse of these parts is lean and looks ill, but in
absolute favor for the purposes of war. The only
weapon used by the horsemen is a sabre; in the use of
which they are so dexterous, that it is supposed the best
European hussar would not be more than a match for a
Mahratta horseman. There are considerable studs
in every province belonging to the Paishwa and differ-
ent chiefs; and there are likewise many jundis or
great herds of horses belonging to particular persons,
who turn those they have no occasion for loose in the
open plains.

The Mahratta horsemen are dressed in a quilted
jacket of cotton, which is supposed to be one of the
best defences against a sword that can easily be con-
trived of equal lightness; but the heat of the climate
frequently renders it necessary to be taken off.
The rest of their dress consists of a pair of trousers, and
a kind of broad turban which descends low enough to
cover the neck and shoulders. In cases of emergency
the horsemen carry provision both for themselves and
their horses in small bags tied upon the saddles: the
food of the rider consists only of a few small cakes with
a little flour or rice, and some salt and spices; the
horse is fed with a kind of pease named gress, or with
balls made of the flour of these pease mixed with but-
ter, prepared after a certain manner, and named ghee,
together with some garlic and hot spices. These balls
are given by way of cordial, and have the property
of invigorating the animal after extraordinary fatigue.
Sometimes it is said that they add a small quantity of
bang; a kind of drug which possesses an exhilarating
virtue, and produces some degree of intoxication.
The Mahratta cavalry seldom make any use of tents;
even the officers frequently have no other accommodation
than a small carpet to sit and lie on; and a single
camel is able to carry the whole baggage of the general.
The officers, however, are generally well mounted, and
have spare horses in the field.

All the subjects and vassals of the Mahratta princes
are generally ready to follow them into the field; and
in any case in which the honour or interest of the na-
tion appears to be concerned, they generally site in the
common cause. Before they invade any country,
the general is at great pains to inform himself of the
nature and situation of it; and they have now made
incursions into so many different parts of Hindo-
stan, that there are very few countries there with
which they are not very well acquainted. Their great
sobriety, and the fatigue they are capable of undergo-
ing, render them very dangerous enemies. In all their
expeditions the soldier first provides for his horse, and
then goes to his own meal; after which he lies down
contented by the side of the animal, and is ready to
mount him at the first sound of the nager or great
drum. They have their horses under the most excel-
ent management; and by perpetually caressing and
conversing with them, the animals acquire a degree of
docility and sagacity unknown in other countries.

When on an expedition, the horses are accustomed to
eat grass pulled up by the roots, which is said to be
very nutritive, and to be destitute of that purgative
quality which belongs to the blade alone. When they
make an invasion, the devastation is terrible; the cattle
are driven off, the harvest destroyed, the villages burn-
el, and every human creature destroyed who comes
in their way. Notwithstanding this barbarity in time
of war, however, they are very humane in time of
peace, living in great harmony among themselves, and
being always ready to entertain and assist strangers.
Many of the cruelties they commit may be justly reck-
oned the effects of retaliation for other cruelties exer-
cised upon them by their adversaries. Thus, in 1771,
after having given Hyder Ally a great defeat, they cut
off the ears and noses of a whole regiment of prisoners,
and in that condition sent them back to their com-
mander, in return for his having done the same to a few
prisoners he had taken some time before.

The revenue of the Paishwa is very considerable;
being not less than ten millions sterling; but after ded-
ucting the expense of collection, and the expense of
troops kept in readiness for the service of the state, it
is supposed that he cannot receive more than four
millions. From this again we must deduct the ex-
penes of the troops immediately belonging to the
Paishwa himself, and which may amount to about three
millions sterling; so that there remains a surplus only
of one million after paying all the necessary expenses
of government. This nevertheless has been managed
with such economy, that though long and expensive
wars were carried on after the death of Narain Row,
the state was not only clear of debt, but there was a
surplus of two millions in the treasury, which Rogobah
dissipated.

9. The Dhecan, as left in 1738 by Nizam al Mulek,
was by far the most important and extensive soubadary
or viceroyship in the empire. It then surpassed in size
the largest kingdom in Europe; but since that time
many provinces have been conquered by the Mahrattas,
and the northern Circars by the British. The pos-
sessions of the Nizam are also diminished by the cession
of the Carnatic to the nabo of Arcot; great part of
the territories of Tippoo Saib; and many other pro-
vinces of less note. Still, however, the Nizam possesses
very considerable territories; but his finances are in such
a wretched condition, and his provinces so ill govern-
ed, that he is accounted a prince of no consequence,
though otherwise he might be reckoned one of the most
considerable powers of Hindostan.

10. The dominions of Tippoo Saib, the son and suc-
cessor of Hyder Ally, are bounded on the north by the
territories of the Paishwa; on the south by Travancore,
the territory of an independent Hindoo prince; on the
west by the sea; and on the east by a great ridge of
mountains, which separate them from the territories of
the nabo of Arcot. The country lying to the eastward
of these mountains is called the Carnatic Payen Ghat,
and to the westward the Carnatic Bhalla Ghat. The
latter belongs to Tippoo Saib; and the two to-
gether make up the country formerly named the Carnatic,
though the name is now restricted to the Payen Ghat.
—The situation of the Bhalla Ghat is considerably
more elevated than the other; by which means the
temperature of the air is much cooler. On the
coast
Hindostan. coast of Coromandel there is a pile of ruins called by the natives Malvanpatam, and by the British the seven pagodas. Concerning this there is a tradition, that it once stood at a considerable distance from the sea, though most of the ruins are now covered with water; and there is likewise a tradition, that the mountains we speak of once formed the boundary of the ocean. The revenue and strength of Hyder Ally are said to have been greatly exaggerated: the former amounting to no more than four millions annually, though by his economy and good management he made it answer every purpose both in time of war and peace. He was at great pains to introduce the European discipline among his troops; but notwithstanding all his endeavours, he was far from being able to make them cope with the British. The advantages he gained were owing to his vast superiority in cavalry, and the celebrity of his marches; which would have been counteracted had his adversaries been possessed of a good body of cavalry; and it is probable that the event of the war would have been decided in a single campaign. His son Tipoo Saib is said to have been a man of less abilities than his father, though more violent in his disposition. Against this prince hostilities commenced by the British in conjunction with the Mahrattas, between whom an alliance had been formed. Tipoo Saib himself fell a victim to his own misguided bravery at the siege of Seringsapatam, which surrendered to the British on the 4th of May 1799.

With regard to the present government of Hindostan, our limits will not allow us to enter particularly upon it, nor indeed is it perhaps of any importance, as the country is divided into so many different kingdoms, the sovereigns of which, however they may differ in other respects, seem all to agree in despotism and oppression of their subjects. As a very considerable part is now under the dominion of Britain, it may be necessary to take some notice of the behaviour of our countrymen in that part of the world, especially as an idea of their excessive despotism and oppression of the natives has of late prevailed so much, that the national character has suffered considerably by it. This has arisen partly from the great pains taken to propagate it, and partly from the ignorance of those among whom the report was circulated; and the exaggerated accounts and contentions of the members of the government themselves, have contributed no less to confirm and heighten the prejudices of the public.

The British territories in the East Indies were originally under the jurisdiction of a governor and 13 members; but this number has fluctuated occasioned from 4 to 4, at which it was fixed by act of parliament. In this council all matters, whether relating to peace or war, government or commerce, were debated, the governor having no other superiority than that of giving the casting vote. In other respects the whole executive power was lodged in his hands, and all the correspondence with the native princes of India was carried on by his means, the dispatches to them being signed by him singly; and all the princes and great men who visited the presidency were first received by him, and then introduced to the counsellors. He was military governor of Fort William, and commander in chief of the presidency; whence, as by his office he was invested with a considerable degree of power, he became an object of some envy and jealousy to the Hindostan members of the council and other considerable people in that part of the world. In consequence of this, the government was divided into two parties, one siding with the governor, and the other opposing him; in consequence of which, the debates were frequently carried on with much heat and violence, that the records of the company were frequently stained with accounts of the contentions of these jarring parties. This indeed may be looked upon as one of the principal causes by which the reputation of the British government in the eastern parts of the world has suffered; for as there were very frequently opinions diametrically opposite to one another recorded upon the same subject, the contending parties in the British parliament had always sufficient authority for what they said, let them take which side they would: and thus the characters of all concerned in the East India government were, by one person or other, set forth in the most opprobrious light.

Another source of reproof to the British government in India was, that the court of directors in England became infested with the same spirit of party and contention which pervaded all other departments of the state. Lord Clive and Mr Sullivan were the two great leaders of these party disputes; and as the interest of the one or the other prevailed, different persons were appointed to the administration, and different measures adopted. The event of all this was, that whenever a new administration was formed, the first object was to condemn the measures of those who had gone before him. Thus, in the year 1764, when Lord Clive was made governor of Bengal, the new directors represented the affairs of the company as in the worst situation imaginable, from which they could only be extricated by the abilities of Clive. On the arrival of the latter in the east, he took care to write home reports to the same purpose, and to condemn in the most violent manner everything that had been done; the whole body of the company’s servants were censured indiscriminately without being allowed any means of defence, as they were in truth ignorant of the charges brought against them. When the affairs of the company were brought under a parliamentary review in the year 1774, the government was brought under a new regulation. It now consisted of a governor-general and four counsellors; three of whom were sent from England; two being military gentlemen of high rank, and the third a gentleman employed in the war-office. On their arrival they proceeded in the same manner that Lord Clive had done before them: they pronounced in the most decisive manner, that the company’s affairs were in a ruinous state; and that every species of corruption had been practised by the former government. This general accusation, unsupported by any kind of evidence, was the constant theme of the dispatches sent by them to England; and thus has the reputation of the British government suffered exceedingly through the unwarrantable liberties which its own servants have been allowed to take with one another. It must also be considered, that from the remote situation of India, and the unavoidable ignorance of its affairs on that account, it was easy for any person, whose malicious purposes it might suit, to prejudice the public against the servants of the company.
Hindustan company to as great a degree as he pleased. Hence some persons, soured by disappointment, or envious of the supposed accomplishments of others, represented matters in such an unfair light to their correspondents in England, that the most unjust and shameful charges were frequently brought against innocent persons, which they could neither prevent nor defend themselves against. The dreadful famine which took place in Bengal in the year 1765, offered to these malevolent persons a most fruitful source of calumny; and many individuals were accused of having brought on this dreadful calamity, which was not directly from a natural cause, viz. the failure of the rains, and which no human power could have prevented or removed.

Opinions of this kind have not only been circulated through the island of Britain in the most open manner, but have even appeared in some very respectable publications. Thus, in Dr Smith’s Treatise on the Wealth of Nations, when speaking of the oppression arising from monopolies, and comparing their effects in different states: “The English company (says he), have not yet had time to establish in Bengal so perfectly destructive a system. The plan of the government, however, has had exactly the same tendency. It has not been uncommon, I am well assured, for the chief, that is, the first clerk of a factory, to order a peasant to plough up a rich field of poppies, and sow it with rice or some other grain. The pretence was to prevent a scarcity of provisions; but the real reason, to give the chief an opportunity of selling at a better price a large quantity of opium he had on hand. Upon other occasions there was a revenue brought on, and a rich field of rice or other grain has been ploughed up to make room for a plantation of poppies, when the chief saw that extraordinary profit was to be made by opium.”

This, however, the following answer has appeared in a late publication, entitled A Short Review of the British government in India. “The poppy is a plant which requires a peculiar soil, and particular care in the culture of it. The medium price of the land on which it is cultivated is about 12 or 13 rupees a begah, or one-third of an English acre. It is sowed at the beginning of October, when the season of the periodical rain expires. The plant begins to be fit for inoculation, in order to extract its juice, of which opium is made, about the end of December, and continues so till March. It requires a dry soil, and can be brought to maturity only in the dry season, when the periodical rains have ceased. Paddy or rice lands let on a medium at three rupees a begah. Rice is sowed about the end of May, just before the periodical rains commence. One crop is raised about the end of September; and another, which is the last, and by far the greatest, about the end of December. It requires a soil saturated with water, and lies soaked in it for a considerable time. On this account it is sowed just before the periodical rains commence; and nine-tenths of the quantity of rice produced in the company’s provinces grow in the kingdom of Bengal, which is so low and flat, that the grounds are either overflowed by the rivers Ganges and Burramooter, with their tributary streams, or soaked with the rain which falls and stagnates upon them. It is therefore evident, that the soil and the season, which alone can fructify the paddy or rice, would rot and destroy the poppy; and it is there-
Hindostan, titled from their office. Notwithstanding this, however, they were sometimes treated by the Mohammedan governors as mere revenue-officers, and used very harshly. At some times there were a set of people bound for the zemindars under the title of wuldeds; and these had either a joint power with the former, or were superior to them in the collection of the revenues; and sometimes they were superseded by officers appointed immediately by government itself, under the various names of awumis, lakshisads, or secaurils.

The zemindaries are not limited in extent or value; there being some in Bengal which yield a revenue as high as 350,000l. sterling, while others scarcely amount to 35l.; but all the great zemindars, and many of these in middling circumstances, having procured for themselves the title of rajah, affect much pomp and state in their different districts, and keep their inferiors in a great subjection as the Mohammedan governors keep them. Some of them also have their power augmented by being of the Brahmin cast; and by the reverence supposed to be due to religion on that account, joined with the power conferred upon them by the sovereign, they are in general rendered exceedingly despotic, with an almost unlimited authority to plunder the tenant farmers, not merely when they are not conscious of any wrong, but to avenge themselves on the statesmen of the country, on whom they have been indulgent nabobs, from the motive of plundering them again.

From the consultations of the select committee in 1769, we are informed that the zemindars have a power of levying fines at pleasure; that they raise large sums from duties collected in the market; and that they frequently oblige the ryot or husbandmen to work for nothing. In short, the same claims made by the European barons on their vassals in the times of the feudal system, are now made by the zemindars on the common people of Hindostan. If one of them is to be married, if he has a child born, if honours are to be conferred upon him; nay, if he is even to be fined for his own misconduct, the poor ryot must always contribute his share. Mr Scrofton, in his history of Hindostan, sets forth the situation of the inhabitants in the following words:—"Unhappily for the Gentoos, themselves are made the ministers of oppression over each other; the Moor-men, haughty, fussy, and voluptuous, are, in the eyes of the populace, the ministers of their oppression. These, in their turn, are the ministers of the zemindars, and their answer is the end of dividing them, and prevents their uniting to fling off the yoke; and by the strange intoxication of power, they are found still more rapacious and cruel than their foreign masters: and what is more extraordinary, the Bramins still exceed the rest in every abuse of power, and seem to think, if they bribe God by bestowing a part of their plunder on cows and fowls, their iniquities will be pardoned."

From this account of the situation of the people of Hindostan under their native rulers, it is by no means probable that they could make a worse exchange by falling under the jurisdiction either of the Mohammedans or Europeans. A notion indeed has been industriously propagated, that the British government has behaved with the greatest cruelty in collecting the revenues, and that they have even invented tortures to make the rich people discover their treasures; but on examining the matter impartially, the reverse of this is found to be true. At the time that the British government interfered in the affairs of Hindostan, the provinces were found to be in a ruinous state, in consequence of the wars which had taken place in the country. Even in the most settled state, and when the administration was most regular, the government was altogether despotic, and the mode of collecting its revenues extremely arbitrary; the punishments inflicted very cruel; and the whole system of government such as would be reckoned quite shocking in Europe. It is only within these few years that the British could effectually interpose in behalf of the natives; and in that short time it has produced a very considerable reformation. It is certain, that the British government has discouraged oppressive measures as much as possible; abolished the cruel modes of punishment used by the Mohammedans; and by instituting a more regular plan of justice, has procured ease and security to the natives, and preserved them in a state of tranquillity altogether unknown to them before its commencement. Many instances of the greatest cruelty exercised upon the zemindars and other collectors are to be met with in the history of Bengal, written by a native historian, and translated by Gladwin; yet the person who exercised these cruelties was denounced with and was the author of servitude and slavery. We are told by Mr. Scrofton that the people were absolutely familiarised with cruelty, and did not know what it was to be under a lenient government. Since the British had the dominion, matters have been totally reversed, and the Hindoos, instead of being treated with cruelty, persecuted on account of their religion, and compelled to renounce it, have been used with at least comparative lenity, and great indulgence has been shown to them even in their most absurd practices and superstitions. When the British government first accepted of the office of dewanny, or collector of the revenues, it was not in their power to interpose with any kind of efficacy for the relief of the inhabitants; because it was at first thought proper to allow the taxes to be collected by natives, who would undoubtedly follow their ancient modes of collection. Even at that time, however, the mildness of the British governors had some effect upon the Asiatics; so that the people in general were treated with more lenity than formerly: and in the year 1772, when the council of Bengal openly assumed the office of dewanny themselves, an immediate stop was put to all those arbitrary and oppressive methods which had been formerly in use. Formerly some zemindars had been flogged even to death, by an instrument called a korah; but from the moment that the British council took the collection into their own hands, not only this instrument was laid aside, but all kind of corporal punishment; by which means the severity of the Mohammedan government has been entirely abolished, and no other punishments inflicted in cases of insolvency than such as are in use in our own country. Still, however, in such extensive dominions, where a great share of power must be one way or other committed to the natives, it is impossible but some arbitrary acts must be committed, as the natives are always prone to acts of despotism whenever they can commit them with impunity; but examples of this kind cannot with any degree of candour be brought as a general charge against the British government in India.—Mr Scrofton gives the following account of the wretched state of the
The provinces now under the British jurisdiction at the time they were ceded to them by the Mogul. "When the governors of the provinces found the weakness of the Mogul, and each set up as sovereign in his own province, although they could not break through these immutable laws, they invented new taxes under new names, which doubled or trebled the value of the original ones, and which the landholder was obliged to levy upon his tenants. The old stock of wealth for some time supported this; but when that failed, and the tenants were still pressed for more, they borrowed money of usurers at an exorbitant interest; and the government still continuing these demands, the lords of the lands were obliged to do the same: but as all this while the value of lands did not increase, the consequence was, that at last, unable to pay the interest of the mortgages, the rents were seized by rapacious usurers. The government finding the revenues fall shorter every year, at last sent collectors and farmers of the revenues into the provinces. Thus the lord of the land was divested of power over his country, and the tenants exposed to merciless plunderers; till the farmer and manufacturer, finding that the more they laboured the more they paid, the manufacturer, his work no more, and the farmer would cultivate no more than was just sufficient for the subsistence of his family. Thus once flourishing and plentiful country has, in the course of a few years, been reduced to such misery, that many thousands are continually perishing through want. "The crown lands are still worse off; let out to the highest bidder; and the Jagheer lands alone remain un plundered. Hence that equal distribution of wealth that makes the happiness of a people, and spreads a face of cheerfulness and plenty through all ranks, has now ceased; and the riches of the country are settled partly in the hands of a few usurers and greedy courtiers, and the rest is carried out of the country by the foreign troops taken into pay to maintain the governors in their usurpations. This unhappy decay the India company has already experienced in the decay of their trade, and the rise and price of their manufactures; and will, I fear, experience more and more annually."

With regard to the deposition of the nabobs by the British, which has been used as a great argument against the general spirit of British government in those parts, it must be remembered, in the first place, that these nabobs were mere usurers, who had not the least title to their dominions, and consequently could not, in point of right, complain more reasonably of being deprived of their dominions, than the persons from whom they had taken them might do of their injustice in driving them out. Their behaviour in government also was such, that it was impossible it could have subsisted for any length of time without the absolute ruin of the countries they possessed. Thus, in the case of Jaffier Ally Cawn, Mr Vansittart declared the country to be in so confused and impoverished a state, that in all human appearance another month could not have been run through before he would have been cut off by his own sepoys for want of pay, and the city become a scene of plunder and disorder. On this account he was degraded, though without any of those circumstances of cruelty which generally characterise the revolutions in this part of the world. The administration was transferred to Hindustan.

His son-in-law Meer Cossim, who being an enemy to the British government altogether, a war followed, terminating in his expulsion. This was followed by the invasion of Sojah Dowlab, and by scenes of horrid barbarity and devastation; when in 1765 Lord Clive took upon him the office of deewan, or minister who superintends the lands and collections of the revenue. An account of his proceedings has already been given; but whatever applause he might gain, and in some respects deservedly at the time, it is now said with some probability, that he raised the expectations of the people of England by far too high. The seeds of the succeeding evils were already sown. Many sources of wealth were dried up. Raw silk, cloth, and other manufactures, had formerly been exported to Guzerat, Lahore, and even Isphahan. This had ceased on the invasion of Nadir Shah; and the influx of wealth from the European nations had ceased before the British government in Bengal had an existence. It was computed that Cossim Aly Cawn robbed the country of near five millions sterling in jewels and specie. China, Madras, and Bombay, were supplied from Bengal to the amount of more than two millions; and several other circumstances besides these contributed to diminish the riches and opulence of the country. In the mean time the internal administration of the country had been extremely defective. The zemindars being under very little restraint, acted in a very arbitrary manner within their own districts; and the tenants had no redress against the impositions and exactions which were laid upon them. Meer Cossim appointed auxiliaries to the collection of the revenues rather than zemindars. The auxiliaries derive their authority directly from the person who has the command of the country for the present time, and consequently are more easily called to an account than the zemindars. At last, however, these auxiliaries, having obtained too great an influence in the country, Lord Clive thought proper to change the plan of collection. Three natives were now appointed, in the nabob's name, to superintend this department; and one English gentleman, through whom the business was transacted, had his residence at the nabob's court, and communicated the intelligence to Calcutta. The principal acting minister in this plan, however, thought proper to change the mode of collection once more, and to re-appoint the auxiliaries in consequence of which the revenue became greatly diminished, and they were besides complained of as greatly oppressing the people. To remedy these evils, it was first proposed by Mr Verelst, to send some of the company's servants into the internal parts of the country with the title of supervisors: but the defects of administration were now beyond their power to remedy; the revenue was not only greatly diminished, but the expense of government exceedingly augmented; and in the year 1771 the company were alarmed by accounts that bills had been drawn upon them to the amount of 1,200,000. At this time Mr Hastings was appointed to be governor of Bengal; and the confused state in which matters were at the commencement of his administration will easily appear from the following extract of a letter from the government of Bengal, dated in the month of November 1772.--- Every zemindary was left to its own particular customs. The articles which
Hindostan, which composed the revenues, the form of keeping the
accounts, the computation of time, even the technical
terms, which ever form the greatest obscurity in
every science, differed as much as the soil and produc-
tions of the province. The nababs exacted what they
could from the zamindars and great farmers of the re-
venue, whom they left at liberty to plunder all below,
reserving to themselves the liberty of plundering them
in their turn, when they were supposed to have en-
riched themselves with the spoils of the country. The
museaddies, who stood between the nabob and zem-
indars, and between them and the people, had each
their shares of the public wealth. These profits were
considered as illegal embezzlements, and therefore were
taken with every precaution which could ensure secre-
cy; and being, consequently, fixed by no rule, de-
pended on the temper, abilities, or power, of each in-
dividual for the amount. It therefore became a duty
to every man to take the most effectual measures to
conceal the value of his property, and evade every in-
quiry into his conduct, while the zamindars and other
landholders, who had the advantage of long pos-
session, availed themselves of it by complex divisions of
the lands, and intricate modes of collection, to per-
plex the officers of government, and confuse the know-
ledge of the rents to themselves. The internal man-
agement of each district varied so less than that of
the whole province. The lands subject to the same
collection, and intermixed with each other, were some
held by farm, some superintended by shikdors or
agents on the part of the collector, and were left to
the zamindars themselves, under various degrees of
control. For some political reasons the company,
though they had acquired the dewanny, had not yet
chosen to assume the executive part of the office itself,
but committed it to the management of natives,
as has already been mentioned, and their plans had been
found extremely defective. By the time that Mr Has-
tings had been invested with the government, the court
of directors had resolved to change their plan, and open-
ly assume the office of the dewanny; and the rules estab-
lished by that gentleman for the collection of the re-
nues, his mode of administering justice, and his police
for the government of the country, are still observed
with very little variation.

The plan for collecting the revenues consisted, in
the first place, in rendering the accounts as simple and
intelligible as possible; in the next, in establishing
fixed rules for the collection; and in the third, mak-
ing the mode of them uniform in all parts of the pro-
vinces; and in the fourth, providing for the equal ad-
ministration of justice. The power of the zamindars
was now circumscribed, and their extortion thoroughly
put a stop to; many vexatious taxes and tolls were
abolished, and a new mode of collecting the customs
was established, to the great relief of the merchants:
and so well were all the parts of this plan found to be
adapted to the purposes they were designed to answer,
that it has hitherto been made the model of all subse-
quent regulations.

One great objection to the India government is, that
the English law, which undoubtedly is better calcu-
lated than any other for securing the liberties of the
people, has not yet been adopted in India; whence it
is thought that the company's servants have still show-
ed a disposition to oppress, rather than to relieve, the
Hindostan oppressed inhabitants of Hindostan. But in answer to
that it is said, that the difference between the two coun-
tries is so great, that there can be no comparison be-
twixt the one and the other, nor can the constitution
of England be in any degree adapted to that of the other.
The religion, laws, manners, and customs, of both Hindus and Mohammedans, are so essentially dif-
ferent from those of this country, that it is impossible
to assimilate them, should ever anything of the kind
be attempted. The only true method therefore of
judging whether the present state of Hindostan is pre-
ferrable to what it formerly was, is to compare it with
what it was under the best Mogul emperors; and in
this comparison it must certainly appear that the pre-
ference is greatly in favour of the British administra-
tion. In Major Rennel's work we are informed, that
during the reign of Acbabar, whom he styles "the glo-
ry of the house of Timur," the country had never en-
joyed so much tranquillity; "but this tranquillity
would hardly be deemed such in any other quarter of
the world, and must therefore be understood to mean
a state short of actual rebellion, or at least commotion."
The same author, speaking of the state of the British
empire there, uses the following words: "The Beng-
gal provinces which have been in our actual possession
near 25 years, have, during that whole period, enjoyed
a greater share of tranquillity than any other part of
India, or indeed than those provinces had ever expe-
rienced since the days of Aurang-zeb." To this we
may add, that the provinces have not only experienced
a perfect freedom from external invasions, but likewise
enjoy a degree of internal tranquillity altogether un-
known before, by the subjection and civilization of a
set of banditti who inhabited the hills of Rajmushal,
and infested the travellers who passed that way; a wan-
dering tribe of religious mendicants, who were wont to
commit the greatest enormities.

Another advantage which the inhabitants of this coun-
try reap from the British government, is the security
from violence and oppression either by their Mohamme-
dan superiors or by one another. Under the article Hin-
do we have already mentioned the particular circum-
stance that these people are liable to the punishment of
losing their east from a variety of causes, and that this
is looked upon by them to be the most grievous cala-
mity they can suffer. The Mohammedan governors
frequently took advantage of their superintendence in this
respect to oppress them; and this circumstance alone
frequently produced the most horrid confusion. In
the instructions given to the surveyors, Mr Verelst
informs them, that "it is difficult to determine whether
the original customs, or the degenerate manners of the Musulmans, have most contributed to confound
the principles of right and wrong of these provinces.
Certain it is (adds he), that almost every decision of
there is a corrupt bargain with the highest bidder.
Compensation was frequently accepted of even for ca-
pital crimes, and fines became at last an intolerable
grievance; nay so venal were the judges at that time,
that it became at last a settled rule to allow each of
them a fourth part of any property in dispute as a
compensation for his trouble.—It is impossible to sup-
pose that such monstrous abuses continue under the
British government: on the contrary we must readily
believe,
believe, what the governors themselves assert, that immediately after the provinces fell under British jurisdiction, both Hindoos and Mohammedans have been left to the free exercise of their religion, laws, and customs. The Hindoos themselves acknowledge this, and are as well pleased with the mildness of the British government, as they are displeased with the superstition and cruelty of the Mohammedans. Under the British government we cannot suppose but that commerce, to which the inhabitants of this country are so much addicted, will be much more encouraged than by the avaricious and barbarous Mohammedans. The latter had imposed so many restraints upon trade of all kinds, by the multitude of taxes collected at the landing-places, watch-houses, markets, &c. that it was almost impossible to carry it on with any advantage. Among other satirical regulations, however, enacted by the British government in 1772, many of those taxes upon commerce were abolished, and a plan laid for effectually liberating the inhabitants from those shackles by which their commerce had been so long fettered. Regard has also been paid to the instruction of the people in useful knowledge; and the seminary established at Calcutta by Sir William Jones, certainly does much honour to the founder. Some regard had indeed been paid to this by the Mohammedan emperors; but at the time that the British government commenced, these had been entirely neglected, their endowments assumed by government, and even the buildings fallen into ruin."

From a comparison of any government to which the Hindoos have hitherto been subject, with that of Britain, indeed, it is evident that the preference must be given greatly in favour of the latter. At the time when the British first visited that country, they were not under the jurisdiction of their native sovereigns, nor had they been so for a long time before. The Moguls were not only foreigners, but a most cruel and detestable race of men; and it was by usurpations of their own rebellious subjects that the anarchy and confusion was introduced, in which the country was involved for so long a time. The British are foreigners as well as the Moguls; but the latter, who profess the intolerable superstition of Mohammed, suffer their conduct to be influenced by it in such a manner as to treat the natives with the utmost cruelty. The greatest evil perhaps which results from the British government is, the exportation of great sums of money to a foreign country; but this evil, with respect to the provinces possessed by the British, existed also under the Mohammedan government. The Mogul emperors resided at Delhi, which is far distant from the provinces of Bengal, Bahar, and Orissa, the territories now possessed by Britain; so that the greatest part of the treasure sent to that capital was totally lost to them. In the time of Aurungzebe, the emperor's tribute amounted to three millions sterling; and of this a considerable part was specie; but since that time the tribute was fixed at only 1,250,000l. and even this was a vast sum; to which if we add that carried out of the country by commanders of mercenary troops, who were all foreigners, it is not unreasonable to suppose that under the Mogul government matters were still worse, even in this respect, than under that of Britain.

We shall conclude this apology for the British government, with the following extract from the treatise Hindostan. lately quoted, A short Review of the British Government in India. "A more detestable or detested race of people never appeared than the Mohammedan conquerors of India; whether we consider the brutality of their passions, the bigotry of their religion, the corruption of their manners, the barbarity of their education, or the tyranny of their government: in all these respects they were the terror and abhorrence of the Hindoos whose country they invaded, and whose dominion they usurped."

The fanatic ignorance of the savage caliph, which dictated his barbarous reason for destroying the Alexandrian library, had neither been tutored nor refined by the Tartar education of Timur and his predecessors. The same superstitious bigotry which incited the Arabian caliphs to destroy the monuments of western learning, likewise impelled the Tartar khans to overthrow the religious temples of the eastern worship. At the commencement of the 11th century Mahmood entered Hindostan, and in the course of 12 expeditions he destroyed the famous temples of Nagraout, Tannasar, Matra, and Sumnaut. In the latter end of the next century, Mahmod Gori penetrated as far as the city of Benares, and committed outrages as Mahmood had done before at Nagraout and Sumnaut. Tamerlane possessed as much of this furious zeal as any of his savage predecessors; and if the enthusiasm of this destructive religion had not occasionally abated among some of his successors, they would scarce have left a Hindu temple or priest in the country they subdued.

Enough, however, had been done to fix an indelible stain on the memory of those intolerant tyrants, and to make a lasting impression on the minds of the Hindoos, who, to the latest period of the Mogul government, were kept in constant dread of doctrines, which, to their apprehensions, seemed to inspire the Mohammedans with sacrilegious cruelty. Idolatry is as great an abomination to a Musulman as it was to the Jews when they most strictly revered the divine command which prohibits it; and most of the Hindu ceremonies being considered by the Mohammedans as acts of idolatry, and all their pagodas as temples of idols, a religious principle excited mutual sentiments of abhorrence and antipathy between the conquerors and their subjects. The rest of the character of the Mohammedans may be summed up in the concise and emphatic words of Mr Scafton, who says, 'their distinguishing qualities are perfidy and sensuality.' "

"But notwithstanding these facts, and that the history of their government is a disgusting repetition of oppression, massacres, and rebellion, the fashion of the times has been to praise it, and to represent the situation of the Hindoos as easy and happy under it, till they were disturbed in this peaceful state of repose and security by the English; who have been described (with unparalleled injustice) as a set of rapacious taskmasters. It surely requires a very small degree of reflection to perceive, that such representations of the two governments must, from the very nature of things, be false."

"The Mohammedan conquerors came into India from a barbarous region, with minds and manners as uncultivated as the wilds from which they issued. The only notion they had of government was absolute power;
in the sovereign, and absolute submission in the subject.
The tenets of their religion, so far from softening the
ercify of their nature, served only to whet the edge
of their persecution towards the suffering Hindoos,
whom they harassed without mercy, and destroyed with-
out remorse. The British conquerors came from a
country famed for arts and sciences; the generous prin-
ciples of public liberty had been instilled into their
minds from their earliest infancy: the mild tenets of
Christianity cherished and commanded every charitable
duty; and they had been taught, by precept and ex-
ample, to rule with equity, and to obey with freedom.
Can it be supposed that under these circumstances, the
two nations should have totally changed characters on
their coming into India? That the barbarous and fer-
cious Tartar should become mild and enlightened; that
the cultivated and generous British should have degene-
rated into a cruel tyrant; and that the British govern-
ors should have rendered the situation of their Hindu
subjects worse than it was under the Mogul emperors?
Reason revolts at the idea; and nothing but the rankest
prejudice could ever suggest or adopt it."

With regard to the geography of this country, Mr. Renne1 observes, that though by the modern Euro-
peans, Hindostan has been understood to mean the tract
situated between the rivers Indus and Ganges on the
east and west, the mountains of Tibet and Tartary on
the north, and the ocean on the south, the extent of
Hindostan, properly so called, is much more circum-
scribed; and the name ought only to be applied to that
part which lies to the northward of 21° or 22° latitude.
The reputed southern boundary of Hindostan is the
Nerbudda river as far as it goes, and the northern fron-
tiers of Bengal and Bihar compose the remainder.
The countries to the south of this line are called Deccan
by the Indian geographers, and comprehend about one
half of the territory generally known by the name of
the Mogul Empire. Our author therefore chooses to
distinguish the northern part by the name of Hindostan
Proper; which has indeed the Indus and mountains of
Tibet and Tartary for its western and northern bound-
daries; but the Burrampoor river is rather to be con-
sidered as the eastern boundary than the Ganges; the
latter intersecting some of the richest provinces in the
empire. According to this supposition, Hindostan
Proper will equal in size the countries of France, Ger-
many, Bohemia, Hungary, Switzerland, Italy, and the
Low Countries; the Deccan and peninsula being about
equal to the British islands, Spain, and Turkey in Eu-

Toward the north, Hindostan is very cold and bar-
ren; but towards the south, very hot, and fertile in corn,
rice, fruits, and other vegetables. The northern pro-
vinces are very mountainous and sandy; while the
southern are for the most part level, and well watered
with several rivers.
The most remarkable mountains are those which
surround it on three sides. Those on the west, separat-
ing it from Persia, called, in general, Soleman Kdy,
or the mountains of Soleman, are of a vast height as
well as breadth, and are only passable in certain places,
through which roads have been made for the sake of
commerce. The chief are those which lead to Cabul,
Gazna, and Candahar. This great chain of mountains
is inhabited by different nations, the principal of which
are the Afghans, or Patans, and the Baloches, who
Hindostan.

The mountains on the north are called Na-
gakut, Hima, or Mas Tág, which has an affinity with
Imoil, and by other names, which are given also in
common to the mountains on each side, separating Hin-
dostan from Tibet. The very prospect of these moun-
tains is frightful, being nothing but hideous precipices,
perpetually covered with snow, and not to be crossed
without the greatest danger and difficulty.
The most remarkable rivers of Hindostan are the In-
dus and Ganges. The former is called by the orient-
tals, Send, Sind, or Sindí. It rises in the mountains
to the north or north-east of Hindostan; whence, after a
long course, first to the south, and then to the south-
west, it falls into the Persian sea, below Lower Ban-
der, by several mouths. In its course it receives sev-
eral other large rivers, as the Niláb, Jamál, Behat, and
Lákká.
The Ganges, called in the Indies Gango, rises in the
kingdom of Tibet; entering Hindostan about the 30th
degree of latitude, it runs first south-eastward by the
cities of Békánér, Minapor, Hálabá, Benárés, and
Patna, to Rájah Maháli, where it divides into two
branches. The eastern having passed by Dákka, the
capital of Bengal, enters the gulf of that name about
Chattan. The western, descending by Kossum-Bazar
and Hughhly, falls into the gulf below Chandernagor
towards Pipeli.

Many of the Jews and ancient Christians believed
this river to be the Pison, one of the four mentioned in
Scripture as the boundaries of the terrestrial paradise.
The Indians retain the greatest reverence for its waters,
going in crowds from the remotest parts of the country
to wash in them, from a persuasion that they deface
from all the spots of sin. The reason of this, is,
because they imagine this river does not take its source
from the bosom of the earth, but descends from heaven
into the paradise of Devendra, and from thence into
Hindostan. Nothing is more childish than the fables
of the Bramins on this subject, yet the people swallow
them all. The Mogul and prince of Golconda drink
no other water than that of the Ganges: foreigners, on
the contrary, pretend that it is the God of Bengal some,
and that it cannot be safely drank till it is first boiled.
There is a great number of superb pagodas on the
banks of the Ganges, which are immensely rich. At
certain festivals, there has been sometimes a concourse
of 100,000 people who came to bathe in it. But what
principal distinguishes this river, besides its greatness
and rapidity, is the gold it brings down in its sands
and throws on its banks; and the precious stones and pearls
it produces, not only in itself, but in the gulf of Ben-
gal, into which it discharges its waters, and which
abounds therewith. The Chun or Jemma, the Guder-
rasu, the Persisli, Lákia, and several other rivers, dis-
charge themselves into it during its course.
The weather and seasons are, for the general, very
regular in this spacious country; the winds blowing
constantly for six months from the south, and six from
the north, with very little variation. The months of
April, May, and the beginning of June, till the rains
fall, are so extremely hot, that the reflection from the
ground is apt to blister one's face; and but for the
breeze or small gale of wind which blows every day,
Hindostan. — there would be no living in that country for people bred in northern climates; for excepting in the rainy season, the coldest day is hotter there at noon than the hottest day in England. However, very surprising changes of heat and cold sometimes happen within a few hours; so that a stifling hot day is succeeded by a night cold enough to produce a thin ice on the water, and that night by a noon as scorching as the preceding.

Sometimes, in the dry season, before the rains, the winds blow with such extreme violence, that they carry vast quantities of dust and sand into the air, which appear black like clouds charged with rain; but fall down in dry showers, filling the eyes, ears, and nostrils of those among whom they descend, and penetrate every chest, cabinet, or cupboard, in the houses or tents, by the key-hole or crevices.

From Surat to Agra, and beyond, it is seldom or never rains, excepting in one season of the year: that is, from the middle of June to the middle of September. These rains generally begin and end with most furious storms of thunder and lightning. During these three months it rains usually every day, and sometimes for a week together without intermission: by these means the land is enriched, like Egypt by the Nile. Although the land looks like the barren sands of the Arabian deserts; yet, in a few days after those showers begin to fall, the surface appears covered with verdure. When the rainy season is over, the sky becomes perfectly serene again, and scarce one cloud appears all the other nine months; however, a refreshing dew falls every night during that dry interval, which cools the air, and cherishes the earth.

The produce of Hindostan is very rich in every kind, whether it be fossil, vegetable, or animal. Besides other precious stones found in it, there is a diamond-mine at the town of Soumelpur in Bengal. Quarries of Theban stone are so plentiful in the Mogul’s empire, that there are both mosques and pagodas built entirely of it. Some travellers tell us, there are mines of lead, iron, and copper, and even silver; but those of the last, if there be any, need not be opened, since the bullion of all nations is sunk in this empire, which will take nothing else in exchange for her commodities, and prohibits the exporting it again. They till the ground with oxen and foot-ploughs, sowing in May and the beginning of June, that all may be over before the rains, and reaping in November and December, which with them are the most temperate months in the year.

The land is nowhere inclosed, excepting a little near towns and villages. The grass is never mowed to make hay, but cut off the ground, either green or withered, as they have occasion to use it. Wheat, rice, barley, and other grain, grow here in plenty, and are very good. The country abounds no less in fruits, as pomegranates, citrons, dates, grapes, almonds, and cocomuts; plums, those especially called mirabolones; plantains, which in shape resemble a slender cucumber, and in taste excel a Norwich pear; mangos, an excellent fruit, resembling an apricot, but larger; annas or pineapples; lemons and oranges, but not so good as in other countries; variety of pears and apples in the northern parts; and the tamarind-tree, the fruit of which is contained in a pod resembling those of beans. There are many other kinds of fruit-trees peculiar to the country. But the valuable trees are the cotton and mulberry, on account of the wealth they bring the natives from the manufactures of callicoes and silks. They plant abundance of sugar-canes here, as well as tobacco, but the latter is not so rich and strong as that of America, for want of knowing how to cure and order it.

Hindostan affords also plenty of ginger, together with carrots, potatoes, onions, garlic, and other roots known to us, besides small roots and herbs for salves; but their flowers, though beautiful to look at, have no scent, excepting roses, and some few other kinds.

There is a great variety of animals in this country, both wild and tame; of the former are elephants, rhinoceroses, lions, tygers, leopards, wolves, jackals, and the like. The jackals dig up and eat dead bodies, and make a hideous noise in the night. The rhinoceros is not common in the Mogul’s empire; but elephants are very numerous, some 12, 14, or 15 feet high. There is plenty of venison and game of several kinds; as red-deer, fallow-deer, elk, antelopes, kids, hares, and such like. None of these are imparked, but all in common, and may be any body’s who will be at the pains to take them. Among the wild animals also may be reckoned the musk-animal, apes, and monkeys.

Hindostan affords variety of beasts for carriage, as camels, dromedaries, mules, asses, horses, oxen, and buffaloes. Most of the horses are white, and many curiously dappled, pied, and spotted all over. The flesh of the oxen is very sweet and tender. Being very tame, many use them as they do horses to ride on.

Instead of a bit, they put one or two small strings through the gristle of the nostrils, and fastening the ends to a rope, use it instead of a bridle, which is held up by a bunch of gristly flesh which he has on the fore-part of his back. They saddle him as they do a horse; and, if spurred a little, he will go as fast. These are generally made use of all over the Indies; and with them only are drawn waggon, coaches, and chariots. Some of these oxen will travel 15 leagues in a day. They are of two sorts; one six feet high, which are rare; another called dwarfs, which are only three. In some places, where the roads are stony, they shoe their oxen when they have to travel far. The buffalo’s skin makes excellent buff, and the female yields very good milk; but their flesh is neither so palatable nor wholesome as beef. The sheep of Hindostan have large heavy tails, and their flesh is good, but their wool coarse.

This country is much infested with reptiles and insects; some of a noxious kind, as scorpions, snakes, and rats; but the lizards, which are of a green colour, are not hurtful. Snakes and serpents, we are told, are sometimes employed to despatch criminals, especially such as have been guilty of some atrocious crime, that kind of death being attended with the most grievous torture. The most troublesome insects in this hot country are flies, musketoes, and chinches, or bugs, the first by day, and the others in the night; when they offend no less by their stench than their bite. See India, Supplement.

HINE, or HIND, a husbandman’s servant. Thus the person who oversees the rest, is called the master’s hine.

HINNOM, or the Valley of Hinnom, in Ancient Geography, a place that lay to the south of Jerusalem.
HINZUAN, one of the Comoro islands, lying between Madagascar and the continent of Africa, otherwise called Anzuame, Anzuan, Joanny, and Johanna. As the accounts given of it by the abbé Raynal and Major Rookes seem to contradict each other, we shall lay before our readers the substance of Sir William Jones’s description of it, by whom the island was visited, and whose regard to veracity will not be controverted.

It resembles a vast amphitheatre, of which a general notion may be formed, by conceiving in the mind a multitude of hills infinitely diversified in figure and in magnitude, thrown together with artless symmetry in all conceivable positions. A series of mountains forms the back ground, one of which is pointed, almost half a mile above the level of the sea, and not more than three miles from the shore. The whole of them are richly clothed with fruit trees of exquisite verdure. Beyond this range is another tier, partly barren and partly verdant. Near the shore there is a vast multitude of cliffs, which bring their verdure almost to the waterside. The rows of palm trees with which it abounds, which give an enchanting beauty and variety to the scene, almost appear to have been planted by design.

The north side of the island shoots out into two points, which are 26 miles distant from each other, with a large bay between them. It is justly considered as a proper place of refreshment for vessels bound to and from the East Indies, as it yields limes, lemons, oranges, and many other valuable antiscorbutics. The town which is the king’s residence, is on the east side of the island, which contains no more than about 200 houses, notwithstanding it is three-fourths of a mile in length.

The cattle of this island are a sort of buffaloes, with a large hump on their shoulders, which is reported to be most delicious eating; but there are no horses, asses, or mules in the island. The original natives may be about 7000, who occupy the hills, and carry on desultory wars with the Arabian interlopers living on the sea coast, and about 3000 in number. The expenses of government are defrayed by a tax on 200 villages, but the three principal towns are exempted. The kingly power is considered as elective by the principles of the constitution; but the line of succession has not been altered since the first election of a sultan.

The price of every article is under proper regulations, and ships who touch here can be plentifully supplied with bullocks, goats, and fowls. The people seem to be extravagantly fond of titles, and therefore lords, dukes, and princes, are common among them. A duke will dispose, in person, of the product of his own estate, which man of a similar rank in Europe will only do by the intervention of agents. The natives are said to be indolent, as is the case in most tropical countries, and neglect the cultivation of that exuberant soil which Providence has bestowed upon them.

There is a sacred lake, about half a mile in circumference, in the interior parts of the island, about fifteen miles from the town of Johanna. The wild ducks frequenting this sequestered spot are said to be worshipped by the natives, and consulted as oracles in all affairs of importance. These people countenance polygamy, and the keeping of concubines. The men are extremely jealous, and never admit strangers of their own sex to see the women.

The chewing the betel nut prevails greatly in Hinzuan, as in most eastern countries, and corresponds to the European custom of smoking tobacco or taking snuff, only with this difference, that the practice is still more general. They are very abstemious as to the use of wine, that article being prohibited by the religion of Mahomet, and perform the duty of prayer three or four times a-day. E. Long. 44. 15. S. Lat. 12. 30.

HIP, in the Materia Medica, the fruit of the dogrose or wild briar. See Rosa, Botany Index. This fruit contains a sourish sweetish pulp; with a rough prickly matter including the seeds, from which the pulp ought to be carefully separated before it be taken internally: the Wirtemberg college observes, that from a neglect of this caution, the pulp of hips sometimes occasions a pruritus and uneasiness about the anus; and the conserve of it has been known to excite violent vomiting. The conserve is the only officinal preparation of this fruit.

HIPPARCHUS, a great astronomer, born at Nice in Bithynia, flourished between the 154th and 163d Olympiads. His commentary upon Aratus’s Phaenomena is still extant. Rhinotus was very much mistaken when he asserted, that this astronomer was not acquainted with the particular motion of the fixed stars from west to east, by which their longitude changes. By foretelling eclipses, he taught mankind not to be frightened at them, and that even the gods were bound by law. Pliny, who tells this, admires him for making a review of all the stars; by which his descendants would be enabled to discover whether they are born and die, whether they change their place, and whether they increase and decrease.

HIPPIA, a genus of plants belonging to the syngenesia class. See Botany Index.

HIPPOBOSCA, or Horse-fly, a genus of insects, belonging to the order of diptera. See Entomology Index.

HIPPOCAMPUS, or Sea-horse, a species of fish belonging to the genus syngnathus. See Syngnathus, Ichthyology Index.

HIPPOCASTANUM, or Common Horse-chestnut. See Aesculus, Botany Index. It may be here added, that from several experiments in the French Mémoires d’Agriculture, it appears that the fruit of the horse-chestnut affords a wholesome nourishment for cattle, and may even be employed with success for fattening them. It is said to render the tallow of those fattened with it particularly firm. The milk yielded by cows fed upon it, is also said to be thicker and richer than that produced from any other kind of food. The fruit of this tree has been likewise used as food for sheep and poultry, and as soap for washing. It is much employed in powder as a sterminatory by an itinerant oculist, and has been recommended by some others in certain states of ophthalmia, headach, &c. in which ophthalmia is indicated. Its effects as a sterminatory may also be obtained by using it under the form of infusion or decoction drawn up into the nostrils. And it is entirely with a view to its sterminatory power that it is now introduced into the pharmacopoeia of the Edinburgh college.
Hippocrates, the greatest physician of antiquity, was born in the island of Cos in the 8th Olympiad, and flourished at the time of the Peloponnesian war. He was the first that we know of who laid down precepts concerning physic; and, if we may believe the author of his life, who goes under the name of Soranus, drew his original from Hercules and Aesculapius. He was first a pupil of his own father Halesicles, then of Herodicus, then of Gorgias of Leontinum the orator, and, according to some, of Democritus of Abdara. After being instructed in physic, and in the liberal arts, and losing his parents, he left his own country, and practised physic all over Greece; where he was so much admired for his skill, that he was publicly sent for with Eurypion, a man superior to him in years, to Persissas king of Macedon, who was then thought to be consumptive. But Hippocrates, as soon as he arrived, pronounced the disease to be entirely mortal, as in truth it was. For upon the death of his father Alexander, Persissas fell in love with Philes, his father's mistress; and this Hippocrates discerning by the great change her presence always wrought upon him, a cure was soon effected.

Being invited by the people of Abdara to come and cure Democritus of a supposed madness, he went; but upon his arrival, instead of finding Democritus mad, he found all his fellow citizens so, and Democritus the only wise man among them. He heard many lectures, and learned much philosophy from him; which has made Cornelius Celsus and some others imagine, that Hippocrates was the disciple of Democritus, though it is probable they never saw each other till this interview which was occasioned by the Abderites. Hippocrates had also public invitations to other countries. Thus, when a plague invaded the Illyrians and Periocians, the kings of those countries begged him to come to their relief: he did not go; but learning from the messengers the course of the winds there, he concluded that the distemper would come to Athens; and foretelling what would happen, applied himself to take care of the city and the students. He was indeed such a lover of Greece, that when his fame had reached as far as Persia, and upon that account Artaxerxes had invited him by his governor of the Hellespont, with a promise of great rewards, to come to him, he refused to go. He also delivered his own country from a war with the Athenians, that was just ready to break out, by prevailing with the Thessalians to come to their assistance, for which he received very great honours from the Coans. The Athenians also conferred great honours upon him: they admitted him next to Hercules in the Eleusinian ceremonies; gave him the freedom of the city; and voted a public maintenance for him and his family in the Prytanecum or council-house at Athens, where none were maintained at the public charge, but such as had done public service to the state. He died among the Larissians, some say in his 59th year, some in his 85th, others in his 104th, and some in his 190th. The best edition of his works is that of Fossius in Greek and Latin. Hippocrates wrote in the Ionic dialect. His aphorisms, prognostics, and all that he has written on the symptoms of diseases, justly pass for masterpieces. See History of Medicine.

Hippocrène, in Ancient Geography, a fountain of Mount Helicon, on the borders of Boeotia, sacred to the muses. Some, as Ovid, make Hippocrène and Aganippe the same. See Aganippe.

Hippocrepis, Common Horse-shoe Vetch, a genus of plants belonging to the diadelphe clavis; and in the natural method ranking under the 32d order, Pappilionacea. See Botany Index.

Hippodrome, Hippodromus (composed of Hippo, "horse" and dromos, "course," of the verb δρέω, curro, "I run"), in antiquity, a list or course wherein chariot and horse races were performed, and horses exercised.

The Olympian hippodrome or horse-course was a space of ground of 600 paces long, surrounded with a wall, near the city Elis, and on the banks of the river Alpheus. It was uneven, and in some degree irregular, on account of the situation; in one part was a hill of a moderate height, and the circuit was adorned with temples, altars, and other embellishments. See Stadion.

There is a very famous hippodrome at Constantinople, which was begun by Alexander Severus, and finished by Constantine. This circus, called by the Turks attelocas, is 400 paces long, and above 100 paces wide. At the entrance of the hippodrome there is a pyramidal obelisk of granite in one piece, about 50 feet high, terminating in a point, and charged with hieroglyphics. The Greek and Latin inscriptions.
HIP [ 502 ]

HIPPONAX, a Greek poet, born at Ephesus 512 years before the Christian era. He cultivated the same satirical poetry as Archilochus, and was not inferior to him in the beauty or vigour of his lines. His satirical raillery obliged him to fly from Ephesus. As he was naturally deformed, two brothers, Buphalus and Anthermus, made a statue of him; which, by the ugliness of its features, exposed the poet to universal ridicule. Hipponax resolved to revenge the injury; and he wrote such bitter invectives and satirical lampoons against them, that they hanged themselves in despair. (Cic. ad Famil. vii. ep. 24.)

HIPPOPHAE, SEA-BUCKTHORN; a genus of plants belonging to the dicot class; and in the natural method ranking under the 16th order, Caryocaraceae. See Botany Index.

HIPPOPHAGI, in Ancient Geography, a people of Scythia, so called from their living on horse-flesh; the fare at this day of the Tartars their descendants. Also a people of Persia (Ptolemy).

HIPPOPODES, HIPPOPEDES, or Hippopodia, composed of ἵππος, horse, and πέδη, foot, in the ancient geography, an appellation given to certain people situated on the banks of the Scythian sea, as being supposed to have had horses feet. The hippocopes are mentioned by Dionysius, Geogr. v. 310. Mela, lib. iii. cap. 6. Pliny, lib. iv. cap. 13. and St Augustine, De Civit. lib. xvi. cap. 8. But it is conjectured, that they had this appellation given them on account of their swiftness or lightness of foot. Mr Pennant supposes them to have been the inhabitants of the Bosphorean gulf, and that they were the same sort of people as the Fanni Lignipedes of Olaus. They wore snow-shoes; which he thinks might fairly give the idea of their being, like horses, hoofed and shod.

HIPPOPOTAMUS, the RIVER-HORSE; a genus of quadrupeds belonging to the order of Cetacea. See Mammalia Index.

HIPPURIS, MARE'S-TAIL, a genus of plants belonging to the monandra class; and in the natural method ranking under the 15th order, Inundatae. See Botany Index.

HIRFIA, a genus of plants belonging to the decandra class. See Botany Index.

HIRAM, a King of Tyre, contemporary with Solomon, whom he supplied with cedar, gold, silver, and other materials for building the temple. He died 1000 years B. C.

HIRAM OF TYRE, an artist who assisted in the construction of Solomon's temple, and other public buildings at Jerusalem, flourished 1015 B. C.

HIRCANYA, in Ancient Geography. See HYRCANIA.

HIRCH-HORN, a town of Germany, in the circle of the Lower Rhine, with a strong castle. It is seated on the side of a hill on the river Neckar, and belongs to Bavaria. E. Long. 9° 0'. N. Lat. 49° 28'.

HIRCUS, in Astronomy, a fixed star of the first magnitude, the same with Capella. It is also made use of by some writers for a comet, encompassed as it were with a mane, apparently rough and hairy.

HIRE, PHILIP DE LA, a French mathematician and astronomer of eminence, was born at Paris in the year 1640. His father, who was paisier to his majesty, designing
HIRTELLEA, a genus of plants belonging to the pentandria class; and in the natural method ranking with those of which the order is doubtful. See BOTANY INDEX.

HIRUDO, the Leech; a genus of insects belonging to the order of vermio intestina. See HELMINTHOLOGY INDEX.

HIRUNDO, a genus of plants belonging to the order of passerex. See ORNITHOLOGY INDEX.

HISPA, in Zoology, a genus of insects belonging to the order coleoptera. See ENTOMOLOGY INDEX.

HISPALIS, a town of Bética, in the Farther Spain; an ancient mart or trading town on the Bética, navigable quite up to it for ships of burthen, and thence to Corduba for river barges. Called Colonía Romulensis. It had also a conventus juridicus, a court of justice or assises, (Pliny). Now called Seville. W. Long. 6. N. Lat. 37.

HISPANIA, called Hesperia Ulitima, (Horace), because the westmost part of Europe; also Iberia, from the river Iberus. Its name Hispania, or Spain, (Greek) is of Phoenician original, from its great number of rabbits: the Phoenicians, who settled several colonies on the coast, calling it Spaniath from these animals. It has the sea on every side, except on that next to Gaul, from which it is separated by the Pyrenees. The Romans at first divided it into the Farther and Hither Spain, under two pretors. In that state it continued down to Augustus; who divided the Farther Spain into Bética, which he left to the people to be governed by a proconsul; and into Lusitania, which he added to his own provinces; calling the Hither Spain Tarraconensis. Hispania was a country celebrated for its fertility, of which it has greatly fallen short in modern times. The people were of a warlike turn, (Strabo); and their bodies being formed for hardships and labour, they ever preferred war to peace, and were remarkably prodigal of life (Justin, Sil. Italicus). Spain has produced several great men, both in a literary and a political capacity. See SPAIN.

HISPANIOLA, called also ST DOMINGO, the largest of the Antilles or Caribbee islands, extending about 420 miles from east to west, and 120 in breadth from north to south; lying between 17° 39′ and 25° of N. Lat. and between 67° 35′ and 74° 15′ W. Long. The climate is hot, but not reckoned unwholesome; and some of the inhabitants are said to arrive at the age of 120. It is sometimes refreshed by breezes and rains; and its salubrity is likewise in a great measure owing to the beautiful variety of hills and valleys, woods and rivers, which everywhere present themselves. It is indeed reckoned by far the finest and most pleasant island of the Antilles, as being the best accommodated to all the purposes of life when duly cultivated.

This island, famous for being the earliest settlement of the Spaniards in the New world, was at first in high estimation for the quantity of gold it supplied: this wealth diminished with the inhabitants of the country, whom they obliged to dig it out of the bowels of the earth;
His [ 504 ]

Hispaniola, earth; and the source of it was entirely dried up, when they were exterminated, which was quickly done by a series of the most shocking barbarities that ever disgraced the history of any nation. Benzoni relates, that of two millions of inhabitants, contained in the island when discovered by Columbus in 1492, scarce 155 were alive in 1545. A vehement desire of opening again this source of wealth inspired the thought of getting slaves from Africa; but, besides that these were found unfit for the labours they were destined to, the multitude of mines, which then began to be wrought on the continent, made those of Hispaniola no longer of any importance. An idea now suggested itself, that their negroes, which were healthy, strong, and patient, might be usefully employed in husbandry; and they adopted, through necessity, a wise resolution, which, had they known their own interest, they would have embraced by choice.

The produce of their industry was at first extremely small, because the labourers were few. Charles V., who, like most sovereigns, preferred his favourites to every thing, had granted an exclusive right of the slave-trade to a Flemish nobleman, who made over his privilege to the Genoese. Those avaricious republicans conducted this infamous commerce as all monopolies are conducted; they resolved to sell dear, and they sold but few. When time and competition had fixed the natural and necessary price of slaves, the number of them increased. It may easily be imagined, that the Spaniards, who had been accustomed to treat the Indians as beasts, did not entertain a higher opinion of these negro Africans, whom they substituted in their place. Degraded still farther in their eyes by the price they had paid for them, even religion could not restrain them from aggravating the weight of their servitude. It became intolerable, and these wretched slaves made an effort to recover the unalienable rights of mankind. Their attempt proved unsuccessful; but they reaped this benefit from their despair, that they were afterwards treated with less inhumanity.

This moderation (if tyranny cramped by the apprehension of revolt can deserve that name) was attended with good consequences. Cultivation was pursued with some degree of success. Soon after the middle of the 16th century, the mother country drew annually from this colony ten millions weight of sugar, a large quantity of wood for dyeing, with tobacco, cocoa, cassia, ginger, and cotton, in abundance. One might imagine, that such favourable beginnings would give both the desire and the means of carrying them further; but a train of events, more fatal each than the other, ruined these hopes.

The first misfortune arose from the depopulation of the island. The Spanish conquests on the continent should naturally have contributed to promote the success of an island, which nature seemed to have formed to be the centre of that vast dominion arising around it, to be the staple of the different colonies. But it fell out quite otherwise: on a view of the immense fortunes raising in Mexico, and other parts, the richest inhabitants of Hispaniola began to despise their settlements, and quitted the true source of riches, which is on the surface of the earth, to go and ransack the bowels of it for veins of gold, which are quickly ex-hausted. The government endeavoured in vain to put a stop to this emigration; the laws were always either artfully eluded, or openly violated.

The weakness, which was a necessary consequence of such a conduct, leaving the coasts without defence, encouraged the enemies of Spain to ravage them. Even the capital of this island was taken and pillaged by that celebrated English sailor, Sir Francis Drake. The cruisers of less consequence contented themselves with intercepting vessels in their passage through those latitudes, the best known at that time of any in the new world. To complete these misfortunes, the Castilians themselves commenced pirates. They attacked no ships but those of their own nation; which were more rich, worse provided, and worse defended, than any others. The custom they had of fitting out ships clandestinely, in order to procure slaves, prevented them from being known; and the assistance they purchased from the ships of war, commissioned to protect the trade, insured to them impunity.

The foreign trade of the colony was its only resource in this distress; and that was illicit: but as it continued to be carried on, notwithstanding the vigilance of the governors, or, perhaps, by their connivance, the policy of an exasperated and short-sighted court exerted itself in demolishing most of the sea-ports, and driving the miserable inhabitants into the inland country. This act of violence threw them into a state of dejection; which the insurrections and settlement of the French on the island afterwards carried to the utmost pitch. The latter, after having made some unsuccessful attempts to settle on the island, had part of it yielded to them in 1697, and afterwards enjoyed by far the best share.

Spain, totally taken up with that vast empire which she had formed on the continent, used no pains to dissipate this lethargy. She even refused to listen to the solicitations of her Flemish subjects, who earnestly pressed that they might have permission to clear these fertile lands. Rather than run the risk of seeing them carry on a contraband trade on the coasts, she chose to bury in oblivion a settlement which had been of consequence, and was likely to become so again.

This colony, which had no longer any intercourse with the mother country but by a single ship of so great burthen, that arrived from thence every third year, consisted, in 1717, of 18,420 inhabitants, including Spaniards, mestizes, negroes, or mulattos. The complexion and character of these people differed according to the different proportions of American, European, and African blood they had received from that natural and transient union which restores all races and conditions to the same level. These demi-savages, plunged in the extreme of sloth, lived upon fruits and roots, dwell in cottages without furniture, and most of them without clothes. The few among them, in whose indolence had not totally suppressed the sense of decency and taste for the conveniencies of life, purchased clothes of their neighbours the French in return for their cattle, and the money sent to them for the maintenance of two hundred soldiers, the priests, and the government.

In the year 1788, the revolutionary principles which began to agitate Europe, made their way to the West Indies.
His [ 505 ]

Indies. The French association for abolishing the slave trade, called Amis des Noirs, kept up a correspondence with such rich Mulattoes as had come to France for their education, and its members laboured to convince them that there was neither civil nor political distinction between them and the white people. These ideas were strengthened by the celebrated declaration of the national assembly, that all men are born and continue free, possessing equal rights. The consequence was, that the Mulattoes of Hispaniola broke out into open rebellion, but for want of unity of design they were soon overpowered.

This spirit, however, still continued to exert itself, and the assembly of France having avowed its design not to interfere with the internal affairs of the colony, discontent and remonstrances were exhibited by the factious friends of the negroes. They considered this as countenancing the African trade, and an acknowledgment that the planters were not colonists, but independent people. This idea struck the colonists themselves, for by a decree they debarred the king's delegate from having a negative on any of their future acts. The Amis des Noirs, in the mean time, exerted all their influence to kindle and cherish a spirit of rebellion in the minds of the people of colour; for which purpose they carefully taught one James Oge, then residing at Paris, the doctrines of equality and the rights of man, urged him to return to St Domingo, place himself at the head of his people, and rescue them from the oppression of the whites, pledging themselves to procure arms and ammunition for him in America, that the affair might be kept as profound a secret as possible. He accordingly set sail for New England in July 1790; but all the vigilance of the parties concerned could not deceive the government of France, and his portrait was sent to St Domingo before him. He made the island in October, and declared soon after by virtue of a manifesto, that if the privileges of the whites were not conferred on all without discrimination, he would instantly take up arms to obtain them by force. With a small detachment of 200 men he massacred all the white people that came in his way, as well as all those of his own colour who refused to join him. This little army was very soon subdued, and their misguided leader was punished as a traitor.

The French national assembly decreed that every person 25 years old and upwards, if he possessed property, and had lived two years in the colony, and paid taxes, should be permitted to elect the members of the colonial assembly, on which account the people of colour inferred, that this privilege was bestowed upon them. It is uncharitable to believe that this was the intention of the national assembly; but Gregoire and others carried their favourite point, that Mulattoes born of free parents might not only elect their own representatives, but also sit as members in the colonial assemblies. In consequence of this measure, all the white people fell victims to the indignation of the people of colour. The negroes were now fully determined to recover their liberty. On the 23d of August 1791, the people in the town of the Cape were informed that the slaves in the adjacent parishes had revolted, a report which was too soon confirmed by the arrival of those who had escaped the massacre. Hostilities commenced between the two parties, and terminated with the loss of 2000 white people, while not fewer than 10,000 Mulattoes and Ne-Hispaniola groans perished by famine and the sword, and several hundreds by the hands of the executioner.

The news of these transactions having reached Paris, the members of the assembly were persuaded that they had carried their principles of equality by much too far, and they repealed their celebrated decree which had placed the people of colour on a footing with the whites. Commissioners (three in number) were sent to restore peace between the whites and Mulattoes, but as two of them were men of infamous characters, and incapable of extinguishing the flames of rebellion, they returned to France without being able to accomplish the object of their mission.

The Amis des Noirs having again acquired the superiority in the national assembly, Santhonax, Polverel, and Ailhaud, with 6000 men from the national guards, were ordered for St Domingo. The governor of the island perceiving that these commissioners took all the authority on themselves, and resolved to reduce him to a cypher, he remonstrated against their proceedings, in consequence of which he was immediately arrested, and sent a state prisoner to France. The commissioners afterwards disagreeing among themselves, Ailhaud was dismissed from their councils.

Unsuccessful attempts were made by the British government to subdue the commissioners and their adherents; but after performing prodigies of valour, the troops of Britain were compelled to relinquish the island, more perhaps by disease than the sword of the enemy. The chief government of it then fell into the hands of Toussaint L'Ouverture, by whom it was converted into an independent republic, the supreme authority over which he continued to hold till the signing the preliminaries of peace in 1801.

When this event took place, Bonaparte, with the consent of the British government, sent a fleet from Brest, with a considerable army under the command of General Le Clerc, who, after various actions, at length subdue Toussaint; and, notwithstanding that French general pledged himself for his safety, he was in a short time sent prisoner to France, where he soon after died, or, according to conjectures not very improbable, was put to death by order, or with the connivance, of the ruler of that kingdom.

The French troops under General Rochambeau being obliged to evacuate Hispaniola, the freedom and independence of the island were proclaimed by the conquering chief, Dessalines, who assured all those who were willing to remain in it, of his cordial protection, and allowing such as were so inclined freely to depart with the French army. The successes which attended the arms of this black chief, and the goodness of the cause in which he fought, were very much tarnished by the horrid massacres of the white people, which be not only countenanced, but attended in person. Attempts to negotiate with Dessalines were made by the British government, but without effect, his demands were so extravagant which he held out as the basis; but his army was in such a forlorn condition, as to create no apprehensions of danger from such an enemy. After this, however, Dessalines experienced a signal defeat on the plain of St Charles from General Ferrand, when 1200 of his men were found dead on the field, and himself obliged to retire towards the Cape.

38
St Domingo was afterwards denominatated Hayti, of which Jacques Dessalines was chosen the first emperor. It was declared a free, sovereign, and independent state, and slavery was abolished. The citizens were pronounced brothers at home, equal in the eye of the law; and it was declared that one man could enjoy no advantage over another, but such as might originate from services done to the cause of liberty and independence. Such as emigrate are to forfeit ever after the title of citizen of Hayti, and also if they are found deserving of disgraceful punishments. Every citizen must have some mechanick art, and no white man is to be permitted to set a foot upon the island with the title of a proprietor. All distinction of colour was ordered to cease, and the people of Hayti to be ever after known by the generic title of Blacks.

The emperor is commander in chief of the army, and the empress is to have a fixed annual allowance after the decease of the emperor, as princess dowager. Laws are made, sealed, and promulgated by the emperor; and he appoints at his pleasure all counsellors of state, generals, and other agents of the empire, sea officers, judges, and other public functionaries. The house of every citizen is by the law declared to be his asylum; marriage is declared a civil rite, divorce is allowed, all religious opinions tolerated, and good faith in commercial transactions is to be religiously maintained.

Dessalines was put to death for his cruelties, and was succeeded by two rival chiefs, Perion and Christophe. Both these chiefs applied with laudable ardour to the domestic improvement of their dominions. Much attention was bestowed on agriculture; and schools, on the Lancasterian plan have been established in different parts. Petion was succeeded by Boyer; and Christophe having since been destroyed, the two districts have again been united under the former (1821).

Hister, a genus of the coleoptera order of insects. See Entomology Index.

HISTORIOGRAPHER, a professed historian, or writer of history. See the next article.

The historiographer to his majesty is an officer under the lord chamberlain; his salary 200l. per annum. There is an office of the same kind in Scotland, with the same salary.

HISTORY.

HISTORY, in general, signifies an account of some remarkable facts which have happened in the world, arranged in the true order in which they actually took place, together with the causes to which they were owing, and the different effects they have produced as far as can be discovered. The word is Greek, ἱστορία; and literally denotes a search of curious things, or a desire of knowing, or even a rehearsal of things we have seen; being formed from the verb ἱστορέω, which properly signifies to know a thing by having seen it. The idea is now much more extensive, and is applied to the knowledge of things taken from the report of others. The origin is from the verb ἱστορέω, "I know," and hence it is, that among the ancients several of their great men were called polyhistor, i.e. persons of various and general knowledge.

Sometimes, however, the word history is used to signify a description of things, as well as an account of facts. Thus Theophrastus calls his work in which he has treated of the nature and properties of plants, an history of plants; and we have a treatise of Aristotle, intitled an history of animals; and to this day the descriptions of plants, animals, and minerals, are called by the general name of natural history.

But what chiefly merits the name of history, and what is here considered as such, is an account of the principal transactions of mankind since the beginning of the world; and which naturally divides itself into two parts, namely civil and ecclesiastical. The first contains the history of mankind in their various relations to one another, and their behaviour, for their own emolument, or that of others, in common life; the second considers them as acting, or pretending to act, in obedience to what they believe to be the will of the Supreme Being. —Civil history, therefore, includes an account of all the different states that have existed in the world, and likewise of those men who in different ages of the world have most eminently distinguished themselves either for their good or evil actions. This last part of civil history is usually termed BIOGRAPHY.

History is now considered as a very considerable branch of polite literature: few accomplishments are more valuable than an accurate knowledge of the histories of different nations; and scarce any literary production is more regarded than a well-written history of any nation.

With regard to the study of history, we must consider, that all the revolutions which have happened in the world have been owing to two causes. 1. The connections between the different states existing together in the world at the same time, or their different situations with regard to one another; and, 2. The different characters of the people who in all ages constituted these states, their different dispositions and situations, &c. by which they were either prompted to undertake such and such actions of themselves, or were easily induced to it by others. The person who would study history, therefore, ought in the first place to make himself acquainted with the state of the world in general in all different ages; what nations inhabited the different parts of it; what their extent of territory was; at what particular time they arose, and when they declined. He is then to inform himself of the various events which have happened to each particular nation; and, in so doing, he will discover many of the causes of those revolutions, which before he only knew as facts. Thus, for instance, a person may know the Roman history from the time of Romulus, without knowing in the least why the city of Rome happened to be built at that time. This cannot be understood without a particular knowledge of the former state of Italy, and even of Greece and Asia;
Sect. I.

Civil History.

Asia; seeing the origin of the Romans is commonly traced as high as Æneas, one of the heroes of Troy. But when all this is done, which indeed requires no small labour, the historian hath yet to study the genius and dispositions of the different nations, the characters of those who were the principal directors of their actions, whether kings, ministers, generals or priests; and when this is accomplished, he will discover the causes of those transactions in the different nations which have given rise to the great revolutions above mentioned: after which, he may assume the character of one who is perfectly versed in history.

The first outline of history, as it may be called, is most easily obtained by the inspection of an historical chart; and that subjoined to the present treatise will answer the purpose as well as any. Along with this it will be proper to peruse a short abridgement of general history, from the creation of the world to the present time; but in this way there have been but very few attempts attended with any tolerable success. The following is collected from respectable authorities, and may serve to help the ideas of the reader on this subject.

Sect. I. Civil History.

HISTORY, though seemingly incapable of any natural division, will yet be found, on a nearer inspection, to resolve itself into the following periods, at each of which a great revolution took place, either with regard to the whole world, or a very considerable part of it. 1. The creation of man. 2. The flood. 3. The beginning of profane history, i.e. when all the fabulous relations of heroes, demi-gods, &c. were expelled from historical narrations, and men began to relate facts with some regard to truth and credibility. 4. The conquest of Babylon by Cyrus, and the destruction of the Babylonian empire. 5. The reign of Alexander the Great, and the overthrow of the Persian empire. 6. The destruction of Carthage by the Romans, when the latter had no longer any rival capable of opposing their designs. 7. The reign of the emperor Trajan, when the Roman empire was brought to its utmost extent. 8. The division of the empire under Constantine. 9. The destruction of the western empire by the Heruli, and the settlement of the different European nations. 10. The rise of Mahomet, and the conquests of the Saracens and Turks. 11. The crusades, and all the space intervening between that time and the present.

Concerning the number of years which have elapsed since the creation of the world, there have been many disputes. The compilers of the Universal History determine it to have taken place in the year 4325 B.C. so that, according to them, the world is now (1806) in the 611th year of its age. Others think it was created only 4000 years B.C. so that it hath not yet attained its 6200th year. Be this as it will, however, the whole account of the creation rests on the truth of the Mosaic history; and this we must of necessity accept, because we can find no other which does not either abound with the grossest absurdities, or lead us into absolute darkness. The Chinese and Egyptian pretensions to antiquity are so absurd and ridiculous, that the bare reading must be a sufficient confirmation of them to every reasonable person. See the articles China and Egypt. Some historians and philosophers are inclined to discredit the Mosaic accounts, from the appearances of volcanoes, and other natural phenomena: but their objections are by no means sufficient to invalidate the authority of the sacred writings; not to mention that every one of their own systems is liable to insuperable objections. See GEOLOGY. It is therefore reasonable for every person to accept of the Mosaic account of the creation as truth: but an historian is under an absolute necessity of doing it, because, without it, he is quite destitute of any standard or scale by which he might reduce the chronology of different nations to any agreement; and, in short, without receiving this account as true, it would be in a manner impossible at this day to write a general history of the world.

1. The transactions during the first period, viz. from the creation to the flood, are very much unknown, nothing indeed being recorded of them but what is to be found in the first six chapters of Genesis. In general, we know, that men were not at that time in a savage state; they had made some progress in the arts, had invented music, and found out the method of working metals. They seem also to have lived in one vast community, without any of those divisions into different nations which have since taken place, and which evidently proceeded from the confusion of languages. The most material part of their history, however, is, that having once begun to transgress the divine commands, they proceeded to greater and greater lengths of wickedness, till at last the Deity thought proper to send a flood on the earth, which destroyed the whole human race except eight persons, viz. Noah and his family. This terrible catastrophe happened, according to the Hebrew copy of the Bible, 1656 years after the creation; according to the Samaritan copy 1537. For the different conjectures concerning the natural causes of the flood, see the article DELUGE. 2. For the history of the second period we must again have recourse to the Scriptures, almost as much as to the flood for that of the first. We now find the human race re-beginning of its progress. 3. The number of those people who were descended to eight persons, possessed of nothing but what they had saved in the ark, and the whole world to be stored with animals from those which had been preserved along with these eight persons. In what country their original settlement was, no mention is made. The ark is supposed to have rested on Mount Ararat in Armenia; but it is impossible to know whether Noah and his sons made any stay in the neighbourhood of Ararat, or not. Certain it is, that some time after the whole or the greatest part of the human race were assembled in Babylonia, where they engaged in building a tower. This gave offence to the Deity; so that he punished them by confounding their language; whence the division of mankind into different nations.

According to a common opinion, Noah when dying left the whole world to his sons, giving Asia to Shem, Africa to Ham, and Europe to Japhet. But this hath not the least foundation in Scripture. By the most deserved probable accounts, Gomer the son of Japhet was the father of the Goemrians or Celtes; that is, all the barbarous nations who inhabited the northern parts of Europe,
The first considerable revolution we read of is the migration of the Israelites out of Egypt, and their establishment in the land of Canaan. For the history of these transactions we must refer to the Old Testament. Where the reader will see that it was attended with the most terrible catastrophes to the Egyptians, and recites with the utter extermination of some nations, the destruction of Ham, who inhabited Judea. Whether the overthrow of Pharaoh in the Red Sea could affect the Egyptian nation in such a manner as to deprive them of the greatest part of their former learning, and to keep them for some ages after in a barbarous state, is not easily determined; but unless this was the case, it seems exceedingly difficult to account for the total silence of their records concerning such a remarkable event, and indeed for the general confusion and uncertainty in which the early history of Egypt is involved. The settlement of the Jews in the promised land of Canaan, is supposed to have happened about 1491 B.C.

For near 200 years after this period, we find no history of accounts of any other nation than those mentioned in the Greek Scriptures. About 1280 B.C. the Greeks began to make other nations feel the effects of that enterprising and martial spirit for which they were so remarkable, and which they had undoubtedly exercised upon one another long before. Their first enterprise was an invasion of Colchis (now Mingrelia), for the sake of the golden fleece. Whatever was the nature of this expedition, it is probable they succeeded in it; and it is likewise probable, that it was this specimen of the riches of Asia which inclined them so much to Asiatic expeditions ever after. All this time we are totally in the dark about the state of Asia and Africa, except in so far as can be conjectured from Scripture. The ancient empires of Babylon, Assyria, and Persia, probably still continued in the former continent, and Egypt and Ethiopia seem to have been considerable kingdoms in the latter.

About 1184 years B.C. the Greeks again distinguished themselves by their expedition against Troy, a city of Phrygia Minor; which they plundered and burnt, massacring the inhabitants with the most unrelenting cruelty. Aeneas, a Trojan prince, escaped with some followers into Italy, where he became the remote founder of the Roman empire. At this time Greece was divided into a number of small principalities, most of which seem to have been in subjection to Agamemnon king of Mycenae. In the reign of Aeetes, the father of this Agamemnon, the Heraclid, or descendants of Hercules, who had been formerly banished by Eurystheus, were again obliged to leave this country. Under their champion Hyllus they claimed the kingdom of Mycenae as their right, pretending that it belonged to their great ancestor Hercules, who was unjustly deprived of it by Eurystheus &c. The controversy was decided by single combat; but Hyllus being killed, they departed, as had been before agreed, under a promise of not making any attempt to return for 50 years. About the time of the Trojan war, also, we find the Lydians, Myssians, and some other nations of Asia Minor, first mentioned in history. The names of the Greek states mentioned during this uncertain period are, 1. Sicyon. 2. Leleg. 3. Messaia. 4. Athens. 5. Crete. 6. Argos. 7. Sparta. 8. Pelasgia. 9. Thessaly.
HISTORY.

Concerning many of these we know nothing besides their names: the most remarkable particulars concerning the rest may be found under their respective articles.

About 1048 B.C. the kingdom of Judea under King David approached its utmost extent of power. In its most flourishing condition, however, it never was remarkable for the largeness of its territory. In this respect it scarce exceeded the kingdom of Scotland; though, according to the accounts given in scripture, the magnificence of Solomon was superior to that of the most potent monarchs on earth. This extraordinary was, was owing partly to the spoils amassed by King David in his conquests over his various enemies, and partly to the commerce with the East Indies which Solomon had established. Of this commerce he owed his share to the friendship of Hiram king of Tyre, a city of Phoenicia, whose inhabitants were now the most famed for commerce and skill in maritime affairs of any in the whole world.

After the death of Solomon, which happened about 975 B.C. the Jewish empire began to decline; and soon after many powerful states arose in different parts of the world. The disposition of mankind in general seems now to have taken a new turn, not easily accounted for. In former times, whatever wars might have taken place between neighbouring nations, we have no account of any extensive empire in the whole world, or that any prince undertook to reduce far distant nations to his subjection. The empire of Egypt indeed is said to have been extended immensely to the east, even before the days of Sesostris. Of this country, however, our accounts are so imperfect, that scarce anything can be concluded from them. But now, as it were all at once, we find almost every nation aiming at universal monarchy, and refusing to set any bounds whatever to its ambition. The first shock given to the Jewish grandeur was the division of the kingdom into two, through the imprudence of Rebozam. This rendered it more easily a prey to Shishak king of Egypt; who five years after came and pillaged Jerusalem, and all the fortified cities of the kingdom of Judah. The commerce to the East Indies was now discontinued, and consequently the sources of wealth in a great measure stopped; and this, added to the perpetual wars between the kings of Israel and Judah, contributed to that remarkable and speedy decline which is now so easily to be observed in the Jewish affairs.

Whether this king Shishak was the Sesostris of profane writers or not, his expedition against Jerusalem as recorded in scripture seems very much to resemble the desultory conquests ascribed to Sesostris. His infantry is said to have been innumerable, composed of different African nations; and his cavalry 60,000, with 1200 chariots, which agrees pretty well with the mighty armament ascribed to Sesostris, and of which an account is given under the article Egypt, No. 2. There indeed his cavalry are said to have been only 24,000; but the number of his chariots is increased to 27,000; which last may not unreasonably be reckoned an exaggeration, and these supernumerary chariots may have been only cavalry; but unless we allow Sesostris to be the same with Shishek, it seems impossible to fix on any other king of Egypt that can be supposed to have undertaken this expedition in the days of Solomon.

Though the Jews obtained a temporary deliverance from Shishak, they were quickly after attacked by new enemies. In 941 B.C. one Zerach an Ethiopian invaded Judea with an army of a million of infantry and 300 chariots; but was defeated with great slaughter by Asa king of Judah, who engaged him with an army of 500,000 men. About this time also we find the Syrians gained a considerable people, and bitter enemies both to the kings of Israel and Judah; aiming in fact at the conquest of both nations. Their kingdom commenced in the days of David, under Hadadader, whose capital was Zobah, and who probably was at last obliged to become David's tributary, after having been defeated by him in several engagements. Before the death of David, however, one Rezon, who it seems had rebelled against Hadadader, having found means to make himself master of Damascus, erected there a new kingdom, which soon became very powerful. The Syrian princes being thus in the neighbourhood of the two rival states of Israel and Judah (whose capitals were Samaria and Jerusalem), found it an easy matter to weaken them both, by pretending to assist the one against the other; but a detail of the transactions between the Jews and Syrians is only to be found in the Old Testament, to which we refer. In 740 B.C. however, the Syrian empire was totally destroyed by Tiglath Pileser king of Assyria; as was also the kingdom of Samaria by Shalmaneser his successor in 721 B.C. The people were either massacred, or carried into captivity into Media, Persia, and the countries about the Caspian sea.

While the nations of the east were thus destroying each other, the foundations of very formidable empires were laid in the west, which in process of time were to swallow up almost all the eastern ones. In Africa, Carthage was founded by a Tyrian colony, about 869 B.C. according to those who ascribe the highest antiquity to that city; but, according to others, it was founded only in 769 or 770 B.C. In Europe a very considerable revolution took place about 500 B.C. The Heraclids, whom we have formerly seen expelled from Greece by Atreus the father of Agenemnon, after several unsuccessful attempts, at last conquered the whole Peloponnesus. From this time the Grecian states became more civilized, and their history becomes less obscure. The institution, or rather the revival and continuance, of the Olympic games, in 776 B.C. also greatly facilitated the writing not only of their history, but that of other nations; for as each Olympiad consisted of four years, the chronology of every important event became indubitably fixed by referring it to such and such an Olympiad. In 748 B.C.
or the last year of the seventh Olympiad, the foundations of the city of Rome were laid by Romulus; and, 43 years after, the Spartan state was new modeled, and received from Lycurgus those laws, by observing of which it afterwards arrived at such a pitch of splendor.

3. With the beginning of the 28th Olympiad, or 568 B.C., commences the third general period above-mentioned, when profane history becomes somewhat more clear, and the relations concerning the different nations may be depended upon with some degree of certainty. The general state of the world was at that time as follows. The northern parts of Europe were either thinly inhabited, or filled with unknown and barbarous nations, the ancestors of those who afterwards destroyed the Roman empire. France and Spain were inhabited by the Celts or Celts. Italy was divided into a number of petty states, arising partly from Gaulish and partly from Grecian colonies; among whom the Romans had already become formidable. They were governed by their king Servius Tullius; had increased their city by the demolition of Alba Longa, and the removal of its inhabitants to Rome; and had enlarged their dominions by several cities taken from their neighbours. Greece was also divided into a number of small states, among which the Athenians and Spartans, being the most remarkable, were rivals to each other. The former had, about 599 B.C., received an excellent legislation from Solon, and were enriching themselves by navigation and commerce: the latter were become formidable by the martial institutions of Lycogoras; and having conquered Messina, and added its territory to their own, were justly esteemed the most powerful people in Greece. The other states of most consideration were Corinth, Thebes, Argos, and Acredia. In Asia great revolutions had taken place. The ancient kingdom of Assyria was destroyed by the Medes and Babylonians, its capital city Nineveh utterly ruined, and the greatest part of its inhabitants carried to Babylon. Of the materials of which it was built were carried off, to adorn and give strength to that stately metropolis, which was then undoubtedly the first city in the world. Nebuchadnezzar, a wise and valiant prince, now sat on the throne of Babylon. By him the kingdom of Judea was totally overthrown in 587 B.C. Three years before this he had taken and razed the city of Tyre, and overrun all the kingdom of Egypt. He is even said by Josephus to have conquered Spain, and reigned there nine years, after which he abandoned it to the Carthaginians; but this seems by no means probable. The extent of the Babylonian empire is not certainly known; but from what is recorded of it we may conclude, that it was not at all inferior even in this respect to any that ever existed; as the scripture tells us it was superior in wealth to any of the succeeding ones. We know that it comprehended Phocacia, Palestine, Syria, Babylonia, Media, and Persia, and not improbably India also; and from a consideration of this vast extent of territory, and the riches with which every one of these countries abounded, we may form some idea of the wealth and power of this monarch. When we consider also, that the whole strength of this mighty empire was employed in beautifying the metropolis, we cannot look upon the wonders of that city as related by Herodotus to be at all incredible. See Babylon, and Architecture, No. 13. As to what passed in the republic of Carthage about this time, we are quite in the dark; there being a chasm in its history for no less than 300 years.

4. The fourth general period of history, namely, Fourth period, from the end of the fabulous times to the conquest of the Medes by Cyrus, is very short, including no other story of the Medes, but that of Nebuchadnezzar. His son, even in his father's lifetime, was eager in a great hunting match on occasion of his marriage, entered the country of the Medes, and some of his troops coming up at the same time to relieve the garrisons in those places, he joined them to those already with him, and without the least provocation began to plunder and lay waste the neighboring country. This produced an immediate revolt, which quickly extended over all Media and Persia. The Medes, headed by Astyages and his son Cyaxares, drove back Evilmerodach and his party with great slaughter; nor doth it appear that they were afterwards reduced even by Nebuchadnezzar himself. The new empire continued daily to gather strength; and at last Cyrus, Astyages's grandson, a prince of great prudence and valor, being made generalissimo of the Median and Persian forces, took Babylon itself in the year 538 B.C., as related under the article Babylon.

During this period the Romans increased in power under the wise administration of their king Servius Tullius, who, though a pacific prince, rendered his people more formidable by a peace of twenty years than his predecessors had done by all their victories. The Greeks, even at this early period, began to interfere with the Persians, on account of the Ionians or Grecian colonies in Asia Minor. These had been subdued by Croesus king of Lydia about the year 562, the time of Nebuchadnezzar's death. Whether the Lydians had been subdued by the Babylonish monarch or not, is not now to be ascertained; though it is very probable that they were either in subjection to him, or greatly awed by his power, as before his death nothing considerable was undertaken by them. It is indeed probable, that during the insanity of Nebuchadnezzar, spoken of by Daniel, the affairs of his kingdom would fall into confusion; and many of those princes whom he formerly retained in subjection would set up for themselves. Certain it is, however, that if the Babylonians did not regard Croesus as their subject, they looked upon him to be a very faithful ally; insomuch that they celebrated an annual feast in commemoration of a victory obtained by him over the Scythians. After the death of Nebuchadnezzar, Croesus subdued many nations in Asia Minor, and among the rest the Ionians, as already related. They were, however, greatly attached to his government; for though they paid in tribute, and were obliged to furnish him with some forces in time of war, they were yet free from all kind of oppression. When Cyrus therefore was proceeding in his conquests of different parts of the Babylonish empire, before he proceeded to attack the capital, the Ionians refused to submit to him, though he offered them very advantageous terms. But soon after, Croesus himself being defeated and taken prisoner, the Ionians sent ambassadors to Cyrus, offering
to submit on the terms which had formerly been pro-
posed. These terms were now refused; and the Ion-
ians, being determined to resist, applied to the Spar-
tans for aid. Though the Spartans at that time
could not be prevailed upon to give their countrymen
any assistance, they sent ambassadors to Cyrus with a
threatening message; to which he returned a contempt-
uous answer, and then forced the Ionians to submit
discretion, five years before the taking of Babylon.
Thus commenced the hatred between the Greeks and
Persians; and thus we see, that in the two first great
monarchies the seeds of their destruction were sown
even before the monarchies themselves were established.
For while Nebuchadnezzar was raising the Babylonish
empire to its utmost height, his son was destroying
what his father built up; and at the very time when
Cyrus was establishing the Persian monarchy, by his
ill-timed severity to the Greeks he made that warlike
people his enemies, whom his successors were by no
means able to resist, and who would probably have
overcome Cyrus himself, had they united in order
to attack him. The transactions of Africa during this
period are almost entirely unknown; though we cannot
doubt that the Carthaginians enriched themselves
by means of their commerce, which enabled them af-
few years to attain such a considerable share of power.

5. Cyrus having now become master of all the east,
the Asiatic affairs continued for some time in a state of
tranquillity. The Jews obtained leave to return to
their own country, rebuild their temple, and again
establish their worship, of all which an account is given
in the sacred writings, though undoubtedly they must
have been in a state of dependence on the Persians
from that time forward. Cambyses the successor of Cy-
rus added Egypt to his empire, which had either not
submitted to Cyrus, or revolted soon after his death.
He intended also to have subdued the Carthaginians;
but as the Phenicians refused to supply him with ships
to fight against their own countrymen, he was obliged
to lay this design aside.

In 517 B.C. the Babylonians finding themselves
grievedly oppressed by their Persian masters, resolved
to shake off the yoke, and set up for themselves. For
this purpose, they took care to store their city with all
manner of provisions; and when Darius Hyksus, the
then king of Persia, advanced against them, they took
the most barbarous method that can be imagined of
preventing an unnecessary consumption of those pro-
visions, which they had so carefully amassed. Having
collected all the women, old men, and children, into
one place, they strangled them without distinction,
whether wives, fathers, mothers, brothers, or sisters;
every one being allowed to save only the wife he liked
best, and a maid servant to do the work of the house.
This cruel policy did not avail them: their city was
taken by treachery (for it was impossible to take it
by force); after which the king caused the walls of
it to be beaten down from 200 to 50 cubits height,
that their strength might no longer give encouragement
to the inhabitants to revolt. Darius then turned
his arms against the Scythians; but finding that expedi-
tion turn out both tedious and unprofitable, he
directed his course eastward, and reduced all the coun-
try as far as the river Indus. In the mean time, the
Ionians revolted; and being assisted by the Greeks, a
war commenced between the two nations, which was
not thoroughly extinguished but by the destruction of
the Persian empire in 330 B.C. The Ionians, how-
ever, were for this time obliged to submit, after a war
of six years; and were treated with great severity by
the Persians. The conquest of Greece itself was then
projected: but the expeditions for that purpose ended
most unfortunately for the Persians, and encouraged
the Greeks to make reprisals on them, in which they
succeeded according to their utmost wishes; and had
it only been possible for them to have agreed among
themselves, the downfall of the Persian empire would
have happened much sooner than it did. See ATHENS,
SPARTA, MACEDON, and PERSIA.

In 459 B.C. the Egyptians made an attempt to recov-
er their liberty, but were reduced after a war of
six years. In 413 B.C. they revolted a second time:
and being assisted by the Sidonians, drew upon the
latter that terrible destruction foretold by the prophets;
while they themselves were so thoroughly humbled, that
they never after made any attempt to recover their
liberty.

The year 403 B.C. proved remarkable for the revo-
lution of Cyrus against his brother Artaxerxes Memnon,
in which, through his own rashness, he miscarried, and
lost his life at the battle of Cunaxa, in the province of
Babylon. Ten thousand Greek mercenaries, who served Xenophon's
in his army, made their way back into Greece, though
retreat.

During all this time, the volatile and giddy temper of
the Greeks, together with their enthusiastic desire
of romantic exploits, were preparing for them-
sewldes, which indeed seemed to be absolutely necessary
to prevent them from destroying one another. A zeal
for liberty was what they all pretended; but on every
occasion it appeared, that this love of liberty was only
a desire of dominion. No state in Greece could bear
to see another equal to itself; and hence their perpetual
contests for pre-eminence, which could not but weaken
the whole body, and render them an easy prey to
an ambitious and politic prince, who was capable of
taking advantage of those divisions. Being all equally
impatient of restraint, they never could bear to submit
to any regular government; and hence their determina-
tions were nothing but the decisions of a mere mob,
of which they had afterwards almost constantly reason
to repent. Hence also their base treatment of those
eminent men whom they ought most to have honoured;
as Miltiades, Aristides, Themistocles, Alcibiades, So-
crates, Phocion, &c. The various transactions be-
tween the Grecian states, though they make a very
considerable figure in particular history, make none at
all in a general sketch of the history of the world. We
shall therefore only observe, that in 404 B.C. the Ath-
cadian power was in a manner totally broken by the
taking

Civil History.

512

taking of their city by the Spartans. In 370 B.C. that of the Spartans received a severe check from the Thebans at the battle of Leuctra; and eight years after was still further reduced by the battle of Mantinea. Epaminondas the great enemy of the Spartans was killed; but this only proved a more speedy means of subjugating all the states to a foreign, and at that time despicable, power. The Macedonians, a barbarous nation, lying to the north of the states of Greece, were two years after the death of Epaminondas reduced to the lowest ebb by the Illyrians, another nation of barbarians in the neighbourhood. The king of Macedon being killed in an engagement, Philip his brother departed from Thebes, where he had studied the art of war under Epaminondas, in order to take possession of his kingdom. Being a man of great prudence and policy, he quickly settled his own affairs; vanquished the Illyrians; and being no stranger to the weakened situation of Greece, began almost immediately to meditate the conquest of it. The particulars of this enterprise are related under the article MACEDON: here it is sufficient to take notice, that by first attacking those who was sure he could overcome, by corrupting those whom he thought it dangerous to attack, by sometimes pretending to assist one state and sometimes another, and by imposing upon all as best served his turn, he at last put it out of the power of the Greeks to make any resistance; at least such as could keep him from gaining his end. In 338 B.C. he procured himself to be elected general of the Amphictyons, or council of the Grecian states, under pretence of settling some troubles at that time in Greece; but having once obtained liberty to enter that country with an army, he quickly convinced the states that they must all submit to his will. He was opposed by the Athenians and Thebans; but the intestine wars of Greece had cut off all her great men, and no general was now to be found capable of opposing Philip with success.

The king of Macedon, being now master of all Greece, projected the conquest of Asia. To this he was encouraged by the ill success which had attended the Persians in their expeditions against Greece, the successes of the Greeks in their invasions, and the retreat of the ten thousand under Xenophon. All these events showed the weakness of the Persians, their vast inferiority to the Greeks in military skill, and how easily their empire might be overthrown by a proper union among the states.

Philip was preparing to enter upon his grand design, when he was murdered by some assassination. His son Alexander was possessed of every quality necessary for the execution of so great a plan; and his impetuosity of temper made him execute it with a rapidity unheard of either before or since. It must be confessed, indeed, that the Persian empire was now ripe for destruction, and could not in all probability have withstood an enemy much less powerful than Alexander. The Asiatics have in all ages been much inferior to the European nations in valour and military skill. They were now sunk in luxury and effeminacy; and what was worse, they seem at this period to have been seized with that infatuation and distraction of councils which scarce ever fails to be a forerunner of the destruction of any nation. The Persian ministers persuaded their sovereign to reject the prudent advice that was given him, of distressing Alexander by laying waste the country, and thus forcing him to return for want of provisions. Nay, they even prevented him from engaging the enemy in the most proper manner, by dividing his forces; and persuaded him to put Charidemus the Athenian to death, who had promised with 100,000 men, of whom one-third were mercenaries, to drive the Greeks out of Asia. In short, Alexander met with only two checks in his Persian expedition. The one was from the city of Tyre, which for seven months resisted his utmost efforts; the other was fromMemnon the Rhodian, who had undertaken to invade Macedonia. The first of these obstacles Alexander at last got over, and treated the governor and inhabitants with the utmost cruelty. The other was scarce felt; for Memnon died after reducing some of the Grecian islands, and Darius had no other general capable of conducting the undertaking. The power of the Persian empire was totally broken by the victory gained over Darius at Arbela in 331 B.C. and next year a total end was put to it by the murder of the king by Bessus one of his subjects.

The ambition of Alexander was not to be satisfied with the possession of the kingdom of Persia, or indeed of any other on earth. Nothing less than the total subjection of the word itself seemed sufficient to him; and therefore he was now prompted to invade every country of which he could only learn the name, whether it had belonged to the Persians or not. In consequence of this disposition, he invaded and reduced Hycania, Bactria, Bopidia, and all that vast tract of country now called Bucharia. At last, having entered India, he reduced all the nations to the river Hyphasis, one of the branches of the Indus. But when he would have proceeded farther, and extended his conquests quite to the eastern extremities of Asia, his troops positively refused to follow him farther, and he was constrained to return. In 323 B.C. this mighty conqueror died of a fever; without having time to settle the affairs of his vast extended empire, or even to name his successor.

While the Grecian empire thus suddenly sprung up in the east, the rival states of Rome and Carthage were making considerable advances in the west. The Romans were establishing their empire on the most solid foundations; to which their particular situation naturally contributed. Being originally little better than a parcel of lawless banditti, they were despised and hated by the neighbouring states. This soon produced wars; in which, at first from accidental circumstances, and afterwards from their superior valour and conduct, the Romans proved almost constantly victorious. The jealousies which prevailed among the Italian states, and their ignorance of their true interest, prevented them from combining against that aspiring nation, and crushing it in its infancy, which they might easily have done; while in the mean time the Romans being kept in a state of continual warfare, became at last such expert soldiers, that no other state on earth could resist them. During the time of their kings they had made a very considerable figure among the Italian nations; but after their expulsion, and the commencement of the republic, their conquests became much more rapid and extensive. In 305 B.C. they subdued the Sabines; eight years after, the Latins; and in 339 B.C. the city...
city of Veii, the strongest in Italy, exceeding Rome itself, was taken after a siege of ten years. But in the midst of their successes a sudden insurrection of the Gauls had almost put an end to their power and nation at once. The city was burnt to the ground in 393 B.C. and the capital on the point of being surprised, when the Gauls, who were climbing up the walls in the night, were accidentally discovered and repulsed. In a short time Rome was rebuilt with much greater splendor than before, but now a general revolt and combination of the nations formerly subdued took place. The Romans, however, still got the better of their enemies; but, even at the time of the celebrated Camillus’s death, which happened about 352 B.C. their territories scarce extended six or seven leagues from the capital. The republic from the beginning was agitated by those dissensions which at last proved its ruin. The people had been divided by Romulus into two classes, namely, Patricians and Plebeians, answering to our nobility and commonalty. Between these two bodies were perpetual jealousies and contentions; which retarded the progress of the Roman conquests, and revived the hopes of the nations they had conquered. The tribunes of the people were perpetually opposing the consuls and military tribunes. The senate had often recourse to a dictator endowed with absolute power; and then the valour and experience of the Roman troops made them victorious; but the return of domestic seditions gave the subjegated nations an opportunity of shaking off the yoke. Thus had the Romans continued for near 400 years, running the same round of wars with the same enemies, and reaping very little advantage from their conquests, till at last matters were compounded by choosing one of the consuls from among the plebeians; and from this time chiefly we may date the prosperity of Rome, so that by the time that Alexander the Great died they were held in considerable estimation among foreign nations.

The Carthaginians in the mean time continued to enrich themselves by commerce; but, being less conversant in military affairs, were by no means equal to the Romans in power, though they excelled them in wealth. A new state, however, makes its appearance during this period, which may be said to have taught the Carthaginians the art of war, and, by bringing them into the neighborhood of the Romans, proved the first source of contention between these two powerful nations. This was the island of Sicily. At what time people were first settled on it, is not now to be ascertained. The first inhabitants we read of were called Sicani, Siculi, Lastrigones, &c. but of these we know little or nothing. In the second year of the 17th Olympiad, or 710 B.C. some Greek colonies are said to have arrived on the island, and in a short time founded several cities, of which Syracuse was the chief. The Syracusans at last subdued the original inhabitants: though it doth not appear that the latter were ever well affected to their government, and therefore were on all occasions ready to revolt. The first considerable prince, or (as he is called by the Greeks) tyrant of Syracuse, was Gelon, who obtained the sovereignty about the year 485 B.C. At what time the Carthaginians first carried their arms into Sicily is not certainly known; only we are assured, that 3T

HISTORY.

they possessed some part of the island as early as 505 B.C. For in the time of the first consuls, the Romans and Carthaginians entered into a treaty chiefly in regard to matters of navigation and commerce; by which it was stipulated, that the Romans who should touch at Sardinia, or that part of Sicily which belonged to Carthage, should be received there in the same manner as the Carthaginians themselves. Whence it appears, that the dominion of Carthage already extended over Sardinia and part of Sicily; but in 28 years after, they had been totally driven out by Gelon: which probably was the first exploit performed by him. This appears from his speech to the Athenian and Spartan ambassadors who desired his assistance against the forces of Xerxes king of Persia. The Carthaginians made many attempts to regain their possessions in this island, which occasioned long and bloody wars between them and the Greeks, as related under the articles CARTHAGE and SYCYL. This island also proved the scene of much slaughter and bloodshed in the wars of the Greeks with one another. Before the year 325 B.C., however, the Carthaginians had made themselves masters of a very considerable part of the island; from whence all the power of the Greeks did not dislodge them. It is proper also to observe, that after the destruction of Tyre by Alexander the Great, almost all the commerce in the western part of the world fell to the share of the Carthaginians. Whether they had at this time made any settlements in Spain is not known. It is certain, that they traded to that country for the sake of the silver, in which it was very rich; as they probably also did to Britain for the tin with which it abounded.

6. The beginning of the sixth period presents us with a historical state of the world entirely different from the preceding. We now behold all the eastern part of the world, from the confines of Italy to the river Indus, and beyond it, newly united into one vast empire, and at the same time ready to fall to pieces for want of a proper head; the western world filled with fierce and savage nations, whom the rival republics of Carthage and Rome were preparing to enslave as fast as they could. The first remarkable events took place in the Macedonian empire.—Alexander, as already observed, had not distinctly named any successor; but he had left behind him a victorious, and, we may say, invincible army, commanded by most expert officers, all of them ambitious of supreme authority. It is not to be supposed that peace could long be preserved in such a situation. For a number of years, indeed, nothing was to be seen or heard of but the most horrid slaughters, and wickedness of every kind, until at last the mother, wives, children, brothers, and even sisters, of Alexander, were cut off; not one of the family of that great conqueror being left alive. When matters were a little settled, four new empires, each of them of no small extent, had arisen out of the empire of Alexander. Cassander, the son of Antipater, had Macedonia and all Greece; Antigonus, Asia Minor; Seleucus had Babylon and the eastern provinces; and Ptolemy Lagus, Egypt and the western ones. One of these empires, however, quickly fell; Antigonus being defeated and killed by Seleucus and Lysimachus at the battle of Ipsus, in 301 B.C. The greatest part of his dominions then fell to Seleucus; but several pro-

HISTORY.

Of the Romans and Carthaginians.

The Romans, ever engaged in war, conquered one city and state after another, till about the year 249 B.C. they had made themselves masters of almost the whole of Italy. During all this time they had met only with a single check in their conquests, and that was the invasion of Pyrrhus, king of Epirus. That ambitious and fickle prince had projected the conquest of Italy, which he fancied would be an easy matter. Accordingly in 271 B.C. he entered that country, and maintained a war with the Romans for six years, till at last, being utterly defeated by Curius Dentatus, he was obliged to return.

The Romans had no sooner made themselves masters of Italy, than they wanted only a pretence to carry their arms out of it, and this pretence was soon found out. Being invited into Sicily to assist the Maminthines against Hiero king of Syracuse and the Carthaginians, they immediately commenced a war with the latter, which continued with the utmost fury for 23 years. The war ended greatly to the disadvantage of the Carthaginians, chiefly owing to the bad conduct of their generals, none of whom, Hamilcar Barbac alone excepted, seem to have been possessed of any degree of military skill; and the state had suffered too many misfortunes before he entered upon the command, for him or any other to retrieve it at that time. The consequence of this war was the entire loss of Sicily to the Carthaginians; and soon after the Romans seized on the island of Sardinia.

Hamilcar perceiving that there was now no alternative, but that in a short time either Carthage must conquer Rome, or Rome would conquer Carthage, bethought himself of a method by which his country might become equal to that haughty republic. This was by reducing all Spain, in which the Carthaginians had already considerable possessions, and from the mines of which they drew great advantages. He had, therefore, no sooner finished the war with the mercenaries, which succeeded that with the Romans, than he set about the conquest of Spain. This, however, he did not live to accomplish, though he made great progress in it. His son Asdrubal continued the war with success; till at last the Romans, jealous of his progress, persuaded him to enter into a treaty with them, by which he engaged himself to make the river Iberas the boundary of his conquests. This treaty probably was never ratified by the senate of Carthage, nor, though it had, would it have been regarded by Hannibal, who succeeded Asdrubal in the command, and had sworn perpetual enmity with the Romans. The transactions of the second Punic war are perhaps the most remarkable which the history of the world can afford. Certain it is, that nothing can show more clearly the slight foundations upon which the greatest empires are built. We now see the Romans, the nation most remarkable for their military skill in the whole world, and who, for more than 500 years, had been constantly victorious, unable to resist the efforts of one single man. At the same time we see this man, though evidently the first general in the world, lost solely for want of a slight support. In former times, the republic of Carthage supplied her generals in Sicily with hundreds of thousands, though their enterprises were almost constantly unsuccessful; but now Hannibal, the conqueror of Italy, was obliged to abandon his design, merely for want of 20 or 30,000 men. That degeneracy and insufficiency, which never fails to overwhelm a falling nation, or rather which is the cause of its fall, had now infected the counsels of Carthage, and the supplies were denied. Neither was Carthage the only infatuated nation at this time. Hannibal, whose prudence never foresaw him either in prosperity or adversity, in the height of his good fortune had concluded an alliance with Philip king of Macedon. Had that prince sent an army to the assistance of the Carthaginians in Italy immediately after the battle of Canno, there can be no doubt but the Romans would have been forced to accept of that peace which they so haughtily refused; and indeed, they, this offer of peace, in the midst of so much success, in the instance of moderation which perhaps does more honour to the Carthaginian general than all the military exploits he performed. Philip, however, could not be roused from his indolence, nor see that his own ruin was connected with that of Carthage. The Romans had now made themselves masters of Sicily; after which they recalled Marcellus, with his victorious army, to be employed against Hannibal; and the consequence of that was, that the Carthaginian armies, unsupported in Italy, could not conquer it, but were recalled into Africa, which the Romans had invaded. The southern nations seem to have been at blind to their own interest as the northern ones. They ought to have seen, that it was necessary for them to preserve Carthage from being destroyed; but instead of this, Masinissa king of Numidia allied with the Romans, and by his means Hannibal was overcame at the battle of Zama, which finished the second Punic war, in 188 B.C.

The event of the second Punic war determined the fate of almost all the other nations in the world. All and Syria, this time, indeed, the empires of Egypt, Syria, and Greece, had been promoting their own ruin by mutual wars and intestine divisions. The Syrian empire was now governed by Antiochus the Great, who seems to have had little right to such a title. His empire, though diminished by the defection of the Parthians, was still very powerful; and to him Hannibal

Civil History.

Hannibal applied, after he was obliged to leave his country, as related under Carthage, No. 152. Antiochus, however, had not sufficient judgment to see the necessity of following that great man's advice; nor would the Carthaginians be prevailed upon to contribute their assistance against the nation which was soon to destroy them without any provocation. The pretence for war on the part of the Romans was, that Antiochus would not declare his Greek subjects in Asia to be free and independent states; a requisition which neither the Romans nor any other nation had a right to make. The event of all was, that Antiochus was everywhere defeated, and forced to conclude a peace upon very disadvantageous terms.

Of Greece. In Europe, matters went on in the same way; the states of Greece, weary of the tyranny of the Macedonians, entered into a resolution of recovering their liberties. For this purpose was framed the Achæan League; but as they could not agree among themselves, they at last came to the imprudent determination of calling in the Romans to defend them against Philip king of Macedon. This produced a war, in which the Romans were victorious. The Macedonians, however, were still formidable; and as the intention of the Romans to enslave the whole world could no longer be doubted, Perseus, the successor of Philip, renewed the war. Through his own cowardice he lost a decisive engagement, and with it his kingdom, which submitted to the Romans in 167 B.C.

Macedon being thus conquered, the next step was utterly to exterminate the Carthaginians; whose republic, notwithstanding the many disasters that had befallen it, was still formidable. It is true, the Carthaginians were giving no offence; nay, they even made the most abject submissions to the republic of Rome; but all was not sufficient. War was declared a third time against that unfortunate state; there was now no Hannibal to command their armies, and the city was utterly destroyed 146 B.C. The same year the Romans put an end to the liberties they had pretended to grant the cities of Greece, by the entire destruction of Corinth. See that article.

After the death of Antiochus the Great, the affairs of Syria and Egypt went on from bad to worse. The degenerate princes which filled the thrones of those empires, regarding only their own pleasures, either spent their time in oppressing their subjects, or in attempting to deprive each other of their dominions, by which means they became a more easy prey to the Romans. So far indeed were they from taking any means to secure themselves against the overgrown power of that republic, that the kings both of Syria and Egypt sometimes applied to the Romans as protectors. Their downfall, however, did not happen within the period of which we now treat. — The only other transaction which makes any considerable figure in the Syrian empire is the oppression of the Jews by Antiochus Epiphanes. After their return from the Babylonish captivity, they continued in subjection to the Persians till the time of Alexander. — From that time they were subject to the kings of Egypt or Syria, as the fortune of either happened to prevail. Egypt being reduced to a low ebb by Antiochus Epiphanes, the Jews fell under his dominion; and being severely treated by him, imprudently showed some signs of joy on a report of his death. This brought him against them with a powerful army; and in 170 B.C. he took Jerusalem by storm, committing the most horrid cruelties on the inhabitants, insomuch that they were obliged to hide themselves in caverns and in holes of rocks to avoid his fury. Their religion was totally abolished, their temple profaned, and an image of Jupiter Olympius set up on the altar of burnt-offerings: which profanation is thought to be the abomination of desolation mentioned by the prophet Daniel. This revolution, however, was of no long continuance. In 167 B.C. Mattathias restored the true worship in most of the cities of Judea; and in 168 the temple was purified, and the worship there restored by Judas Maccabæus. This was followed by a long series of wars between the Syrians and Jews, in which the latter were almost always victorious; and before these wars were finished, the destruction of Carthage happened, which puts an end to the sixth general period formerly mentioned.

The beginning of the seventh period presents us with a view of the ruins of the Greek empire in the declining states of Syria and Egypt; both of them much circumscribed in bounds. The empire of Syria at first comprehended all Asia to the river Indus, and beyond it; but in 312 B.C. most of the Indian provinces were by Seleucus ceded to one Sandrocottus, or Androcottus, a native, who in return gave him 500 elephants. Of the empire of Sandrocottus we know nothing farther than that he subdued all the countries between the Indus and the Ganges; so that from this time we may reckon the greatest part of India independent on the Syro-Macedonian princes. In 250 B.C. however, the empire sustained a much greater loss by the revolt of the Parthians and Bactrians from Antiochus Theus. The former could not be subdued; and as they held in subjection to them the vast tract which now goes under the name of Persia, we must look upon their defection as an irreparable loss. Whether any part of their country was afterwards recovered by the kings of Egypt or Syria is not very certain; nor is it of much consequence, since we are assured that in the beginning of the seventh period, i.e. 146 B.C. the Greek empires of Syria and Egypt were reduced by the loss of India, Persia, Armenia, Pontus, Bithynia, Cappadocia, Pergamum, &c. The general state of the world in 146 B.C. therefore was as follows. In Asia were the empires of India, Parthia, and Syria, with the lesser states of Armenia, Pontus, &c. above mentioned; to which we must add that of Arabia, which during the sixth period had grown into some consequence, and had maintained its independency from the days of Ishmael the son of Abraham. In Africa were the kingdoms of Egypt and Ethiopia; the Carthaginian territories now subject to the Romans; and the kingdoms of Numidia, Mauritania, and Getulia, ready to be swallowed up by the same ambitious and insatiable power, now that Carthage was destroyed, which served as a barrier against it. To the south lay some unknown and barbarous nations, secure by reason of their situation and insignificance, rather than their strength, or distance from Rome. In Europe we find none to oppose the progress of the Roman arms, except the Gaul, Ger-

T 2
HISTORY.

The Spaniards had indeed been subdued by Scipio Africanus in the time of the second Punic war: but, in 135 B.C. they revolted; and, under the conduct of one Viriathus, formerly a robber, held out for a long time against all the armies the Romans could send into Spain. Him the consul Scipio caused to be murdered about 138 B.C. because he found it impossible to reduce him by force. The city of Numantia defied the whole Roman power for six years longer; till at last, by dint of treachery, numbers, and perseverance, it was not taken, but the inhabitants, reduced to extremity by famine, set fire to their houses, and perished in the flames or killed one another, so that not one remained to grace the triumph of the conqueror: and this for the present quieted the rest of the Spaniards. About the same time Attalus, king of Pergamus, left by will the Roman people heirs to all his goods; upon which they immediately seized on his kingdom as part of those goods, and reduced it to a Roman province, under the name of Asia Propper. Thus they continued to enlarge their dominions on every side, without the least regard to justice, to the means they employed, or to the miseries they brought upon the conquered people. In 122 B.C. the Balearic islands, now called Majorca, Minorca, and Ibiza, were subdued, and the inhabitants exterminated; and soon after, several of the nations beyond the Alps were obliged to submit.

In Africa the crimes of Jugurtha soon gave this ambitious republic an opportunity of conquering the kingdoms of Numidia and Mauritania: and indeed this is almost the only war in which we find the Romans engaged where their pretensions had the least colour of justice; though in no case whatever could a nation show more degeneracy than the Romans did on this occasion. The particulars of this war are related under the articles Numidia and Rome. The event of it was the total reduction of the former about the year 105 B.C. but Mauritania and Getulia preserved their liberty for some time longer.

In the east, the empire of Syria continued daily to decline; by which means the Jews not only had an opportunity of recovering their liberty, but even of becoming as powerful, or at least of extending their dominions as far, as in the days of David and Solomon. This declining empire was still farther reduced by the civil dissensions between the two brothers Antiochus Grypus and Antiochus Cyzicus; during which the cities of Tyre, Sidon, Ptolemais, and Gaza, declared themselves independent, and in other cities tyrants started up who refused allegiance to any foreign power. This happened about 100 B.C.; and 17 years after, the whole was reduced by Tigranes king of Armenia. On his defeat by the Romans, the latter reduced Syria to a province of their empire. The kingdom of Armenia itself, with those of Pontus, Cappadocia, and Bithynia, soon shared the same fate; Pontus, the most powerful of them all, being subdued about 64 B.C. The kingdom of Judea also was reduced under the same power much about this time. This state owed the loss of its liberty to the same cause that had ruined several others, namely, calling in the Romans as arbitrators between two contending parties. The two sons of Alexander Janneus (Hyrcanus and Aristobulus) contended for the kingdom. Aristobulus, being defeated by the party of Hyrcanus, applied to the Romans. Pompey the Great, who acted as ultimate judge in this affair, decided it against Aristobulus, but at the same time deprived Hyrcanus of all power as a king; not allowing him even to assume the regal title, or to extend his territory beyond the ancient borders of Judea. To such a length did Pompey carry this last article, that he obliged him to give up all those cities in Cæsarea and Phœnicia which had been gained by his predecessors, and added them to the newly acquired Roman province of Syria.

Thus the Romans became masters of all the eastern parts of the world, from the Mediterranean sea to the borders of Parthia. In the west, however, the Gauls were still at liberty, and the Spanish nations bore the Roman yoke with great impatience. The Gauls infested the territories of the republic by their frequent incursions, which were sometimes very terrible; and though several attempts had been made to subdue them, they always proved insufficient till the time of Julius Caesar. By him they were totally reduced, from the river Rhine to the Pyrenæan mountains, and many of their nations almost exterminated. He carried his arms also into Germany and the southern parts of Britain; but in neither of these parts did he make any permanent conquests. The civil wars between him and Pompey gave him an opportunity of seizing on the kingdom of Mauritania and those parts of Numidia which had been allowed to retain their liberty. The kingdom of Egypt alone remained, and to this nothing belonged except the country properly so called. Cyrene was bequeathed by will to the Romans about 58 B.C.; and about the same time the island of Cyprus was seized by them without any pretence, except a desire of possessing the treasure of the king.—The kingdom of Egypt continued for some time longer at liberty; which in some measure must be ascribed to the internal dissensions of the republic, but more especially to the amours of Pompey, Julius Caesar, and Mark Antony, with the famous Cleopatra queen of Egypt. The battle of Actium, however, determined the fate of Antony, Cleopatra, and Egypt itself; which last was reduced to a Roman province about 30 B.C.

While the Romans thus employed all means to reduce the world to their obedience, they were making progress of king one another feel the same miseries at home which they inflicted upon other nations abroad. The first civil dissensions took their rise at the siege of Numantia in Spain. We have already observed, that this small city resisted the whole power of the Romans for six years. Once they gave them a most terrible and shameful defeat, whereof 30,000 Romans died before 4000 Numantines. Twenty thousand were killed in the battle, and the remaining ten thousand so shut up, that there was no possibility of escaping. In this extremity they were obliged to negotiate with the enemy, and a peace was concluded upon the following terms: 1. That the Numantines should suffer the Romans to retire unmolested; and, 2. That Numantia should maintain
maintain its independence, and be reckoned among the Roman allies. The Roman senate, with an injustice and ingratitude hardly to be matched, broke this treaty, and in return ordered the commander of their army to be delivered up to the Numantines; but they refused to accept of him, unless his army was delivered along with him; upon which the war was renewed, and ended as already related. The fate of Numantia, however, was soon revenged. Tiberius Sempronius Gracchus, brother-in-law to Scipio Africanus the second, had been a chief promoter of the peace with the Numantines already mentioned, and of consequence had been in danger of being delivered up to them along with the commander in chief. This disgrace he never forgot; and, in order to revenge himself, undertook the cause of the plebeians against the patricians, by whom the former were greatly oppressed. He began with reviving an old law, which had enacted that no Roman citizen should possess more than 500 acres of land. The surplus he designed to distribute among those who had no lands, and to reimburse the rich out of the public treasury. This law met with great opposition, bred many tumults, and at last ended in the death of Gracchus and the persecution of his friends, several hundreds of whom were put to cruel deaths without any form of law.

The disturbances did not cease with the death of Gracchus. New contests ensued on account of the Sempronian law, and the giving to the Italian allies the privilege of Roman citizens. This last not only produced great commotions in the city, but occasioned a general revolt of the states of Italy against the republic of Rome. This rebellion was not quelled without the utmost difficulty; and in the mean time, the city was deluged with blood by the contending factions of Sylla and Marius; the former of whom sided with the patricians, and the latter with the plebeians. These disturbances ended in the perpetual dictatorship of Sulla, about 82 B.C.

From this time we may date the loss of the Roman liberty; for though Sylla resigned his dictatorship two years after, the succeeding contests between Caesar and Pompey proved equally fatal to the republic. These contests were decided by the battle of Pharsalia, by which Caesar became in effect master of the empire in 43 B.C. Without loss of time he then crossed over into Africa; totally defeated the republican army in that continent; and, by reducing the country of Mauritania to a Roman province, completed the Roman conquests in these parts. His victory over the sons of Pompey at Munda 40 B.C. secured him from any further apprehensions of a rival. Being therefore sole master of the Roman empire, and having all the power of it at his command, he projected the greatest schemes; tending, according to some, not less to the happiness than to the glory of his country: when he was assassinated in the senate-house, in the 56th year of his age, and 39 B.C.

Without investigating the political justice of this action, or the motives of the perpetrators, it is impossible not to regret the death of this great man, when we contemplate his virtues, and the designs which he was said to have formed (See Rome). Nor is it possible to justify, from ingratitude at least, even the most virtuous of the conspirators, when we consider the obligations under which they lay to him. And as to the measure itself, even in the view of expediency, it seems to be generally condemned. In fact, from the transactions which had long preceded, as well as those which immediately followed, the murder of Caesar, it is evident, that Rome was incapable of preserving its liberty any longer, and that the people had become unfit for being free. The efforts of Brutus and Cassius were therefore unsuccessful, and ended in their own destruction and that of great numbers of their followers in the battle of Philippi. The defeat of the republicans was followed by numberless disturbances; murders, proscriptions, &c. till at last Octavianus, having cut off all who had the courage to oppose him, and finally got the better of his rivals by the victory at Actium, put an end to the republic in the year 27 B.C.

The destruction of the Roman commonwealth proved advantageous to the few nations of the world who still retained their liberty. That outrageous desire of conquest which had so long marked the Roman character, now in a great measure ceased; because there was now another way of satisfying the desires of ambitious men, namely, by courting the favour of the emperor. After the fall of the Spanish, therefore, and the conquest of the countries of Massilia, Pannonia, and some others adjacent to the Roman territories, and which in a manner seemed naturally to belong to them, the empire enjoyed for some time a profound peace.

The only remarkable transactions which took place during the remainder of the period of which we treat, were the conquest of Britain by Claudius and Agricola, and the destruction of Jerusalem by Vespasian and Titus. The war with the Jews began A.D. 67; and was occasioned by their obstinately claiming the city of Cæsarea, which the Romans had added to the province of Syria. It ended in 73, with the most terrible destruction of their city and nation; since which time they have never been able to assemble as a distinct people. The southern parts of Britain were totally subdued by Agricola about ten years after.

In the 98th year of the Christian era, Trajan was created emperor of Rome; and being a man of great valour and experience in war, carried the Roman conquests to their utmost extent. Having conquered the Dacians, a German nation beyond the Danube, and who had of late been very troublesome, he turned his arms eastward; reduced all Mesopotamia, Chaldea, Assyria; and having taken Ctesiphon, the capital of the Parthian empire, appointed them a king, which he thought would be a proper method of keeping that warlike people in subjection. After this he proposed to return to Italy, but died by the way; and with his reign the seventh general period above mentioned is concluded.

8. The beginning of the eighth period presents us with a view of one vast empire, in which almost all the nations of the world were swallowed up. This empire comprehended the best part of Britain, all Spain, France, the Netherlands, Italy, part of Germany, Egypt, Barbary, Bithynia, Turkey in Europe, Turkey in Asia, and Persia. The state of India at this time is unknown. The Chinese lived in a remote part of the world, unheard of and unmolested by the western nations.
HISTORY.

Civil History.

nations who struggled for the empire of the world. The northern parts of Europe and Asia were filled with barbarous nations, already formidable to the Romans, and who were soon to become more so. The vast empire of the Romans, however, had no sooner attained its utmost degree of power, than, like others before it, it began to decline. The provinces of Babylonia, Mesopotamia, and Assyria, almost instantly revolted, and were abandoned by Adrian the successor of Trajan in the empire. The Parthians having recovered their liberty, continued to be very formidable enemies, and the barbarians of the northern parts of Europe continued to increase in strength; while the Romans, weakened by intestine divisions, became daily less able to resist them. At different times, however, some warlike emperors arose, who put a stop to the incursions of these barbarians; and about the year 215, the Parthian empire was totally overthrown by the Persians, who had long been subject to them. This revolution proved of little advantage to the Romans. The Persians were enemies still more troublesome than the Parthians had been; and though often defeated, they still continued to infest the empire on the east, as the barbarous nations of Europe did on the north. In 263, the defeat and captivity of the emperor Valerian by the Persians, with the disturbances which followed, threatened the empire with utter destruction. Thirty tyrants seized the government at once, and the barbarians pouring in on all sides in prodigious numbers ravaged almost all the provinces of the empire. By the vigorous conduct of Claudius, Aurelian, Tacitus, Probus, and Carus, the empire was restored to its former lustre; but as the barbarians were only repulsed, and never thoroughly subdued, this proved only a temporary relief. What was worse, the Roman soldiers, growing impatient of restraint, commonly murdered those emperors who attempted to revive among them the ancient military discipline, which alone could ensure them victory over their enemies. Under Dioclesian, the disorders were so great, that though the government was held by two persons, they found themselves unable to bear the weight of it, and therefore took other two partners in the empire. Thus was the Roman empire divided into four parts; which by all historians is said to have been productive of the greatest mischiefs. As each of these four sovereigns would have as many officers both civil and military, and the same number of forces that had been maintained by the state when governed only by one emperor, the people were not able to pay the same necessary for supporting them. Hence the taxes and imposts were increased beyond measure, the inhabitants in several provinces reduced to beggary, the land left untilled for want of hands, &c. An end was put to these evils when the empire was again united under Constantine the Great; but in 330 a mortal blow was given it, by removing the imperial seat to Byzantium, now Constantinople, and making it equal to Rome. The introduction and establishment of Christianity, already corrupted with the grossest superstitions, proved also a most grievous detriment to the empire. Instead of that ferocious and obstinate valor in which the Romans had so long been accustomed to put their trust, they now imagined themselves secured by signs of the cross, and other external symbols of the Christian religion. These they used as a kind of magical incantations, which undoubtedly proved at all times inefficient; and hence also in some measure proceeded the great revolution which took place in the next period.

9. The ninth general period shows us the decline and fall of the western part of the Roman empire. De. We see that mighty empire, which formerly occupied half the surface of the almost the whole world, now weakened by division, pitted against the barbarous nations, surrounded and surrounded by enemies. On the north, the Scyths, Cimmerians, Goths, and a multitude of other barbarous nations, watched all occasions to break into it, and miscarried in their attempts, rather through their own barbarity, than the strength of their enemies. The devastations committed by those barbarians when they made their incursions are incredible, and the relation shocking to human nature. Some authors seem much inclined to favour them; and even inhuman, that barbarity and ignorant ferocity were their chief if not their only faults: but from their history it plainly appears, that not only barbarity and the most shocking cruelty, but the highest degree of avarice, perfidy, and disregard to the most solemn promises, were to be numbered among their vices. It was ever a sufficient reason for them to make an attack, that they thought their enemies could not resist them. Their only reason for making peace, or for keeping it, was because their enemies were too strong: and their only reason for committing the most horrid massacres, rapes, and all manner of crimes, was because they had gained a victory. The Romans, degenerate as they were, are yet to be esteemed much better than these savages; and therefore we find not a single province of the empire that would submit to the barbarians while the Romans could possibly defend them.

Some of the Roman emperors indeed withstood this inundation of savages; but as the latter grew daily more numerous, and the Romans continued to weaken themselves by their intestine divisions, they were at last obliged to take large bodies of barbarians into their pay, and teach them their military discipline, in order to drive away their countrymen, or others who invaded the empire. This at last proved its total destruction; for, in 476, the barbarians who served in the Roman armies, and were dignified with the title of allies, demanded the third part of the lands of Italy as a reward for their services: but meeting with a refusal, they revolted, and made themselves masters of the whole country, and of Rome itself, which from that time ceased to be the head of an empire of any consequence.

This period exhibits a most unfavourable view of General the western parts of the world: The Romans, from the height of grandeur, sunk to the lowest slavery, nay, in all-probability, almost exterminated; the provinces they formerly governed, inhabited by human beings scarce above the brutes, every art and science lost; and the savage conquerors even in danger of starving for want of a sufficient knowledge of agriculture, having now no means of supporting themselves by plunder and robbery as before. Britain had long been abandoned to the mercy of the Scots and Picts; and in 450 the inhabitants had called in the Saxons to their assistance, whom they soon found worse enemies than those against whom they had implored
In 487, Clovis, the founder of the French monarchy, possessed himself of all the countries lying between the Rhine and the Loire. By force or treachery, he conquered all the petty kingdoms which had been erected in that country. His dominions had been divided, reunited, and divided again; and were on the point of being united a second time, when the great impostor Mahomet began to make a figure in the world.

In Spain, the Visigoths erected a kingdom ten years before the conquest of Rome by the Heruli. This kingdom they had extended eastward, about the same time that Clovis was extending his conquests to the west; so that the two kingdoms met at the river Loire. The consequence of this approach of such barbarous conquerors towards each other was an immediate war. Clovis proved victorious, and subdued great part of the country of the Visigoths, which put a final stop to their conquests on that side.

Another kingdom had been founded in the western parts of Spain by the Suevi, a considerable time before the Romans were finally expelled from that country. In 409, this kingdom was entirely subverted by Theodoric king of the Goths; and the Suevi were so pent up in a small district of Lusitania and Galicia, that it seemed impossible for them to recover themselves. During the above-mentioned period, however, while the attention of the Goths was turned another way, they had found means again to erect themselves into an independent state, and to become masters of considerably extended territories. But this success proved of short duration. In 584, the Goths attacked them; totally destroyed their empire a second time; and thus became masters of all Spain, except some small part which still owned submission to the emperors of Constantinople. Of this part, however, the Goths became masters also in the year 622; which concludes the 4th general period.

Africa, properly so called, had changed its masters Of Africa three times during this period. The Vandals had expelled the Romans, and erected an independent kingdom, which was at last overturned by the emperors of Constantinople; and from them the greatest part of it was taken by the Goths in 620.

At the commencement of the tenth general period (which begins with the flight of Mahomet in the year 622, from whence his followers date their conquests of the Sarrasins for the great revolution which was now to take place: ceased the Roman empire in the west annihilated; the Persian empire and that of Constantinople weakened by mutual wars and intestine divisions; the Indians and other eastern nations unaccustomed to war, and ready to fall a prey to the first invader; the southern parts of Europe in a distracted and barbarous state; while the inhabitants of Arabia, from their earliest origin accustomed to war and plunder, and now united by the most violent superstition and enthusiastic desire of conquest, were like a flood pent up, and ready to overwhelm the rest of the world. The northern nations of Europe and Asia, however formidable in earlier times, were at present unknown, and peaceable, at least with respect to their southern neighbours; so that there was in no quarter of the globe any power capable of opposing the conquests of the Arabs. With amazing
amazing celerity, therefore, they overran all Syria, Palestine, Persia, Bukhara, and India, extending their conquests farther to the eastward than ever Alexander had done. On the west side, their empire extended over Egypt, Barbary, and Spain, together with the islands of Sicily, Sardinia, Majorca, Minorca, &c. and many of the Archipelago islands; nor were the coasts of Italy itself free from their incursions; nay, they are even said to have reached the distant and barren country of Iceland. At last this great empire, as well as others, began to decline. Its ruin was very sudden, and owing to its internal divisions. Mahomet had not taken care to establish the apostleship in his family, or to give any particular directions about a successor. The consequence of this was, that the caliphate, or succession to the apostleship, was seized by many usurpers in different parts of the empire; while the true caliphs, who resided at Bagdad, gradually lost all power, and were regarded only as a kind of highpriests. Of these divisions the Turks took advantage to establish their authority in many provinces of the Mohammedan empire; but as they embraced the same religion with the Arabs, and were filled with the same enthusiastic desire of conquest, it is of little consequence to distinguish between them; as indeed it signified little to the world in general whether the Turks or Saracens were the conquerors, since both were cruel, barbarous, ignorant, and superstitious.

While the barbarians of the east were thus grasping at the empire of the whole world, great disturbances happened among the less barbarous nations of the west. Superstition seems to have been the ruling motive in both cases. The Saracens and Turks conquered for the glory of God, or of his apostle Mahomet and his successors; the western nations professed an equal regard for the divine glory, but which was only to be perceived in the respect they paid to the pope and clergy. Ever since the establishment of Christianity by Constantine, the bishops of Rome had been gradually extending their power; and attempting not only to render themselves independent, but even to assume an authority over the emperors themselves. The destruction of the empire was so far from weakening their power, that it afforded them opportunities of greatly extending it, and becoming judges of the sovereigns of Italy themselves, whose barbarity and ignorance prompted them to submit to their decisions. All this time, however, they themselves had been in subjection to the emperors of Constantinople; but on the decline of that empire, they found means to get themselves exempted from this subjection. The principal authority in the city of Rome was then engrossed by the bishop; though of right it belonged to the duke appointed by the exarch of Ravenna. But though they had now little to fear from the eastern emperors, they were in great danger from the ambition of the Lombards, who aimed at the conquest of all Italy. This aspiring people the bishops of Rome determined to check; and therefore, in 726, when Liutprand, king of the Lombards, had taken Ravenna and expelled the exarch, the pope undertook to restore him. For this purpose he applied to the Venetians, who are now first mentioned in history as a state of any consequence; and by their means the exarch was restored. Some time before, a quarrel had happened between the pope (Gregory II.) and Leo emperor of the east, about the worship of images. Leo, who it seems, in the midst of so much barbarism, had still preserved some sense of common barbarism, had been reproached with the worship of images in the strongest terms, and commanded them to be destroyed throughout his dominions. The pope, whose cause was favoured by the most absurd superstitions, and by those only, refused to obey the emperor's commands. The exarch of Ravenna, as a subject of the emperor, was ordered to force the pope to a compliance, and even to seize or assassinate him in case of a refusal. This excited the pious zeal of Liutprand to assist the pope, whom he had formerly designed to subdue: the exarch was first excommunicated, and then torn in pieces by the enraged multitude: the duke of Naples shared the same fate; and a vast number of the Iconoclasts, or Imagebreakers, as they were called, were slaughtered without mercy: and to complete all, the subjects of the exarchate, at the instigation of the Pope, renounced their allegiance to the emperor.

Leo was no sooner informed of this revolt than he ordered a powerful army to be raised, in order to reduce the rebels, and take vengeance on the Pope. Alarmed at these warlike preparations, Gregory looked round for some power on which he might depend for protection. The Lombards were possessed of sufficient force, but they were too near and too dangerous neighbours to be trusted; the Venetians, though zealous Catholics, were as yet unable to withstand the force of the empire; Spain was overrun by the Saracens: the French seemed, therefore, the only people to whom it was advisable to apply for aid; as they were able to oppose the emperor, and were likewise enemies to his edict. Charles Martel, who at that time governed France as mayor of the palace, was therefore applied to; but before a treaty could be concluded, all the parties concerned were removed by death. Constantine Copronymus, who succeeded Leo at Constantinople, not only persisted in the opposition to image-worship begun by his predecessor, but prohibited also the invocation of saints. Zachary, who succeeded Gregory III. in the pontificate, proved as zealous an adversary as his predecessor. Pepin, who succeeded Charles Martel in the sovereignty of France, proved as powerful a friend to the pope as his father had been. The people of Rome had nothing to fear from Constantinople; and therefore drove out all the emperor's officers. The Lombards, saved by the power of France, for some time allowed the pope to govern in peace, the dominions of the exarchate; but in 754, Astolphus king of Lombardy not only reduced the greatest part of the pope's territories, but threatened the city of Rome itself. Upon this application was made to Pepin, who obliged Astolphus to restore the places he had taken, and gave them to the pope, or, as he said, to St Peter. The Greek emperor to whom they of right belonged, demurred to no purpose. The pope from that time became possessed of considerable territories in Italy; which, from the manner of their donation, go under the name of St Peter's Patrimony. It was not, however, before the year 774, that the pope was fully secured in these new dominions. This was accomplished when the kingdom of the Lombards was totally destroyed by
by Charlemagne, who was thereupon crowned king of Italy. Soon after this, the monarch made himself master of all the Low Countries, Germany, and part of Hungary; and in the year 800 was solemnly crowned by the pope emperor of the west.

Thus was the world once more divided into three great empires. The empire of the Arabs or Saracens extended from the river Ganges to Spain; comprehending almost all of Asia and Africa which has ever been known to Europeans, the kingdoms of China and Japan excepted. The eastern Roman empire was reduced to Greece, Asia Minor, and the provinces adjoining to Italy. The empire of the west, under Charlemagne, comprehended France, Germany, and the greatest part of Italy. The Saxons, however, as yet possessed Britain un molested by external enemies, though the seven kingdoms erected by them were engaged in perpetual contests. The Venetians also enjoyed a nominal liberty; though it is probable that their situation would render them very much dependent on the great powers which surrounded them. Of all nations on earth, the Scots and Picts, and the remote ones of China and Japan seem to have enjoyed, from their situation, the greatest share of liberty; unless, perhaps, we except the Scandinavians, who, under the names of Danes and Normans, were soon to infest their southern neighbours. But of all the European potentates, the popes certainly exercised the greatest authority; since even Charlemagne himself submitted to accept the crown from their hands, and his successors made them the arbiters of their differences.

Matters, however, did not long continue in this state. The empire of Charlemagne was on the death of his son Lewis divided among his three children. Endless disputes and wars ensued among them, till at last the sovereign power was seized by Hugh Capet in 987. The Saxon heptarchy was dissolved in 927, and the whole kingdom of England reduced under one head. The Dunes and Normans began to make depredations, and infest the neighbouring states. The former conquered the English Saxons, and seized the government, but were in their turn expelled by the Normans in 1066. In Germany and Italy, the greatest disturbances arose from the contests between the popes and the emperors. To all this we add the internal contests which happened through the ambition of the powerful barons of every kingdom, we can scarce form an idea of times more calamitous than those of which we now treat. All Europe, may, all the world, was one great field of battle; for the empire of the Mahometans was not in a more settled state than that of the Europeans. Caliphs, sultans, emirs, &c. waged continual war with each other in every quarter; new sovereignties every day sprang up, and were as quickly destroyed. In short, through the ignorance and barbarity with which the whole world was overspread, it seemed in a manner likely that the human race could long continue to exist; when happily the usual method by directing the attention of the Europeans to one particular object, made them in some measure suspend their slaughters of one another.

11. The crusades originated from the superstition of the two grand parties into which the world was at this time divided, namely, the Christians and Mahometans. Both looked upon the small territory of Palestine, which they called the Holy Land, to be an invaluable acquisition, for which no sum of money could be an equivalent; and both took the most unjustifiable methods to accomplish their desires. The superstition of Omar the second caliph had prompted him to invade this country, part of the territories of the Greek emperor, who was doing him no hurt; and now when it had been so long under the subjection of the Mahometans, a similar superstition prompted the pope to send an army for the recovery of it. The crusaders accordingly poured forth in multitudes, like those with which the kings of Persia formerly invaded Greece; and their fate was pretty similar. Their impetuous valor at first, indeed, carried everything before them; they recovered all Palestine, Phoenicia, and part of Syria, from the infidels; but their want of conduct soon lost what their valour had obtained, and very few of that vast multitude which had left Europe ever returned to their native countries. A second, a third, and several other crusades, were preached, and were attended with a like success in both respects: vast numbers took the cross, and repaired to the Holy Land; which they polluted with the most abominable massacres and treacheries, and from which very few of them returned. In the third crusade Richard I. of England was embarked, who seems to have been the best general that ever went into the east: but even his valor and skill were not sufficient to repair the faults of his companions; and he was obliged to return even after he had entirely defeated his antagonists, and was within sight of Jerusalem.

But while the Christians and Mahometans were thus Conquests surreptitiously contending for a small territory in the of Western parts of Asia, the nations in the more easterly parts were threatened with total extermination. Jenghiz Khan, the greatest as well as the most bloody conqueror that ever existed, now makes his appearance. The rapidity of his conquests exceeds that of Alexander the Great; and the cruelties he committed were altogether unparalleled. It is worth observing, that Jenghiz Khan and all his followers were neither Christians nor Mahometans, but strict deists. For a long time even the sovereign had not heard of a temple, or any particular place on earth appropriated by the deity to himself, and treated the notion with ridicule when it was first mentioned to him.

The Moguls, over whom Jenghiz Khan assumed the sovereignty, were a people of East Tartary, divided into a great number of petty governments as they are at this day, but who owned a subjection to one sovereign, whom they called Wang Khan, or the Great Khan. Temujin, afterwards Jenghiz Khan, was one of these petty princes; but unjustly deprived of the greatest part of his inheritance at the age of 13, which he could not recover till he arrived at that of 40. This corresponds with the year 1201, when he finally reduced the rebels; and as a specimen of his lenity caused to be thrown into as many calderons of boiling water. In 1202, he defeated and killed Wang Khan himself (known to the Europeans by the name of Prester John of Asia); and possessing himself of his vast dominions, became from thenceforward altogether irresistible. In 1206, having still continued to enlarge his dominions, he was declared khan of the Moguls and Tartars;
HISTORY.

Sect. I.

Tartars; and took upon him the title of Jenghiz Khan, or The most Great Khan of Khans. This was followed by the reduction of the kingdom of Hya in China, Tangut, Kitay, Turkestan, Karazam (the kingdom of Gacna founded by Maimud Gacni), Great Bukharis, Persia, and part of India; and all these vast regions were reduced in 26 years. The devastations and slaughters with which they were accomplished are unparalleled, no fewer than 14,470,000 persons being computed to have been massacred by Jenghiz Khan during the last 22 years of his reign. In the beginning of 1227 he died, thereby freeing the world from a most bloody tyrant. His successors completed the conquest of China and Korea; but were foiled in their attempts on Cochin-China, Tong-king, and Japan. On the western side the Tartar dominions were not much enlarged till the time of Holtrak, who conquered Medi, Babylonia, Mesopotamia, Armenia, Georgia, Persia, and almost all Asia Minor; putting an end to the empire of the Saracens by the taking of Bagdad in 1248.

The empire of Jenghiz Khan had the fate of all others. Being far too extensive to be governed by one head, it split into a multitude of small kingdoms, as it had been before his time. All these princes, however, owned allegiance to the family of Jenghiz Khan till the time of Timur Bek, or Tamerlane. The Turks, in the mean time, urged forward by the invasions of Tartars who poured in from the east, were forced upon the remains of the Greek empire; and at the time of Tamerlane above mentioned, they had almost confined this once mighty empire within the walls of Constantinople.

In the year 1335, the family of Jenghiz Khan becoming extinct in Persia, a long civil war ensued; during which Timur Bek, one of the petty princes among which the Tartar, who conquered Medi, divided, found means to aggrandize himself in a manner similar to what Jenghiz Khan had done about 250 years before. Jenghiz Khan, indeed, was the model whom he proposed to imitate; but it must be allowed that Timur was more merciful than Jenghiz Khan, if indeed the word can be applied to such inhuman tyrants. The plan on which Jenghiz Khan conducted his expeditions was that of total extermination. For some time he utterly extirpated the inhabitants of those places which he conquered, designing to people them anew with his Mogule; and in consequence of this resolution, he would employ his army in beheading 100,000 prisoners at once. Timur's cruelty, on the other hand, seldom went farther than the pounding of 3000 or 4000 people in large mortars, or building them among bricks and mortar into a wall. We must observe, however, that Timur was not a deist, but a Mahometan, and conquered expressly for the purpose of spreading the Mahometan religion; for the Mogule had been adopted by the conquered tribes of Mahomet. Thus was all the eastern quarter of the world threatened anew with the most dreadful devastations, while the western nations were exhausting themselves in fruitless attempts to regain the Holy Land. The Turks were the only people who seem at this period to have been gathering strength, and by their perpetual encroachments threatened to swallow up the western nations as the Tartar had done the eastern ones.

In 1362, Timur invaded Bukharis, which he reduced in five years. He proceeded in his conquests, though not with the same celerity as Jenghiz Khan, till the year 1387, when he had subdued all Persia, Armenia, Georgia, Karazam, and great part of Tartary. After this he proceeded westward, subduing all the countries to the Euphrates; made himself master of Bagdad; and even entered Russia, where he pillaged the city of Moscow. From thence he turned his arms to the east, and totally subdued India. In 1393, he invaded and reduced Syria; and having turned his arms against the Turks, forced their sultan Bajazet to raise the siege of Constantinople. This brought on an engagement, in which Bajazet was entirely defeated and taken prisoner; which broke the power of the Turks to such a degree, that they were not for some time able to recover themselves. At last this great conqueror died in the year 1405, while on his way to conquer China, as Jenghiz Khan had done before him.

The death of Timur was followed almost immediately by the dissolution of his empire. Most of the western nations he had conquered recovered their liberty at that time. The Turks had now no further obstacle to their conquest of Constantinople. The western nations having exhausted themselves in the holy wars, as they were called, had lost that insatiable thirst after conquest which for so long time possessed the minds of men. They had already made considerable advances in civilization, and began to study the arts of peace. Gunpowder was invented, and its application to the purposes of war already known; and, though no invention threatened to be more destructive, perhaps none was ever more beneficial to the human race. By the use of these arms, nations are put on an equal level with each other than formerly they were; war is reduced to a regular system, which may be studied with as much success as any other science. Conquests are not now to be made with the same ease as formerly; and hence the last ages of the world have been much more quiet and peaceful than the former ones. In 1453, the conquest of Constantinople by the Turks fixed that wandering people to one place; and though now they possess very large regions both in Europe, Asia, and Africa, an effectual stop hath long been put to their further progress.

About this time, also, learning began to revive in Europe, where it had been long lost; and the invention of printing, which happened about the same time, rendered it in a manner impossible for barbarism ever to take place in such a degree as formerly. All nations of the world, indeed, seem now at once to have laid aside much of their former ferocity; and, though wars have by no means been uncommon, they have not been waged with such circumstances of fury and rage as before. Instead of attempting to enrich themselves by plunder, and the spoils of their neighbours, mankind in general have applied themselves to commerce, the only true and durable source of riches. This soon produced improvements in navigation; and these improvements led to the discovery of many regions formerly unknown. At the same time, the European

European powers, being at last thoroughly sensible that extensive conquests could never be permanent, applied themselves more to provide for the security of those dominions which they already possessed, than to attempt the conquest of one another: and this produced the policy to which so much attention was lately paid, namely, the preserving of the balance of Europe; that is, preventing any one of the nations from acquiring sufficient strength to overpower another.

In the end of the 15th century, the vast continent of America was discovered; and, almost at the same time, the passage to the East Indies by the Cape of Good Hope. The discovery of these rich countries gave a new turn to the ambition of the Europeans. To enrich themselves either by the gold and silver produced in these countries, or by traffic with the natives, now became the object. The Portuguese had the advantage of being the first discoverers of the eastern, and the Spaniards of the western countries. The former did not neglect so favourable an opportunity of enriching themselves by commerce. Many settlements were formed by them in the East India islands, and on the continent; but their avarice and perfidious behaviour towards the natives proved at last the cause of their total expulsion. The Spaniards enriched themselves by the vast quantities of the precious metals imported from America, which were not obtained but by the most horrid massacres committed on the natives, and of which an account is given under the different names of the American countries. These possessions of the Spaniards and Portuguese soon excited other European nations to make attempts to share with them in their treasures, by planting colonies in different parts of America, and making settlements in the East Indies: and thus has the rage of war in some measure been transferred from Europe to these distant regions; and, after various contests, the British at last obtained a great superiority both in America and the East Indies.

In Europe the only considerable revolutions which happened during this period, were, the total expulsion of the Moors and Saracens from Spain, by the taking of Granada in 1491; the union of the kingdoms of Aragon and Castile, by the marriage of Ferdinand and Isabella; and the revolt of the states of Holland from the Spaniards. After much contention and bloodshed, these last obtained their liberty, and were declared a free people in 1609; since which time they have continued an independent and very considerable nation of Europe.

In Asia nothing of importance hath happened since the taking of Constantinople by the Turks. That continent is now divided among the following nations. The most northerly part, called Siberia, extending to the very extremity of the continent, is under the power of Russia. To the southward, from Asia Minor to China, and Korea, are the Tartars, formidable indeed from their numbers, but, by reason of their barbarity and want of union, incapable of attempting any thing. The Turks possess the western part of the continent, called Asia Minor, to the river Euphrates. The Arabs are again confined within their own peninsula; which they possess, as they have ever done, without owning subjection to any foreign power. To the east of Turkey in Asia lies Persia, now more confined in its limits than before; and to the eastward of Persia lies India, or the kingdom late of the Mogul, comprehending all the country from the Indus to the Ganges, and beyond that river. Still farther to the east lie the kingdoms of Siam, Pegu, Thibet, and Cochchin-China, little known to the Europeans. The vast empire of China occupies the most easterly part of the continent; while that of Japan comprehends the islands which go by that name, and which are supposed to lie at no great distance from the western coasts of America.

In Africa the Turks possess Egypt, which they conquered in 1517, and have a nominal jurisdiction over the states of Barbary. The interior parts are filled with barbarous and unknown nations, as they have always been. On the western coasts are many settlements of the European nations, particularly the British and Portuguese; and the southern extremity is possessed by the Dutch. The eastern coasts are almost totally unknown. The Asiatic and African islands are either possessed by the Europeans, or inhabited by savage nations.

The European nations at the beginning of the 17th century were Sweden, Muscovy, Denmark, Poland, Britain, Germany, Holland, France, Spain, Portugal, Italy, and Turkey in Europe. Of these the Russians, though the most barbarous, were far the most considerable, both in regard to numbers and the extent of their empire; but their situation made them little feared by the others, who lay at a distance from them. The kingdom of Poland, which was first set up in the year 1000, proved a barrier between Russia and Germany; and at the same time the policy above mentioned, of keeping up the balance of power in Europe, rendered it probable that no one European nation, whatever wars it might be engaged in, would have been totally destroyed, or ceased to exist as a distinct kingdom. The late dismemberment of Poland, however, or its partition between the three powers Russia, Hungary, and Prussia, was a step very inconsistent with the above political system; and it is surprising with what tameness it was acquiesced in by the other powers. Subsequent circumstances, particularly the passiveness with which the ambitious designs of Russia against the Porte have been so long beheld, seem to indicate a total dereliction of that scheme of equilibrium, formerly so wisely, though perhaps sometimes too anxiously, attended to.

The revolt of the British colonies in America, it was hoped by the enemies of Britain, would have given a fatal shock to her strength and wanted superiority. The consequences, however, have been very different. These colonies, it is true, have been disjoined from the mother-country, and have attained an independent rank among the nations. But Britain has had no cause to repent at the separation. Divested only of a splendid encumbrance, an expensive and invasions apogee, she has been left to enjoy the undivided benefits of her native vigour, and to display new energies, which promise her mild empire a long and prosperous duration. On the other hand, it has been said, the flame which was to have blazed only to her prejudice, has brought confusion on her chief foe; and the ambition and tyranny of that branch of the house of Bourbon which has been long the pest of Europe, now lie humbled in the dust. The French, indeed, have thus become a nation
of freemen as well as ourselves, and as well as the Americans; who, by the way, were never otherwise, nor ever knew what oppression was except in inflicting it upon their African brethren. But neither is the French revolution an event which Britons, as lovers of liberty and friends to the rights of mankind, should regret; or which, even in a political view, if duly considered, ought to excite either their jealousy or apprehension. The papal power, too, is declining; and the period seems to be approaching when the Roman pontiff will be reduced to his original title of bishop of Rome. Such was the language held for some years during the progress of the French revolution. But the extraordinary events which have since occurred, have totally changed the views and sentiments of mankind. The fair prospect of liberty which the friends of humanity hoped had begun to dawn on France, has quite vanished; and unfortunately the most powerful despot, as well as the most capricious tyrant, has seated himself on the throne of his ancient kings. The prediction with regard to the pope was more than verified by this usurper, at whose nod the head of the catholic church holds his authority; and at this moment (December 1806) the continent of Europe seems to be threatened with universal subjugation to the same restless and ambitious power.

Sect. II. Ecclesiastical History.

The history of religion, among all the different nations that have existed in the world, is a subject no less important and interesting than that of civil history. It is, however, less fertile of great events, affords an account of fewer revolutions, and is much more uniform than civil history. The reason of this is plain. Religion is conversant about things which cannot be seen, and which of consequence cannot suddenly and strongly affect the senses of mankind, as natural things are apt to do. The expectation of worldly riches can easily induce one nation to attack another; but it is not easy to find any thing which will induce a nation to change its religion. The invisible nature of spiritual things, the prejudice of habit and of early education, all stand in the way of changes of this kind. Hence the revolutions in religion have been but few, and the duration of almost any religion of longer standing than the most celebrated empires; the changes which have happened, in general, have required a long time to bring them about, and history scarce affords an instance of the religion of any nation being essentially and suddenly changed for another.

With regard to the origin of religion, we must have recourse to the Scriptures; and are as necessarily constrained to adopt the account there given, as we are to adopt that of the creation given in the same book; namely, because no other hath made its appearance which seems in any degree rational, or consistent with itself. In what manner the true religion given to Adam was falsified or corrupted by his descendants before the flood, doth not clearly appear from Scripture. Idolatry is not mentioned; nevertheless we are assured that the inhabitants of the world were then exceedingly wicked; and as their wickedness did not consist in worshipping false gods, it may be concluded that they worshipped none at all; i.e. that the crime of the antediluvians was deism or atheism.

After the flood, idolatry quickly made its appearance; but what gave rise to it is not certainly known. This superstition indeed seems to be natural to man, especially when placed in such a situation that he hath little opportunity of instruction, or of improving his rational faculties. This seems also probable from the caution given to the Jews, lest, when they looked up to the sun, moon, and stars, and the rest of the host of heaven, they should be driven to worship them. The origin of idolatry among the Syrians and Arabians, and also in Greece, is therefore accounted for with great probability in the following manner by the author of the Ruins of Balbec. "In those uncomfortable deserts, where the day presents nothing to the view but the uniform, tedious, and melancholy prospect of barren sands, the night discloses a most delightful and magnificent spectacle, and appears arrayed with charms of the most attractive kind. For the most part unclouded and serene, it exhibits to the wondering eye the host of heaven in all their variety and glory. In the view of this stupendous scene, the transition from admiration to idolatry was too easy to uninstructed minds; and a people whose climate offered no beauties to contemplate but those of the firmament, would naturally look thither for the objects of their worship. The form of idolatry in Greece was different from that of the Syrians; which perhaps may be attributed to that smiling and variegated scene of mountains, valleys, rivers, woods, groves, and fountains, which the transported imagination, in the midst of its pleasing astonishment, supposed to be the seats of invisible deities."

A difficulty, however, arises on this supposition; for if idolatry is naturally produced in the mind of uninstructed and savage man from a view of the creation, why hath not idolatry of some kind or other taken place among all the different nations of the world? This certainly hath not been the case; of which the most striking examples are the Persians of old, and the Mogule in more modern times. Both these nations were strict deists; so that we must allow some other causes to concur in producing idolatry besides these already mentioned; and of these causes an imperfect and obscure notion of the true religion seems to be the most probable.

Though idolatry, therefore, was formerly very prevalent, it neither extended over the whole earth, nor account of were the superstitions of the idolaters all of one kind. Every nation had its respective gods, over which one then super-marcate excelled than the rest was said to preside; yet in such a manner, that this supreme deity himself was controlled by the rigid empire of the fates, or by what philosophers called eternal necessity. The gods of the east were different from those of the Gauls, the Germans, and the other northern nations. The Grecian divinities differed widely from those of the Egyptians, who deified plants, animals, and a great variety of the productions both of nature and art. Each people also had their own particular manner of worshipping and appealing their respective deities, entirely different from the sacred rites of other countries. All this variety of religions, however, produced neither wars nor disensions among the different nations; each nation suffered its neighbours to follow their own method of worship, without discovering any displeasure on that account.

There
There is nothing surprising in this mutual toleration, when we consider, that they all looked upon the world as one great empire, divided into various provinces, over each of which a certain order of divinities presided; for which reason they imagined that none could behold with contempt the gods of other nations, or force strangers to pay homage to theirs. —The Romans exercised this toleration in the most ample manner; for though they would not allow any change to be made in the religions that were publicly professed in the empire, nor any new form of worship to be openly introduced, yet they granted to their citizens a full liberty of observing in private the sacred rites of other nations, and of honouring foreign deities as they thought proper. The heathen deities were honoured with rites and sacrifices of various kinds, according to their respective natures and offices. Their rites were absurd and ridiculous; while the priests, appointed to preside over this strange worship, abused their authority, by deceiving and imposing upon the people in the grossest manner.

From the time of the flood to the coming of Christ, idolatry prevailed among almost all the nations of the world, the Jews alone excepted; and even they were on all occasions ready to run into it, as is evident from their history in the Old Testament. At the time of Christ’s appearance, the religion of the Romans, as well as their empire, extended over a great part of the world. Some people there were among the heathens who perceived the absurdities of that system; but being destitute of means, as well as of abilities, to effect a reformation, matters went on in their old way. Though there were at that time various sects of philosophers, yet all of them proceeded upon false principles, and consequently could be of no service to the advancement or reformation of religion. Nay, some, among whom were the Epicureans and Academics, declared openly against every kind of religion whatever.

Two religions at this time flourished in Palestine, viz. the Jewish and Samaritan; between whose respective followers reigned the most violent hatred or contempt. The difference between them seems to have been chiefly about the place of worship; which the Jews would have to be in Jerusalem, and the Samaritans on Mount Gerizim. But though the Jews were certainly right as to this point, they had greatly corrupted their religion in other respects. They expected a Saviour indeed, but they mistook his character; imagining that he was to be a powerful and warlike prince, who should set them free from the Roman yoke, which they bore with the utmost impatience. They also imagined that the whole of religion consisted in observing the rites of Moses, and some others which they had added to them, without the least regard to what is commonly called morality or virtue; as is evident from the many charges our Saviour brings against the Pharisees, who had the greatest reputation for sanctity among the whole nation. To these corrupt and vicious principles, they added several absurd and superstitious notions concerning the divine nature, invisible powers, magic, &c. which they had partly imbibed during the Babylonian captivity, and partly derived from their neighbours in Arabia, Syria, and Egypt. The principal sects among them were the Essenes or Essenians, Pharisees, and Sadducees. The Samaritans, according to the most general opinion, had corrupted their religion still more than the Jews.

When the true religion was preached by the Saviour of mankind, it is not to be wondered at if he became on that account obnoxious to a people so deeply sunk in corruption and ignorance as the Jews then were. It is not here requisite to enter into the particulars of the doctrine advanced by the Christians; but the position he met with from the Jews, as a full account of these things, and likewise of the preaching of the gospel by the apostles, may be found in the New Testament. —The rapid progress of the Christian religion, under these faithful and inspired ministers, soon alarmed the Jews, and raised various persecutions against its followers. The Jews, indeed, seem at first to have been everywhere the chief promoters of persecution; for we find that they officiously went from place to place, wherever they heard of the increase of the gospel, and by their calumnies and false suggestions endeavoured to excite the people against the apostles. The Heathens, however, though at first they showed no very violent spirit of persecution against the Christians, soon came to hate them as much as the Jews themselves. Tacitus acquaints us with the causes of this hatred, when speaking of the first general persecution under Nero. That inhuman emperor having, as was supposed, set fire to the city of Rome, to avoid the imputation of this wickedness, transferred it on the Christians. Our author informs us that they were at "Tacitus's" account the first ready abhorred on account of their many and enormous crimes. "The author of this name (Christians)," says he, "was Christ, who, in the reign of Tiberius, was executed under Pontius Pilate, procurator of Judaea. The pestilent superstition was for a while suppressed: but it revived again, and spread, not only over Judea, where this evil was first broached, but reached Rome, whither from every quarter of the earth is constantly flowing whatever is hideous and abominable amongst men, and is there readily embraced and practised. First, therefore, were apprehended such as openly avowed themselves to be of that sect; then by them were discovered an immense multitude; and all were convicted, not of the crime of burning Rome, but of hatred and enmity to mankind. Their death and tortures were aggravated by cruel derision and sport; for they were either covered with the skins of wild beasts and torn in pieces by devouring dogs, or fastened to crosses, or wrapped up in combustible garments, that, when the day-light failed, they might, like torches, serve to dispel the darkness of the night. Hence, towards the miserable sufferers, however guilty and deserving the most exemplary punishment, compassion arose; seeing they were doomed to perish not with a view to the public good, but to gratify the cruelty of one man."

That this account of Tacitus is downright misrepresentation and calumny, must be evident to every one who reads it. It is impossible that any person can be convicted of hatred and enmity to mankind, without specifying a number of facts by which this hatred showed itself. The burning of Rome would indeed have been a very plain indication of enmity to mankind; but of this Tacitus himself clears them, and...
HISTORY.

The second century commences with the third year of the emperor Trajan. The Christians were still persecuted; but as the Roman emperors were for the most part of this century princes of a mild and moderate character, they persecuted less violently than formerly. Marcus Aurelius, notwithstanding the clemency and philosophy for which he is so much celebrated, treated the Christians worse than Trajan, Adrian, or even Severus himself did, who was noted for his cruelty. This respite from vigorous persecution proved a very favourable circumstance for the spreading of the Christian religion; yet it is by no means easy to point out the particular countries through which it was diffused. We are, however, assured, that in the second century, Christ was worshipped as God almost through the whole east; as also among the Germans, Spaniards, Celts, and many other nations: but which of them received the gospel in the first century, and which in the second, is a question unanswerable at this distance of time. The writers of this century attribute the rapid progress of Christianity chiefly to the extraordinary gifts that were imparted to the first Christians, and the miracles which were wrought at their command; without supposing that any part of the success ought to be ascribed to the intervention of human means, or secondary causes. Many of the moderns, however, are so far from being of this opinion, that they are willing either to deny the authenticity of all miracles said to have been wrought since the days of the apostles, or to ascribe them to the power of the devil. To enter into the particulars of this controversy is foreign to our present purpose; for which reason we must refer the writers of polemic divinity, who have largely treated of this and other points of a similar nature.

The corruptions which had been introduced in the first century, and which were almost coeval with Christianity itself, continued to gain ground in the second. Ceremonies, in themselves futile and useless, but which must be considered as highly pernicious when joined to a religion incapable of any other ornament than the upright and virtuous conduct of its professors, were multiplied for no other purpose than to please the ignorant multitude. The immediate consequence of this was, that the attention of Christians was drawn aside from the important duties of morality; and they were led to imagine, that a careful observance of the ceremonies might make amends for the neglect of moral duties. This was the most pernicious opinion that could possibly be entertained; and was indeed the very foundation of that enormous system of ecclesiastical power which afterwards took place, and held the whole world in slavery and barbarism for many ages.

Another mischief was the introduction of mysteries. Mysteries, as they were called, into the Christian religion; that is, insinuating that some parts of the worship in common use had a hidden efficacy and power far superior to the plain and obvious meaning assigned to them by the vulgar: and by paying peculiar respect to these mysteries, the pretended teachers of the religion of Jesus accommodated their doctrines to the taste of their heathen neighbours, whose religion consisted in a heap of mysteries, of which nobody knew the meaning.
HISTORY.

By these, and other means of a similar kind, the Christian pastors greatly abridged the liberty of their flocks. Being masters of the ceremonies and mysteries of the Christian religion, they had it in their power to make their followers worship and believe whatever they thought proper; and this they did not fail to make use of for their own advantage. They were not content with the people, that the ministers of the Christian church succeeded to the character, rights, and privileges, of the Jewish priesthood; and accordingly the bishops considered themselves as invested with a rank and character similar to those of the high-priest among the Jews, while the presbyters represented the priests, and the deacons the Levites. This notion, which was first introduced in the reign of Adrian, proved a source of very considerable honour and profit to the clergy.

The form of ecclesiastical government was in this century rendered permanent and uniform. One inspector or bishop presided over each Christian assembly, to which office he was elected by the voices of the whole people. To assist him in his office, he formed a council of presbyters, which was not confined to any stated number. To the bishops and presbyters the ministers or deacons were subject; and the latter were divided into a variety of classes, as the different exigencies of the church required. During a great part of this century, the churches were independent of each other; nor were they joined together by association, confederacy, or any other bonds but those of charity. Each assembly was a little state governed by its own laws, which were either enacted, or at least approved of, by the society. But in process of time all the Christian churches of a province were formed into one large ecclesiastical body, which, like confederate states, assembled at certain times, in order to deliberate about the common interests of the whole. This institution had its origin among the Greeks; but in a short time it became universal, and similar assemblies were formed in all places where the gospel had been planted. These assemblies, which consisted of the deputies or commissioners from several churches, were called synods by the Greeks, and councils by the Latins; and the laws enacted in these general meetings were called canons, i.e. rules.

Changes produced by the institution of councils.

During the second century, all the sects continued an account of which had sprung up in the first, with the addition of the Ascetics; several others; the most remarkable of which were the Ascetics. These owed their rise to an error propagated by some doctors of the church, who asserted that Christ had established a double rule of sanctity and virtue for two different orders of Christians. Of these rules, one was ordinary, the other extraordinary; the one of a lower dignity, the other more sublime: the first for persons in the active scene of life; the other for those who, in a sacred retreat, aspired after the glory of a celestial state. In consequence of this system, they divided into two parts all those moral doc-

trines and instructions which they had received either by writing or tradition. One of these divisions they called precepts, and the other counsels. They gave the name of precepts to those laws that were universally obligatory upon all orders of men; and that of counsels to those which related to Christians of a more sublime rank, who proposed to themselves great and glorious ends, and breathed after an intimate communion with the Supreme Being. Thus were produced all at once a new set of men, who made pretensions to uncommon sanctity and virtue, and declared their resolution of obeying all the precepts and counsels of Christ, in order to their enjoyment and communion with God himself, and also that, after the dissolution of their mortal bodies, they might ascend to him with the greater facility, and find nothing to retard their approach to the centre of happiness and perfection. They looked upon themselves as prohibited from the use of things which it was lawful for other Christians to enjoy; such as wine, flesh, marriage, and commerce. They thought it their indispensable duty to extenuate their body by watchings, abstinence, labour, and hunger. They looked for felicity in solitary retreats, and desert places; where, by severe and arduous efforts of sublime meditation, they raised the soul above all external objects, and all sensual pleasures. They were distinguished from other Christians, not only by the titles of Ascetics, Eremites, Philosopher, and philosophers, but also by their garb. In this century, indeed, those who embraced such an austere kind of life, submitted themselves to all these mortifications in private, without breaking awnder their social bands, or withdrawing themselves.
HISTORY

This they absolutely refused to comply with: upon which Victor cut them off from communion with the church of Rome; though, by means of the intercession of some prudent people, the difference was made up for the present.

During most of the third century, the Christians were allowed to enjoy their religion, such as it was, without molestation. The emperors Maximinus and Decius, indeed, made them feel all the rigours of a severe persecution; but their reigns were short, and from the death of Decius to the time of Dioclesian the church enjoyed tranquillity. Thus vast multitudes were converted; but, at the same time, the doctrine grew daily more corrupt, and the lives of professured Christians more wicked and scandalous. New ceremonies were invented in great numbers, and an unaccountable passion now prevailed for the oriental superstitions concerning demons, whence proceeded the whole train of exorcisms, spells, and fears for the apparition of evil spirits, which to this day are nowhere eradicated. Hence also the custom of avoiding all connections with those who were not baptized, or who lay under the penalty of excommunication, as persons supposed to be under the dominion of some evil spirit. And hence the rigour and severity of that discipline and penance imposed upon those who had incurred, by their immorality, the censure of the church. Several alterations were now made in the manner of celebrating the Lord’s supper. The prayers used on this occasion were lengthened, and the solemnity and pomp with which it was attended were considerably increased. Gold and silver vessels were used in the celebration; it was thought essential to salvation, and for that reason administered even to infants. Baptism was celebrated twice a year, such as, after a long course of trial and preparations, offered themselves candidates. The remission of sins was thought to be its immediate consequence; while the bishop, by prayer and imposition of hands, was supposed to confer those sanctifying gifts of the Holy Ghost that were necessary to a life of righteousness and virtue. An evil demon was supposed naturally to reside in every person, who was the author and source of all the corrupt dispositions and unrighteous actions of that person. The driving out of this demon was therefore an essential requisite for baptism; and in consequence of this opinion, the baptized persons returned home clothed in white garments, and adorned with crowns, as sacred emblems, the former of their inward purity and innocence, and the latter of their victory over sin and the world. Fasting began now to be held in more esteem than formerly. A high degree of sanctity was attributed to this practice; it was even looked upon as indispensably necessary, from a notion that the demons directed their force chiefly against those who pampered themselves with delicious fare, and were less troublesome to the lean and hungry who lived under the severities of a rigorous abstinance. The sign of the cross also was supposed to administer a victorious power over all sorts of trials and calamities; and was more especially considered as the surest defence against the snares and stratagems of malignant spirits; for which reason, no Christian undertook any thing of moment, without arming himself as he imagined, with the power of this triumphant sign. The heresies which troubled

themselves from mankind; but in process of time they retired into deserts, and, after the example of the Essenes and Therapeutae, they formed themselves into certain companies.

This austere sect arose from an opinion which has been more or less prevalent in all ages and in all countries, namely, that religion consists more in prayers, meditations, and a kind of secret intercourse with God, than in fulfilling the social duties of life in acts of benevolence and humanity to mankind. Nothing can be more evident than that the Scripture reckons the fulfilling of these infinitely superior to the observance of all the ceremonies that can be imagined: yet it somehow or other happens, that almost every body is more inclined to observe the ceremonial part of devotion than the moral; and hence, according to the different humours or constitutions of different persons, there have been numberless forms of Christianity, and the most virulent contentions among those who profess themselves followers of the Prince of Peace. It is obvious, that if the moral conduct of Christians was to be made the standard of faith, instead of speculative opinions, all these divisions must cease in a moment; but when Christianity, or any part of it, is made to consist in speculation, or the observance of ceremonies, it is impossible there can be any end of sects or heresies.

No opinion whatever is so absurd, but some people have pretended to argue in its defence; and no ceremony so insignificant, but it hath been explained and sanctified by hot-headed enthusiasts; and hence ceremonies, sects, and absurdities, have been multiplied without number, to the prejudice of society and of the Christian religion. This short relation of the rise of the Ascetic sect will also serve to account for the rise of any other; so that we apprehend it is needless to enter into particulars concerning the rest, as they all took their origin from the same general principle variously modified, according to the different dispositions of mankind.

The Ascetic sect began first in Egypt, from whence it passed into Syria and the neighbouring countries. At length it reached the European nations; and hence that train of austere and superstitious vows and rites which is obscured, or rather annihilated, Christianity; the celibacy of the clergy, and many other absurdities of the like kind. The errors of the Ascetics, however, did not stop here: In compliance with the doctrines of some Pagan philosophers, they affirmed, that it was not only lawful, but even praiseworthy, to deceive, and to use the expedient of a lie, in order to advance the cause of piety and truth; and hence the pious frauds for which the church of Rome hath been so notorious, and with which she hath been so often and justly reproached.

As Christians thus deviated more and more from the true practice of their religion, they became more zealous in the external profession of it. Anniversary festivals were celebrated in commemoration of the death and resurrection of Christ, and of the effusion of the Holy Ghost on the apostles. Concerning the days on which these festivals were to be kept, there arose violent contentions. The Asiatic churches in general differed in this point from those of Europe; and towards the conclusion of the second century, Victor bishop of Rome took it in his head to force the eastern churches to follow the rules laid down by the western ones.
the church during this century, were the Gnostics, (whose doctrines were new-modelled and improved by Manes, from whom they were afterwards chiefly called Monichaeus), the Hieracites, Noetians, Sabellians, and Novatians) for a particular account of which, see those articles.

The fourth century is remarkable for the establishment of Christianity by law in the Roman empire; which, however, did not take place till the year 324. In the beginning of the century, the empire was governed by four chiefs, viz. Dioclesian, Maximian, Constantius Chlorus, and Galerius, under whom the church enjoyed a perfect toleration. Dioclesian, though much addicted to superstition, had no ill-will against the Christians; and Constantius Chlorus, having abandoned polytheism, treated them with condescension and benevolence. This alarmed the Pagan priests, whose interests were so closely connected with the continuance of the ancient superstitions; and who apprehended, not without reason, that the Christian religion would at length prevail throughout the empire. To prevent the downfall of the Pagan superstition, therefore, they applied to Dioclesian and Galerius Caesar, by whom a most bloody persecution was commenced in the year 303, and continued till 311. An asylum, however, was opened for the Christians in the year 304. Galerius having dethroned Dioclesian and Maximian, declared himself emperor in the east; leaving all the western provinces, to which great numbers of Christians resorted to avoid the cruelty of the former, to Constantius Chlorus. At length Galerius being overtaken with an incurable and dreadful disease, published an edict ordering the persecution to cease, and restoring freedom to the Christians, whom he had most inhumanly oppressed for eight years. Galerius died the same year; and in a short time after, when Constantine the Great ascended the throne, the Christians were freed from any farther unassimilability, by his abrogating all the penal laws against them; and afterwards issuing edicts, by which no other religion than the Christian was tolerated throughout the empire.

This event, however, so favourable to the outward peace of the church, was far from promoting its internal harmony, or the reformation of its leaders. The clergy, who had all this time been augmenting their power at the expense of the liberty of the people, now set no bounds to their ambition. The bishop of Rome, was the first in rank, and distinguished by a sort of pre-eminency above the rest of the prelates. He surpassed all his brethren in the magnificence and splendour of the church over which he presided, in the riches of his revenues and possessions, in the number and variety of his ministers, in his credit with the people, and in his sumptuous and splendid manner of living. Hence it happened, that when a new pontiff was to be chosen by the presbyters and people, the city of Rome was generally agitated with dissensions, tumults, and cabals, which often produced fatal consequences. The intrigues and disturbances which prevailed in that city in the year 366, when, upon the death of Liberius, another pontiff was to be chosen in his place, are a sufficient proof of what we have advanced. Upon that occasion, one faction elected Damascus to that high dignity; while the opposite party chose Ursicinus, a deacon of the vacant church, to succeed Liberius. This double election gave rise to a dangerous schism, and to a sort of civil war within the city of Rome; which was carried on with the utmost barbarity and fury, and produced the most cruel massacres and desolations. The inhuman contest ended in the victory of Damasus; but whether his cause was more just than that of Ursicinus, is not so easily determined.

Notwithstanding the pomp and splendour which surrounded the Roman see, it is certain that the bishops of Rome had not yet acquired that pre-eminence of power and jurisdiction which they afterwards enjoyed. In the ecclesiastical commonwealth, indeed, they were the most eminent order of citizens; but still they were citizens as well as their brethren, and subject, like them, to the laws and edicts of the emperors. All religious causes of extraordinary importance were examined and determined either by judges appointed by the emperors, or in councils assembled for that purpose; while those of inferior moment were decided in each district by its respective bishop. The ecclesiastical laws were enacted either by the emperor or councils. None of the bishops acknowledged that they derived their authority from the permission and appointment of the bishop of Rome, or that they were created bishops by the favour of the apostolic see. On the contrary, they all maintained that they were the ambassadors and ministers of Jesus Christ, and that their authority was derived from above. At most, however, be observed, that even in this century several of those steps were laid by which the bishops of Rome mounted afterwards to the summit of ecclesiastical power and despotism. This happened partly by the imprudence of the emperors, partly by the dexterity of the Roman prelates themselves, and partly by the inconsiderate zeal and precipitate judgment of certain bishops. The imprudence of the emperor, and precipitation of the bishops, were remarkably discovered in the following event, which favoured extremely the ambition of the Roman pontiff. About the year 352, Valentinian enacted a law, empowering the bishop of Rome to examine and judge other bishops, that religious disputes might not be decided by any profane or secular judges. The bishops assembled in council at Rome in 358, not considering the fatal consequences that must arise from this imprudent law both to themselves and to the church, declared their approbation in the strongest terms, and recommended the execution of it in their address to the emperor Gratian. Some think, indeed, that this law empowered the Roman bishop to judge only the bishops within the limits of his jurisdiction; others, that his power was given only for a certain time, and for a particular purpose. This last notion seems the most probable; but still this privilege must have been an excellent instrument in the hands of ascendant ambition.

By the removal of the seat of empire to Constantinople, the emperor raised up, in the bishop of this new metropolis, a formidable opponent to the bishop of Rome, and a bulwark which threatened a vigorous opposition to his growing authority. For as the emperor, in order to render Constantinople a second Rome, enriched it with all the rights and privileges, honours and ornaments, of the ancient capital of the world;

HISTORY.

forms of divine worship, the offices of priests, the vice of the ecclesiastical orders, &c. The external administration of the church the emperor assumed to himself. This comprehended all those things which related to the outward state and discipline of the church; it likewise extended to all contests that should arise between the ministers of the church, superior as well as inferior, concerning their possessions, their reputation, their rights and privileges, their offenses against the laws, &c. but no controversies that related to matters purely spiritual were cognizable by this external inspection. In consequence of this artful division of the ecclesiastical government, Constantine and his successors called councils, presided in them, appointed the judges of religious controversies, terminated the differences which arose between the bishops and the people, fixed the limits of the ecclesiastical provinces, took cognizance of the civil causes that subsisted between the ministers of the church, and punished the crimes committed against the laws by the ordinary judges appointed for that purpose; giving over all causes purely ecclesiastical to the bishops and councils. But this famous division of the administration of the church was not explained with sufficient accuracy; so that both in the fourth and fifth centuries, there are frequent instances of the emperors determining matters purely ecclesiastical, and likewise of bishops and councils determining matters which related merely to the external form and government of the church.

After the time of Constantine many additions were made by the emperors and others to the wealth and lives of the honors of the clergy; and these additions were followed by a proportional increase of their vices and luxury, particularly among those who lived in great and opulent cities. The bishops, on the one hand, contended with each other in the most scandalous manner concerning the extent of their respective jurisdictions; while, on the other, they trampled on the rights of the people, violated the privileges of the inferior ministers, and imitated in their conduct and in their manner of living the arrogance, voluptuousness, and luxury of magistrates and princes. This pernicious example was soon followed by the several ecclesiastical orders. The presbyters, in many places, assumed an equality with the bishops in point of rank and authority. Many complaints are also made by the authors of this century about the vanity and effeminacy of the deacons. Those more particularly of the presbyters and deacons who filled the first stations of these orders, carried their pretensions to an extravagant length, and were offended at the notion of being placed on an equality with their colleagues. For this reason they not only assumed the titles of arch-presbyters, and arch-deacons, but also claimed a degree of authority and power much superior to that which was vested in the other members of their respective orders.

In the fifth century, the bishops of Constantinople having already reduced under their jurisdiction all the Asiatic provinces, began to grasp at still further acquisitions of power. By the 28th canon of the council held at Chalcedon in 451, it was resolved, that the same ecclesiastical rights and honors which had been conferred on the bishop of Rome were due to the bishop of Constantinople, on account of the equal dignity and luster of the two cities in which these prelates exercised their authority.

forms of divine worship, the offices of priests, the vice of the ecclesiastical orders, &c. The external administration of the church the emperor assumed to himself. This comprehended all those things which related to the outward state and discipline of the church; it likewise extended to all contests that should arise between the ministers of the church, superior as well as inferior, concerning their possessions, their reputation, their rights and privileges, their offenses against the laws, &c. but no controversies that related to matters purely spiritual were cognizable by this external inspection. In consequence of this artful division of the ecclesiastical government, Constantine and his successors called councils, presided in them, appointed the judges of religious controversies, terminated the differences which arose between the bishops and the people, fixed the limits of the ecclesiastical provinces, took cognizance of the civil causes that subsisted between the ministers of the church, and punished the crimes committed against the laws by the ordinary judges appointed for that purpose; giving over all causes purely ecclesiastical to the bishops and councils. But this famous division of the administration of the church was not explained with sufficient accuracy; so that both in the fourth and fifth centuries, there are frequent instances of the emperors determining matters purely ecclesiastical, and likewise of bishops and councils determining matters which related merely to the external form and government of the church.

After the time of Constantine many additions were made by the emperors and others to the wealth and lives of the honors of the clergy; and these additions were followed by a proportional increase of their vices and luxury, particularly among those who lived in great and opulent cities. The bishops, on the one hand, contended with each other in the most scandalous manner concerning the extent of their respective jurisdictions; while, on the other, they trampled on the rights of the people, violated the privileges of the inferior ministers, and imitated in their conduct and in their manner of living the arrogance, voluptuousness, and luxury of magistrates and princes. This pernicious example was soon followed by the several ecclesiastical orders. The presbyters, in many places, assumed an equality with the bishops in point of rank and authority. Many complaints are also made by the authors of this century about the vanity and effeminacy of the deacons. Those more particularly of the presbyters and deacons who filled the first stations of these orders, carried their pretensions to an extravagant length, and were offended at the notion of being placed on an equality with their colleagues. For this reason they not only assumed the titles of arch-presbyters, and arch-deacons, but also claimed a degree of authority and power much superior to that which was vested in the other members of their respective orders.

In the fifth century, the bishops of Constantinople having already reduced under their jurisdiction all the Asiatic provinces, began to grasp at still further acquisitions of power. By the 28th canon of the council held at Chalcedon in 451, it was resolved, that the same ecclesiastical rights and honors which had been conferred on the bishop of Rome were due to the bishop of Constantinople, on account of the equal dignity and luster of the two cities in which these prelates exercised their authority.
authority. The same council confirmed also, by a solemn act, the bishop of Constantinople in the spiritual government of those provinces over which he had usurped the jurisdiction. Leo the Great, bishop of Rome, opposed with vehemence the passing of these laws; and his opposition was seconded by that of several other prelates. But their efforts were vain, as the emperors threw in their weight into the balance, and thus supported the decisions of the Grecian bishops. In consequence, then, of the decisions of this famous council, the bishop of Constantinople began to contend obstinately for the supremacy with the Roman pontiff, and to crush the bishops of Antioch and Alexandria. About the same time, Juvenal, bishop of Jerusalem, attempted to withdraw himself and his church from the jurisdiction of the bishop of Cesarea, and aspired after a place among the first prelates of the Christian world. The high degree of veneration and esteem in which the church of Jerusalem was held among all other Christian societies (on account of its rank among the apostolical churches, and its title to the appellation of mother-church, as having succeeded the first Christian assembly formed by the apostles), was extremely favourable to the ambition of Juvenal, and rendered his project much more practicable than it would otherwise have been. Encouraged by this, and likewise by the protection of Theodosius the younger, this aspiring prelate not only assumed the dignity of patriarch of all Palestine, a rank which rendered him independent of all spiritual authority; but also invaded the rights of the bishop of Antioch, and usurped his jurisdiction over the provinces of Phoenicia and Arabia. Hence arose a warm contest between Juvenal and Maximus bishop of Antioch; which the council of Chalcedon decided, by restoring to the latter the provinces of Phoenicia and Arabia, and confirming the former in the spiritual possession of all Palestine and in the high rank which he had assumed in the church.

In 588, John, bishop of Constantinople, surmounted the Easter, either by his own authority or that of the emperor Mauricius, summoned a council at Constantinople to acquire into an accusation brought against Gregory, bishop of Antioch; and upon this occasion assumed the title of ecumenical or universal bishop. This title had been formerly enjoyed by the bishops of Constantinople without any offence: but now, Gregory the Great, at that time bishop of Rome, suspecting that John was aiming at the supremacy over all the churches, opposed his claim with the greatest vigour. For this purpose he applied by letters to the emperor, and others, whom he thought capable of assisting him in his opposition; but all his efforts were without effect; and the bishops of Constantinople were allowed to enjoy the disputed title, though not in the sense which had alarmed the Roman pontiff.

Gregory, however adhered tenaciously to his purpose, raised new tumults and dissensions among the clergy, and aimed at nothing less than an unlimited supremacy over the Christian church. This ambitious design succeeded in the west; while in the eastern provinces, his arrogant pretensions were scarcely respected by any but those who were at enmity with the bishop of Constantinople. How much the people were at this time deluded by the Roman pontiffs, appears from the expression of Eunodius, one of the flatterers of Symmachus (who was a prelate of but ambiguous fame), that the Roman pontiff was constituted judge in the place of God, which he filled as the vicegerent of the Most High. On the other hand, it is certain, from a variety of the most authentic records, that both the emperors and the nations in general were far from being disposed to bear with patience the yoke of servitude which the see of Rome was arrogantly imposing on the whole church.

In the beginning of the seventh century, according to the most learned historians, Boniface III. engaged the emperor Phocas, emperor of Constantinople, to take from the see of the bishop of that metropolis the title of ecumenical or pope, universal bishop, and to confer it upon the Roman pontiff; and thus was first introduced the supremacy of the pope. The Roman pontiffs used all methods to maintain and enlarge this authority and pre-eminence, which they had acquired from one of the most odious tyrants that ever disgraced the annals of history.

In the eighth century, the power of the bishop of Rome, and of the clergy in general, increased prodigiously. The chief cause of this, beside the superstition of the people, was the method at that time used by the European princes to secure themselves on their thrones. All these princes being then employed either in usurpation or in self-defence, and the whole continent being in the most unsettled and barbarous condition, they endeavoured to attach warmly to their interests these whom they considered as their friends and clients. For this purpose they distributed among them extensive territories, cities, and fortresses, with the various rights and privileges belonging to them; reserving only to themselves the supreme dominion, and the military service of these powerful vassals. For this reason it was by the European princes reckoned a high instance of political prudence to distribute among the bishops and other Christian doctors the same sort of donations which had formerly been given to their generals and clients. By means of the clergy, they hoped to check the seditious and turbulent spirits of their vassals; and to maintain them in their obedience by the influence and authority of their bishops, whose commands were highly respected, and whose spiritual thunderbolts, rendered formidable by ignorance, struck terror into the boldest and most resolute hearts.

This prodigious accession to the opulence and authority of the clergy in the west, began at their head, viz. the Roman pontiff; from whence it spread gradually among the inferior sacerdotal orders. The barbarous nations who had received the gospel, looked upon the bishop of Rome as the successor of their chief druid or high priest: and as this tremendous druid had enjoyed, under the darkness of Paganism, a kind of boundless authority; so these barbarous nations thought proper to confer upon the chief bishop the same authority which had belonged to the chief druid. The pope received these august privileges with great pleasure; and lest, upon any change of affairs, attempts should be made to deprive him of them, he strengthened his title to these extraordinary honours by a variety of passages drawn from ancient history, and, what is still more astonishing, by arguments of a religious nature. This swelled the Roman druid to an enormous size; and gave to the see of Rome that pre-eminence and despotic authority in civil and political
political matters, that were unknown to former ages. Hence, among other unhappy circumstances, arose that monstrous and pernicious opinion, that such persons as were excluded from the communion of the church, the pontiff himself, or any of the bishops, thus forfeited, not only their civil rights and advantages as citizens, but even the common claims and privileges of humanity. This horrid opinion, which was a fatal source of wars, massacres, and rebellions without number, and which contributed more than anything else to confirm and augment the papal authority, was borrowed by the clergy from the Pagan superstitions.—Though excommunication, from the time of Constantine the Great, was in every part of the Christian world attended with many disagreeable effects; yet its highest terrors were confined to Europe, where its aspect was truly formidable and hideous. It acquired also, in the eighth century, new successions of terror; so that from that period the excommunication practised in Europe differed entirely from that which was in use in other parts of Christendom. Excommunicated persons were indeed considered in all places as objects of hatred both to God and man; but they were not, on that account, robbed of the privileges of citizens, nor of the rights of humanity; much less were those kings and princes, whom an insolent bishop had thought proper to exclude from the communion of the church, supposed to forfeit on that account their crowns or their territories. But from this century it was quite otherwise in Europe. Excommunication received that infernal power which dissolved all connexions; so that those whom the bishops, or their chief, excluded from church communion, were degraded to a level with the beasts. The origin of this unnatural and horrid power was as follows:—On the conversion of the barbarous nations to Christianity, these ignorant proselytes confounded the excommunication in use among Christians with that which had been practised in the times of Paganism, and which was attended with all the dreadful effects above mentioned. The Roman pontiffs, on the other hand, were too artful not to encourage this error; and therefore employed all sorts of means to gain credit to an opinion so well calculated to gratify their ambition, and to aggrandize in general the episcopal order.

The annals of the French nation furnish us with the following instance of the enormon power which was at this time vested in the Roman pontiff. Pepin, who was mayor of the palace to Chilperic III. king of France, and who in the exercise of that high office was possessed in reality of the royal power and authority, aspired to the titles and honours of majesty also, and formed a scheme of dethroning his sovereign. For this purpose he assembled the states in 753; and though they were devoted to the interests of this ambitious usurper, they gave it as their opinion that the bishop of Rome was previously to be consulted whether the execution of such a scheme was lawful or not. In consequence of this, ambassadors were sent by Pepin to Zachary, the reigning pontiff, with the following question, "Whether the divine law did not permit a valiant and warlike people to dethrone a pusillanimous and indolent prince who was incapable of discharging any of the functions of royalty; and to substitute in his place one more worthy to rule, and who had already rendered most important services to the state?" The situation of Zachary, who stood much in need of the succour of Pepin against the Greeks and Lombards, rendered this answer such as the usurper desired: and when this favourable decision of the Roman oracle was published in France, the unhappy Chilperic was stripped of his royalty without the least opposition; and Pepin, without the smallest resistance, stepped into the throne of his master and his sovereign. This decision was solemnly confirmed by Stephen II. the successor of Zachary; who undertook a journey into France in the year 754, in order to solicit assistance against the Lombards. The pontiff at the same time dissolved the obligation of the oath of fidelity and allegiance which Pepin had sworn to Chilperic, and violated by his usurpation in the year 751; and to render his title to the crown as sacred as possible, Stephen anointed and crowned him, with his wife and two sons, for the second time. This compliance of the pope was rewarded with the exarchate of Ravenna and all its dependencies, as we have already related. See Civil History, No. 44. supra; and History of Italy.

In the succeeding centuries, the Roman pontiffs continued to increase their power by every kind of artifice still inserted, and fraud which can dis honour the heart of man; and, by continually taking advantage of the civil dissensions which prevailed throughout Italy, France, and Germany, their influence in civil affairs rose to an enormous height. The increase of their authority in religious matters was not less rapid. The wisest and most impartial among the Roman Catholic writers acknowledge, that from the time of Louis the Meek the ancient rules of ecclesiastical government were gradually changed in Europe by the counsels and instigation of the church of Rome, and new laws substituted in their place. The European princes suffered themselves to be divested of the supreme authority in religious matters, which they had derived from Charlemagne; the power of the bishops was greatly diminished, and even the authority of both provincial and general councils began to decline. The pope, elated with their overgrown prosperity, and become arrogant beyond measure by the daily dossages that were made to their authority, were eagerly bent upon establishing the maxim, That the bishop of Rome was constituted and appointed by Jesus Christ supreme legislator and judge of the church universal; and that therefore the bishops derived all their authority from him. This opinion, which they inculcated with the utmost zeal and ardour, was opposed in vain by such as were acquainted with the ancient ecclesiastical constitutions, and the government of the church in the earlier ages. In order to gain credit to this new ecclesiastical code, and to support the pretensions of the pope to supremacy, it was necessary to produce the authority of ancient deeds, in order to stop the mouths of such as were disposed to set bounds to their usurpations. The Bishops of Rome were aware of this; and as those means were looked upon as the most lawful that tended best to the accomplishment of their purposes, they employed some of their most ingenious and zealous partisans in forging conventions, acts of councils, epistles, and such like records, by which it might appear, that in the first ages of the church the

Roman
Roman pontiffs were clothed with the same spiritual majesty and supreme authority which they now assumed. There were not, however, wanting among the bishops some men of prudence and sagacity, who saw through these impious frauds, and perceived the chains that were forging both for them and the church. The French bishops distinguished themselves eminently in this respect: but their opposition was soon quashed; and as all Europe was sunk in the grossest ignorance and darkness, none remained who were capable of detecting these odious impostures, or disposed to support the aspiring liberty of the church.

This may serve as a general specimen of the character and conduct of the pretended viceregentes of Jesus Christ to the 16th century. In the 11th century, indeed, their power seems to have risen to its utmost height. They now received the pompous titles of Masters of the World, and Popes, i.e. universal fathers. They presided everywhere in the councils by their legates, assumed the authority of supreme arbiters in all controversies that arose concerning religion or church-discipline, and maintained the pretended rights of the church against the encroachments and usurpations of kings and princes. Their authority, however, was confined within certain limits: for, on the one hand, it was restrained by sovereign princes, that it might not arrogantly aim at civil dominion; and on the other, it was opposed by the bishops themselves, that it might not arise to a spiritual despotism, and utterly destroy the privileges and liberty of synods and councils. From the time of Leo IX. the popes employed every method which the most artful ambition could suggest to remove those limits, and to render their dominion both despotic and universal. They not only aspired to the character of supreme legislators in the church, to an unlimited jurisdiction over all synods and councils whether general or provincial, to the sole distribution of all ecclesiastical honours and benefices, as divinely authorised and appointed for that purpose; but they carried their insolent pretensions so far, as to give themselves out for lords of the universe, arbiters of the fate of kingdoms and empires, and supreme rulers over the kings and princes of the earth. Hence we find instances of their giving away kingdoms, and loose subjects from their allegiance to their sovereigns; among which the history of John, king of England, is very remarkable. At last they plainly assumed the whole earth as their property, as well where Christianity was preached as where it was not; and therefore, on the discovery of America and the East Indies, the pope, by virtue of this spiritual property, granted to the Portuguese a right to all the countries lying eastward, and to the Spaniards all those lying to the westward, of Cape Non in Africa, which they were able to conquer by force of arms; and that nothing might be wanting to complete their character, they pretended to be lords of the future world also, and to have a power of restraining even the divine justice itself, and remitting that punishment which the Deity hath denounced against the workers of iniquity. All this time the powers of superstition reigned triumphant over those remains of Christianity which had escaped the corruptions of the first four centuries. In the 10th century began the invocation of the happy souls of departed saints. Their assistance was treated by many fervent prayers, while none stood up to oppose this preposterous kind of worship. The images of those who during their lives had acquired the reputation of uncommon sanctity, were now honoured with a particular worship in several places; and many imagined that this drew into the images the propitious presence of the saints or celestial beings which they were supposed to represent. A singular and irresistible efficacy was attributed to the bones of martyrs, and to the figure of the cross, in defeating all the temptations of Satan, in removing all sorts of calamities, and in bearing not only the diseases of the body, but also those of the mind. The famous Pagan doctrine concerning the purification of departed souls by means of a certain kind of fire, i.e. purgatory, was also confirmed and explained more fully than it had formerly been; and every one knows of how much consequence this absurd doctrine hath been to the wealth and power of the Roman clergy.

In the sixth century, Gregory the Great advanced an opinion, That all the words of the sacred writings were images of invisible and spiritual things; for which reason he loaded the churches with a multitude of ceremonies the most insignificant and futile that can be imagined; and hence arose a new and most difficult science, namely, the explication of these ceremonies, and the investigation of the causes and circumstances whence they derived their origin. A new method was contrived of administering the Lord's Supper, with a magnificent assemblage of pompous ceremonies. This was called the canon of the mass. Baptism, except in the cases of necessity, was administered only on the great festivals. An incredible number of temples was erected in honour of the saints. The places set apart for public worship were also very numerous: but now they were considered as the means of purchasing the protection and favour of the saints; and the ignorant and barbarous multitude were persuaded, that these departed spirits defended and guarded against evils and calamities of every kind, the provinces, cities, and villages in which they were honoured with temples. The number of these temples was almost equalled by that of the festivals, which seem to have been invented in order to bring the Christian religion as near the model of Paganism as possible.

In the seventh century, religion seemed to be almost altogether buried under a heap of superstitious ceremonies; the worship of the true God and Saviour of the world was exchanged for the worship of bones, bits of wood (said to be of the cross), and the images of saints. The eternal state of misery threatened in Scripture to the wicked was exchanged for the temporary punishment of purgatory; and the expressions of faith in Christ by an upright and virtuous conduct, for the augmentation of the riches of the clergy by donations to the church, and the observance of a heap of idle ceremonies. New festivals were still added; one in particular was instituted in honour of the true cross, on which our Saviour suffered; and churches were declared to be sanctuaries to all such as fled to them, whatever their crimes might have been. Superstition, it would seem, had now attained its highest pitch; nor is it easy to conceive a degree of ignorance and degeneracy beyond what we have already mentioned. If anything can possibly be imagined:
more contrary to true religion, it is an opinion which prevailed in the eighth century, namely, that Christians might appease an offended Deity by voluntary acts of mortification, or by gifts and oblations lavished on the church; and that people ought to place their confidence in the works and merits of the saints. The piety in this and some succeeding ages consisted in building and embellishing churches and chapels; in endowing monasteries and basilicas; hunting after the relics of saints and martyrs, and treating them with an absurd and excessive veneration; in procuring the intercession of the saints by rich oblations, or superstitious rites; in worshipping images; in pilgrimages to those places which were esteemed holy, particularly to Palestine, &c. The genuine religion of Jesus was now utterly unknown both to clergy and people, if we except a few of its general doctrines contained in the creed. In this century also, the superstitious custom of solitary masses had its origin. These were celebrated by the priest alone in behalf of souls detained in purgatory, as well as upon some other occasions. They were prohibited by the laws of the church, but proved a source of immense wealth to the clergy. Under Charlemagne they were condemned by a synod assembled at Mentz, as criminal acts of avarice and sloth. A new superstition, however, still sprung up in the tenth century. It was imagined, from Rev. xx. 1. that Antichrist was to make his appearance on the earth, and that soon after the world itself would be destroyed. An universal panic ensued; vast numbers of people, abandoning all their connections in society, and giving over to the churches and monasteries all their worldly effects, repaired to Palestine, where they imagined that Christ would descend from heaven to judge the world. Others devoted themselves by a solemn and voluntary oath to the service of the churches, convents, and priesthood, whose slaves they became, in the most rigorous sense of that word, performing daily their heavy tasks; and all this from a notion that the supreme Judge would diminish the severity of their sentence, and look upon them with a more favourable and propitiatory eye, on account of their having made themselves the slaves of his ministers. When an eclipse of the sun or moon happened to be visible, the cities were deserted, and their miserable inhabitants fled for refuge to hollow caverns, and hid themselves among the craggy rocks, and under the bending summits of steep mountains. The opulent attempted to bribe the saints and the Deity himself by rich donations conferred upon the sacerdotal tribe, who were looked upon as the immediate viceregents of heaven. In many places, temples, palaces, and noble edifices both public and private, were suffered to decay, nay, were deliberately pulled down, from a notion that they were no longer of any use, as the final dissolution of all things was at hand. In a word, no language is sufficient to express the confusion and despair that tormented the minds of miserable mortals upon this occasion. The general delusion was indeed opposed and combated by the discerning few, who endeavoured to dispel these terrors, and to efface the notion from which they arose in the minds of the people. But their attempts were ineffectual; nor could the dreadful apprehensions of the superstitious multitude be removed before the end of the century, and this terror became one of the accidental causes of the Croisades.

That nothing might now be wanting to complete that antichristian system of religion which had overspread all Europe, it was in the 11th century determined that divine worship should be celebrated in the Latin tongue, though now unknown throughout the whole continent. During the whole of this century, also, Christians were employed in the rebuilding and ornamenting their churches, which they had destroyed through the superstitions fears already taken notice of.

In much the same way with what is above related, or worse if possible, matters went on till the time of the reformation. The clergy were immersed in crimes of the deepest dye; and the laity, imagining themselves able to purchase pardon of their sins for money, followed the examples of their pastors without remorse. The absurd principle formerly mentioned, namely, that religion consists in acts of austerity, and an unknown mental correspondence with God, produced the most extravagant and ridiculous behaviour in the devotees and reputed saints. They not only lived among the wild beasts, but also after the manner of these savage animals: they ran naked through the lonely deserts with a furious aspect, and all the agitation of madness and frenzy; they prolonged their wretched life by grass and wild herbs, avoided the sight and conversation of men, remained almost motionless in certain places for several years, exposed to the rigour and inclemency of the seasons, and towards the conclusion of their lives shut themselves up in narrow and miserable huts; and all this was considered as true piety, the only acceptable method of worshipping the Deity and attaining a share in his favour. But all the instances of superstitious frenzy which disgraced the times we now speak of, none was held in higher veneration, or excited more the wonder of the multi-
of Simeon, the neighbouring bishops ordered it to be pulled down.

The practices of austere worship and discipline in other respects, however, gained ground throughout all parts of Christendom. Monks of various kinds were to be found in every country in prodigious numbers. But though their discipline was at first exceedingly severe, it became gradually relaxed, and the monks gave into all the prevailing vices of the times. Other orders succeeded, who pretended to still greater degrees of sanctity, and to reform the abuses of the preceding ones; but these in their turn became corrupted, and fell into the same vices they had blamed in others. The most violent anomiaries, disputes, and hatred, also reigned among the different orders of monks; and indeed, between the clergy of all ranks and degrees, whether we consider them as classed in different bodies, or as individuals of the same body. To enter into a detail of their wranglings and disputes, the methods which each of them took to aggrandise themselves at the expense of their neighbours, and to keep the rest of mankind in subjection, would require many volumes. We shall only observe, therefore, that even the external profession of the austere and absurd piety which took place in the fourth and fifth centuries, continued gradually to decline. Some there were, indeed, who boldly opposed the torrent of superstition and wickedness which threatened to overflow the whole world: but their opposition proved fruitless, and all of these towards the era of the reformation had been either silenced or destroyed: so that, at that time, the pope and clergy reigned over mankind without control, had made themselves masters of almost all the wealth in every country of Europe, and may truly be said to have been the only sovereigns; the rest of the human race, even kings and princes, being only their vassals and slaves.

While the Popish superstition reigned thus violently in the west, the absurd doctrines of Mahomet overspread all the east. The rise of this impostor is related under the article Arabia. His successors conquered in order to establish the religion of their apostle; and thus the very name of Christianity was extinguished in many places where it had formerly flourished. The conquests of the Tartars having mingled them with the Mahometans, they greedily embraced the superstitions of that religion, which thus almost entirely overspread the whole continents of Asia and Africa; and, by the conquest of Constantinople by the Turks in 1453, was likewise established throughout a considerable part of Europe.

About the beginning of the 16th century, the Roman pontiffs lived in the utmost tranquillity; nor had they, according to the appearance of things at that time, any reason to fear an opposition to their authority in any respect, since the commotions which had been raised by the Waldenses, Albigenases, &c. were now entirely suppressed. We must, not, however, conclude from this apparent tranquillity, nor security of the pontiffs and their adherents, that their measures were universally applauded. Not only private persons, but also the most powerful princes and sovereign states, exclaimed loudly against the tyranny of the popes, and the unbridled licentiousness of the clergy of all denominations. They demanded, therefore, a reformation of the church in its head and members, and a general council to accomplish that necessary purpose. But these complaints and demands were not carried to such a length as to produce any good effect; since they came from persons who never entertained the least doubt about the supreme authority of the pope in religious matters, and who, of consequence, instead of attempting themselves to bring about that reformation which was so ardently desired, remained entirely inactive, or looked for redress to the court of Rome, or to a general council. But while the so much desired reformation seemed to be at such a great distance, it suddenly arose from a quarter whence it was not at all expected. A single person, Martin Luther, a monk of the order of St. Augustine, ventured to oppose himself to the whole torrent of papal power and despotism. This bold attempt was first made public on the 30th of Sept. 1517; and notwithstanding all the efforts of the pope and his adherents, the doctrines of Luther continued daily to gain ground. Others, encouraged by his success, lent their assistance in the work of reformation; which at last produced new churches, founded upon principles quite different from that of Rome, and which still continue. But for a particular account of the transactions of the first reformers, the opposition they met with, and the final settlement of the reformed churches in different nations in Europe, see the articles Luther and Reformation.

The state of religion in other parts of the world seems as yet to be but little altered. Asia and Africa are sunk in the grossest superstitions either of the Mahometan or Pagan kinds. The southern continent of America, belonging to the Spaniards, continues immersed in the most absurd superstitions of Popery. The northern continent, being mostly peopled with colonies from Great Britain, professes the reformed religion. At the same time it must be owned, that some kind of reformation hath taken place even in Popery and Mahometanism themselves. The popes have no longer that authority over states and princes, even those most bigotted to Popery, which they formerly had. Neither are the lives either of the clergy or laity so corrupt as they were before. The increase of learning in all parts of the world has contributed to cause men open their eyes to the light of reason, and this hath been attended with a proportional decrease of superstition. Even in Mahometan countries, that furious enthusiasm which formerly emboldened their inhabitants to face the greatest dangers, hath now almost vanished; so that the credit of Mahomet himself seems to have sunk much in the estimation of his followers. This is to be understood even of the most ignorant and bigotted multitude; and the sensible part of the Turks are said to incline much towards deism. With regard to those nations which still profess Paganism, the intercourse of Europeans with them is so small, that it is impossible to say any thing concerning them. As none of them are in a state of civilization, however, it may be conjectured, that their religion is of the same unpollished cast with their manners, and that it consists of a heap of barbarous superstitions which have been handed down among them from time immemorial, and which they continue to observe without knowing why or wherefore.
Sect. III. Of the Composition of History.

Cicero has given us the whole art of composing history, in a very short and comprehensive manner. We shall first transcribe what he says, and then consider the several parts of it in their proper order. "No one is ignorant (says he), that the first law in writing history is, Not to dare to say any thing that is false; and the next, Not to be afraid to speak the truth; that on the one hand there be no suspicion of affection, nor of prejudice on the other. These foundations are what all are acquainted with. But the superstructure consists partly in things, and partly in the style or language. The former require an order of times, and descriptions of places. And because, in great and memorable events, we are desirous to know first their causes, then the actions themselves, and lastly their consequences; the historian should take notice of the springs or motives that occasioned them; and, in mentioning the facts themselves, should not only relate what was done or said, but likewise in what manner; and, in treating upon their consequences, show if they were the effects of chance, wisdom, or imprudence. Nor should he only recite the actions of great and eminent persons, but likewise describe their characters. The style ought to be fluent, smooth, and even, free from that harshness and poignancy which is usual at the bar." Thus far Cicero.

A history written in this manner, and furnished with all these properties, must needs be very entertaining, as well as instructive. And perhaps few have come nearer this plan than Tacitus; though his subject is attended with this unhappy circumstance, or at least unpleasant one, that it affords us examples rather of what we ought to avoid than what to imitate. But it is the business of the historian, as well as of the philosopher, to represent both virtues and vices in their proper colours; the latter doing it by precepts, and the former by examples. Their manner is different; but the end and design of both is, or should be, the same: And therefore history has not improperly been said by some to be moral philosophy exemplified in the lives and actions of mankind.

We shall reduce these several things mentioned by Cicero to three heads, Matter, Order, and Style; and treat upon each of them separately. But as Truth is the basis and foundation of all history, it will be necessary to consider that in the first place.

Art. I. Of Truth in History.

Of historic truth.

Truth is, as it were, the very life and soul of history, by which it is distinguished from fable or romance. A historian therefore ought not only to be a man of probity, but void of all passion or bias. He must have the steadiness of a philosopher, joined with the vivacity of a poet or orator. Without the former, he will be insensibly swayed by some passion to give a false colouring to the actions or characters he describes, as favour or disfavour to parties or persons affect his mind. Whereas he ought to be of no party, nor to have either friend or foe while writing; but to preserve himself in a state of the greatest indifference to all, that he may judge of things as they really are in their own nature, and not as connected with this or that person or party. And with this firm and sedate temper, a lively imagination is requisite; without which his descriptions will be flat and cold, nor will he be able to convey to his readers a just and adequate idea of great and generous actions. Nor is the assistance of a good judgment less necessary than any of the former qualities, to direct him what is proper to be said and what to be omitted, and to treat every thing in a manner suitable to its importance. And since these are the qualifications necessary for a historian, it may perhaps seem the less strange that we have so few good histories.

But historical truth consists of two parts; one is, Not to say any thing we know to be false: Though it is not sufficient to excuse a historian in relating a falsehood that he did not know it was so when he wrote it, unless he first used all the means in his power to inform himself of the truth; for them, undoubtedly, an inexcusable error is as unpardonable in history as in morality. But the generality of writers in his kind content themselves with taking their accounts from hearsays, or transcribing them from others, without duly weighing the evidence on which they are founded, or giving themselves the trouble of a strict inquiry. Few will use the diligence necessary to inform themselves of the certainty of what they undertake to relate. And as the want of this greatly abates the pleasure of reading such writers, while persons read with difficulty, so nothing more recommends an historian than such industry. Thus we are informed of Thucydides, that when he wrote his history of the Peloponnesian war, he did not satisfy himself with the best accounts he could get from his countrymen the Athenians, fearing they might be partial in their own cause; but spared no expense to inform himself how the same facts were related by their enemies the Lacedemonians; that, by comparing the relations of both parties, he might better judge of the truth. And Polybius took greater pains than he, in order to write his history of the Roman affairs; for he travelled into Africa, Spain, and Gaul, and other parts of the world, that by viewing the several scenes of action, and inferring himself from the inhabitants, he might come at a greater certainty of the facts, and represent them in a juster light. But as an historian ought not to assert what he knows to be false; so he should likewise be cautious in relating things which are doubtful, and acquaint his readers with the evidence he goes upon in such facts, from whence they may be able to judge how far it is proper to credit them. So Herodotus tells us what things he saw himself in his travels, and what he heard from the information of the Egyptian priests and others with whom he conversed. And Curtius, in the life of Alexander, speaking of the affairs of India, ingenuously confesses, that he wrote more than he fully believed.

"For (says he) I neither dare to affirm positively what I doubt of, nor can I think it proper to omit what I have been told." By such a conduct the author secures his credit, whether the things prove really true or false; and gives room for further inquiry, without imposing on his readers.

The other branch of historical truth is, Not to omit any thing that is true, and necessary to set the matter treated of in a clear and full light. In the actions of past
HISTORY.

past ages or distant countries, wherein the writer has no personal concern. He can have no great inducement to break in upon this rule. But where interest or party is engaged, it requires no small candour, as well as firmness of mind, constantly to adhere to it. Affection to some, aversion to others, fear of disoblige friends or those in power, will often interpose and try his integrity. Besides, an omission is less obvious to censure than a false assertion: for the one may be easily ascribed to ignorance or forgetfulness; whereas the other will, if discovered, be commonly looked upon as a lie. He therefore, in such circumstances, from a generous love to truth, is superior to all motives to betray or stifle it, justly deserves the character of a brave as well as honest man. What Polybius says upon this head is very well worth remarking: "A good man ought to love his friends and his country, and to have a like disposition with them, both towards their friends and enemies. But when he takes upon him the character of a historian, they must all be forgot. He must often speak well of his enemies, and commend them when their actions deserve it; and sometimes blame, and even upbraid his greatest friends, when their conduct makes it necessary. Nor must he forbear sometimes to reprove, and at other times to commend the same persons; since all are liable to mistake in their management, and there are scarce any persons who are always in the wrong. Therefore, in history, all personal considerations should be laid aside, and regard had only to their actions."

What a different view of mankind and their actions should we have were these rules observed by all historians? Integrity is undoubtedly the principal qualification of a historian; when we can depend upon this, other imperfections are more easily passed over. Suetonius is said to have written the lives of the first twelve Roman emperors with the same freedom with which they themselves lived. What better character can be given of a writer? The same ingenuous temper appears in the two Grecian historians above mentioned, Thucydides and Polybius: The former of whom, though banished by his countrymen the Athenians, yet expresses no marks of resentment in his history, either against them in general, or even against the chief authors of it, when he has occasion to mention them; and the latter does not forbear censuring what he thought blameable in his nearest relations and friends. But it is often no easy matter to know whether a historian speaks truth or not, and keeps up to the several characters here mentioned; though it seems reasonable, upon the common principles of justice due to all mankind, to credit him where no marks of partiality or prejudice appear in his writings. Sometimes, indeed, a judgment may in good measure be formed of the veracity of an author from his manner of expressing himself. A certain candour and frankness, that is always uniform and consistent with itself, runs through their writings who have nothing in view but truth, which may be justly esteemed as a very good evidence of their sincerity. Whereas those who have partial designs to answer are commonly more close and covert; and if at other times they assume an air of openness and freedom, yet this is not constant and even, but soon followed again with the appearance of some bias and reserve: for it is very difficult to act a part long together without lying open to a discovery. And therefore, though craft and design is exceeding various, and, Protesilaus-like, assumes very different shapes, there are certain characters by which it may often be perceived and detected. Thus, where things are uncertain by reason of their being reported various ways, it is partiality in a historian to give into the most unfavourable account, where others are as well known and equally credible. Again, it is a proof of the same bad temper, when the facts themselves are certain and evident, but the design and motives of those concerned in them are unknown and obscure, to assign some ill principle, such as avarice, ambition, malice, interest, or any other vicious habit, as the cause of them. This conduct is not only unjust to the persons whose actions they relate; but hurtful to mankind in general, by endeavouring to destroy the principal motive to virtue, which springs from example. Others, who affect to be more covert, content themselves with suspicions and sly insinuations; and then endeavour to come off, by intimating their unwillingness to believe them, though they would have their readers do so. And to mention no more, there are others, who, when they have loaded persons with unjust calumnies and reflections, will allow them some slight commendations, to make what they have said before look more credible, and themselves less partial. But the honest and faithful historian contends all such low and mean arts; he considers things as they are in themselves, and relates them as he finds them without prejudice or affection.

ART. II. THE SUBJECT OR ARGUMENT OF HISTORY.

The subject in general is facts, together with such subjects of things as are either connected with them, or may at least be requisite to set them in a just and proper light. But although the principal design of history be to acquaint us with facts, yet all facts do not merit the regard of an historian; but such only as may be thought of use and service for the conduct of human life. Nor is it allowable for him, like the poet, to form the plan and scheme of his work as he pleases. His business is to report things as he finds them, without any colouring or disguise to make them more pleasing and palatable to his reader, which would be to convert his history into a novel. Indeed some histories afford more pleasure and entertainment than others, from the nature of the things of which they consist; and it may be esteemed the happiness of an historian to meet with such a subject, but it is not his fault if it be otherwise. Thus Herodotus begins his history with showing, that the barbarians gave the first occasion to the wars between them and the Greeks, and conducted it with an account of the punishment which, after some ages, they suffered from the Greeks on that account. Such a relation must not only be very agreeable to his countrymen the Grecians, for whose sake it was written; but likewise very instructive, by informing them of the justice of Providence in punishing public injuries in this world, wherein societies, as such, are only capable of punishment. And therefore those examples might be of use to caution them against the like practices. On the contrary, Thucydides begins his history with the unhappy state of his countrymen the Athenians; and in...
the course of it plainly intimates, that they were the cause of the calamitous war between them and the Lacedaemonians. Whereas, had he been more inclined to please and gratify his countrymen than to write the truth, he might have set things in such a light as to have made their enemies appear the aggressors. But he scorned to court applause at the expense of truth and justice, and has set a noble example of integrity to all future historians. But as all actions do not merit a place in history, it requires no small judgement in an historian to select such only as are proper. Cicero observes very justly, that history "is conversant in great and memorable actions." For this reason, an historian should always keep posterity in view; and relate nothing which may not, upon some account or other, be worth the notice of after-ages. To descend to trivial and minute matters, such as frequently occur in the common affairs of life, is below the dignity of history. Such writers ought rather to be deemed journalists than historians, who have no view or expectation that their works should survive them. But the skilful historian is fired with a more noble ambition. His design is to acquaint succeeding ages with what remarkable occurrences happened in the world before them; to do justice to the memory of great and virtuous men; and at the same time to perpetuate his own. Pliny the younger has some fine reflections upon this head, in a letter to a friend. "You advise me (says he) to write a history; and not you only, for many others have done the same, and I am myself inclined to it. Not that I believe myself qualified for it, which would be rash to think till I have tried it; but because I esteem it a generous action not to suffer those to be forgotten whose memory ought to be esteemed; and to perpetuate the names of others, together with one's own. For there is nothing I am so desirous or ambitious of, as to be remembered hereafter; which is a thing worthy of a man, especially of one who, conscious of no guilt, has nothing to fear from posterity. Therefore I am thinking day and night by what means, as Virgil says,

--- My name
To raise aloft;
That would suffice me; for it is above my wish to add with him,
---
and win my flight to fame.

But oh!
---

Lib. v.
ep. 3.

However, this is enough, and what history alone seems to promise." This was Pliny's opinion with regard to the use and advantage of history; the subjects of which are generally matters of weight and importance. And therefore, when a prudent historian thinks it convenient to take notice of things in themselves less considerable, he either does it with brevity, or for some apparent reason, or accounts for it by some just apology. So Dion Cassius, when he has mentioned some things of less moment in the life of Commodus (as indeed that emperor's life was chiefly filled up with cruelty and folly), makes this excuse for himself: "I would not have it thought that I descend below the gravity of history in writing these things: For, as they were the actions of an emperor, and I was present and saw them all, and both heard and conversed with him, I did not think it proper to omit them." He seems to think those actions, when performed by an emperor might be worth recording, which, if done by a person of inferior rank, would scarce have deserved notice. Nor does he appear to have judged amiss, if we consider what an influence the conduct and behaviour of princes, even in the common circumstances of life, have upon all beneath them; which may sometimes render them not unworthy the regard of an historian, as examples either for imitation or caution.

But although facts in general are the proper subject of history, yet they may be differently considered with regard to the extent of them, as they relate either to particular persons or communities of men. And from this consideration history has been distinguished into three sorts, viz. biography, particular and general history. The lives of single persons is called biography. By particular history is meant that of particular states, whether for a shorter or longer space of time. And general history contains an account of several states existing together in the same period of time.

1. The subjects of biography are the lives either of public or private persons; for many useful observations in the conduct of human life may be made from just accounts of those who have been eminent and beneficial to the world in either station. Nay, the lives of vicious persons are not without their use, as warnings to others, by observing the fatal consequences which sooner or later generally follow such practices. But for those who exposed their lives, or otherwise employed their time and labour, for the service of their fellow-creatures, it seems but a just debt that their memories should be perpetuated after them, and posterity acquainted with their benefactors. The expectation of this was no small incentive to virtue in the Pagan world. And perhaps every one, upon due reflection, will be convinced how natural this passion is to mankind in general. And it was for this reason, probably, that Virgil places not only his heroes, but also the inventors of useful arts and sciences, and other persons of distinguished merit, in the Elysian Fields, where he thus describes them:

Here patriots live, who, for their country's good,
In fighting fields were proudest of blood;
Priests of unblemish'd lives here make abode,
And poets worthy their inspiring god;
And searching wits of more mechanic parts,
Who gave their age with new invented arts;
Those who to worth their bounty did extend,
And those who knew that bounty to commend:
The heads of these with holy fillets bound,
And all their temples were with garlands crown'd.

Aenid, vi. 66.

In the lives of public persons, their public characters are principally, but not solely, to be regarded. The world is inquisitive to know the conduct of princes and other great men, as well in private as public. And both, as has been said, may be of service, considering the influence of their examples. But to be over-inquisitive in searching into the weaknesses and infirmities of the greatest or best of men, is, to say no more of it, but a needless curiosity. In the writers of this kind, Plutarch is justly allowed to excel.

But it has been a matter of dispute among the learned,
learned, whether any one ought to write his own history. It may be pleaded in favour of this, that no one can be so much master of the subject as the person himself: and besides, there are many instances both ancient and modern, to justify such a conduct. But on the other hand it must be owned, that there are many inconveniences which attend it; some of which are mentioned by Cicero. If (says he) there is anything commendable, persons are obliged to speak of themselves with greater modesty, and to omit what is blameable in others. Besides, what is said is not so soon credited, and has less authority; and after all, many will not stick to censure it." And Piso says very well to the same purpose, "Those who proclaim their own virtues, are thought not so much to proclaim them because they did them, as to have done them that they might proclaim them. So that which would have appeared great if told by another, is lost when related by the party himself. For when men cannot deny the fact, they reflect upon the vanity of its author. Wherefore, if you do things not worth mentioning, the actions themselves are blamed; and if the things you do are commendable, you are blamed for mentioning them." These reflections will be generally allowed to be very just; and yet considering how natural it is for men to love themselves, and to be inclined in their own favour, it seems to be a very difficult task for any one to write an impartial history of his own actions. There is scarce any treatise of this kind that is more celebrated than Cæsar's Commentaries. And yet Suetonius tells us, that "Asinius Pollio (who lived at that time) thought they were neither written with due care nor integrity: that Cæsar was often too credulous in his accounts of what was done by other persons; and misrepresented his own actions, either designedly, or through forgetfulness; and therefore he supposed he would have revised and corrected them." However, at some times it may doubtless be justifiable for a person to be his own historian. Plutarch mentions two cases wherein it is allowable for a man to commend himself, and be the publisher of his own merits. These are, when the doing of it may be of considerable advantage either to himself or others. It is indeed less invidious for other persons to undertake the province. And especially for a person to talk or write of his own virtues, at a time when vice and a general corruption of manners prevails, let what he says be ever so true, it will be apt at least to be taken as a reflection upon others. "Anciently (says Tacitus), many wrote their own lives, rather as a testimony of their conduct, than from pride." Upon which he makes this judicious remark: "That the more virtue abounds, the sooner the reports of it are credited." But the ancient writers had a way of taking off the reader's attention from themselves in recording their own actions, and so rendering what they said less invidious; and that was, by speaking of themselves in the third person, and not in the first. Thus Cæsar never says, "I did," or "I said, this or that;" but always, "Cæsar did, or said, so and so." Why the moderns have not more chosen to follow them in this, we know not, since it seems less exceptionable.

2. In a continued history of particular states, some account may be given of their original, and founders; the nature of their soil, and situation; what advantages they have for their support or improvement, either within themselves, by foreign traffic, or conquest; with the form of their government. Then notice should be taken of the methods by which they increased in wealth or power, till they gradually advanced to their highest pitch of grandeur; whether by their virtue, the goodness of their constitution, trade, industry, war, or whatever cause. After this the reasons of their declension should be shown; what were the vices that principally occasioned it; (for that is generally the case); whether avarice, ambition, luxury, discord, cruelty, or several of these in conjunction. And lastly, where that has been their unhappy fate, how they received their final ruin and subversion. Most of these things Livy had in view when he wrote his History of the Roman State, as he acquaints his readers in the preface. "The accounts (says he) of what happened either before or while the city was building, consisting rather of poetical fables than any certain records of facts, I shall neither assert nor confute them. Let antiquity be allowed to make the origin of their cities more venerable, by uniting things human and divine. But if any nation may be said to have originated from the gods, such is the military glory of the Romans, that when they represent Mars as the father of their founder, other nations may as easily acquiesce in this as they do in their government. But I lay no great stress upon these things, and others of the like nature, whatever may be thought of them. What I am desirous every one should carefully attend to, are our lives and manners: by what men, and what arts, civil and military, the empire was both acquired and enlarged: then let him observe, how our manners gradually declined with our discipline; afterwards grew worse and worse; and at length so far degenerated, that at present we can neither bear with our vices nor suffer them to be remedied. This is the chief benefit and advantage to be reaped from history, to fetch instruction from eminent examples of both kinds; in order to imitate the one, which will be of use both to yourself and your country, and avoid the other, which are equally base in their rise and event." Thus far Livy. And how well he has executed this design must be acknowledged by all who will be at the pains to peruse his work.

3. But as a particular history consists in a number of facts relating to the same state, suitably connected and laid together in a proper series; so a general history is made up of several particular histories, whose separate transactions within the same period of time, or part of it, should be so distinctly related as to cause no confusion. Such was the history of Diodorus Siculus, which contained an account of most of the eminent states and kingdoms in the world, though far the greatest part of it is now unhappily lost. Of the same nature is the history of Herodatus, though not so extensive; to whom we are especially indebted for the Persian affairs. And to this kind may likewise be referred Justin's history, though it be only the epitome of a larger work written by another hand. The rules proper for conducting such histories are much the same as those above mentioned concerning particular histories; excepting what relates to the order, of which we shall have occasion to speak hereafter.

But the histories both of particular states and those
which are more general frequently contain only the affairs of some short period of time. Thus the history of the Peloponnesian war, written by Thucydides, comprises only what was done in the first 20 years of that war, which lasted seven years longer than his account reaches; though indeed the reason of that might be, because Thucydides died before the war was finished, otherwise he would very probably have continued his history to the conclusion of it. But the history of the war between the Romans and King Jugurtha in Africa, given us by Sallust, as also Caesar's histories of the Gallic and Civil wars, are all confined within a much less number of years than that of Thucydides. Nay, sometimes one single transaction is thought sufficient to furnish out a history. Such was the conspiracy of Catiline to subvert the Roman state, written likewise by Sallust. As to more general histories, Xenophon's history of Greece may be esteemed as such; which in order of time succeeds that of Thucydides, and contains the affairs of 48 years. And Polybius called his a general history; which, though it principally contained the Roman affairs, yet took in the most remarkable transactions of several other states, for the space of 53 years: though it has met with the same hard fate as that of Diodorus Siculus, so that only the first two books out of forty, of which it consisted at first, now remain entire. And to mention no more, the celebrated history of Thuanus is another instance of this sort, in which the principal transactions of Europe for about 60 years, chiefly in the 16th century, are described with that judgment and fidelity, and in a manner so accurate and beautiful, that he has been thought scarcely inferior to any of the ancient historians. Now, in such histories as these, to go farther back is not necessarily to set the subject in a just light, seems as improper as it is unnecessary.

The general subject or argument of history, in its several branches, may be reduced to these four heads; narration, reflections, speeches, and digressions.

I. By narration is meant a description of facts or actions, with such things as are necessarily connected with them; namely, persons, time, place, design, and event.

As to actions themselves, it is the business of the historian to acquaint his readers with the manner in which they were performed; what measures were concerted on all sides, and how they were conducted, whether with vigilance, courage, prudence, and caution, or the contrary, according to the nature of the action; as likewise, if any unforeseen accidents fell out, by which the designed measures were either promoted or broken. All actions may be referred to two sorts, military and civil. And as war arises from injustice and injuries received on one side or the other, it is fit the reader should be informed who were the aggressors. For though war is never to be desired, yet it is sometimes necessary. In the description of battles, regard should be had equally to both parties; the number of forces, conduct of the generals, in what manner they engaged, what turns and chances happened in the engagement, either from accidents, courage, or stratagem, and how it issued. The like circumstances should all be observed in sieges and other actions. But the most agreeable scene of history arises from a state of peace. Here the writer acquaints us with the constitution of states, the nature of their laws, the manners and customs of the inhabitants, the advantages of concord and unanimity, with the disadvantages of contention and discord; the invention of arts and sciences, in what manner they were improved and cultivated, and by whom; with many other things, both pleasant and profitable in the conduct of life.

As to persons, the characters of all those should be described who act any considerable part in a history. This excites the curiosity of the reader, and makes him more attentive to what is said of them; as one is more inquisitive to hear what relates to others in proportion to his knowledge of them. And it will likewise be of use to observe, how their actions agree with their characters, and what were the effects of their different qualifications and abilities.

The circumstances of time and place are carefully to be regarded by an historian, without which his accounts of facts will be frequently very lame and imperfect. And therefore chronology and geography seem not improperly to have been called the two eyes of history. Besides, they very much add to the memory; for it is much easier to remember any thing said to be done at such a time, and in such a place, than if only related in general; nay, the remembrance of these often recalls those things to mind which otherwise had been obliterated. By time is meant not only the year of any particular era or period; but likewise the season, as summer or winter; and the age of particular persons. For it is oftentimes from hence that we are principally enabled to make a just estimate of facts. Thus Cicero commends Pompey for undertaking and finishing the Piratic war at a season of the year when other generals would not have thought it safe to venture out at sea. This double danger, as well from the weather as the enemy, considering the necessity of the case, heightens the glory of the action; since to have done the same thing in summer would not have been an equal proof of the courage and intrepidity of the general. And there is nothing more surprising in the conquests of Alexander than that he should subdue so large a part of the world by the time he was little more than 30 years old; an age at which few other generals have been much distinguished. Had we not known this, a considerable part of his character had been lost.

The like advantages arise from the other circumstances of place. And therefore in marches, battles, and other military actions, the historian should take notice of the nature of the country, the passes, rivers, distances of places, situation of the armies, and strength of the towns either by nature or art; from which the reader may the better form a judgment of the difficulties and greatness of any enterprise. Caesar is generally very particular in these things, and seems to have thought it highly requisite in order to give his readers a just idea of his actions. The descriptions of countries, cities, and rivers, are likewise both useful and pleasant; and helps us to judge of the probability of what is related concerning the temper and genius of the inhabitants, their arts, traffic, wealth, power, or whatever else is remarkable among them.

But an accurate historian goes yet further, and considers
HISTORY.

Sect. III.

Composition of History.

Consider the causes of actions, and what were the designs and views of those persons who were principally concerned in them. Some, as Polybius has well observed, are apt to confound the beginnings of actions with their springs and causes, which ought to be carefully separated. For the causes are often very remote, and to be looked for at a considerable distance from the actions themselves. Thus, as he tells us, some have represented Hannibal's besieging Saguntum in Spain, and passing the Ebro, contrary to a former agreement between the Romans and Carthaginians, as causes of the second Punic war. But these were only the beginnings of it. The true causes were the jealousies and fears of the Carthaginians from the growing power of the Romans; and Hannibal's inveterate hatred to them, with which he had been impressed from his infancy. For his father, whom he succeeded in the command of the Carthaginian army, had obliged him, when but nine years old, to take a most solemn oath upon an altar never to be reconciled to the Romans; and therefore he was no sooner at the head of the army, than he took the first opportunity to break with them. Again, the true springs and causes of actions are to be distinguished from such as are only feigned and pretended. For generally the worse designs men have in view, the more solicitous they are to cover them with specious pretences. It is the historian's business, therefore, to lay open and expose to view these arts of politicians. So, as the same judicious historian remarks, we are not to imagine Alexander's carrying over his army into Asia to have been the cause of the war between him and the Persians. That had its being long before. The Greeks had formerly two armies in Asia, one under Xenophon and the other commanded by Agesilaus. Now the Asiatics did not venture to oppose or molest either of these armies in their march. This made King Philip, Alexander's father, who was an ambitious prince, and aspired after universal monarchy, think it might be a practicable thing to make a conquest of Asia. Accordingly, he kept it in his view, and made preparations for it; but did not live to execute it. That was left for his son. But as King Philip could not have done this without bringing the other states of Greece into it, his pretence to them was only to avenge the injuries they had all suffered from the Persians; though the real design was an universal government, both over them and the Persians, as appeared afterwards by the event. But in order to our being well assured of a person's real designs, and to make the accounts of them more credible, it is proper we should be acquainted with his disposition, manners, way of life, virtues, or vices; that by comparing his actions with these, we may see how far they agree and suit each other. For this reason Sallust is so particular in his description of Catiline, and Livy of Hannibal; by which it appears credible, that the one was capable of entering into such a conspiracy against his country, and the other of performing such great things as are related concerning him. But if the causes of actions lie in the dark, and unknown, a prudent historian will not trouble himself or his readers with vain and trifling conjectures, unless something very probable offers itself.

Lastly, an historian should relate the issue and event of the actions he describes. This is undoubtedly the most useful part of history; since the greatest advantage arising from it is to teach us experience from what has happened in the world before us. When we learn from the examples of others the happy effects of wisdom, prudence, integrity, and other virtues, it naturally excites us to an imitation of them, and to pursue the same measure in our own conduct. And, on the contrary, by perceiving the unhappy consequences which have followed from violence, deceit, rashness, or the like vices, we are deterred from such practice. But since the wisest and most prudent measures do not always meet with the desired success, and events across accidents may happen to frustrate the best conceived designs; when we meet with instances of this nature, it prepares us for the like events, and keeps us from too great a confidence in our own schemes. However, as this is not commonly the case, but in the ordinary course of human affairs like causes usually produce like effects; the numerous examples of the happy consequences of virtue and wisdom recorded in history are sufficient to determine us in the choice of our measures, and to encourage us to hope for an answerable success, though we cannot be certain we shall in no instance meet with a disappointment. And therefore Polybius very justly observes, that "he who takes from history the causes, manner, and end of actions, and omits to take notice whether the event was answerable to the means made use of, leaves nothing in it but a bare amusement, without any benefit or instruction." These, then, are the several things necessary to be attended to in historical narrations; but the proper disposition of them must be left to the skill and prudence of the writer.

II. Reflections made by the writers. Some have condemned these, as having a tendency to bias the reader; who should be left to draw such conclusions from the accounts of facts as he sees proper. But since all readers are not capable of doing this for themselves, what disadvantage is it for the author to suggest to them such observations as may assist them to make the best use of what they read? And if the philosopher is allowed to draw such inferences from his precepts as he thinks just and proper, why has not the historian an equal right to make reflections upon the facts he relates? The reader is equally at liberty to judge for himself in both cases, without danger of being prejudiced. And therefore we find, that the best historians have allowed themselves this liberty. It would be easy to prove this by a large number of instances, but one or two here may suffice. When Sallust has given a very distinct account of the designs of Catiline, and of the whole scheme of the conspiracy, he concludes it with this reflection: "All that time the empire of the Romans seems to me to have been in a very unhappy state. For when they had extended their conquests through the whole world from east to west, and enjoyed both peace and plenty, which mankind esteem their greatest happiness; some persons, were obstinately bent upon their own ruin, and that of their country. For notwithstanding two decrees were published by the senate, not one out of so great a multitude was prevailed with, by the rewards that were offered, either to discover the conspiracy or to leave the army of Catiline. So desperate a disease, and as it were infection, had seized the minds of most people!" And it is a very handsome observation.
observation that Livy makes upon the ill-conduct of Hannibal in quartering his army in Capua after the battle of Cannae; by which means they lost their martial vigour through luxury and ease. "Those (says he) who are skilled in military affairs reckoned this a greater fault in the general, than his not marching his army immediately to Rome after his victory at Cannae; for such a delay might have seemed only to defer the victory, but this ill step deprived him of the power to gain it." The modesty of the historian in this passage is worth remarking, in that he does not represent this as his own private opinion, and by that means undertake to censure the conduct of so great a general as Hannibal was, but as the sense of those who were skilled in such affairs. However, a historian should be brief in such remarks; and consider, that although he does not exceed his province by appealing virtue, expressing a just indignation against vice, and interposing his judgment upon the nature and consequences of the facts he relates; yet there ought to be a difference between his reflections and the encomiums or declamations of an orator.

III. Speeches inserted by historians. These are of two sorts, oblique and direct. The former are such as the historian recites in his own person, and not in that of the speaker. Of this kind is that of Hannibal in Justin; by which he endeavours to persuade King Antiochus to carry the seat of the war against the Romans into Italy. It runs thus: "Having desired liberty to speak, he said none of the present counsels and designs pleased him; nor did he approve of Greece for the seat of the war, which might be managed in Italy to greater advantage: because it was impossible to conquer the Romans but by their own arms, or to subdue Italy but by its own forces; since both the nature of those men, and of that war, was different from all others. In other wars, it was of great importance to gain an advantage of place or time, to ravage the countries and plunder the towns; but though you gain some advantage over the Romans, or defeat them, you must still fight with them when beaten. Wherefore, should any one engage with them in Italy, it was possible for him to conquer them by their own power, strength, and arms, as he himself had done; but should he attempt it out of Italy, the source of their power, he would be as much deceived, as if he endeavoured to alter the course of a river, not at the fountain-head, but where its streams were largest and deepest. This was his judgment in private, and what he had offered as his advice, and now repeated in the presence of his friends; that all might know in what manner a war ought to be carried on against the Romans, who were invincible abroad, but might be conquered at home. For they might sooner be driven out of their city than their empire, and from Italy than their provinces; having been taken by the Gauls, and almost subdued by himself. That he was never defeated till he withdrew out of their country; but upon his return to Carthage, the fortune of the war was changed with the place." He seems to intimate by this speech, that the Romans were like some fierce and impetuous animals, which are no otherwise to be subdued than by wounding them in some vital part. In speeches related after this manner, we are not necessarily to suppose the historian gives us the very words in which they were at first delivered, but only the sense. But in direct speeches, the person himself is introduced as addressing his audience; and therefore the words as well as the sense are to be suited to his character. Such is the speech of Eumenes, one of Alexander's captains and successors, made to his soldiers when they had traitorously bound him in chains, in order to deliver him up to his enemy Antigonus, as we have it in the same writer. "You see, soldiers (says he), the habits and ornaments of your general, which have not been put upon me by mine enemies; that would afford me some comfort: it is by you, that of a conqueror I am become conquered, and of a general a captive; though you have sworn to be faithful to me four times within the space of a year. But I omit that, since reflections do not become persons in calamity. One thing I intreat, that, if Antigonus must have my life, you would let me die among you. For it no way concerns him how or where I suffer, and I shall escape an ignominious death. If you grant me this, I free you from your oath, with which you have been so often engaged to me. Or, if shame restrains you from offering violence to me at my request, give me a sword, and suffer your general to do that for you without the obligation of an oath which you have sworn to do for your general."

But this likewise is a matter in which critics have been divided in their sentiments; whether any, or what kind of speeches ought to be allowed in history. Some have thought all speeches should be excluded: and the reason given for that opinion is this; that it breaks the thread of the discourse, and interrupts the reader, when he is desirous to come to the end of an action, and know how it issued. This is true, indeed, when speeches are either very long or too frequent; but otherwise they are not only entertaining, but likewise instructive. For it is of service to know the springs and reasons of actions; and these are frequently opened and explained in the speeches of those by whom they were performed. Others therefore have not been against all speeches in general, but only direct ones.

And this was the opinion of Trogus Pompeius, as Justin informs us; though he did not think it fit to follow him in that opinion, when he abridged him, as we have seen already by the speech of King Eumenes. The reason offered against direct speeches is, because they are not true; and truth is the foundation of all history, from which it never ought to depart. Such speeches, therefore, are said to weaken the credit of the writer; since he who will tell us that another person spoke such things which he does not know that he ever did speak, and in such language as he could not use, may take the same liberty in representing his actions. Thus, for example, when Livy gives us the speeches of Romulus, the Sabine women, Brutus, and others, in the first ages of the Roman state, both the things themselves are imaginary, and the language wholly disagreeable to the times in which those persons lived. Accordingly we find, that when several historians relate some particular speech of the same person, they widely differ both in the subject-matter and expressions. So the speech of Veturia, by which she dissuaded her son Coriolanus from besieging Rome when he came against it with an army of

of Valerians to avenge the injuries he had received, is very differently related by Livy, Dionysius of Halicarn.

nassus, and Plutarch. Such fictitious speeches therefore are judged more fit for poets, who are allowed a greater liberty to indulge their fancy than historians. And if any direct speeches are to be inserted, they should be such only as were really spoken by the persons to whom they are ascribed, where any such have been preserved. These have been the sentiments of some critics both ancient and modern. However, there is scarce an ancient historian now extant, either Greek or Latin, who has not some speeches, more or less, in his works; and those not only oblique, but also direct. They seem to have thought it a necessary ornament to their writings: and even where the true speeches might be come at, have chosen rather to give them in their own words; in order, probably, to preserve an equality in the style. Since therefore the best and most faithful historians have generally taken this liberty, we are to distinguish between their accounts of facts and their speeches. In the former, where nothing appears to the contrary, we are to suppose they adhere to truth, according to the best information they could get; but in the latter, that their view is only to acquaint us with the causes and springs of actions, which they choose to do in the form of speeches, as a method most ornamental to the work, and entertaining to the reader: Though the best historians are cautious of inserting speeches, but where they are very proper, and upon some solemn and weighty occasions. Thucydides is said to have been the first who brought complete and finished speeches into history, those of Herodotus being but short and imperfect. And though Dionysius of Halicarnassus, in his censure upon Thucydides, seems then to have disliked that part of his conduct; yet he afterwards thought fit to imitate it in his Antiquities of Rome, where we find many not only oblique, but also direct speeches.

What has been said of speeches, may likewise be understood of letters, which we sometimes meet with in histories; as that of Alexander to Darius in Quintus Curtius, those of Tiberius and Drusus in Tacitus, and many others. Some letters are wholly fictitious; and in others perhaps the historian represents the substance of what was really said, but gives it his own dress. Thus we find that short letter of Lentulus to Catiline at the time of his conspiracy differently related by Cicero and Sallust. The reason of which seems to be this: That as Cicero recited it publicly to the people of Rome in his third oration against Catiline, it is reasonable to imagine he did it in the very words of the letter, which he had by him; whereas Sallust, as an historian, might think it sufficient to give the sense of it in his own words.

IV. Digressions. These if rightly managed, afford the reader both delight and profit. Like speeches, they should neither be too long nor frequent; lest they interrupt the course of the history, and divert the reader from the main design of the work. But now and then to introduce a beautiful description, or some remarkable incident, which may give light to the subject, is so far from an interruption, that it is rather a relief to the reader, and excites him to go on with greater pleasure and attention. See further on this head, Oratoric.

ART. III. Of Order.

Since most histories consist of an introduction and the body of the work, in each of which some order is requisite, we shall discuss them separately.

1. The design of the introduction is the same here as in orations. For the historian proposes three things by his introduction, which may be called its parts; to give his reader some general view of the subject, to engage his attention, and to possess him with a candid opinion of himself and his performance. Some have thought this last unnecessary for an historian. But if we consider how differently mankind are apt to judge of the same persons and actions, it seems as requisite for an historian to be well esteemed as an orator. And therefore we find some of the best historians have not omitted this part. Livy's introduction has been very much applauded by the learned, as a masterpiece in its kind. It begins with an account of his design. "Whether (says he) it may answer any valuable end for me to write the history of the Roman affairs from the beginning of the city, I neither am certain, nor if I was should I venture to declare it." Soon after he endeavours to prepare the reader's attention, by representing the grandeur and usefulness of the subject in the following words: "Either I am prejudiced in favour of my subject, or there never was any state greater, more virtuous, and fruitful of good examples, or in which avarice and luxury had a later admittance, or poverty and thriftiness were either more highly or longer esteemed, they always coveting less the less they enjoyed." And then he presently proceeds to ingratiate himself with his readers, and gain their favourable opinion: "Although my name is obscure in so great a number of writers, yet it is a comfort that they cloud it by their fame and character. But I shall gain this advantage by my labour, that I shall be diverted for a time from the prospect of those evils which the age has seen for so many years; while my mind is wholly intent upon former times, free from all that care which gives the writer an unceasingness, though it cannot bias him against the truth." In this passage we see he endeavours to gain the good esteem of his readers from two very powerful motives, modesty and a strict regard to truth. It may scarce seem necessary to observe, that those introductions are esteemed the best which are most natural; that is, such as are taken from the subject-matter of the history itself, and closely connected with it. Such are those of Herodotus, Thucydides, Livy, Tacitus, and others. And therefore Sallust is greatly blamed by Quintilian on the account of his introductions, which are so general that they might suit other histories as well as those to which they are prefixed. Introductions should likewise be proportioned to the length of the work. We meet with some few histories, in which the writers immediately enter upon their subject, without any introduction; as Xenophon in his Expedition of the younger Cyrus, and Caesar in his Commentaries of the Gallic and Civil Wars. But the latter does not profess to write a just history; and therefore left himself more at liberty, as well in this respect as in some others.

2. But order is principally to be regarded in the body of the work. And this may be managed two ways; either by attending to the time in a chronologi-
HISTORY.

Sect. III.

ical series, or the different nature and circumstances of the things contained in the history. However, as these two methods do not equally suit all subjects, we shall a little consider to what kind of histories each of them seems more properly adapted. All history then, as we have observed already, may be reduced to three sorts: biography, the history of particular states, and the general history of several states existing at the same time.

In biography, or the lives of particular persons, most writers follow the order of time; though some reduce them to certain general heads, as their virtues and vices, or their public and private character. Plutarch and Cornelius Nepos have taken the former method, and Suetonius the latter.

As to the history of particular states, the order of time is generally best, as being most natural and easy. And therefore it has usually been observed by the best historians, as Thucydides, Livy, and others. Tacitus, indeed, wrote two distinct works; one of which he called Annales, and the other Histories. And as in both he has kept to the order of time, critics have been at a loss to assign any other reason for these different titles, unless that in the former work he confines himself more closely to the facts themselves, and does not treat so largely upon the causes, manner, or event of them, as he has done in the latter. And even in the circumstances of facts, there is a certain order proper to be observed, for rendering the account more plain and intelligible. Thus, for instance, in the description of a battle or siege, the time should first be known, then the chief person or persons who conducted it, then the number of forces, and other requisites, afterwards the nature of the place, then the action itself, and lastly the event. But sometimes it is necessary to add the time in which several of the other circumstances happened, especially in actions of any considerable length. Where the order of these circumstances is confused, it perplexes the account, and renders it both less entertaining to the reader, and more difficult to remember.

In a general history, the order of time cannot always be preserved; though, where the actions of different communities have respect to one as the principal, they should all, as far as possible, be referred to the transactions of that state. But even here the several affairs of those different states ought to be related separately, which will necessarily occasion the anticipating some things, and postponing others, so that they cannot all stand in the order of time in which they were performed. However, Velleius Paterculus says very justly with regard to this subject, “That every entire action placed together in one view, is much better apprehended than if divided by different trifles.” In this case, therefore, for better preserving the chronology, it is usual with historians, when they have finished any particular narrative, in passing to the next, to express the time by some short and plain transitions; and sometimes to apologize for themselves, by assigning the reasons of their conduct. So Polybius, whose history is of this kind, says concerning himself: “As in writing the actions of each year, in the order of time, I endeavour to represent the affairs of the same nation together in one summary view, it is plain that inconvenience must of course attend this way of writing.” Curtius professes only to write the actions of Alexander king of Macedon; but his history contains in it the principal affairs of the greatest states in the world during that period. Now although, in the course of those transactions, the war between Archelaus governor of Macedonia, and Agis king of Sparta, happened before the battle of Alexander at Arbela; yet the historian not only relates that battle first, but carries on the account of Alexander’s affairs in Asia to the death of Darius without interruption; for which he gives this reason: “If I should relate the affairs of Alexander, which happened in the mean time, either in Greece or Illyricum and Thrace, each in their proper order and time, I must interrupt the affairs of Asia; which it is much better to represent together in one continued series as they fell out, to the flight and death of Darius.” Such anachronisms, therefore, are nothing more than what necessarily arise sometimes from the nature of the subject: As every thing, the more complex it is, and contains under it a great number of parts, is more difficult to be digested in a regular order. But in a history composed of several states, whose affairs are independent of one another, the actions of each nation must necessarily be separated, in order to represent them in a just view, and prevent confusion. This is the method which Herodotus has taken, as likewise Diodorus Siculus and Justin. Now both the pleasure and benefit which such histories afford, arise from observing the conduct of each state separately in the course of their affairs, and then comparing one with the other. And as the order of time must frequently be interrupted, it is not unusual to continue the chronology at proper distances in relating the affairs of each nation; which preserves an unity in the whole, and connects it in one consistent body.

The division of histories into books was designed only for the better distinction of the subject and ease of the reader. And the dividing these books again into chapters, is rather a practice of latter editors (founded, as they have thought, on the same reasons) than countenance by the example of ancient writers.

ART. IV. OF STYLE.

An historical style is said to be of a middle nature, between that of a poet and an orator, differing from both not only in the ornamental parts, but likewise in the common idioms and forms of expression. Cicero observes, that “nothing is more agreeable in history than brevity of expression, joined with purity and perspicuity.” Purity indeed is not peculiar to history, but yet it is absolutely necessary; for no one will ever think him fit to write a history who is not master of the language in which he writes: and therefore when Albinus had written a history of the Roman affairs in Greek, and apologised for any slips or improprieties that might be found in the language upon the account of his being a Roman, Cato called him a trifler, for choosing to do that which, after he had done it, he was obliged to ask pardon for doing. Nor is perspicuity less requisite in a historical style. The nature of all the subject, plainly directs to this. For as history consists principally in narration, clearness and perspicuity are nowhere more necessary than in a relation of facts.
HISTORY.

Now from these several properties laid down by ancient writers, as requisite for an historical style, it seems upon the whole to agree best with the middle character. And this will further appear, by what they say relating to the ornamental parts of style; namely, composition and dignity. As to the former of these, which respects the structure of sentences, and the several parts of them, Demetrius remarks, that "An historical period ought neither to rise very high, nor sink very low, but to preserve a medium." This simplicity (he says) "becomes the gravity and credit of history; and distinguishes it from oratory on the one hand, and dialogue on the other." His meaning is, that historical periods should neither be so full and sonorous as is frequent in oratory: nor yet so short and flat as in dialogue: the former of which, as he says, require a strong voice to pronounce them; and the latter have scarce the appearance of periods. So that, according to this judicious writer, the periods best suited for history are those which, being of a moderate length, will admit of a just rise and cadency, and may be pronounced with ease. And Dionysius tells us, that "History should flow smooth and even, everywhere consistent with itself, without roughness or changes in the sound." This relates to the harmony of periods, which arises from such a position of the words as renders the sound pleasant and agreeable, and as he thinks ought to be attended to in history. And as to dignity, which respects the use of tropes and figures, the same author says, that "History should be embellished with such figures as are neither vehement nor carry in them the appearance of art." This is agreeable to what Cicero observes, in comparing Xenophon and Calisthenes, two Greek historians. "Xenophon the Socratic (says he) was the first philosopher, and after him Calisthenes the scholar of Aristotle, who wrote an history: the latter almost like a rhetorician: but the style of the former is more moderate, and has not the force of an orator, less vehement perhaps, but in my opinion more sweet and pleasant." The difference between these two writers, with De Orat. regard to their style, consisted chiefly in the choice of their figures: which in Xenophon were more gentle and moderate, and therefore in the judgment of Cicero more agreeable to history. Now these several properties relating to the ornaments of language, as well as those before mentioned, which by ancient writers have been thought requisite for history, are all suited to the middle style, as we have elsewhere shown at large. See Oratory, N° 99—121.

But notwithstanding this general account of the several properties which constitute an historical style, it admits of considerable varieties from the different nature and dignity of the subject. The lives of particular persons do not require that strength and majesty of expression, nor all those ornaments of language, as an history of the Roman empire. And accordingly we find the style of Nepos and Suetonius very different from that of Livy. The former is smooth and easy, scarce rising above the low character; but the latter often approaches near to the sublime. And other historians again have kept a medium between these. Upon the whole, therefore, we may conclude, that the middle style is the proper character for history; though historians may sometimes sink into the
HISTORY.

HISTORY of Nature, or Natural History. See NATURAL HISTORY.

HISTRIO, in the ancient drama, signified an actor or comedian; but more especially a pantomime, who exhibited his part by gestures and dancing. Livy informs us that the histriones were brought to Rome from Etruria, in the year of the city 361, (Dec. i. lib. 7.)

HISTRIX. See HYSTRIX.

HITCHING, a large and populous town of Hertfordshire in England, situated near a large wood called Hitchwood. The manor was the ancient demesne of the kings of England, as it continues at this day; and it has been the dower of several of their queens. The town is reckoned the second in the county for number of streets, houses, and inhabitants. It was formerly famous for the staple commodities of the kingdom, and divers merchants of the staple of Calais resided here, since which that trade is lost. The inhabitants now make large quantities of malt; and the market is one of the greatest in England for wheat. Population 3608. W. Long. 0. 10. N. Lat. 51° 58'.

HITHE, or HYTHE, a town of Kent in England, 70 miles from London. It is one of the five ports; and had formerly five parishes, but by the closing up of its harbour and other accidents is now reduced to one. In the reign of Henry IV. numbers of its inhabitants were cut off by a pestilence, 200 of their houses consumed by fire, and five of their ships sunk at sea, with the loss of 100 men; so that the people were going to abandon the town, but not the king by his charter generously released to them, for five years next following, their service of five ships of 100 men and five horses, which they were to have furnished out and kept at their own charge in the king’s wars for 15 days. It was first incorporated by the name of barons of the town and port of Hithe; but the government was afterwards changed. It was incorporated by Queen Elizabeth with the name of the mayor, jurats, and commonalty of the town and port of Hithe, who with the freemen elect the members of parliament. The mayor is chosen yearly on Candlemas-day. Here is a market on Saturdays, and fairs in July and December. From hence to Canterbury is a paved Roman military way, called Stoney Street; and at a little distance from hence are the remains of the walls of a castle, which included 20 acres. There is a remarkable pile of dry bones in the town, 28 feet long, 6 broad, and 8 high; they are kept in a vault under the church in as good order as books in a library, consisting of several thousand heads, arms, legs, thigh-bones, &c. some very gigantic, and appear by an inscription to be the remains of the Danes and Britons killed in a battle near this place, before

the Norman conquest. From hence to Boulogne is reckoned the shortest cut to France. Population 2318 in 1811. E. Long. 1. 10. N. Lat. 51. 8. HITTITES, the descendants of Het. See HETH.

HIVE, in country affairs, a convenient receptacle for bees. See API and BEE.

HIVITES, a people descended from Canaan. They dwelt at first in the country which was afterwards possessed by the Caphtorim, or Philistines. There were Hivites likewise at Shechem and Gibeon, and consequently in the centre of the promised land; for the inhabitants of Shechem and the Gibeonites were Hivites, (Joshua xi. 19. Genesis xxxiv. 2.) Lastly, there were some beyond Jordan, at the foot of Mount Hermon (Joshua xi. 3.) Bochart is of opinion, that Cadmus, who carried a colony of Phoenicians into Greece, was an Hivite. His name, Cadmus, comes from the Hebrew Kedem, "the east," because he was of the eastern part of the land of Canaan. The name of his wife Hermione, comes from Mount Hermon, at the foot whereof the Hivites had their dwelling. The metamorphosis of Cadmus's companions into serpents is grounded on the signification of the name Hivites, which in Phoenician signifies "serpents."

HORACE, in Natural History, a kind of earth approaching to the nature of chalk, but harder, and feeling like soap; whence some think that it is either the same with the soap-rock of Cornwall, or very like it. The Chinese mix it with water till the liquor is of the consistence of cream, and then varnish their china-ware with it.

HOADELY, BENJAMIN, successively bishop of Bangor, Hereford, Salisbury, and Winchester, was born in 1676. His first prebend in the church was the rectory of St Peter le Poore, and the lectureship of St Mildred's in the Poultry. In the year 1706, he published some Remarks on the late Bishop Atterbury's sermon at the funeral of Mr Bennet, in which Dr Atterbury had, in the opinion of Mr Hoadley, laid down some dangerous propositions. Two years after, Mr Hoadley again entered the lists against this formidable antagonist; and in his exceptions against a sermon published by Dr Atterbury, intitled "The Power of Charity to Cover Sin," he attacked the doctor with his usual strength of reasoning and impassionate inquiry. In 1709, another dispute arose between these two learned combattants, concerning the doctrine of non-resistance, occasioned by a performance of Mr Hoadley's, intitled "The Measures of Obedience;" some positions in which Dr Atterbury endeavoured to confute in his elegant Latin sermon preached that year before the London clergy. In this debate Mr Hoadley signalized himself in so eminent a degree, that.
HISTORICAL CHART.
Representing at one view the rise and progress of the Principal States & Empires of the known World.
that the honourable house of commons gave him a particular mark of their regard, by representing, in an address to the queen, the signal services he had done to the cause of civil and religious liberty.—The principles, however, which he espoused being repugnant to the general temper of those times, drew on him the virulence of a party; yet it was at this period (1710, when, as he himself expressed it, fury seemed to let loose upon him) that the late Mrs Howland presented him to the rectory of Streatham in Surry, unasked, unapplauded to, and without his either having seen her or been seen by her. Soon after the accession of King George I. Mr. Hoadley was consecrated to the see of Bangor; and, 1717, having broached some opinions concerning the nature of Christ’s kingdom, &c. he again became the object of popular clamour. At this juncture he was distinguished by another particular mark of the royal regard, by means of which the conviction was successively protracted, and it was not permitted to sit, or do any business, till that resentment was entirely subsided. In 1721 he was translated to Hereford; and from thence, in 1723, to Salisbury. In 1734, he was translated to Winchester (on the demise of Dr. Willis), and published his Plain Account of the Sacrament: a performance which served as a butt for his adversaries to shoot at; yet impartiality owns it to be clear, rational, and manly, written with great candour and judgment, and suited to the capacity of every serious and considerate inquirer after truth.—His latter days were embittered by a most vile instance of fraud and ingratitude. The bishop took a French priest, who pretended to abjure his religion, under his protection, with no other recommendation than that of his necessities; in return for which act of humanity, the priest found an opportunity of getting the bishop’s name written by his own hand, and, causing a note of some thousand pounds to be placed before it, offered it in payment. But the bishop denying it to be his, it was brought before a court of justice and was found to be a gross imposition. The ungrateful villain had now recourse to a pamphlet, in which he charged the bishop with being a drunkard; and alleged that he had the note of him when he was in liquor. To this calumny the bishop made a full and nervous answer; in which he exposed the man’s falsehood, and solemnly averred that he was never drunk in his whole life. The world with becoming ardour embraced his defence, and he had the happiness to find himself perfectly acquitted even of any suspicion of such a charge. As a writer, he possessed uncommon abilities. His sermons (published in 1754 and 1755) are esteemed inferior to few writings in the English language, for plainness and perspicuity, energy and strength of reasoning, and a free and masterly manner. In private life, he was naturally facetious, easy, and complying; fond of company, yet would frequently leave it for the purposes of study or devotion. He was everywhere happy; and particularly in his own family, where he took all opportunities of instructing by his influence and example. He died in 1761, aged 83. Besides the works already mentioned, he wrote, 1. Tracts of Acceptance, 8vo. 2. Reflections on the Sacrament. His tracts and pamphlets are extremely numerous: and the reader may see a complete catalogue of them in his life inserted in the supplement to the Biographia Britannica.

Hoadley, Benjamin, M.D. son of the former, was born in 1706; and studied at Bennet college, Cambridge, under the tuition of Dr Herring, afterwards archbishop of Canterbury. He took his degree in physic; and particularly applying himself to mathematical and philosophical studies, was, when very young, admitted a member of the royal society. He was made register of Hereford while his father filled that see, and was early appointed physician to his majesty’s household, but died at his house in Chelsea in 1755. He wrote, 1. Three letters on the organs of respiration, 4to. 2. The Suspicious Husband, a comedy. 3. Observations on a series of electrical experiments; and, 4. Ora- 

Hoi-an. See Makkubium, Botany Index.

Hoarseness, in Medicine, a diminution of the voice, commonly attended with a preternatural asperity and roughness thereof. The parts affected are the aspera arteria and larynx. For its causes and cure, see Medicine Index.

Hobal, in Mythology, an idol of the ancient Arabs, the worship of which at Mecca was destroyed by Mahomet.

Hobbes, Thomas, a political writer, was born at Malmsbury in 1588. He was the son of a clergyman; and having completed his studies at Oxford, he was afterwards governor to the eldest son of William Cavendish earl of Devonshire. He travelled through France and Italy with that young nobleman, and at length applied himself entirely to the study of polite literature. He translated Thucylides into English; and published his translation in 1628, in order to show his countrymen, from the Athenian history, the disorders and confusions of a democratical government. In 1626 his patron the earl of Devonshire died; and in 1628 his son died also; which loss affected Mr. Hobbes to such a degree, that he very willingly accepted an offer made him of going abroad a second time with the son of Sir Gervase Clifton; whom he accordingly accompanied into France, and stayed there some time. But while he continued there, he was solicited to return to England, and to resume his concern for the hopes of that family to whom he had attached himself so early, and to whom he owed so many and so great obligations. In 1631, the countess dowager of Devonshire desired to put the young earl under his care, who was then about
Hobbes about the age of 13. This was very suitable to Mr Hobbes's inclinations, who discharged that trust with great fidelity and diligence. In 1634, he republished his translation of Thucydides, and prefixed to it a dedication to that young nobleman, in which he gives a great character of his father, and represents in the strongest terms the obligations he was under to that illustrious family. The same year he accompanied his noble pupil to Paris, where he applied his vacant hours to the study of natural philosophy, and more especially to the perfect understanding of mechanism, and the causes of animal motion. He had frequent conversations upon these subjects with Father Marin Mersenne; a man deservedly famous, and who kept up a correspondence with almost all the learned in Europe. From Paris he attended his pupil into Italy, where at Pisa he became known to that great astronomer Galileo Galilei, who communicated to him his notions very freely; and after having seen all that was remarkable in that country, he returned with the earl of Devonshire into England. Afterwards, foreseeing the civil wars, he went to seek a retreat at Paris; where, by the good offices of his friend Father Mersenne, he became known to the famous Renatus des Cartes, and afterwards held a correspondence with him upon several mathematical subjects, as appears from the letters of Mr Hobbes published in the works of Des Cartes. But when this philosopher printed afterwards his Meditations, wherein he attempted to establish points of the highest consequence from innate ideas, Mr Hobbes took the liberty of dissenting from him; as did also the French king's mathematical professor, the illustrious Peter Gassendi, with whom Mr Hobbes contracted a very close friendship, which was not interrupted till the death of the former. In 1642, Mr Hobbes printed a few copies of his famous book De Civis, which, in proportion as it became known, raised him many adversaries, who charged him with instilling principles which had a dangerous tendency. Among many illustrious persons who, upon shipwreck of the royal cause, retired to France for safety, was Sir Charles Cavendish, brother to the duke of Newcastle; and this gentleman, being skilled in every branch of the mathematics, proved a constant and zealous patron to Mr Hobbes, who, by embarking in 1645 in a controversy about squaring the circle, was grown so famous for it, that in 1647 he was recommended to instruct Charles prince of Wales, afterwards King Charles II. in mathematical learning. His care in the discharge of this office gained him the esteem of that prince in a very high degree: and though he afterwards withdrew his public favour to Mr Hobbes on account of his writings, yet he always retained a sense of the services he had done him; and showed him various marks of his favour after he was restored to his dominions; and, as some say, had his picture hanging in his closet. This year also was printed in Holland, by the care of M. Sorbière, a second and more complete edition of his book De Civis; to which are prefixed two Latin letters to the editor, the one by Mr Gassendi, the other by Father Mersenne, in commendation of it: and in 1650 was published at London a small treatise of Mr Hobbes's, entitled Human Nature; and another De curpore politico, or "Of the elements of the law."

All this time Mr Hobbes had been digesting with great care and pains his religious, political, and moral principles, into a complete system, which he called the Leviathan, and which was printed in English at London in 1650 and 1651. After the publication of his Leviathan be returned to England, and passed the summer commonly at his patron the earl of Devonshire's seat in Derbyshire, and some of his winters in town, where he had for his intimate friends some of the greatest men of the age. In 1660, upon the Restoration, he quitted the country, and came up to London, where he obtained from the king assurance of protection, and had an annual pension of 100l. settled upon him out of the privy purse. Yet this did not render him entirely safe: for, in 1666, his Leviathan and his treatise De Civis were censured by parliament; which alarmed him very much, as did also the bringing in of a bill into the house of commons to punish atheism and profaneness. When this storm was a little blown over, he began to think of procuring a beautiful edition of his pieces that were in print; but finding this impracticable in England, he caused it to be undertaken abroad, where they were published in quarto in 1668, from the press of John Bleau. In 1669, he was visited by Cosmo de Medicis, then prince, afterwards duke of Tuscany, who gave him ample marks of his esteem and respect; and having received his picture, and a complete collection of his writings, caused them to be reprinted, the former among his curiosities, the latter in his noble library at Florence. The like visits he received from foreign ambassadors and other strangers of distinction; who were curious to see a person whose singular opinions and numerous writings had made so much noise all over Europe. In 1672, he wrote his own life in Latin verse, when, as he observes, he had completed his 84th year: and, in 1674, he published in English verse four books of Homer's Odyssey; which was so well received, that it encouraged him to undertake the whole Iliad and Odyssey, which he likewise performed and published in 1675. About this time he took his leave of London, and went to spend the remainder of his days in Derbyshire: where, however, he did not remain inactive, notwithstanding his advanced age; but published from time to time several poems, to be found in the collection of his works. He died in 1679, aged 92.

As to his character and manners, they are thus described by Dr White Kennet, in his Memoirs of the Cavendish family. "The earl of Devonshire (says he) for his whole life entertained Mr Hobbes in his family, as his old tutor rather than as his friend or confidant. He let him live under his roof in ease and plenty, and in his own way, without making use of him in any public, or so much as domestic affairs. He would frequently put off the mention of his name, and say, 'He was a humorist, and nobody could account for him.' There is a tradition in the family, of the manners and customs of Mr Hobbes, somewhat observable. His professed rule of health was to dedicate the morning to his exercise, and the afternoon to his studies. And therefore, at his first rising, he walked out, and climbed any hill within his reach; or if the weather was not dry, he fatigued himself within doors by some exercise or other, to be in a sweat recommending that practice upon this opinion, that an old man had more moisture than heat, and therefore by such
HOBBER, or Hobby, the name of a hawk called by some authors *subbuteo*. See FALCO, ORNITHOLOGY Index.

Hobby was a hawk of the lure, and not of the fist; and is very like the saker, only much less. It makes excellent sport with net and spaniels; for when the birds see the hobby, they dare not commit themselves to the wing, but lie close to the ground, and so are taken in nets.

HOBBY is also a name formerly given to strong active horses of a middling size: they are reported to have been originally natives of Ireland, and were much liked and used. Nags answer the same description as to size, qualities, and employments.

HOGBOBLIN, is a name vulgarly applied to fairies or apparitions. Skinner calls the word *rogboblins*, and derives it from Robin Goodfellow, Hob being the nick-name of Robin, but Wallis and Junius, with greater probability, derive it from *hugoboblins, empuse*, because they are supposed to hop without moving both their feet.

HOBLERS, or HOBLERS, Hobelarii, in our ancient customs, were men who, by their tenure, were obliged to maintain a light horse or hobby, for the certifying any invasion towards the sea-side. —The name was also used for certain Irish knights, who used to serve as light horsemen upon hobbies.

HOBNAIL, a nail with a thick strong head, used in shoeing a hobby or little horse.

HOBNOB, or HAB-NAB, a cant word formed from *hap ne hap*, and denoting an event which happens at random or by mere chance.

HOBOO, a name given by the people of Otabeite, and in the neighbouring islands of the South sea, to their superfine cloth. It is the thinnest and most finished preparation of the souta.

HOBSHEE COFFRES, a kind of Abyssinian slaves very frequent in the empire of Hindostan. They come mostly from a province subject to the Negus of Ethiopia, called Imanaria, to the south of his other dominions, and bordering upon Negroland in Africa; from whence they are selected, and a great traffic made of them over all Mogolistan and Persia; but it is chiefly from the ports of Arabia and the Red sea that they are brought. Nothing can be imagined more smooth and glossy, and perfectly black, than their skin; in which they far surpass the negroes on the coast of Guinea; and, generally speaking, have not any thing of their thick lips, though otherwise as woolly haired as they. They are highly valued for their courage, fidelity, and shrewdness; in which they so far excel, as often to rise to posts of great honour, and are made governors of places under the title Siddrez.

HOBSON'S-CHOICE, a vulgar proverbial expression, applied to that kind of choice in which there is no alternative. It is said to be derived from the name of a carrier at Cambridge, who let out hackney horses, and obliged each customer to take in his turn that horse which stood next the stable door.

HOCHER, LAZARUS, a republican French general. This extraordinary man, and particularly favourite of fortune, was born on the 24th of June 1768, at the village of Montereul, in the suburbs of Versailles. His father, in the early part of his life, had been a soldier; but acted afterwards in the capacity of a menial servant, and was appointed to feed the hounds of Louis XV. His mother died soon after the birth of young Hocher, by which he was left in a great measure destitute,
Hoche was unable to contribute to his support. By the humanity of an aunt, however, who kept a green stall at Versailles, he was rescued from absolute beggary. She sent him to a small school, where he acquired a tolerable knowledge of reading and writing, shewing himself at once the best and most mischievous scholar in the whole school. He was made a chorister by the rector of St Germain-en-Laye, because he found him to be a boy of a very lively disposition. He very soon discovered an invatiable thirst for information upon every subject, asking questions at those who were much older than himself, and listening with the utmost attention to the answers they returned. The ingenuity of his remarks and inquiries was often perplexing to others; but as he gradually approached towards manhood, a very remarkable change took place, both in his manners and disposition. His loquacity was succeeded by a musing, contemplative turn, and he proved by the importance of his conversation, that he had not meditated in vain.

Finding that his wants grew more numerous than could be supplied by the industry of his aunt, he formed the commendable resolution of earning his own subsistence, and accordingly became a sort of assistant in the royal stables of Versailles. His ardent character, however, soon found this situation by far too degrading; he already viewed it with abhorrence; and having accidentally met with some part of the works of Rousseau, a spirit of independence instantly seized upon him. Apprehending that he might better his situation by going abroad, to which he was strongly urged by a rascal who made a prey of him, even offered him money to enable him to prosecute the undertaking, and then gave him to understand that he was now a soldier in the French guards. Hoche, finding it wholly unavailing to remonstrate, was sent at the age of 16 to join his regiment, which was then quartered at Paris. Here he found himself possessed of no more than 125 livres (about 51. sterling), the united result of his own economy, and the bounty he received on entering the army. Even out of this small sum he was obliged to treat his fellow soldiers with a breakfast, which exhausted his whole stock. A military life, however, soon appeared to be exactly suited to his disposition, so that he surpassed all the other recruits in the rapidity with which he learned the manual exercise; and in a single month was fit for the veteran ranks.

His limbs were admirably proportioned, his dress was always neat, and his conduct so regular, that he was made a grenadier at the request of the company. He now felt the circumscribed nature of his education, of which he was ashamed, and he determined to achieve that by his own exertions which the penury of his relations prevented them from accomplishing. He saw the necessity of a command of books, and as his pay was inadequate to the purchase of these, he determined to make up the deficiency by manual labour, with no species of which he was ever disgusted, while it put the means of intellectual improvement within his reach. He rose at the dawn of day, either to draw water, or trench ground for the gardeners in the vicinity of Paris; and at night he embroidered vests and caps.

The fruits of his industry were, at the end of the week, divided into three parts; the first was given to the substitute who mounted guard for him; the second was devoted to the incidental expenses of a convivial hour with his companions; and the third defrayed the expenses of the books which he borrowed. He now turned his whole attention to the attainment of a better knowledge of his own profession, and even ventured to point out the radical defects of the prevailing system of military tactics, and reproved some of the regulations which obtained in the army. In spite, however, of the general gravity of his deportment, he was no enemy to occasional conviviality. Having once understood that a companion had been murdered during a quarrel in the vicinity of the metropolis, he determined not to sleep till he had taken vengeance on the assassin. Marching forth at the head of a body of his companions, to the house where the deed was perpetrated, he demolished all the windows, and destroyed the furniture; but for this he was sentenced to three months confinement in the black hole. At the expiration of this period he exhibited a spectacle truly deserving of commiseration, being destitute of linen, clothes and shoes, his face pale and disfigured, and in this condition he arrived at the barracks, where he was received by his companions with every demonstration of joy. He soon after fought a duel with a tyrannical corporal, of whom the whole regiment was afraid except the gallant Hoche. The latter fell, and Hoche received a deep cut in his forehead, which added greatly to his martial appearance.

Soon after this period appeared the celebrated pamphlet of Sieyes respecting the Third Estate, and almost every Frenchman was ready to prove that he belonged to it. The guards, it is well known, took a decided part in the people; and on the 14th of July 1789, Hoche, at the head of his companions, was among the first who seized on the Bastile. The guards were formed into the 102d, 103d, and 104th regiments, into the last of which Hoche was admitted with the rank of second adjutant, when he had an opportunity of manifesting his talents in a different channel. Improper hands having obtained the administration of the military hospital of the French guards, he minutely investigated the state of the accounts, which had been veiled with ambiguity for the purpose of deceiving. He amended the discipline of the army, and his active talents did not pass unrewarded. While the regiment was reviewed in the Elysian fields, Servan, the minister at war, was so delighted with the platoons of Hoche's company, that he enquired who the young man was by whom it was conducted, and he bestowed on him some flattering compliments, and in four days after sent him the brevet of lieutenant in the regiment of Rouergue. He left Paris on the 24th of June 1792, in order to join his regiment, then in garrison at Thionville. General Leveneur, who held the command in the absence of Vaulence, sent Lieutenant Hoche with a regiment of hussars, to procure provisions for the troops which Miranda had ordered to lay siege to Maastricht. This he executed with universal applause; and when the army of the Ardennes was ordered to recross the Meuse, Hoche succeeded in removing the powder from the abbey of Merlen, in bringing away the military chest of the division, and conducting the sick in the hospital, when every thing appeared to be in the power of the enemy's hussars. Having fought in the capacity of aide-de-camp to General Leveneur, at Gutenhoven, Neerwinden,
the heights of Vertrich, and at Blanquef, the republican army repassed the Dyle, breaking down the bridges; and Hochel enabled it to effect a retreat, by disputing every inch of ground along with the rear-guard.

When Dumezier threw off the disguises at the camp of Maude, arresting the deputies from the convention, General Levenevu entrusted to young Hochel the delicate charge of carrying the news to Paris. His conduct on this occasion was so highly approved of by the administration, that he was raised to the rank of adjutant-general, and chief of battalion; but he declined a higher rank than captain and aide-de-camp to his patron.

When the British troops and the Austrians besieged Dunkirk, Houde, who was ordered to cover the place, threw in supplies under the command of Souham and Adjutant-general Hochel, the latter of whom inspired all around him with enthusiasm; keeping up the spirits of the troops and harassing the enemy by frequent sallies, while the right wing and centre of the besieging army were attacked by Jourdan. Hochel constructed several advanced works before the place, and for six weeks together was never in a bed. The representatives with the army, as a reward for his activity, appointed him chief of brigade.

Having obtained this rank, he was sent into Austrian Flanders, where invariable success attended all his movements. And when only 25 years of age, he was appointed commander in chief of the army of the Moselle, which had remained for a long time inactive, and even experienced some disgrace under Houde. Few scenes of action could be more inauspicious than that upon which Hochel was now about to enter. The Austrians and Prussians were about 100,000 strong, under the command of the first officers in Europe, which presented a formidable front from the Upper Palatinate to the Hunsrück: and almost every position might be deemed impregnable. The troops of General Hochel were nearly undisciplined, and the nature of their situation rendered them dispirited; but their leader first endeavoured to gain their confidence, which he conceived made a general invincible; he restored military discipline; investigated the characters and talents of his officers; and punished or rewarded as necessity required.

To inspire the inhabitants on the frontiers with courage was his next object, for which purpose he visited the different towns in his vicinity, frequented popular societies, and addressed them in person; so that he not only secured a high degree of confidence, but even procured volunteers, clothes, and provisions. Having received instructions from the committee of public safety to raise the siege of Bitche and Landau; he drew a number of troops from the different garrisons, and on the event of an attack on the quarter he had weakened, he gave orders to General Moreau to shut himself up in Thionville, which place he charged to defend until death. He formed such a general plan of operations as gave the strongest evidence of his great military talents; for if the subordinate parts of it miscarried (which was actually the case), the grand object, the effecting a junction with Picquet, who commanded the army on the Rhine, was still within his reach. By a sudden and formidable manœuvre, he so astonished the enemy, that they immediately quitted the Sarre, and after experiencing a defeat, retired towards the heights of Bliscaestrel, with the loss of 700 men killed upon the field. The duke of Brunswick retreated towards Kayserlautern, at which place the whole of the Prussian columns formed a junction. General Hochel was well aware that his great object could be attained, if he could tranquillize the enemy at this place, and therefore he began to scale the mountains, and when he reached the plain on the top, he found them deeply entrenched. In defiance of this advantageous position, he determined to give them battle, and as soon as the signal gun was fired, he advanced from the ranks, and tossing his hat in the air, he exclaimed “Long live the republic!” The attack on his part was bold, and the defence of the enemy was obstinate; about 40,000 were engaged on each side, but the able manner in which the duke of Brunswick had fortified his position, gave him evidently the advantage. After fighting for two days, Hochel obtained little or no advantage. The ammunition of the Prussians being exhausted, he next day determined to carry their entrenchments at the point of the bayonet; but being informed that they held obtained a supply during the night, he found it necessary to retreat. But he soon after relieved Landau, and effected a junction with General Picquet, being appointed commander in chief of both armies.

The victorious Hochel afterwards made himself master of Gernsheim; Worms and Spire opened their gates to receive him; and Fort Vauban was retaken. It was his determination to cross the Rhine at Kassel, or Offenbach, and venture into the heart of Germany with 25,000 men; to which movement Picquet was unfriendly, and had the address to prevail with the representatives then present to refuse their sanction. Robespierro now regarded him with a jealous eye; all his plans were treated with unmerited indignity, and his arrest was resolved on. This, however, would have been a desperate attempt at the head of his victorious troops, and therefore he was offered the chief command of the army of Italy; but no sooner had he arrived at Nice than he was sent a prisoner to Paris, where he remained confined for many months, almost entirely forgotten.

Another temporary revolution procured his liberty, and Carnot consented to his being again employed, although he was far from being his warm friend.

He was appointed to the command of the army destined to protect the coasts of Cherbourg, a situation which by no means agreed with his disposition; for he was often heard to exclaim “how much happier are they who fight against the Prussians!” His situation was indeed disagreeable, for it was Frenchmen fighting against Frenchmen, and he succeeded a number of generals who had been nearly all of them degraded. His keen discernment enabled him to observe that ignorance and superstition were at the bottom of the contest, which made him adopt a plan of procedure very different from those of his predecessors; and he made this singular assertion to the committee of public safety, that a “few proclamations would be productive of infinitely more effect than sixteen pounds.” He checked the depredations of his own soldiers, restored the confidence of the peasantry, and so highly satisfied the government, that the command of the district of Brest was committed to him. So profligate and abandoned had been the conduct of his predecessors, that he could not
Hoche. not procure a lodging at Rennes, which he had come to protect from the insurgents, although he offered an extravagant prize for it. Soon, however, he was enabled to disarm their prejudices; for instead of hunting down the priests, he allowed the celebration of the mass, ordered the clergy to be protected, and took many of the confessors into pay. These were not like the plas of so young a man; they would have done honour to one who had studied human nature much longer than he had been in existence.

We have said that he protected both the priests and the people, but he discovered no disposition to negotiate with the chiefs. But the government having positively ordered him to do so, he began a treaty with Carmartin and some others, from which he was decidedly of opinion that the chief leaders might be gained over by money, and commissions in the republican army. He was accustomed to say, "with two hundred thousand livres and ten part of epauletts, I could gain over a majority of these men; as for the rest, a cane will suffice." The chiefs imposed upon the representatives of the army, but the general was not so easily deceived. Clermont having been permitted to travel through the cantons in which he had some influence, ostensibly to put a period to hostilities, was arrested by orders of General Hoche, being taken in the act of issuing false emissaries. Carmartin, another rebel chief, gave the money to the royalists which he had received from the republic, and recruited an army of Chouans in the name of Louis XVIII. Government now perceived the necessity of giving General Hoche a discretionary power, who in consequence thereof arrested Carmartin; and being apprehensive that it was the design of Decius to take possession of the arsenal of Cisy, he marched against that leader, putting him and 300 of his associates to the bayonet.

When the ill-fated expedition against Quiberon was undertaken, and an English flotilla with ten thousand emigrants made a descent, and took possession, without opposition, of Penthièvre, and the peninsula it commands, Hoche having received strong reinforcements, commenced offensive operations, and determined to carry Fort Penthièvre by assault. This was opposed by the engineers as by far too desperate an undertaking, who recommended a regular siege; but the general was not to be diverted from the steady execution of his purpose. Having divided his army into three columns, he marched during the night, though assailed by a dreadful tempest. The fort was discovered about the dawn of day, which poured upon them such a tremendous fire of grape shot, that two of the divisions began to retire; but a general cry of victory soon made them return. Three hundred emigrants were put to death.

His next great military project was an expedition against Guernsey and Jersey, which we are told, was rejected by the influence of Boissy d'Anglas, who was at that time a member of the committee of public safety. But having obtained the chief command of the army of the West, the whole charge of the war in La Vendee was committed to his management, to which he was resolved to put a glorious termination, presenting the deluded people with the olive branch in one hand, and the sword in the other. Having granted a pardon to all who had been deceived, he proposed to unite the armies of Cherbourg, Brest, and the West, under the appellation of the army of the coasts of the Ocean, which by the influence of Barras, was instantly adopted. Having marched against Charette with a body of troops, that chief was seized and ordered to be executed. In passing through Sarthe, Maine, Loire, and Morbihan, with his moving columns, he gave no quarter to the chiefs; but when he beheld the ignorant peasantry in arms, and at his mercy, he used to exclaim, These unfortunate people are Frenchmen! He declared the principal towns to be no longer in a state of siege; abolished martial law, dissolved military tribunals; and, after succeeding in the accomplishment of his wishes in the space of eight weeks, he was honoured with the title of Pacificateur of La Vendee.

The next object which attracted his whole attention was the conquest of England, a country with which he appears to have been little acquainted. His plan, however, was much approved of by the minister of marine (Truguet); but every thing was wanting for the accomplishment of an undertaking so very extraordinary; and the attempt was restricted to Ireland alone. For this purpose he set out for Brest, and procured the removal of Admiral Villaret-Joyeuse, because it was insalutable to his favourite project. General Hoche, instead of the dock-yards, hastened the public works, and prepared every thing connected with a great naval equipment. It was the declaration of Rear-admiral Bruix, who fell at Aboukir, that Hoche would become the best minister of marine that France ever beheld, if he had only a single year's experience. When every thing was in readiness for the proposed descent upon Ireland, General Hoche embarked on board the frigate La Fraternité, this being the first time he was ever at sea. In a gale of wind he was separated from his army, which consisted of 15,000 men; part of the fleet appeared off the coast of Ireland, and some ships entered Bantry Bay; but without their general they could undertake nothing; and therefore after holding a council of war, they determined to return. General Hoche arrived some time after, but learning that the fleet had given up the enterprise, he steered back to the French coast, weeping, it is said, when he got the last sight of Ireland.

It was believed by some, that General Hoche would be disgraced on account of the total failure of this expedition; but instead of any such attempt, he was chosen to the command of the army of the Sambre and Meuse, which at different periods had been commanded by Jourdan, Kleber, and Bernadotte. The troops had continued for some time inactive, and so shocking were the excesses they had been accustomed to commit, that the officer whom he succeeded called them a hordes of robbers. These unfavourable circumstances, however, did not terrify young Hoche, who commenced his labours with the reformation of the officers: he then bettered the situation of the men; attended to the very minutiae of the service, and cast an eagle's eye on the conduct of the commissaries. Being also entrusted with the administration of the conquered countries, he appointed a board of five members to redress all grievances which might be brought before it.

Having signified to the enemy that the armistice was at an end, he dispatched a courier to the directory to inform
HODGE, a term purely Greek, ἕδος, signifying guide. The word is chiefly used as the title of a book composed by Anastasius the Senate, towards the close of the fifth century; being a method of disputing against the heretics, particularly the Acephali.

Mr. Toland has also published a dissertation under the same title. Its subject is the pillar of fire, &c. which went before the Israelites as a guide in the desert.

HODGECODGE. See HODGEPOT.

HODGEMAN, a term formerly used for a young scholar admitted from Westminster-school to be student in Christ-church in Oxford.

HODY, Humphry, a learned English divine, was born in 1659. At 21 years of age, he published his celebrated dissertation against Aristotle's history of the 70 interpreters; which was received with great applause by all the learned, Isaac Vossius excepted, who could not bear to have his opinions opposed by such a youth. Twenty years after, he treated the subject more fully in a work entitled, De Bibliorum testibus originalibus, versionibus Gracis, et Latina vulgata, libri IV. In 1689, he wrote the Prolegomena to John Melai's Chronicle, printed at Oxford; and the year after was made chaplain to Dr. Stillingsfield bishop of Worcester. The deprivation of the nonjuring bishops engaged him in a controversy with Mr. Dodwell; which recommended him to Archbishop Tillotson, to whom, and his successor Dr. Tennison, he was domestic chaplain. In 1698 he was made regius professor of the Greek tongue at Oxford, and archdeacon of Oxford in 1704. On occasion of the controversy about the convocation, he, in 1701, published A History of English councils and convocations, and of the clergy's sitting in parliament, &c. He died in 1706, leaving in MS. An Account of those learned Grecians who retired to Italy on the taking of Constantinople, &c. which was published in 1742 by Dr. Jebb.

HOE, or HOE, a husbandman's tool, made like a cooper's adz, to cut up weeds in gardens, fields, &c. This instrument is of great use, and ought to be much more employed than it is in hacking and clearing the several corners and patches of land in spare times of the year, which would be of no small advantage to it.

HORSE-HOE, a large kind of hoe drawn by horses, and used to stir the intervals in the new husbandry, and clear the corn from weeds. See Agriculture.

HOEING, in the new husbandry, is the breaking or dividing the soil by tillage while the corn or other plants are growing therein.—It differs from common tillage (which is always performed before the corn or plants are sown or planted) in the time of performing it; and it is much more beneficial to the crop than any other tillage. This sort of tillage is performed various ways, and by means of different instruments, as described under the article Agriculture.

HOEI-CHOU, the most southern city of the province of Kiang-nan in China, and one of the richest of the empire. The people are economical and temperate, but they are active and enterprising in trade; they boast of their tea, varnish, and engravings, which are indeed the most esteemed in China. It has dependent upon it six cities of the third class; the mountains which surround this canton contain gold, silver, and copper mines.

HOEMATOPUS, a genus of birds of the order of grallae. See Ornithology Index.

HOFFMAN, the name of several eminent physicians; of whom Maurice Hoffman, and John Maurice Hoffman his son, practised at Altorf. Maurice died in 1698, leaving behind him many works; and was succeeded.
succeeded by his son John Maurices, who wrote as well as his father, and died in 1727, highly esteemed by the faculty.—Frederic Hoffman, probably of the same family, was born at Magdeborg in 1660. The principal known circumstances of his life are, his journey into Holland and England, where he became intimately acquainted with Paul Herman and Robert Boyle, never taking any fees, being supported by his annual stipend; his curate the emperor Charles VI. and Frederic I. king of Prussia of invertebrate diseases; to which may be added, his accurate knowledge of the nature and virtues of mineral waters. He survived his 80th year, and his works, which are in great esteem, were printed in six volumes folio at Geneva, in 1740.

HOFFMANISTS, in ecclesiastical history, denote those who espoused the sentiments of Daniel Hoffman, professor of the university of Helmstadt, who, from the year 1598, maintained, that philosophy was a mortal enemy to religion, and that what was true in philosophy was false in theology. These absurd and pernicious tenets occasioned a warm and extensive controversy: at length Hoffman was compelled by Julius duke of Brunswick to retract his invectives against philosophy, and to acknowledge, in the most open manner, the harmony and union of sound philosophy with true and genuine theology.

HOG. See Sus, Mammalia Index.

Hog, on board of a ship, is a sort of flat scrubbing broom, formed by inclosing a number of short twigs of birch or such wood between two pieces of plank fastened together, and cutting off the ends of the twigs; and serving to scrape the filth from a ship's bottom under water, particularly in the act of boot-topping. For this purpose they fit to this broom a long staff with two ropes; one of which is used to thrust the hog under the ship's bottom, and the other to guide and pull it up again close to the planks. This business is commonly performed in the ship's boat, which is confined as close as possible to the vessel's side during the operation, and shifted from one part of the side to another till the whole is completed.

Hog's Dung is by Mortimer reckoned one of the richest manures we are acquainted with, and the next in value to sheep's dung; and is found to be equal in virtue to twice the quantity of any other dung except this. The ancients seem to have been displeased with it on account of its breeding woods; but this is only accusing it of being too rich; for any dung will do this when laid too thick. It is an excellent manure for pasture-grounds, and excels all other kinds of dung for trees. The farmers who use this dung for their lands, generally take care to save it, by well-paving the sty, and increase the quantity by throwing in bean-stalks, stubble, and many other things of a like nature; and, by good management of this kind, many farmers have procured 50 or 60 loads of excellent manure a-year out of a small sty. The very best way of using this dung is by mixing it with horse-dung; and for this reason it is best to have the sty near the stable, that the two cleansings may be mixed in one heap, and used together.

They have in many parts of Staffordshire a poor, light, shallow land, on which they sow a kind of white
Hogarth. can be ascertained to be the work of Hogarth, it may
be presumed that he began business on his own account
at least as early as 1720.

His first employment seems to have been in engraving
of arms and shop bills. The next was to design
and furnish plates for booksellers. Mr Bowles, at the
Black Horse in Gough Hill, was one of his earliest pa-
trons, whose prices were very low. His next friend
in that line was Mr Philip Overton, who paid him
somewhat better for his labour and ingenuity.

There are still many family pictures by Hogarth
existing, in the style of serious conversation-pieces. What
the prices of his portraits were, Mr Nichols strove in
vain to discover; but he suspects they were originally
very low, as the people who are best acquainted with
them choose to be silent on that subject.

It happened, in the early part of Hogarth's life, that
a nobleman who was uncommonly ugly and deformed
came to sit for his picture. It was executed
with a skill that did honour to the artist's abilities;
but the likeness was rigidly observed, without even the
necessary attention to compliment or flattery. The
peer, disgusted at this counterpart of his dear self, nev-
er once thought of paying for a reflector that would
only insult him with his deformities. Some time was
wasted to elapse before the artist applied for his mo-
ney; but afterwards many applications were made by
him (who had then no need of a banker) for payment
without success. The painter, however, at last hit
upon an expedient, which he knew must alarm the
nobleman's pride, and by that means answer his pur-
pose. It was couched in the following card: "Mr
Hogarth's dutiful respects to Lord ——; finding that
he does not mean to have the picture which was drawn
for him, is informed again of Mr H's necessity for the
money; if, therefore, his lordship does not send for it
in three days, it will be disposed of, with the addition
of a tail, and some other little appendages, to Mr
Hare, the famous wild-beast man; Mr H having
given that gentleman a conditional promise of it for an
exhibition-picture on his lordship's refusal." This inti-
mation had the desired effect. The picture was sent
home, and committed to the flames.

Mr Walpole has remarked, that if our artist "in-
dulged his spirit of ridicule in personalities, it never
proceeded beyond sketches and drawings;" and won-
ders "that he never, without intention, delivered the
very features of any identical person." Mr Nichols as-
sures us, from unquestionable authority, that almost all
the personages who attended the levees of the Rake
were undoubted portraits; and that in "Southwark Fair,"
and the "Modern Midnight Conversation," as many
more were discoverable. While Hogarth was painting
the "Rake's Progress," he had a summer residence at
Lisleworth; and never failed to question the company
who came to see these pictures, if they knew for whom
one or another figure was designed. When they guessed
wrong, he set them right.

The duke of Leeds has an original scene in the
"Beggar's Opera," painted by Hogarth. It is that
in which Lucy and Polly are on their knees, before
their respective fathers, to intercede for the life of the
hero of the piece. All the figures are either known
or supposed to be portraits. If we are not misinformed,
the late Sir Thomas Robinson (perhaps better known
by the name of Sir Thomas Newman) is standing in one
of the side-boxes. Macbeth, unlike his spruce repre-
sentative on our present stage, is a slouching bully;
and Polly appears happily disembarrassed of such a
hoop as the daughter of Fagin within our younger
memories has worn. Mr Walpole has a picture of a
scene in the same piece, where Macbeth is going to
execution. In this also the likenesses of Walpole
and Miss Fenton, afterwards duchess of Bolton (the first
and original Macbeth and Polly) are preserved. In
the year 1726, when the affair of Mary Tofts, the
rabbit-brother of Godalming, engaged the public atten-
tion, a few of our principal surgeons subscribed their
guinea a-piece to Hogarth, for an engraving from a
ludicrous sketch he had made on that very popu-
lar subject. This plate, among other portraits, con-
tains that of St Andrews, then anatomist to the royal
household, and in high credit as a surgeon. In 1727,
Hogarth agreed with Morris an upholsterer to furnish
him with a design on canvas, representing the element
of earth as a pattern for tapestry. The work not being
performed to the satisfaction of Morris, he refused to
pay for it; and our artist, by a suit at law, recovered
the money.

In 1730, Mr Hogarth married the only daughter of
Sir James Thornhill, by whom he had no child.
This union, indeed, was a stolen one, and consequent-
lly without the approbation of Sir James, who, consi-
dering the youth of his daughter, then barely 18, and
the slender finances of her husband, as yet an obscure
artist, was not easily reconciled to the match. Soon
after this period, however, he began his "Harlot's
Progress" (the coffin in the last plate is inscribed Sept.
2, 1731;) and was advised by Lady Thornhill to have
some of the scenes of it placed in the way of his father-
in-law. Accordingly, one morning early, Mrs Hog-
arth undertook to convey several of them into his
dining-room. When he arose, he inquired from whence
they came; and being told by whom they were intro-
duced, he cried out, "Very well; the man who can
furnish representations like these can also maintain a
wife without a portion." He designed this remark as
an excuse for keeping his purse-strings close; but, soon
after, became both reconciled and generous to the
young people. An allegorical ceiling by Sir James
Thornhill is at the house of the late Mr Hoggins,
at Headly Park, Hants. The subject of it is the story of
Zeephyrus and Flora; and the figure of a satyr and others
were painted by Hogarth.

In 1732, Hogarth ventured to attack Mr Pope, in
a plate called "The Man of Taste;" containing a
view of the Gate of Burlington-house, with Pope white-
washing it and bespattering the duke of Chandos's
coach. This plate was intended as a satire on the
translator of Homer, Mr Kent the architect, and the
earl of Burlington. It was fortunate for Hogarth that
he escaped the lash of the former. Either Hogarth's
obscenity at that time was his protection, or the bard
was too prudent to exasperate a painter who had al-
day given such proof of his abilities for satire.

Soon after his marriage, Hogarth had summer lodg-
ings at South Lambeth: and being intimate with Mr
Tyers, contributed to the improvement of the Spring
Gardens at Vauxhall, by the hint of embellishing them
with paintings, some of which were the suggestions of
Hogarth, his own truly comic pencil. For his assistance, Mr. Tyres gratefully presented him with a gold ticket of admission for himself and his friends.

In 1733, his genius became conspicuously known. The third scene of his "Harlot's Progress" introduced him to the notice of the great. At a board of treasury which was held a day or two after the appearance of that print, a copy of it was shown by one of the lords, as containing, among other excellencies, a striking likeness of Sir John Gonson. It gave universal satisfaction: from the treasury each lord repaired to the print-shop for a copy of it, and Hogarth rose completely into fame.

The ingenious Abbé Du Bos has often complained that no history-painter of his time went through a series of actions, and thus, like an historian, painted the successive fortunes of an hero from the cradle to the grave. What Du Bos wished to see done, Hogarth performed. He launches out his young adventurer a simple girl upon the town, and conducts her through all the vicissitudes of wretchedness to a premature death. This was painting to the understanding and to the heart; none had ever before made the pencil subservient to the purposes of morality and instruction: a book like this is fitted to every soil and every observer, and he that runs may read. Nor was the success of Hogarth confined to his persons. One of his excellencies consisted in what may be termed the furniture of his pieces; for as, in sublime and historical representations, the fewer trivial circumstances are permitted to divide the spectator's attention from the principal figures, the greater is their force; so, in scenes copied from familiar life, a proper variety of little domestic images contributes to throw a degree of verisimilitude on the whole. "The Rake's levee-room," says Mr. Walpole, "the nobleman's dining-room, the apartments of the husband and wife in Marriage à la Mode, the alderman's parlour, the bed-chamber, and many others, are the history of the manners of the age."

In 1745, Hogarth sold about 20 of his capital pictures by auction; and in the same year acquired additional reputation by the six prints of "Marriage à la Mode," which may be regarded as the groundwork of a novel called "The Marriage Act," by Dr. Shebbeare, and of "The Clandestine Marriage."

Soon after the peace of Aix la Chapelle, he went to France, and was taken into custody at Calais while he was drawing the gate of that town; a circumstance which he has recorded in his picture, entitled "O the Roast Beef of Old England!" published March 26, 1749. He was actually carried before the governor as a spy, and after a very strict examination committed a prisoner to Grasraine, his landlord, on his promising that Hogarth should not go out of his house till he was to embark for England.

In 1753, he appeared to the world in the character of an author, and published a quarto volume, entitled, "The Analysis of Beauty, written with a view of fixing the fluctuating ideas of taste." In this performance he shows, by a variety of examples, that a curve is the line of beauty, and that round swelling figures are most pleasing to the eye; and the truth of his opinion has been countenanced by subsequent writers on the subject. In this work, the leading idea of which was hieroglyphically thrown out in a frontispiece to his works in 1745, he acknowledges himself indebted to his friends for assistance, and particularly to one gentleman for his corrections and amendments of at least a third part of the wording. This friend was Dr. Benjamin Hoadley the physician, who carried on the work to about the third part, Chap. IX. and then, through indisposition, declined the friendly office with regret. Mr. Hogarth applied to his neighbour Mr. Ralph; but it was impossible for two such persons to agree, both alike vain and positive. He proceeded no farther than about a sheet, and they then parted friends, and seem to have continued such. The kind office of finishing the work, and superintending the publication, was lastly taken up by Dr. Morell, who went through the remainder of the book. The preface was in like manner corrected by the Reverend Mr. Townley. The family of Hogarth rejoiced when the last sheet of the "Analysis," was printed off; as the frequent disputes he had with his coadjutors, in the progress of the work, did not much harmonize his disposition. This work was translated into German by Mr. Myllin, when in England, under the author's inspection; and the translation was printed in London, price five dollars. A new and correct edition was in 1734 proposed for publication at Berlin, by Ch. Fr. Vok, with an explanation of Mr. Hogarth's satirical prints, translated from the French; and an Italian translation was published at Leghorn in 1761.

Hogarth had one failing in common with most people who attain wealth and eminence without the aid of liberal education.—He affected to despise every kind of knowledge which he did not possess. Having established his fame with little or no obligation to literature, he either conceived it to be needless, or decreed it because it lay out of his reach. His sentiments, in short, resembled those of Jack Cade, who pronounced sentence on the clerk of Chatham because he could write and read. Till, in evil hour, this celebrated artist commenced author, and was obliged to employ the friends already mentioned to correct his "Analysis of Beauty," he did not seem to have discovered that even spelling was a necessary qualification; and yet he had ventured to ridicule the late Mr. Rich's deficiency as to this particular, in a note which lies before the Rake whose play is refused while he remains in confinement for debt. Previous to the time of which we are now speaking, one of our artist's common topics of declamation was the uselessness of books to a man of his profession. In "Beer-street," among other volumes consigned by him to the pastry-cook, we find Turnbull "on Ancient Painting," a treatise which Hogarth should have been able to understand before he ventured to condemn. Garrick himself, however, was not more ductile to flattery. A word in praise of "Sigismunda," his favourite work, might have commanded a proof print, or forced an original sketch out of our artist's hands. The following authenticated story of our artist will also serve to show how much more easy it is to detect ill placed or hyperbolical adulation respecting others than when applied to ourselves. Hogarth being at dinner with the great Cheselden and some other company, was told that Mr. John Freke, surgeon of St. Bartholomew's hospital, a few evenings before, at Dick's coffeehouse, had asserted that Greene was
Hogarth was as eminent in composition as Handel. "That fellow Freke," replied Hogarth, "is always shooting his bolt absurdly one way or another! Handel is a giant in music!"

Greene only a light Florimel kind of a composer."—"Aye," says our artist's informant; "but at the same time Mr Freke declared you were as good a portrait-painter as Vandyck."—"There he was in the right," adds Hogarth; "and so by G—I am, give me my time, and let me choose my subject!"

A specimen of Hogarth's propensity to merriment, on the most trivial occasions, is observable in one of his cards requesting the company of Dr Arnold King to dine with him at the Mitre. Within a circle, to which a knife and fork are the supporters, the written part is contained. In the centre is drawn a pyes, with a mitre on the top of it; and the invitation of our artist concludes with the following sort on the Greek letters—to Eta Beta Pi. The rest of the inscription is not very accurately spelt. A quibble by Hogarth is surely as respectable as a conundrum by Swift.

In one of the early exhibitions at Spring-Gardens, a very pleasing small picture by Hogarth made its first appearance. It was painted for the earl of Charlemont, in whose collection it remains, and was entitled "Picquet, or Virtue in Danger"; and shows a young lady who during a tête à tête had just lost all her money to a handsome officer of her own age. He is represented in the act of returning her a handful of bank bills, with the hope of exchanging them for a softer acquisition and more delicate plunder. On the chimney-piece a watch case and a figure of Time over it, with the motto—NUNC. Hogarth has caught his heroine during this moment of hesitation, this struggle with herself, and has marked her feelings with uncommon success.

In the "Miser's Feast," Mr Hogarth thought proper to pillory Sir Isaac Sharpe, a gentleman proverbially avaricious. Hearing this, the son of Sir Isaac, the late Isaac Pacatus Sharpe, Esq. a young man of spirit, just returned from his travels, called at the painter's to see the picture; and, among the rest, asking the Ciceron "whether that odd figure was intended for any particular person?" on his replying "that it was thought to be very like one Sir Isaac Sharpe," he immediately drew his sword and slashed the canvas. Hogarth appeared instantly in great wrath; to whom Mr Sharpe calmly justified what he had done, saying, "that this was a very unwarrantable licence; that he was the injured party's son, and that he was ready to defend any suit at law," which, however, was never instituted.

About 1757, his brother-in-law, Mr Thornhill, resigned the place of king's serjeant-painter in favour of Mr Hogarth.

The last remarkable circumstance of his life was his contest with Mr Churchill. It is said that both met at Westminster-hall; Hogarth to take by his eye a ridiculous likeness of the poet, and Churchill to furnish a description of the painter. But Hogarth's print of the poet was not much esteemed, and the poet's letter to him was but little admired. Some pretend, indeed to say that it broke the painter's heart; but this we can from good authority say is not true. Indeed the report falls of itself; for we may as well say, that Hogarth's pencil was as efficacious as the poet's pen, Hogarth since neither long survived the contest.

It may be truly observed of Hogarth, that all his powers of delighting were restrained to his pencil. Having rarely been admitted into polite circles, none of his sharp corners had been rubbed off, so that he continued to the last a gross uncultivated man. The slightest contradiction transported him into rage. To some confidence in himself he was certainly entitled; for, as a comic painter, he could have claimed no honour that would not most readily have been allowed him; but he was at once unprincipled and variable in his political conduct and attachments. He is also said to have beheld the rising eminence and popularity of Sir Joshua Reynolds with a degree of envy; and, if we are not misinformed, frequently spoke with asperity both of him and his performances. Justice, however, obliges us to add, that our artist was liberal, hospitable, and the most punctual of paymasters; so that, in spite of the emoluments his works had procured to him, he left but an inconsiderable fortune to his widow. His plates indeed are such resources to her as may not speedily be exhausted. Some of his domestics had lived many years in his service; a circumstance that always reflects credit on a master. Of most of these he painted strong likenesses on a canvas still in Mrs Hogarth's possession.

Of Hogarth's lesser plates many were destroyed. When he wanted a piece of copper on a sudden, he would take any from which he had already worked off such a number of impressions as he supposed he could sell. He then sent it to be effaced, beat out, or otherwise altered to his present purpose. The plates which remained in his possession were secured to Mrs Hogarth by his will, dated Aug. 12. 1764, chargeable with an annuity of 8ol. to his sister Anne, who survived him. When, on the death of his other sister, she left off the business in which she was engaged, he kindly took her home, and generously supported her, making her, at the same time, useful in the disposal of his prints. Want of tenderness and liberality to his relations was not among the failings of Hogarth.

The following character of Hogarth as an artist is given by Mr Gipson in his Essay on Prints. "The works of this master abound in true humour, and the entire which is generally well directed: they are admirable moral lessons, and a fund of entertainment suited to every taste; a circumstance which shows them to be just copies of nature. We may consider them too as valuable repositories of the manners, customs, and dresses of the present age. What a fund of entertainment would a collection of this kind afford, drawn from every period of the history of Britain!—How far the works of Hogarth will bear a critical examination, may be the subject of a little more inquiry."

"In design, Hogarth was seldom at a loss. His invention was fertile, and his judgment accurate. An improper accident is rarely introduced, a proper one rarely omitted. No one could tell a story better, or make it, in all its circumstances, more intelligible. His genius, however, it must be owned, was suited only to low or familiar subjects; it never soared above common life; to subjects naturally sublime, or which from antiquity or other accidents borrowed dignity, he could not..."
Hogarth.

In composition we see little in him to admire. In many of his prints the deficiency is so great as plainly to imply a want of all principle, which makes us ready to believe, that when we do meet with a beautiful group, it is the effect of chance. In one of his minor works, the Idle Prentice, we seldom see a crowd more beautifully managed than in the last print. If the sheriff officers had not been placed in a line, and had been brought a little lower in the picture, so as to have formed a pyramid with the cart, the composition had been unexceptionable; and yet the first print of this work is such a striking instance of disagreeable composition, that it is amazing how an artist who had any idea of beautiful forms could suffer so unmastery a performance to leave his hands. Of the distribution of light Hogarth had as little knowledge as of composition. In some of his pieces we see a good effect, as in the Execution just mentioned; in which, if the figures at the right and left corners had been kept down a little, the light would have been beautifully distributed on the fore-ground, and a fine secondary light spread over part of the crowd. But at the same time, there is so obvious a deficiency in point of effect in most of his prints, that it is very evident he had no principles. Neither was Hogarth a master in drawing. Of the muscles and anatomy of the head and hands he had perfect knowledge; but his trunks are often badly moulded, and his limbs ill set on; yet his figures, upon the whole, are inspired with so much life and meaning, that the eye is kept in good-humour in spite of its inclination to find fault. The author of the Analysis of Beauty, it might be supposed, would have given us more instances of grace than we find in the works of Hogarth; which shows strongly that theory and practice are not always united. Many opportunities his subjects naturally afford of introducing graceful attitudes, and yet we have very few examples of them. With instances of picturesque grace his works abound. Of this expression, in which the force of his genius lay, we cannot speak in terms too high. In every mode of it he was truly excellent. The passions he thoroughly understood, and all the effects which they produce in every part of the human frame. He had the happy art also of conveying his ideas with the same precision with which he conceived them. He was excellent too in expressing any humorous oddity which we often see stamped upon the human face. All his heads are cast in the very mould of nature. Hence that endless variety which is displayed through his works; and hence it is that the difference arises between his heads and the affected caricatures of those masters who have sometimes amused themselves with patching together an assemblage of features from their own ideas. Such are Spanioloit’s: which, though admirably executed, appear plainly to have no archetypes in nature. Hogarth’s, on the other hand, are collections of natural curiosities. The Oxford-heads, the Physicians arms, and some of his other pieces, are expressly of this humorous kind. They are truly comic, though ill-natured effusions of mirth: more entertaining than Spanioloit’s, as they are pure nature; but less innocent, as they contain ill-directed ridicule.—But the species of expression in which this master perhaps most excels, is that happy art of catching those peculiarities of art and gesture which the ridiculous part of every profession contract, and which for that reason become characteristic of the whole. His counsellors, his undertakers, his lawyers, his usurers, are all conspicuous at sight. In a word, almost every profession may see in his works that particular species of affectation which they should most endeavour to avoid. The execution of this master is well suited to his subjects and manner of treating them. He etches with great spirit, and never gives one unnecessary stroke.

Hogshead, in Commerce, a measure of capacity containing 63 gallons; = 16 gallons in Scotland.

Hogue, a town and cape on the north-west point of Normandy in France; near which Admiral Rook burnt the French admiral’s ship called the Rising Sun, with 12 more large men of war, the day after the victory obtained by Admiral Russell near Cherbourg in May 1692. W. Long. 2°. N. Lat. 49° 50’.

Hoist, in sea-language, denotes the perpendicular height of a flag or ensign, as opposed to the fly, which signifies its breadth from the staff to the outer edge.

Hoisting signifies the operation of drawing up any body by the assistance of one or more tackles. Hoisting is never to be applied to the art of pulling up any body by the help of a single block, except in the exercise of extending the sails by drawing them upwards along the masts or stays, to which it is invariably applied.

Hoke-Day, Hock-Day, or Hock-Tuesday, in our ancient customs (dies Martis, quem quindecim postae vacant), the second Tuesday after Easter week; a solemn festival celebrated for many ages in England in memory of the great slaughter of the Danes in the time of King Ethelred, they having been in that reign almost all destroyed in one day in different parts of the kingdom, and that principally by women. This is still kept up in some counties; and the women bear the principal sway in it, stopping all passengers with ropes and chains, and exacting some small matter from them to make merry with. This day was very remarkable in former times, insomuch as to be used on the same footing with Michaelmas for a general term or time of account. We find leases without date reserving so much rent payable ad duos anni terminus, scil. ad hoke-day, et ad festum Michaelis. In the account of Magdalen college, Oxford, there is yearly an allowance pro mulctuabilis hockantibus of some manors of theirs in Hampshire; where the men hock the women on Mondays and the women hock them on Tuesdays. The meaning of it is, that on that day the women in merriment stopped the way with ropes, and pulled passengers to them, desiring something to be laid out for pious uses.

Hoke-Day Money, or Hoke-Tuesday Money, a tribute anciently paid the landlord, for giving his tenants and bondmen leave to celebrate hock-day, or hoke-day, in memory of the expulsion of the domineering Danes.

Ho-kién-fú, a city of China, and one of the principal in the province of Pe-tcheli. It has two cities of the second, and fifteen of the third class in its district, but is remarkable for nothing but the neatness of its streets.

Holbein, Hans, a celebrated painter, born at Basel in Switzerland in 1498, learned the rudiments of his art from his father, who was a painter; but soon showed his superior genius. In the town-house of
HOL

of Basil he painted our Saviour's Passion; and in the
fish-market of the same city Death's Dance, and a
Dance of Peasants, which were extremely admired;
and Erasmus was so pleased with them, that he desired
him to draw his picture, and was ever after his friend.
He staid some years longer at Basil, till his necessities,
occaisioned by his own extravagance and an increasing
family, made him comply with Erasmus's persuasions
to go to England. In his journey he staid some days
at Strasburg, where it is said he applied to a very great
painter for work, who took him in, and ordered him
to give a specimen of his skill. On which Holbein
finished a piece with great care, and painted a fly on the
most eminent part of it; after which he privately with-
drew in the absence of his master, and pursued his jour-
ney, without saying any thing to any body. When
the painter returned home, he was astonished at the
beauty and elegance of the drawing; and especially at
the fly, which he at first took for a real one, and
devoured to remove it with his hand. He now sent all
ever the city for his journeyman; and after many in-
quires, discovered that he had been thus deceived by
the famous Holbein.—Holbein having in a manner
begged his way to England, presented a letter of re-
commendation from Erasmus to Sir Thomas More, and
also showed him Erasmus's picture. Sir Thomas, who
was then lord chancellor, received him with all the joy
imaginable, and kept him in his house between two
and three years; in which time he drew Sir Thomas's
picture, and those of many of his relations and friends.
Holbein one day happening to mention a nobleman
who had some years before invited him to England,
Sir Thomas was very solicitous to know who it was.
Holbein said that he had forgot his title, but re-
collected his face so well, that he believed he could draw
his likeness; which he did so perfectly, that the noble-
man, it is said, was immediately known by it. The
chancellor having now adorned his apartments with the
productions of this great painter, resolved to introduce
him to Henry VIII. For this purpose he invited
that prince to an entertainment; having, before he
came, hung up all Holbein's pieces in the great hall,
in the best order, and placed in the best light. The
king, on his first entrance into this room, was so
charmed with the sight, that he asked whether such an
artist was now alive, and to be had for money! Upon
this, Sir Thomas presented Holbein to his majesty,
who immediately took him into his service, and brought
him into great esteem with the nobility and gentry, by
which means he drew a vast number of portraits. But
while he was here, there happened an affair which
might have proved fatal to him, had he not been pro-
tected by the king. On the report of this painter's
character, a lord of the first quality came to see him
when he was drawing a figure after the life. Holbein
sent to desire his lordship to defer the honour of his
visit to another day; which the nobleman taking for
an affront, broke open the door, and very rudely went
up stairs. Holbein hearing a noise, came out of his
chamber; and meeting the lord at his door, fell into a
violent passion, and pushed him backwards from the
top of the stairs to the bottom. However, immediately
reflecting on what he had done, he escaped from the
tumult he had raised, and made the best of his way to
the king. The nobleman, much hurt, though not so
much as he pretended, was there soon after him; and
upon opening his grievance, the king ordered Holbein
to ask his pardon. But this only irritated the noble-
man the more, who would not be satisfied with less
than his life; upon which the king sternly replied,
"My lord, you have not now to do with Holbein
but with me; whatever punishment you may contrive
by way of revenge against him, shall certainly be in-
flicted on yourself. Remember, pray, my lord, that
I can whenever I please make seven lords of seven
ploughmen, but I cannot make one Holbein of even
seven lords." Holbein died of the plague at his lodg-
ings at Whitehall in 1544. "It is amazing (says De
Piles, that a man born in Switzerland, and who had
never been in Italy, should have so good a gusto,
and so fine a genius for painting." He painted alike in every
manner; in fresco, in water-colours, in oil, and in
miniature. His genius was sufficiently shown in the
historical style, by two celebrated compositions which
he painted in the hall of the Styllard company. He
was also eminent for a rich vein of invention, which he
showed in a multitude of designs which he drew for
engravers, statuaries, jewellers, &c. and he had this
singularity, that he painted with his left hand.
HOLCUS, INDIAN MILLER, or CORZ, a genus of
plants belonging to the polygamia class, and in the
natural method ranking under the 4th order, Gramina.
See Botany Index.

HOLD, the whole interior cavity or belly of a
ship, or all that part of her inside which is compre-
hended between the floor and the lower-deck through-
out her whole length.—This capacious apartment usu-
ally contains the ballast, provisions, and stores of a ship
of war, and the principal part of the cargo in a mer-
chantman. The disposition of these articles with re-
gard to each other, naturally falls under considera-
tion in the article Stowage; it suffices in this place to say,
that the places where the ballast, water, provisions,
and liquors are stowed, are known by the general
name of the hold. The several store-rooms are sepa-
rated from each other by bulk-heads, and are deno-
nimated according to the articles which they contain,
the sail-room, the bread-room, the fish-room, the spiri-

troom, &c.

HOLDER, William, D. D. an English divine,
was born in Nottinghamshire, educated in Pembroke-
hall, Cambridge, and in 1642 became rector of Blech-
ingdon of Oxford. In 1660 he proceeded D. D. was
afterwards canon of Ely, fellow of the Royal Society,
canon of St Paul's, sub-dean of the royal chapel, and
sub-almoner to his majesty. Dr Holder was a very
accomplished scholar, and greatly distinguished himself,
by making a young gentleman of rank who was born
defect and dumb, to speak. This gentleman's name
was Alexander Popham, son of Colonel Edward Pop-
ham, who was some time an admiral in the service of
the long parliament. The cure was performed by him
in his house at Blechington in 1693; but Popham lost
what he had been taught by Holder after he was
called home to his friends, was sent to Dr Wallis, who
brought him to his speech again. Holder published a
book, entitled "The Elements of Speech; an essay of
enquiry into the natural Production of Letters; with
an appendix concerning persons that are deaf and
dumb," 1669, 8vo. In the appendix he relates how
soon, and by what methods, he brought Popham to speak. In 1678, he published in 4to "A Supplement to the Philosophical Transactions of July 1670, with some reflections on Dr Wallis's letter there inserted." This was written to claim the glory of having taught Popham to speak, which Wallis in the said letter had claimed to himself; upon which the Doctor soon after published "A Defence of the Royal Society, and the Philosophical Transactions, particularly those of July 1670, in answer to the Cavils of Dr William Holder, 1678," 4to. Holder was skilled in the theory and practice of music, and wrote "A Treatise of the natural Grounds and Principles of Harmony, 1694," 8vo. He wrote also "A Discourse concerning Time, with Application of the natural Day, lunar Month, and solar Year, &c. 1694," 8vo. He died at Amen Corner in London, January 24, 1696-7, and was buried in St Paul's.

HOLDERNESS, a district of the east riding of Yorkshire, having the German sea on the east, and the Humber on the south. This district is remarkable for its rich soil and a large breed of horned cattle and horses. It had the title of an earldom, now extinct.

HOLDSWORTH, Edward, a very polite and elegant scholar, was born about 1685, and educated at Winchester school. He was thence elected deny of Magdalen college, Oxford, in July 1705; took the degree of M. A. in April 1711; became a college-tutor, and had many pupils. In 1715, when he was to be chosen into a fellowship, he resigned his demesny and left the college, because unwilling to swear allegiance to the new government. The remainder of his life was spent in travelling with young noblemen and gentlemen as tutor; in 1741 and 1744 he was at Rome in this capacity. He died of a fever at Lord Digby's house at Coleshill in Warwickshire, December 30, 1747. He was the author of the "Musicipula," a poem, esteemed a master-piece in its kind, and of which there is a good English translation by Dr John Holdler, in vol. v. of Dodsley's Miscellanies. He was the author also of a dissertation, entitled "Phrasalia and Philippis; or the two Philippis in Virgil's Georgics attempted to be explained and reconciled to History," 1741, 4to: and of Remarks and Dissertations on Virgil; with some other classical Observations, published with several notes and additional remarks by Mr Spence, 1768, 4to. Mr Spence speaks of him in Polymathes, as one who understood Virgil in a more masterly manner than any person he ever knew.

HOLORACEÆ (from hoíros, "pot-herbs"); the name of the 12th order in Linnaeus's fragments of a natural method, consisting of plants which are used for the table, and enter into the economy of domestic affairs. See Botany Index.

HOLIBUT. See Pleuronectes, Ichthyology Index.

HOLINESS, or Sanctity; a quality which constitutes or denominates a person or thing holy: i.e. pure, or exempt from sin. The word is also used in respect of persons and things that are sacred, i.e. set apart to the service of God, and the uses of religion.

HOLINESS is also a title of quality attributed to the pope; as that of majesty is to kings. Even kings, when writing to the pope, address him under the venerable appellation of Your Holiness, or Holy Father; in Latin, Sanctissimi vel Beattissimi Patris. Anciely the same title was given to all bishops. The Greek emperors also were addressed under the title of Holiness, in regard of their being anointed with holy oil at their coronation. Du Cange adds, that some of the kings of England have had the same attribute; and that the orientals have frequently refused it to the pope.

HOLINGSHED, Ralph, or Raphael, was one of the humble but useful class of historians called chronologers. He was educated at Cambridge, according to Bishop Tanner, and became A. M. in the year 1544. The nature and extent of his education, as well as his profession, are involved in uncertainty. It seems probable, however, that he was steward to Thomas Burdett, Esq. of Boscote in Warwickshire, where he died about the year 1580. He has given name to a compilation of Chronicles of English history from the earliest times, the first edition of which was published at London in 1577, in two volumes folio, and the second edition in three volumes, was printed about seven years after his death, brought down to 1586. This work, according to the testimony of Holingshed himself, was begun by the advice of Reginald Wolfe, printer to Queen Elizabeth. Part of it was compiled by himself, but he received considerable assistance from William Harrison, John Hooker, Abraham Fleming, Francis Thynne, and some others. It was continued by John Stowe after the death of Holingshed. Some parts of the first edition were altered in the second and third, because they gave offence to Queen Elizabeth and the ministry, who laid many restrictions on the liberty of the press. The first edition of consequence is both scarce and valuable; but the suppressed sheets were afterwards printed by themselves. The chronicles of Holingshed, although considered as both tedious and vulgar, contain many important facts, which tend to illustrate the customs and manners of remote periods.

HOLLAND, Philemon, M. D. commonly called the translator general of his age, was educated in the university of Cambridge. He was for many years a schoolmaster at Coventry, where he also practised physic. He translated Livy, Pliny's Natural History, Florio's Morals, Suetonius, Ammianus Marcellinus, Xenophon's Cyropedia, and Camden's Britannia, into English; and the geographical part of Speed's Theatre of Great Britain into Latin. The Britannia, to which he made many useful additions, was the most valuable of his works. It is surprising that a man of two professions could find time to translate so much; but it appears from the date of the Cyropedia, that he continued to translate till he was 82 years of age. He died in 1637, aged 85. He made the following epigram upon writing a large folio with a single pen:

With one sole pen I wrote this book,
Made of a grey goose quill;
A pen it was when it I took,
And a pen I leave it still.

HOLLAND, the largest of the seven United Provinces, divided into South and North Holland, the latter of which is also called West Friesland, is bounded on the west by the German ocean, or North sea; to the
Holland, one of the divisions of Lincolnshire in England. It so much resembles the province of that name upon the continent, in most respects, being low and marshy, with the sea on one side, and canals running through it, that it must either have had its name from thence or on the same account. On the east it has what the ancient geographers call Estuarium, now the Washes, which are overflowed at high water, and part of Cambridgeshire on the south. The lower part of it is full of bogs and marshes, and has huge banks to defend it against the sea and land floods. The ground is so soft that horses are worked uneas; and it produces plenty of grass, but little corn. The whole tract seems to have been gained from the sea; and is divided into Upper and Lower, the latter of which was impassable; but since the fens have been drained, the lands are grown more solid, and the inhabitants sow cole-seed upon them to their great profit. Though there are no stones to be found in or upon the ground, yet most of the churches are of stone. They have no fresh water but from the clouds, which is preserved in pits: but if these are deep, it soon turns brackish; and if they are shallow, they soon become dry.

New Holland, the largest island in the world, reaching from 30° to 40° S. Lat. and between 114° and 153° E. Long. from London. It received its name from having been chiefly explored by Dutch navigators. The land first discovered in those parts was called Eendraght (Concord) Land, from the name of the ship on board which the discovery was made in 1619; 24° and 25° south. In 1618, another part of this coast, nearly in 15° south, was discovered by Zeachen, who gave it the name of Arnheim and Diemen; though a different part from what afterwards received the name of Diemen's Land from Tasman, which was supposed to be the southern extremity, in latitude 43°. This is now found to be an island separated from New Holland by Bass's Straits. See Diemen's Land.

In 1619, Jan van Edels gave his name to a southern part of New Holland. Another part situated between 30° and 33° received the name of Leuven. Peter van Nuitz gave his name, in 1627, to a coast which communicates to Leuven's Land towards the westward; and a part of the western coast, near the tropic of Capricorn, bore the name of De Wit's. In 1628, Peter Carpenter, a Dutchman, discovered the great gulf of Carpentaria, between 10° and 20° south. In 1627, Dampier, an Englishman, sailed from Timor, and coasted the western parts of New Holland. In 1699, he left England, with a design to explore this country, as the Dutch suppressed whatever discoveries had been made by them. He sailed along the western coast of it, from 28° to 15°. He saw the land of Eendraght and of De Wit. He then returned to Timor, from whence he went out again; examined the isles of Papua; coasted New Guinea; discovered the passage that bears his name; called a great island which forms this passage or strait on the east side, New Britain; and

HOL

sailed back to Timor along New Guinea. This is the
same Dampier who between 1683 and 1691, sailed
round the world by changing his ships. Notwith-
sanding the attempts of all these navigators, however,
the eastern part of this vast tract was totally unknown
till Captain Cook made his voyages; and by fully ex-
ploring that part of the coast, gave his country an un-
doubted title to the possession of it; which accordingly-
ly has since been taken possession of under the name of
New South Wales.

Some have disputed whether the title of island can
be properly applied to a country of such vast extent,
or whether it ought not rather to be denominated a
continent; while others have replied, that though the
word island, and others similar to it, do indeed signify
a tract of land surrounded by sea, yet in the usual ac-
ceptation it means only a land of moderate extent
surrounded in this manner. Were it otherwise, we
might call the whole world an island, as it is every
where surrounded by the sea; and in fact, Dionysius
Periegetes applies this term to it, with the addition of
the word immense, to distinguish it from other islands.
The best rule, according to Mr. Stockdale, for deter-
mining when a country ought to lose the name of island
and begin to be called a continent, is when it begins to
lose the advantages of an insular situation. The first
and principal of these, is the being capable of an union
under one government, and thence deriving a security
from all external attacks excepting those by sea; but
in countries of great extent, this is not only difficult,
but impossible. If we consider, therefore, New Hol-
land as extending about a thousand miles every way,
we shall find that its claim to be called a continent is
undoubted; its length from east to west being about
2400 English miles, and 2300 from north to south.

This coast was first explored by Captain Cook in
the year 1770; but his stay was too short to examine
the nature of the country with the accuracy which he
would otherwise have done had he continued longer in
it. In general, it was found rather barren than
otherwise. Many brooks and springs were found along
the eastern coast, but no river of any consequence.
They found only two kinds of trees useful as timber,
the pine, and another which produces a sort of gum.
They found three kinds of palm trees; but few esculent
plants, though there are abundance of such as might
gratify the curiosity of the botanist. A great variety
of birds were met with, which have since been particu-
larly described; but the number of quadrupeds bears
but a very small proportion to that of the other ani-
mal. The most remarkable insects seen at this time
were the green ants (A), who build their nests upon
trees in a very singular manner.

A colony has now become an object of serious
attention in consequence than formerly, by reason of the establish-
ment of a British colony in New Hol-
land. Whether

(a) These little animals form their habitations, by bending down the leaves of trees, and glueing the ends of
them together, so as to form a purse. Though these leaves are as broad as a man's hand, they perform this feat
by main strength, thousands of them being employed in holding down the leaves, while multitudes of others
apply the glutinous matter. Captain Cook's people ascertained themselves that this was the case, by some-
times disturbing them at their work; in which case the leaf always sprung up with an elasticity, which they
could not have supposed that such minute insects were capable of overcoming. For this curiosity, however,
they smarmed pretty severely; for thousands of these little enemies instantly threw themselves upon the aggress-
sors, and revenged themselves by their bites or stings for the interruption they had met with. These were little
less painful at first than the sting of a bee; but the pain did not last above a minute. Another species of ants
borrow themselves in the root of a plant which grows on the bark of trees like the mistletoe, and which is com-
monly as big as a small turnip. When this is cut, it appears intersected with innumerable winding passages all
filled with these animals; notwithstanding which, the vegetation of the plant suffers no injury. These do not give
pain by their stings, but produce an intolerable itching by crawling about on the skin. They are about the size
of the small red ant in this country. Another sort, which do not molest in any manner, resemble the white
ant of the East Indies. They construct nests three or four times as big as a man's head on the branches of
trees; the outsides being composed of some vegetable matter along with a glutinous substance. On breaking the
outer crusts of these hives, innumerable cells appear swarming with inhabitants, in a great variety of winding
directions, all communicating with each other, and with several other nests upon the same tree. They have also
another house built on the ground, generally at the root of a tree; formed like an irregular sided cone; some-
times more than six feet high, and nearly as much in diameter. The outside of these is well-tempered clay about
two inches thick; and within are the cells, which have no opening outward. One of these is their summer
and the other their winter dwelling, communicating with each other by a large avenue leading to the
ground, and by a subterraneous passage. The ground structures are proof against wet, which those on the branches
are not.

New Holland.

nant H. L. Ball; three store-ships, the Golden-grove, Fishburn, and Borrowdale, for carrying provisions and stores for two years; and lastly, six transports, the Scarborough and Lady Penenby from Portsmouth, the Friendship and Charlotte from Plymouth, and the Prince of Wales and Alexander from Woolwich. These were to carry the convicts, with a detachment of marines in each proportioned to the nature of the service; the largest where resistance was most expected, viz. in those which carried the greatest number of male convicts. On the arrival of Governor Phillip at the station, he hoisted his flag on board the Sirius as commodore of the squadron; and the embarkation being completed, he gave the signal to weigh anchor on the 13th of May at day-break. The number of convicts was 778, of whom 538 were men. They touched at the island of Teneriffe on the 3d of June, without meeting with any bad accident. Here they staid a week, in order to procure such refreshments as were necessary for preventing the disorders mostly to be dreaded in such a long and perilous voyage. In this they succeeded to their wish; and were about to depart on the 4th of June, when it was discovered that one of the convicts had made his escape, having found means to cut away a boat and make off with it. He offered himself as a sailor aboard a Dutch vessel at that time in the harbour, but was refused; on which he attempted to conceal himself in a cove. In this he would probably have succeeded, had it not been for the boat, which he could not conceal; so that he was soon discovered and brought back to the ship, where, however, he obtained his pardon from the governor.

On the 10th of June the fleet set sail from Santa Cruz in the island of Teneriffe, and on the 13th came in sight of the Cape Verde islands, where they steered for St Jago; but the want of a favourable wind and other circumstances prevented their getting in; so that as Governor Phillip did not choose to waste time, they did not touch land till they came to Rio Janeiro on the coast of Brazil. It may seem surprising, that a voyage to the eastward, which of itself may be accounted of sufficient length, should thus be wilfully made so much longer, by sailing twice across the Atlantic. The calms, however, so frequent on the coast of Africa, seem of themselves to be a sufficient inducement for navigators to preserve a westerly course; and even the islands at which it is so necessary to touch, are not far distant from the American coast. The returning tracks of Captain Cook's three voyages are all within a little space of the 45th degree of west longitude, which is even 10 degrees farther west than Cape St Roque; and that course appears to have been taken voluntarily, without any extraordinary inducement.

During the time of their stay at Santa Cruz the weather had been very moderate; the barometer about 30 inches, and the thermometer never above 72; as they approached the Cape Verde islands it rose to 82, and did not exceed 82° 51' the way from thence to Rio Janeiro. Here they met with a very favourable reception, contrary to that which Captain Cook experienced on a similar occasion. Provisions were so cheap, that though the allowance of meat was fixed by the governor at 20 ounces per day, the men were victualled completely at 34d. each, including rice, vegetables, and every other necessary. Wine was not at this time to be had except at an advanced price: but rum was laid in, and such seeds and plants procured as were thought most likely to flourish in New South Wales; particularly coffee, indigo, cotton, and the cochineal fig. A hundred sacks of cassada were likewise purchased as a substitute for bread, if it should happen to be scarce. By the kindness of the viceroy also, some deficiencies in the military stores were made up from the royal arsenal, and every assistance given which the place could afford. They arrived here on the 5th of August 1787, and set sail on the 4th of September, receiving as the last compliment from the governor a salute of 21 guns.

From Rio Janeiro the fleet had a fine run to Table Bay, in the southern extremity of Africa, which they accomplished in 39 days; where they took in the refreshments meant to supply them during the remainder of the voyage. Here they arrived on the 13th of October; and having supplied themselves with a great number of live stock, they set sail on the 12th of November, but were long impeded by contrary winds from the south-east. On the 25th they were only 20 leagues distant from the Cape, when Governor Phillip left the Sirius and went aboard the Supply tender; in hopes, by leaving the convoy, to gain sufficient time for examining the country round Botany Bay, that the most proper situation for the new colony might be chosen before the transports should arrive. They now met with favourable winds, blowing generally in very strong gales from the north-west, west, and south-west. The wind shifted only once to the east, but did not continue in that direction above a few hours. On the 3d of January 1788 the Supply came within sight of New South Wales; but the winds then became variable, and a current, which at times set very strongly to the southward, impeded her course so much, that it was not till the 18th of the month that she arrived at Botany Bay.

Governor Phillip no sooner landed than he had an interview opportunity of conversing with the natives, who were with the assembled on shore. As it was the intention of this gentleman to conciliate if possible their friendship, he used every method at this first interview to inspire them with a favourable idea of the Europeans. For this purpose he presented them with beads and other trinket ornaments, which they seemed pleased to wear, though Captain Cook found them very indifferent about any kind of finery he could furnish them with. They seemed, according to the account of that celebrated navigator, to be so attached to their own ornaments, that they made no account of anything else. They received indeed such things as were given them, but made no offer to return any thing in exchange; nor could they be made to comprehend that any thing of the kind was wanted. Many of the presents which they had received were afterwards found thrown away in the woods.

Governor Phillip having parted with his new acquaintance in a friendly manner, next set about an examination of the country about Botany Bay, which had been strongly recommended by Captain Cook as the most eligible place for a settlement. He found, however, that the bay itself was very inconvenient for shipping; being exposed to the easterly winds, and so shallow that ships even of a moderate burden could not get

4 B 2
get far enough within land to be sheltered from the fury of the ocean. Neither did the land about any part of this bay appear eligible for a colony; being in some places entirely swampy, in others quite destitute of water. Point Sutherland seemed to afford the situation most free from objections, but the ships could not approach it; and even here the ground seemed to be universally damp and spongy: so that, on the whole, finding no place within the compass of the bay proper for the new settlement, they found themselves obliged to remove somewhere else.

The rest of the fleet arrived in two days after the Supply; and that no time might be lost, Governor Phillip ordered the ground about Point Sutherland to be cleared, and preparations to be made for landing, while he went with several officers in three boats to examine Port Jackson, which was only three leagues distant. Here they had the satisfaction to find one of the finest harbours in the world, where 1000 sail of the line might ride in perfect safety. On examining the different coves, one was preferred which had a fine run of spring water, and where ships could anchor so close to the shore, that at a very small expense quays might be constructed for loading and unloading the largest vessels. This was named by the governor Sydney Cove, in honour of Lord Sydney, and the country around it destined for the place of settlement. It is about half a mile long, and a quarter of a mile broad at the entrance.

On the governor's return to Botany Bay, the reports made to him concerning the adjacent country were so exceedingly unfavourable, that orders were immediately given for the removal of the fleet to Port Jackson. On the morning of the 23rd, therefore, the governor sailed from Botany Bay, and was soon followed by the whole fleet. In the mean time, they were surprised by the appearance of two other European vessels, which had been first seen off Botany Bay on the 24th. These were found to be two French ships, named the Astrolabe and Boussole, which had left France on a voyage of discovery under the command of M. la Peyrouse, in the year 1785. They had touched at the island of Santa Catharina on the coast of Brazil, and from thence gone by the extremity of South America into the Pacific ocean, where they had run along by the coasts of Chili and California; after which they had visited Easter Island, Nootka Sound, Cook's river, Kamtschatka, Manilla, the isles des Navigateurs, and the Sandwich and Friendly Isles.

They had also attempted to land on Norfolk Island, but found it impossible on account of the surf. During the whole voyage none were lost by sickness; but two boats crews had unfortunately perished in a surf on the north-west coast of America; and at Masuna, one of the isles des Navigateurs, M. L'Angle, captain of the Astrolabe, with 12 of his people, officers and men, were murdered by the savages. This was the more surprising, as there had been an uninterrupted friendship with them from the time the French touched at the island, till that unfortunate moment. M. L'Angle had gone ashore with two long boats for the purpose of filling some water-casks. His party amounted to forty men; and the natives, from whom the French had already received abundance of refreshments, did not show any signs of a hostile disposition: But from whatever motive their resentment was excited, the men had no sooner begun to get out the boats, than the savages New Hol

made a most furious and unexpected assault with stones. In this encounter M. L'Angle himself, with the people above mentioned, fell a sacrifice to the treachery of these barbarians. The remainder of the party escaped with great difficulty; the ships having at that time passed a point of land which intercepted their view of the fray.

The convicts and others destined to remain in New South Wales being landed, no time was lost in beginning to clear ground for an encampment, store-houses, &c. The work, however, went on but slowly, partly owing to the natural difficulties they had to encounter, and partly to the habitual indolence of the convicts, which indeed was naturally to be expected considering their former way of life. Nevertheless, by the end of the first week of February, the plan of an encampment was formed, the places were marked out for different purposes, so that the colony already began to assume some appearance of order and regularity. The materials and frame-work of a slight temporary habitation for the governor had been brought out from England ready formed, which were landed and put together with as much expedition as circumstances would allow. Hospital tents were also erected; and the sickness which soon took place showed the propriety of so doing. In the passage from the Cape there had been but little sickness, and few of the convicts had died; but a little time after they landed a dysentery began to prevail, which proved fatal in several instances, and the scurvy began to rage with great violence, so that the hospital-tents were soon filled with patients. The disorder proved more virulent as fresh provisions could but rarely be obtained; nor were esculent vegetables often obtained in such plenty as could produce any material alleviation of the complaint: the only remedy for the dysentery was found to be a kind of red gum, produced in plenty by the trees growing upon this coast. The yellow gum has the same properties, though in an inferior degree.

In the beginning of February, a most violent storm of thunder and lightning destroyed five of the sheep which had a shed erected for them under a tree, which proved a prelude to other misfortunes among the cattle. The encampment, however, was carried on with great activity; the foundations of the store-houses were laid, and every thing began to wear a promising appearance.

On the 7th of the month a regular form of government establishment was established in the colony, with all the solemn form of assembly which could possibly be given: the governor made a proper speech to the convicts, reminding them of the situation in which they stood; and that now, if they continued their former practices, it was impossible they could hope for mercy if detected; neither could they expect to escape detection in so small a society. Offenders, therefore, he said, would certainly be punished with the utmost rigour; though such as behaved themselves in a proper manner, might always depend upon encouragement. He particularly noticed the illegal intercourse between the sexes, as a practice which encouraged prodigality in every respect; for which reason he recommended marriage: and this exhortation seemed not to be altogether in vain, as 14 marriages were celebrated that very week in consequence.

Heavy rains took place during the remainder of this month,
month, which showed the necessity of going on with the work as soon as possible. The want of carpenters, however, prevented this from being done so expeditiously as could have been wished. Only 16 of these could be hired from all the ships; and no more than 12 of the convicts were of this profession, of whom several were sick; so that the party were by far too few for the work they had to perform. A hundred convicts were added as labourers; but with every effort it was found impossible to complete either the barracks or the huts for the officers so soon as could be wished.

On the 14th of February a small party was sent out to settle on Norfolk Island, who have since established a colony there which promises to be of considerable utility. It was soon found, however, absolutely necessary to make examples of some of the convicts at Port Jackson. Towards the end of February it was found necessary to convene a criminal court, in which six of the convicts received sentence of death. One who was the head of the gang was executed the same day: one of the rest was pardoned; the other four were reprieved, and afterwards exiled to a small island within the bay, where they were kept on bread and water. They had frequently robbed both the stores and other convicts. The fellow who was executed, and two others, had been detected in stealing the very day on which they received a week's provision; and at the same time that their allowance was the same as that of the soldiers, spirituous liquors only excepted.

In the beginning of March the governor went out with a small party to examine Broken Bay, lying about eight miles to the northward of Port Jackson. This was found very extensive, with many openings. One of the latter ended in several small branches, and a large lagoon, which they could not at that time examine. Most of the land about the upper part of this branch was low and full of swamps, with great numbers of pelicans, and other aquatic birds. Among the rest they met with an uncommon bird, called at that time the Hooded Gull, but afterwards found to be the species named by Mr Latham the Caspian Tern.

From this north-west branch they proceeded across the bay to the south-west branch, which is also very extensive, with a second opening to the westward capable of affording shelter to almost any number of ships, with depth of water for vessels of almost any burden. The land was found much higher here than at Port Jackson, more rocky, and equally covered with timber. Large trees were seen growing even on the summits of the mountains, which appeared totally inaccessible to the human species. Round the headland which forms the southern entrance into the bay is a third branch, which Governor Phillip thought the finest piece of water he had ever seen; which for that reason he honoured with the name of Pitt-water. This branch, as well as the former, is sufficient to contain all the navy of Great Britain; but the latter has a bar at the entrance of only 19 feet at low water. Within are from 7 to 15 fathoms. The land here is more level than on the south-west branch, and some situations are proper for cultivation. The governor determined to have returned by land, in order to explore the country betwixt Port Jackson and Broken Bay, but the continual rains prevented him.

On the 10th of March the French ships departed, little intercourse having passed between them and the English during the time of their stay. While the former remained in Botany Bay, Father la Reveleur, who had come out in the Astrolabe as a naturalist, died of the wounds he had received in the battle with the inhabitants of Masuma. A kind of monument was erected to his memory, with the following inscription:

His jacet LA RECEVEUR
E. F. F. minimis Galliae sacerdos,
Physicus in circumnavigacione
Mundi
Duce DE LA PEYROUSE,

This monument, however, was soon after destroyed by the natives; on which Governor Phillip caused the inscription to be engraved on copper and nailed to a neighbouring tree. M. de la Peyrouse had paid a similar tribute to the memory of Captain Clerke at Kamchatka.

On the 15th of April, the governor, attended by Excursions several officers and a small party of marines, set out into the interior parts of the country. Their first landing was at the head of a small cove named Shell-cove, near the entrance of the harbour on the north side. Proceeding in this direction, they arrived with great labour at a large lake, surrounded on all sides with bog and marshy ground to a considerable extent, and in which they frequently plunged up to the waist. Here they observed that bird so rare in other parts of the world, viz. a black swan. On being fired at, it rose, and showed that its wings were edged with white, the bill being tinged red. They spent three days in a very laborious manner in passing the marshes and swamps which lie in the neighbourhood of the harbour: and here they had an opportunity of observing, that all the small streams which descend into Port Jackson proceed from swamps, occasioned by the stagnation of the water in the low grounds as it rises from the springs. On leaving these low grounds, they found them succeeded by a rocky and barren country; the hills covered with various flowering shrubs, though frequently inaccessible by reason of various natural obstacles. At about 15 miles distance from the sea, the governor had a fine view of the internal parts of the country, which were mountainous. To the most northerly chain of these he gave the name of Carmarthen, and to the most southerly that of Landow Hill; and to one which lay between these he gave the name of Richmond Hill. It was conjectured, that a large river must rise from these mountains; but there was now a necessity for returning. On the 22d, however, another expedition was undertaken. Governor Phillip with his party landed near the head of the harbour. Here they found a good country; but in a short time arrived at a close thicket through which they found it impossible to make their way, so that they were obliged to return. Next day, by keeping close to the banks of a small creek, they made a shift to pass that obstacle, and continued their course for three days to the westward. The country was now extremely fine, either entirely level or rising in small hills; the soil excellent, but stony in a few places. The trees grew at the distance of from 20 to 40 feet from each other, in general totally destitute of underwood, which was confined to the barren and stony spots.
On the 4th day they saw for the first time in this expedition Cartmaben and Lansdown hills; but the country all round was so beautiful, that Governor Phillip gave it the name of Bellevue. They were still apparently 30 miles from the mountains which they had intended to reach; but not having been able to carry more than six days provisions along with them, they found it necessary to return; and even with this small stock the officers as well as men were obliged to carry heavy loads. During all this time they had not proceeded farther in a direct line than 30 miles, so great were the obstructions they had met with from deep ravines, &c. Their return, however, was effected with much greater ease, having cleared a track, and marked trees all the way as they went along to direct them in their journey back. The country explored at this time appeared so fine, that Governor Phillip determined to form a settlement there as soon as a sufficient number could be spared from those works which were immediately necessary. On his return he had the mortification to find, that five ewes and a lamb had been killed very near the camp, and in the middle of the day. This mischief was supposed to have been done by some dogs belonging to the natives.

All this time the scurvy had continued to rage with great violence: so that by the beginning of May near 200 people were incapable of work. For this reason, and on account of the great difficulty of clearing the ground, no more than eight or ten acres of wheat and barley had been sown, besides what private individuals had sown for themselves; and it was even feared that this small crop would suffer from the depredations of ants and field mice. To procure as much relief as possible therefore in the present exigence, the Supply was sent in the beginning of May to Lord Howe Island, in hopes of procuring some turtle and other provisions; but unfortunately the vessel returned without any turtle, having met with equally weather, and being obliged to cut away her best bowser anchor. The natives now began to show an hostile disposition, which they had not hitherto done. One of the convicts, who had wandered away from the rest in quest of vegetables, returned with a very dangerous wound in the back; giving information also, that another who had gone out for the same purpose had been carried off in sight by the natives, after being wounded in the head. A shirt and hat were afterwards found in some of the huts of the natives, but no intelligence of the man could be gained. This was followed by other misfortunes of the same nature.

On the 30th of the month, two men who had been employed in cutting rushes for thatch at some distance from the camp were found dead. One of them had four spears in his body, one of which had pierced quite through it; but the other had no marks of violence upon him. In this case, however, it was proved, that those who suffered had been the aggressors; as they had been seen with one of the canoes of the natives which they had taken from one of the fishing places. All possible inquiry was made after the natives who had been guilty of the murder, but to no purpose. In the course of this inquiry, it was found that one of the natives had been murdered, and several wounded, previous to the attack upon the rush-cutters. The governor promised liberty to any convict who should discover the aggressors; but no information was procured, though it is probable that it may prevent accidents of that kind for the future. About this time the two bulls and four cows belonging to government and to the governor, having been left for some time by the man who had the charge of them, strayed into the woods and could not be recovered, though they were afterwards traced to some distance.

The 4th of June being his majesty's birth-day, was celebrated with as much festivity as circumstances would allow; and on this occasion it was first made public that the governor had given the name of Cumberland County to this part of the territory. The appointed boundaries were Cartmaben and Lansdown hills on the west, the northern parts of Broken Bay on the north, and the southern parts of Botany Bay on the south; thus including these three principal bays, with Sydney Cove nearly in the centre.

The misfortunes which attended those convicts who A convict strayed to too great a distance from the settlement, executed, were not sufficient to prevent some of them from rambling into the woods, in hopes of subsisting themselves there and regaining their liberty. One of these, who had been guilty of a robbery, fled into the woods on the 4th of June, but was obliged to return half-starved on the 24th. He had found it impossible to subsist in the woods, and had met with very little relief from the natives. One of them gave him a fish, but made signs for him to go away. According to his account, they themselves were in a very miserable situation; and he pretended to have seen four of them apparently dying of hunger, who made signs to him for something to eat. He pretended also to have fallen in with a party who would have burnt him, and that he made his escape from them with difficulty. He said also, that he had seen the remains of a human body lying on a fire; and endeavoured to inculcate the idea of these savages eating human flesh when other provisions were scarce. This poor wretch was tried and executed for the theft he had committed before his departure, along with another criminal.

By this time the colony was so far advanced, that regular the plan of a regular town had been marked out. The plan of a principal street, when finished, is to be 200 feet wide, terminated by the governor's house, the main guard, and criminal court. The plans of other streets are likewise marked out; and it is the governor's intention, that when houses are built here, the grants of land shall be made with such clauses as will prevent the building of more than one house on one allotment, which is to consist of 60 feet in front and 150 in depth. Thus a kind of uniformity will be preserved in the building, narrow streets prevented, and many inconveniences avoided, which a rapid increase of inhabitants might otherwise occasion. It has likewise been an object of the governor's attention to place the public buildings in such situations as will be eligible at all times, and particularly to give the store-houses and hospital sufficient space for future enlargement, should it be found necessary. The first huts erected in this place were composed only of the soft wood of the cabbage palm, in order to give immediate shelter, and which had the further inconvenience of being used quite green. The huts of the convicts were constructed only of upright posts wattled with slight twigs, and plastered up with clay. Buildings of stone might easily have been
been raised, had there been any means of procuring lime for mortar. There were three kinds of stone met with about Sydney Cove, one equal in goodness to Portland stone, an indifferent kind of sandstone or freestone, and a sort which seems to contain iron; but neither chalk nor any species of limestone has yet been discovered. Lime was indeed procured from oyster-shells collected in the neighbouring coves to construct a small house for the governor; but it cannot be expected that a sufficient quantity can thus be procured for many or very extensive buildings. Good clay for bricks has been found near Sydney Cove, and very good bricks have been made of it; the wood also, notwithstanding the many reports to the contrary, is found abundantly fit for various purposes after being thoroughly seasoned. Such specimens as have been sent to England were fine-grained and free of knots, but heavy.

On the point of land that forms the west side of the Cove a small observatory has been erected, the longitude of which has been ascertained to be $150^\circ 19^\prime 30^\prime$ east from Greenwich, and the latitude $32^\circ 52^\prime 30^\prime$ south. Instead of thatch they now make use of shingles made from a certain tree, which has the appearance of a fir, but produces wood like English oak.

With regard to the state of this colony there have been various and discordant accounts. Some of these have represented the country in such a light, that it would seem impossible to subsist on it; and it has been said, that the people who have had the misfortune to go there already were in the utmost danger of starving before any assistance could be sent from Britain. These reports, however, appear not to be well founded. Difficulties must undoubtedly be felt at the first settlement of every uninhabited country; and we are not to expect that a colony, most of whom are wretches exiled for their crimes from their own country, can thrive in an extraordinary manner for some time. It appears, indeed, that so far from the transportation to this place having had any good effect in reforming them, the governor has been obliged to execute the utmost rigor of the law by hanging several of them. A good number of others have unaccountably disappeared, and are supposed to have been murdered by the natives, or perished with hunger in the woods; so that, unless the numbers be recruited by more respectable inhabitants, it is not likely that much can be expected from the Port Jackson settlement for a long time to come. Of this, however, there seems to be little doubt: the general spirit of emigration which prevails through most, indeed we may say all the countries of Europe, will undoubtedly soon supply a sufficient number; and even some of the Americans, notwithstanding the extent and fertility of their own country, and the liberty they enjoy in it, are said to be willing to exchange these blessings for the precarious hopes of what may be obtained in New Holland among British convicts and slaves. This rambling disposition may perhaps be accounted for from an observation which has been made, viz. that it may admit of a doubt whether many of the accommodations of a civilized life be not more than counterbalanced by the artificial wants to which they give birth. That these accommodations do not give a satisfaction equivalent to the trouble with which they are procured, is certain; and it is no wonder, then, to find numbers of people in every country who are willing to exchange them for independent ease and tranquillity, which belong, comparatively speaking, to few individuals in those countries which are called civilized.

With regard to the geography of this extensive General country, which may perhaps be reckoned a fifth gene-ral division of the world, Captains Cook and D'Urville so fully explored its coast, that succeeding navigators have added little to their labours. What they left unfinished has been completed by Captain Flinders, whose laborious and accurate surveys of the coast leaves little more to be desired. The discovery of Bass's straits has completed our idea of the general outline of the coast; and in future, discoveries of importance can only be looked for in the interior.

A vast chain of lofty mountains runs nearly in a north and south direction farther than the eye can trace, about 60 miles inland. The general face of the country is pleasing, diversified with gentle risings and small winding valleys, covered for the most part with large spreading trees, affording a succession of leaves in all seasons. A variety of flowering shrubs, almost all entirely new to an European, and of exquisite fragrance, abound in those places which are free from trees; and among these, a tall shrub, bearing an elegant flower which smells like English may, is peculiarly delightful, and perfumes the air to a great distance. There are but few trees; and, as Captain Tench and others relate, of so had a grain, that they can scarcely be used for any purpose: This, however, Mr Stockdale Red and ascribes to their being used in an unseasoned state, as yellow gum has been already mentioned. In return for these bad qualities, however, the trees yield vast quantities of the gum already mentioned, as a cure for the dysentery. It is of an acrid quality, and therefore requires to be given along with opiates. The tree which yields it is of very considerable size, and grows to a great height before it puts out any branches. The gum itself is usually compared to sanguis draconis, but differs from it in being perfectly soluble in water, which the sanguis draconis is not. It may be extracted from the wood by tapping, or taken out of the veins when dry. The leaves are narrow, and not unlike those of a willow; the wood fine-grained and heavy; but wares to such a degree, when not properly seasoned, as soon to become entirely useless.

The yellow gum is properly a resin, being entirely insoluble in water. It greatly resembles gamboge, but has not the property of staining. It is produced by a low small plant with long grassy leaves; but the fructification shoots out in a surprising manner from the centre of the leaves on a single straight stem to the height of 12 or 14 feet. This stem is strong and light, and is used by the natives for making their spears. The resin is generally dug up from the soil under the tree, not collected from it, and may perhaps be the same as Tasman calls gum lac of the ground. It has been tried by Dr Blane, physician to St Thomas's hospital, who found it very efficacious in the cure of old fluxes, and that in many and obstinate cases. Many of the New Holland plants have been already imported into Britain, and are now flourishing in perfection.
The soil immediately around Sydney Cove is sandy, with here and there a stratum of clay; but hitherto the produce has not been remarkable. The principal difficulty hitherto experienced in clearing the ground arises from the size of the trees, which is said to be so enormous, that 12 men have been employed for five days in grubbing up one. Captain Cook speaks of some fine meadows about Botany Bay; but none of these have been seen by the present settlers, and Governor Phillip supposes them to have been swamps seen at a distance. Grass grows in almost every place, but in the swamps with the greatest vigour and luxuriance, though not of the finest quality. It is found to agree better with cows and horses than sheep. A few wild fruits are sometimes procured; among which is a kind of small purple apple mentioned by Captain Cook; and a fruit which has the appearance of a grape, but tasting like a green gooseberry, and excessively sour.

From the first discovery of this continent, the extreme scarcity of fresh water has been mentioned by every navigator. None have been fortunate enough to enter the mouth of any navigable river such as might be expected in a country of such extent. The settlers about Port Jackson found enough for the common purposes of life; but Captain Tench informs us, that when he left the country, towards the end of 1788, there had been no discovery of a stream large enough to turn a mill. Since that time, however, Governor Phillip has been more successful; as we are informed by a letter of his to Lord Sydney, of date February 13, 1790: In this letter he relates, that soon after the ships sailed in Nov. 1788, he again made an excursion to Botany Bay, where he stayed five days; but the researches he made there tended only to confirm him in the opinion he already entertained that the country round it was by no means an eligible situation for a colony. After having visited Broken Bay several times with boats, a river was found, which has since been traced, and all those branches explored, which afford any depth of water. This river has obtained the name of Hawkesbury, is from 300 to 800 feet wide, and seems navigable for the largest merchant ships as far up as Richmond hill, at which it becomes very shallow, and divides into two branches; on which account the governor calls Richmond hill the head of the river. As after very heavy rains, however, the water sometimes rises 30 feet above its level, it would not be safe for ships to go up so far; but 15 or 20 miles below it they would lie in fresh water, and be perfectly safe.

The country about Broken Bay is at first high and rocky, but as we proceed up the river it becomes more level, the banks being covered with timber, and the soil a light rich mould, supposed to be very capable of cultivation. The other branches of this river are shallow, but probably run many miles up into the country. Great number of black swans and wild ducks were seen on these rivers, and the natives had several decoys for catching quails.

Richmond hill, near which a fall prevented the boats from proceeding farther up, is the most southerly of a large range of hills which run to the northward, and probably join the mountains nearly parallel to the coast from 50 to 60 miles inland. The soil of this hill is good, and it lies well for cultivation. There is a very extensive prospect from the top, the whole country round seeming a level covered with timber. There is a flat of six or seven miles between Richmond hill and a break in the mountains which separates Landsdown and Carmarthen hills; in which flat the governor supposes that the Hawkesbury continues its course; though the river could not be seen on account of the timber with which the ground is everywhere covered where the soil is good. Six miles to the southward of Port Jackson is a small river; and 20 to the westward is one more considerable, which probably empties itself into the Hawkesbury. As far as this river was at that time explored, the breadth was computed at from 300 to 400 feet. It was named the Nepean, and, like the Hawkesbury, sometimes rises 30 feet above its level. A party who crossed the river attempted to reach the mountains, but found it impossible, probably for want of provisions. After the first day's journey they met with such a succession of deep ravines, the sides of which were frequently so inaccessible, that in five days they could not proceed further than 15 miles. At the time they turned back, they supposed themselves to be 12 miles from the foot of the mountains. With regard to the state of the colony, it appears from this letter to be as flourishing as could in any reasonable manner be expected. Another has been formed at a place called Rosehill, at the head of the harbour of Sydney Cove. At this place is a creek, which at half flood has water for large boats to go three miles up; and one mile higher the water is fresh and the soil good. Some ground having been cleared and cultivated, the governor in the above letter writes, that 27 acres were sown with corn, and that in December the crop was got in: That the corn was exceedingly good; about 200 bushels of wheat and 60 of barley, with a small quantity of flax, Indian corn, and oats; all which is preserved for seed: That if settlers are sent out, and the convicts divided amongst them, this settlement will very shortly maintain itself; but without which this country cannot be cultivated to any advantage. "At present (continues the governor) I have only one person, who has about 100 convicts under his direction, who is employed in cultivating the ground for the public benefit, and he has returned the quantity of corn above mentioned into the public store: the officers have raised sufficient to support the little stock they have: some ground I have had in cultivation will return about 40 bushels of wheat into store; so that the produce of the labour of the convicts employed in cultivation has been very short of what might have been expected, and which I take the liberty of pointing out to your lordship in this place; to show as fully as possible the state of this colony, and the necessity of the convicts being employed by those who have an interest in their labour. The country for 20 miles to the westward is very capable of cultivation; though the labour of cutting down the trees is very great. At Sydney Cove the stores had been infested by a swarm of rats which destroyed no less than 12,000 lb. weight of flour and rice. The gardens also had suffered very considerably; so that, having met with such a considerable loss
of provision, and a sufficient supply not being procured from the Cape, Governor Phillip thought proper to send a further detachment to Norfolk Island, where the fertility of the soil afforded great hopes of their being able in a short time to sustain themselves independent of any assistance from the stores.

In the year 1813 a few private individuals made an excursion across the Blue mountains, and discovered Macquarie river flowing to the north-west; through a rich, beautiful, undulating country. After a road was made, the governor himself visited this newly discovered region, and founded the town of Bathurst on the river, about seventy miles from its source. This new establishment has prospered greatly. The land yields excellent crops; and the cattle are found to thrive extremely. The direction of Macquarie river away from the nearest sea coast, into the vast interior of the country, gave rise to many speculations; and the Lachlan, another river, having a similar course, was found out shortly after. Two successive expeditions, conducted by Mr Oxley, were fitted out in 1817, to explore the country farther west. The result, however, disappointed the sanguine expectations entertained. The Macquarie, after being traced for two or three hundred miles, and the Lachlan for a greater distance, were found to terminate in a vast extended marsh. The soil, as they approached this marsh, became gradually worse; and the hills sunk by degrees till the country became a dreary flat. A great extent of excellent land however has been ascertained to exist on the upper part of the Macquarie; and to this district the eyes of the colonists are now directed.

With regard to the civil establishment in this colony, Governor Phillip's jurisdiction extends from 43° 49' to 10° 37' south, being the northern and southern extremities of the continent. It commences again in 135° E. Long. from Greenwich, and proceeding in an easterly direction, includes all the islands within the above-mentioned latitudes in the Pacific ocean; by which partition it is supposed that every source of litigation will be cut off, as all these are indisputably the discovery of the British navigators.

The powers of the governor are absolutely unlimited, no mention being made of a council to assist him in any thing; and no stated time is appointed for assembling the courts similar to the assizes and gaol deliveries in England, the duration of imprisonment is altogether in his hands. He is likewise invested with a power of summoning general courts martial; but the insertion in the marine mutiny act, of a smaller number of officers than 13 being able to compose such a tribunal, has been neglected; so that a military court, should detachments be made from head quarters, or sickness prevail, may not always be found practicable to be obtained, unless the number of officers in the settlement at present be increased. The governor is allowed to grant pardons in all cases, treason and willful murder excepted; and even in these he has authority to stay the execution of the law until the king's pleasure shall be signified. In case of the governor's death, the lieutenant governor takes his place; and on his decease, the authority is lodged in the hands of the senior officer.

It was not long after the convicts were landed that there appeared a necessity for assembling a criminal court; and it was accordingly convened by warrant from the governor. The members were the judge advocate, who presided, three naval, and three military officers. The number of members is limited by act of parliament to seven; who are expressly ordered to be officers either of his majesty's sea or land forces. The court being met, completely arrayed and armed as a military tribunal, the judge advocate proceeds to administer the usual oaths taken by jurymen in England to each member; one of whom afterwards swears him in a like manner. The ceremony being over, the crime is laid to the prisoner's charge, and the question "guilty or not guilty" put to him. No law officer being appointed on the part of the crown, the party at whose suit he is tried is left to prosecute the prisoner entirely by himself. All the witnesses are examined on oath; and the decision must be given according to the laws of England, or "as nearly as may be, allowing for the circumstances and situation of the settlement," by a majority of votes, beginning with the youngest member, and ending with the president of the court. No verdict, however, can be given in cases of a capital nature, unless at least five of the seven members concur therein. The evidence on both sides being finished, and the prisoner's defence heard, the court is cleared, and, on the judgment being settled, is thrown open again, and sentence pronounced. During the time of sitting, the place in which it is assembled is directed to be surrounded by a guard under arms, and admission granted to every one who chooses to enter it.

The first trials which came before this court were those of three convicts, one of whom was convicted of having struck a marine with a cooper's adze, and &c. behaving otherwise in a most scandalous and riotous manner. For this he was condemned to receive 150 lashes, being a smaller punishment than a soldier would have suffered in a similar case. A second, for having committed a petty theft, was sent to a small barren island, and kept there on bread and water only for a week. The third was sentenced to receive 50 lashes, but being recommended by the court to the governor, had his sentence remitted. The same lenity, however, could not be observed in all cases. One fellow, who had been condemned to be hanged, was pardoned while the rope was about his neck, on condition that he would become the common executioner ever after. He accepted the horrid office, but not without a pause. Some examples of severity were undoubtedly necessary; and among these it is impossible to avoid feeling some regret for the fate of one who suffered death for stealing a piece of soap of eight pence value: but by a letter of Governor Phillip, we are informed that the convict in general had begun to behave much better; more so indeed than ever was expected; and at this time one woman had suffered for a robbery; five children had died, and 28 had been born. The whole amount of the deaths 77, of the births 87.

Besides the criminal court, there is an inferior one, composed of the judge advocate, and one or more justices of the peace, for the trial of small misdemeanors. This court is likewise empowered to decide all lawsuits; and its verdict is final, except where the sum exceeds 300l. in which case an appeal can be made to England from its decree. In case of necessity, an admiralty
New Holland, admiral court, of which the lieutenant governor is judge, may also be summoned for the trial of offences committed on the high seas.

The quadrupeds on the continent of New Holland hitherto discovered, are principally of the oppossum kind, of which the most remarkable is the kangaroo. There is also a species of dogs very different from those known in Europe. They are extremely fierce, and never can be brought to the same degree of familiarity with those we are acquainted with. Some of them have been brought to England, but still retain their usual ferocity. There are a great many beautiful birds of various kinds; among which the principal are the black swans already mentioned, and the ostrich or cassowary; which last arrives frequently at the height of seven feet or more. Several kinds of serpents, large spiders, and scolopendra, have also been met with. There are likewise many curious fishes; though the fishy tribe seem not to be so plentiful on the coast as to give any considerable assistance in the way of provisions for the colony. Some very large sharks have been seen in Port Jackson, and two smaller species, one named the Port Jackson shark, the other Wattle's shark. The latter, notwithstanding its diminutive size, the mouth scarce exceeding an inch in breadth, is excessively voracious. One of them having been taken and flung down upon the deck, lay there quiet for two hours; after which Mr. Watts's dog happening to pass by, the fish sprung upon it with all the ferocity imaginable, and seized it by the leg in such a manner that the animal could not disengage himself without assistance.

The climate of this continent appears not to be disagreeable, notwithstanding the violent complaints which some have made about it. The heat has never been excessive in summer, nor is the cold intolerable in winter. Storms of thunder and lightning are frequent; but these are common to all warm countries; and it has been supposed, (though upon what foundation does not well appear) that were the country cleared of wood, and inhabited, these would in a great measure cease. A shock of an earthquake has likewise been felt; but these natural calamities are incident to some of the finest countries in the world. It is not known whether or not there are any volcanoes.

The inhabitants of New Holland are by all accounts represented as the most miserable and savage race of mortals perhaps existing on the face of the earth. They go entirely naked; and though pleased at first with some ornaments which were given them, they soon threw them away as useless. It does not appear, however, that they are insensible of the benefits of clothing, or of some of the conveniences which their neighbours are in possession of. Some of them, whom the colonists partly clothed, seemed to be pleased with the comfortable warmth they derived from it; and they all express a great desire for the iron tools which they see their neighbours make use of. Their colour, in the opinion of Captain Cook, is rather a deep chocolate than a full black; but the skin with which their skins are covered, prevents the true colour of them from appearing. At some of their interviews with the colonists, several drjoll instances happened of their mistaking the negroes among the colonists for their own countrymen. Notwithstanding their disregard for European society, they are fond of adornning, or rather deforming, their bodies with scars; so that some of them cut the most hideous figure that can be imagined. The scars themselves have an uncommon appearance. Sometimes the skin is raised several inches from the flesh, and appears as if filled with wind; and all these seem to be reckoned marks of honour among them. Some of them perforate the cartilage of the nose, and thrust a large bone through it, a hideous kind of ornament, humorously called by the sailors their spirit-nail yard. Their hair is generally so much oiled with the red gum already mentioned, that they resemble a mop. They also paint themselves with various colours like most other savages; they will also sometimes ornament themselves with beads and shells, but make no use of the beautiful feathers procurable from the birds of the country. Most of the men want one of the fore-teeth in the upper jaw; a circumstance mentioned by Dampier and other navigators; and this also appears to be a badge of honour among them. It is very common among the women to cut off the two lower joints of the little finger; which, considering the clumsiness of the amputating instruments they possess, must certainly be a very painful operation. This was at first supposed to be peculiar to the married women, or those who had been children; but some of the oldest women were found without this distinction, while it was observed in others who were very young.

The New Hollanders appear extremely deficient in the useful arts. Of the cultivation of the ground they have no notion; nor can they even be prevailed upon to eat bread or dressed meat. Hence they depend entirely for subsistence on the fruits and roots they can gather, with the fish they catch. Governor Phillip also mentions their frequent setting fire to the grass, in order to drive out the oppossum and other animals from their retreats: and we have already taken notice of their using decay for fuel. As all these resources, however, must be at best precarious, it is no wonder that they are frequently distressed for provisions. Thus, in the summer-time, they would eat neither the shark nor sting-ray; but in winter any thing was acceptable. A young whale being driven ashore, was quickly cut in pieces and carried ashore. They boiled it only long enough to scour the outside, and in this state they eat all their fish. They boil also the fern roots and another whose species is unknown. Among the fruits used by them is a kind of wild fig; and they eat also the kernels of a fruit resembling the pine apple. The principal part of their subsistence, however, is fish; and when these happened to be scarce, they were wont to watch the opportunity when the colonists hauled the seine, and often seized the whole, though a part had formerly been offered or given them. They sometimes strike the fish from the canoes with their spears, sometimes catch them with hooks, and also make use of nets, contrary to the assertion of Dr. Hawkesworth, who says that none of these are to be met with among them. Their nets are generally made of the fibres of the flex plant, with very little preparation, and are strong and heavy; the lines of which they are composed twisted like whip-cord. Some of them, however, appear to be made of the fur of an animal, and others of cotton. The meshes of their nets are made of very large loops artfully inserted into each other, but
but without any knots. Their hooks are made of the inside of a shell very much resembling mother-of-pearl. The canoes in which they fish are nothing more than large pieces of bark tied up at both ends with vines; and considering the slight texture of these vessels, we cannot but admire the dexterity with which they are managed, and the boldness with which they venture in out to sea. They generally carry fire along with them in these canoes, to dress their fish when caught. When fishing with the hook, if the fish appears too strong to be drawn ashore by the line, the canoe is paddled to the shore; and while one man gently draws the fish along, another stands ready to strike it with a spear, in which he generally succeeds. There is no good season for supposing them to be cannibals, and they never eat animal substances but raw or next to it. Some of their vegetables are poisonous when raw, but deprived of this property when boiled. A convict unhappily experienced this by eating them in an unprepared state; in consequence of which he died in 24 hours. The dislike of the New Hollanders to the European provisions has already been mentioned; if bread be given them, they chew and spit it out again, seldom choosing to swallow it. They like salt beef and pork rather better; but they could never be brought to taste spirits a second time.

The huts of these savages are formed in the most rude and barbarous manner that can be imagined. They consist only of pieces of bark laid together in the form of an oven, open at one end, and very low, though long enough for a man to lie at full length. There is reason, however, to believe, that they depend less on them for shelter than on the caverns with which the rocks abound. They go invariably naked, as has already been observed; though we must not imagine that the custom of going naked injures them so to the climate as to make them insensible to the injuries of the weather. The colonists had repeated opportunities of observing this, by seeing them shivering with cold in the winter time, or huddling together in heaps in their huts or in caverns, till a fire could be kindled to warm them. It is probable, however, notwithstanding their extreme barbarity, that some knowledge of the arts will soon be introduced among them, as some have been seen attentively considering the utensils and conveniences of the Europeans, with a view, seemingly, of making similar improvements of their own. It has also been observed, that in some things they possess a very great power of imitation. They can imitate the songs and language of the Europeans almost instantaneously, much better than the latter can imitate theirs by long practice. Their talent for imitation is also discernible in their sculptures representing men and other animals everywhere met with on the rocks; which, though rude, are very surprising for people who have not the knowledge even of constructing habitations in the least comfortable for themselves, or even clothes to preserve them from the cold.

In their persons, the new Hollanders are active, vigorous, and stout, though generally lean. Dampier asserts that they have a dimness of sight; though later navigators have determined this to be a mistake, ascribing to them, on the contrary, a quick and piercing sight. Their sense of smelling is also very acute. One of them having touched a piece of pork, held out his finger for his companion to smell with strong marks of disgust. The only kind of food they eagerly accept of is fish. Their behaviour with regard to the women has been hitherto unaccountable to the colonists. Few of them, comparatively speaking, have been seen, and these have sometimes kept back with the most jealous sensibility; sometimes offered with the greatest familiarity. Such of the females as have been seen, have soft and pleasing voices; and notwithstanding their barbarity and excessive rudeness, seem not to be entirely destitute of modesty.

The New Hollanders generally display great personal bravery on the appearance of any danger. An old man, whom Governor Phillip had treated with some familiarity, took occasion to steal a spade; but being taken in the fact, the governor gave him a few slight slaps on the shoulder; on which the old man caught hold of a spear, and coming up to him, seemed for some time determined to strike, though had he done so, it would have been impossible for him to escape, being then surrounded by the officers and soldiers. No encounters between parties of the natives themselves have been observed, though from some circumstances it appears that wars are carried on among them. They have more than once been seen assembled as if bent on some expedition. An officer one day met 14 of them marching along in a regular Indian file through the woods, each man having a spear in one hand and a stone in the other. A chief appeared at their head, who was distinguished from the rest by being painted. They passed on peaceably, though greatly superior in number to our people. On another occasion they offered no hostilities when assembled to the number of 200 or 300, and meeting the governor attended only by a small party. With all their courage, however, they are much afraid of a musket, and almost equally so of a red coat, which they know to be the martial dress of the Europeans. The mischief which they have hitherto done has been exercised only on some straggling convicts, most of whom probably have been the first aggressors.

Though these savages allow their beards to grow to a considerable length, it does not appear that they look upon them to be any ornament, but rather the contrary, as appears from the following instance. Some young gentlemen belonging to the Sirius, one day met an old man in the woods with a beard of considerable length. This new acquaintance let him know that they would rid him of, stroaking their chins, and showing him the smoothness of them at the same time. At length the old fellow consented; and one of the youngsters taking a penknife from his pocket, and making the best substitute for lather he could, performed the operation with such success, that the Indian seemed highly delighted. In a few days he paddled alongside of the Sirius again, pointing to his beard; but could not by any means be prevailed upon to enter the ship. On this a barber was sent down to him, who again freed him from his beard, at which he expressed the utmost satisfaction. It has, however, been found impossible to form any kind of permanent intercourse with the natives, though many attempts
New Holland. attempts have been made for that purpose; but in his letter above quoted, Governor Phillip declares that he has not the least apprehension of their doing any damage to the colony. At first the colonists imagined the spears of the New Hollanders to be very trivial weapons; but it now appears that they are capable of inflicting very grievous and mortal wounds. They are sometimes pointed with a sharp piece of the same reed of which the shafts are made, but more frequently with the sharp bone of the sting-ray. They certainly burn their dead, which perhaps has given rise to the report of their being cannibals. Governor Phillip, observing the ground to be raised in several places, caused one of these tumuli to be opened, in which were found a jaw-bone half consumed and some ashes. From the manner in which the ashes are deposited, it appears that the body has been laid at length, raised from the ground a little space, and consumed in that posture, being afterwards lightly covered with mould.

The only domestic animals they have are the dogs already mentioned, which resemble the fox-dog of England. In their language these animals are called dingos; but all other quadrupeds without exception they name kangaroo. They seem very little given to thieving in comparison with the inhabitants of most of the South Sea islands; and are very honest among themselves, leaving their spears and other implements open on the beach, in full and perfect security of their remaining untouched. They are very expert at throwing their javelins, and will hit a mark with great certainty at a considerable distance; and it seems that sometimes they kill the kangaroo with this weapon, as a long splinter of one of the spears was taken out of the thigh of one of these animals, the flesh having closed over it completely. The people are more numerous than was at first imagined, though still the number of inhabitants must be accounted few in comparison to the extent of country; and there is great reason to believe that the interior parts are uninhabited.

The New Hollanders bake their provisions by the help of hot stones, like the inhabitants of the South Sea islands. They produce fire with great facility according to Captain Cook, but with difficulty according to later accounts, and spread it in a wonderful manner. To produce it, they take two pieces of dry soft wood: one is a stick about eight or nine inches long, the other piece is flat. The stick they shape into an oblong point at one end; and pressing it upon the other, turn it nibly, by holding it between both their hands, as we do a chocolate mill; often shifting their hands up, and then moving them down upon it, to increase the pressure as much as possible. By this method they get fire in less than two minutes, and from the smallest spark they increase it with great speed and dexterity. "We have often seen (says Captain Cook) one of them run along the shore, to all appearance with nothing in his hand, who stooping down for a moment, at the distance of every fifty or an hundred yards, left fire behind him, as we could see, first by the smoke, and then by the flame along the drift of wood and other litter which was scattered along the place. We had the curiosity to examine one of these planters of fire when he set off, and we saw him wrap up a small spark in dry grass, which, when he had run a little way, having been fanned by the air that his motion produced, began to blaze; he then laid it down in a place convenient for his purpose, including a spark of it in another quantity of grass, and so continued his course."

Besides the black swans already mentioned, which the ancients despaired of ever seeing, this country produces that beautiful bird called menura superba, of which an interesting description is given by Mr Collins, in the second volume of his Account of the English Colony. Here also there is a considerable number of very uncommon and exquisitely fragrant shrubs. There is also an extraordinary amphibious animal found here, called the ornithorhynchus paradoxa, of which Mr Home has given a description, which was published in the Philosophical Transactions for 1801.

In 1801, there were in circulation the following coins, which were made legal tender by authority of the governor.

The successive accounts published of the colony, show a very rapid progress in wealth and population. At the close of the year 1797 the colony had of live stock, 26 horses, 58 mares, 132 bulls and oxen, 195 cows, 4247 hogs, 743 sheep, 1714 he and 1495 she goats. Of land in a state of cultivation, there were 3361² acres in wheat, 1527 for maize, and 265 in barley, besides a considerable quantity of garden ground, which produced potatoes, calvarees, and vines.

From the 27th of January 1798, to the 7th of June 1800, not fewer than 120 ships and vessels of various descriptions, and from different quarters of the globe, have visited this country; a convincing proof that they either found it a place of refreshment after the fatigues of a long voyage, or an advantageous market for their commercial speculations. Thirty-seven of them went from England with convicts, to the number of 5000, of whom about 157 were females.

In the year 1801 the increasing prosperity of the colony was still conspicuous, for the live stock of different individuals consisted of 6269 sheep, 362 cattle, 217 horses, 1259 goats, and 4766 hogs; and what belonged to government consisted of 488 sheep, 931 cattle, and 32 hogs. There were 5324 acres of land sown with wheat, and 3864 acres with maize; and the inhabitants amounted to 6708.

In 1818, the horned cattle amounted to 40,000, the horses to 3300, the sheep to 73,000, and the hogs to 22,000, exclusive of the stock of Van Diemen's Land. The population of the colony, including that of Van Diemen's Land, was 25,000.
HOLLAND. Holland, in commerce, a fine and close kind of linen, so called from its being first manufactured in Holland.

HOLLAR, WENCESLAUS, a celebrated engraver, born at Prague in 1607. His parents were in a genteel line of life; and he was at first designed for the study of the law. But the civil commotions which happened in his youth, ruining his family affairs, he was obliged to shift for himself; and by discovering some genius for the arts, he was placed with Marian, a very able designer and engraver of views. Being himself a man of great ingenuity, he profited hastily from the instruction of his tutor. He principally excelled in drawing geometrical and perspective views and plans of buildings, ancient and modern cities and towns, also landscapes, and every kind of natural and artificial curiosities, which he executed with a pen in a very peculiar style, excellently well adapted to the purpose. He travelled through several of the great cities of Germany: and, notwithstanding all his merit, met with so little encouragement, that he found it very difficult to support himself. The earl of Arundel, being in Germany, took him under his protection, brought him to England, and recommended him to the favour of Charles I. He engraved a variety of plates from the Arundel collection, and the portrait of the earl himself on horseback. The civil wars which happened soon after in England, ruined his fortune. He was taken prisoner, with some of the royal party, and with difficulty escaped; when he returned to Antwerp, and joined his old patron the earl of Arundel. He settled in that city for a time, and published a considerable number of plates: but his patron going to Italy soon after for the benefit of his health, Hollar fell again into distress, and was obliged to work for the print and booksellers of Antwerp at very low prices. At the Restoration he returned to England; where, though he had sufficient employment, the prices he received for his engravings were so greatly inadequate to the labour necessarily required, that he could but barely subsist, and the plague, with the succeeding fire of London, putting for some time an effectual stop to business, his affairs were so much embarrassed, that he was never afterwards able to improve his fortune. It is said that he used to work for the booksellers at the rate of fourpence an hour, and always had an hour glass before him. He was so very scrupulously exact, that when obliged to attend the calls of nature, and whilst talking, though with the persons for whom he was working, and about their own business, he constantly laid down the glass to prevent the sand from running. Nevertheless, all his great industry, of which his numerous works bear ample testimony, could not procure him a sufficient maintenance. It is melancholy to add, that on the verge of his 70th year, he was attached with an execution at his lodgings in Gardener's lane, Westminster, when he desired only the liberty of dying in his bed, and that he might not be removed to any other prison than the grave, a favour which it is uncertain whether he obtained or not. He died, however, in 1677. His works amount nearly to 24,000 prints, according to Vertue's Catalogue, and the lovers of art are always zealous to collect them. Generally speaking, they are etchings performed almost entirely with the point, and their merits are thus characterized by Mr Strutt: "They possess great spirit, with astonishing freedom and lightness, especially when we consider how highly he has finished some of them. His views of abbeys, churches, ruins, &c. with his shells, muffs, and every species of still life, are admirable; his landscapes frequently have great merit; and his distant views of towns and cities are not only executed in a very accurate, but a very pleasing manner." A somewhat colder character is given of them by Mr Gilpin in his Essay on Prints: "Hollar gives us views of particular places, which he copies with great truth, unornamented as he found them. If we are satisfied with exact representations, we have them nowhere better than in Hollar's works; but if we expect pictures, we must seek them elsewhere. Hollar was an antiquarian and a draughtsman, but seems to have been little acquainted with the principles of painting. Stiffness is his characteristic, and a painful exactness void of taste. His larger views are mere plans. In some of his smaller, at the expense of infinite pains, something of an effect is sometimes produced. But in general, we consider him as a repository of curiosities, a record of antiquated dresses, abolished ceremonies, and edifices now in ruins."

HOLLOA, in the sea language, an exclamation of answer, to any person who calls to another to ask some question, or to give a particular order. Thus if the master intends to give any order to the people in the main-top, he previously calls, Main top, hooy! to which they answer, Holoa! to show that they hear him and are ready. It is also the answer in sailing a ship at a distance. See HAILING.

SCA-HOLLY. See ERYNGIUM, BOTANY INDEX.

HOLM (Sax. hulmus, insula amnica), denotes an isle or fenny ground, according to Bede, or a river island. And where any place is called by that name, and this syllable is joined with any other in the names of places, it signifies a place surrounded with water, as the Flat holmes and Stepholmes in the Severn near Bristol; but if the situation of the place is not near the water, it may then signify a hilly place; holm in Saxon signifying also "a hill or cliff."

HOLOCAUST (formed from ἔλο, "whole", and οἰκος, "I consume with fire"), a kind of sacrifice, wherein the whole offering is burnt or consumed by fire, as an acknowledgment that God, the creator, preserver, and lord of all, was worthy of all honour and worship, and as a token of men's giving themselves entirely up to him. It is called also in Scripture a burn-offering. Sacrifices of this sort are often mentioned by the heathens as well as Jews; particularly by Xenophon, Cyroped.lib. viii. p. 446. ed. Hutchins. 1738, who speaks of sacrificing holocausts of oxen to Jupiter, and of horses to the sun; and they appear to have been in use long before the institution of the other Jewish sacrifices, by the law of Moses; (see Job. i. xii. 8. and Gen. viii. 20. xxii. 13.). On this account, the Jews, who would not allow the Gentiles to offer on their altar any other sacrifices peculiarly enjoined by the law of Moses, admitted them by the Jewish priests to offer holocausts; because these were a sort of sacrifices prior to the law, and common to all nations. During
time when this war between Holofernes and the Jews happened. Some date it from the captivity of Babylon, in the reign of Manasseh, and pontificate of Elia-

kin the high-priest; others place it at some time after the captivity; and some doubt the truth of the whole

transactin. See the article JUDDITH.

HELOGRAPHUM (composed of θέγραμ, "all," and γραμν, "I write"), in the civil law, something written wholly in the hand-writing of the person who signs it. The word is chiefly used in speaking of a testament written wholly in the testator's own hand.

The Romans did not approve of holographic testaments; and, though Valentinian authorised them by a novel, they are not used where the civil law is in full

force.

HOLESTEUM, a genus of plants belonging to the triandria class; and in the natural method ranking under the 22d order, Caryophyllaei. See BOTANY

Index.

HOLOTHURIA, a genus of the order vermnes, belonging to the class mollusca. See HELMINTHOLOGY

Index.

HOLSTEIN, a duchy of Germany, bounded by the German ocean on the west; the Baltic, or the gulf of Lubeck, on the east; the duchy of Mecklenburg on the south-east; that of Bremen, with the river Elbe, on the south-west, and Lauenburg, with the territory of Hamburg, on the south. Its greatest length is about 80 miles, and its breadth 60. The diocese of Eutin, and the county of Ranzau, though they make a part of the duchy of Holstein, yet being lands belonging to the empire and circle, shall be described separately.

A great part of this country consists of rich marsh land, which being much exposed to inundations both from the sea and rivers, dikes have been raised at a great expense to guard and defend them. The pastures in the marshes are so rich, that cattle are bred in vast numbers and fattened in them, and great quantities of excellent butter and cheese made of their milk. They are also very fruitful in wheat, barley, pease, beans, and rape-seed. In the more barren, sandy, and heathy parts of the country, large flocks of sheep are bred and fed: nor are orchards wanting, or woods, especially of oak and beech; nor turf, poultry, game, and wild-fowl. Here is a variety both of sea and river fish; and the beef, veal, mutton, and lamb, are very fat and palatable. Holstein is also noted for beautiful horses. The gentry usually farm the cows upon their estates to a Holland, as he is called, who for every cow pays from six to ten rix-dollars; the owner providing pasture for them in summer, and straw and hay in winter. It is no uncommon thing here to drain the ponds and lakes once in three or four years, and sell the carp, lamprey, pikes, and perch, found in them; then sow them for several years after with oats, or use them for pastureage; and after that lay them under water again, and breed fish in them. There are hardly any hills in the country; but several rivers, of which the principal are the Eyder, the Stor, and the Trave. The duchy contains about 30 towns great and small; most part of the peasants are under vassallage, being obliged to work daily for their lords, and not even at liberty to quit their estates. The nobility and the proprietors
Holstein of manors are possessed of the civil and criminal jurisdiction, with other privileges and exemptions. Formerly there were diets, but now they seem to be entirely laid aside: meetings, however, of the nobility are still held at Kiel. The predominant religion here is Lutheranism, with superintendencies as in other Lutheran countries. In several places the Jews are allowed the exercise of their religion. At Gluckstadt and Altena are both Calvinist and Popish churchyards; and at Kiel a Greek Russian chapel. Besides the Latin schools in the towns, at Altena is a gymnasi-um, and at Kiel an university. Notwithstanding this country's advantageous situation for commerce, there are few manufacturers and little trade in it. Hamburg and Lubeck supply the inhabitants with what they want from abroad; from whence and Altena they export some grain, malt, groats, starch, buckwheat, peas, beans, rape-seed, butter, cheese, sheep, swine, homed cattle, horses, and fish. The manufactures of the duchy are chiefly carried on at Altena, Kiel, and Gluckstadt. The duchy of Holstein consists of the ancient provinces of Holstein, Stormar, Dithmarsch, and Wagria. It belonged partly to the king of Denmark, and partly to the dukes of Holstein Gottorf and Ploen. Anciently the counts of Holstein were vassals of the dukes of Saxony; but afterwards they received the investiture of their territories from the emperor, or the bishops of Lubeck in the emperor's name, though the investiture was afterwards given by the emperor in person. The king of Denmark appoints a regency over his part of Holstein and the islands of Schleswig, which has its office at Gluckstadt. The seat of the great duke's privy council and regency-court, together with the chief assistor, is at Kiel: there are many inferior courts and consistories, from which an appeal lies to the higher. In the duchy of Holstein, the government of the convent and nobility is alternately in the king and duke for a year, from Michaelmas to Michaelmas. The person in whom the government is lodged administers it by his regency. In some cases an appeal lies from this court to the Audiencia council or chamber at Wetzlar: the convents, the nobility, and the proprietors of manors in the country, have a civil and criminal jurisdiction over their estates. The revenues of the sovereigns arise principally from their demesnes and regalia; besides which, there is a land and several other taxes and imposts. The king usually keeps here some regiments of foot and one of horse. The king, on account of his share in this country, styles himself duke of Holstein, Stormar, and Dith-marsch. The dukes both of the royal and private houses style themselves lords of Norway, duke of Sleswick, Holstein, Stormar, and Dithmarsch, and counts of Oldenburg and Delmenhorst. In 1733, Duke Charles Frederick of Holstein Gottorf founded an order of knighthood here, viz. that of St Anne, the ensign of which is a red cross, enamelled, and worn pennant at a red ribbon edged with yellow. The principal places of that part of the duchy belonging to the king of Denmark and the duke of Ploen are Gluckstadt, Itzho, Reedsburg, and Ploen; and that part belonging to the great duke are Kiel, Oldenburg, Preetz, and Altena.

The king of Denmark had originally a seat in the German diet, in consequence of possessing this duchy; but he was deprived of this privilege when the Confederation of the Rhine was organized in 1806. In 1815, on the establishment of the new Germanic constitution, he was re-admitted into the diet; and was allowed for Holstein and Lauenburg three votes in the general assembly, and a place, the tenth in rank, at the ordinary diet. The population of Holstein, in 1818, amounted to 360,000. The Danish court has lately been endeavouring to make some improvements in the interior administration of the duchy. HOLT, SIR JOHN, knight, eldest son of Sir Thomas Holt, sergeant-at-law, was born in 1642. He entered himself at Gray's Inn in 1678, and applied to the common law with so much industry, that he soon became a very eminent barrister. In the reign of James II. he was made recorder of London, which office he discharged with much applause for about a year and a half; but lost his place for refusing to expound the law suitably to the king's designs. On the arrival of the prince of Orange, he was chosen a member of the convention parliament, which afforded him a good opportunity of displaying his abilities; so that, as soon as the government was settled, he was made lord chief justice of the court of king's bench and a privy counsellor. He continued chief justice for 22 years, with great repute for steadiness, integrity, and thorough knowledge in his profession. Upon great occasions he asserted the law with intrepidity, though he ventured to incur by turns the indignation of both the houses of parliament. He published some reports, and died in 1709.

HOLT (Sat.) "a wood" whereby the names of towns beginning or ending with Hol, as Buck-holt, &c. denote that formerly there was great plenty of wood in those places.

HOLY. See HOLY.

HOLY-GHOST, one of the persons of the holy Trinity. See TRINITY.

Order of the Holy Ghost, the principal military order in France, instituted by Henry III. in 1569. It consists of 100 knights, who are to make proof of their nobility for these degrees. The king is the grand-master or sovereign; and success takes an oath on his coronation-day to maintain the dignity of the order. The knights wear a golden crown, hung about their necks by a blue silk ribbon or collar. But before they receive the order of the Holy-Ghost, that of St Michael is conferred as a necessary degree; and for this reason their arms are surrounded with a double collar.

HOLYHEAD, a town and capital of the isle of Anglesey, in Wales, and in the Irish channel, where people usually embark for Dublin, there being three packet-boats that sail for that city every Monday, Wednesday, and Friday, wind and weather permitting. It is 276 miles from London, and has a very convenient harbour for the northern trade, when taken short by contrary winds. It is situated near the extremity of the isle, and is joined to the north-west part of it by a stone bridge of one arch. It has a small market on Saturdays. The parish is about five or six miles long, and two or three broad, bounded nearly by the sea. The church stands above the harbour, within an old quadrangular fortification, with a bastion at each corner, built about 450. On a mountain near it is another old fortification called Turris Munimentum, which.
HOLY-ISLAND, a small island lying on the coast of England, 10 miles south-east of Berwick, in Northumberland. Bede calls it a semi-island, being, as he observes, twice an island and twice continent in one day; for at the flowing of the tide, it is encompassed by water; and at the ebb, there is an almost dry passage, both for horses and carriages, to and from the main land; from which, if measured on a straight line, it is distant about two miles eastward; but on account of some quicksands passengers are obliged to make many detours, that the length of way is nearly doubled. The water over these flats at spring-tides is only seven feet deep. This island was by the Britons called Inis Medicante; also Landisfarne, from the small rivulet of Lindis or Landia, which here runs into the sea, and the Celtic word faeren or recess; and on account of its being the habitation of some of the first monks in this country, it afterwards obtained its present name of Holy-island. It measures from east to west about two miles and a quarter, and its breadth from north to south is scarcely a mile and a half. At the north-west part there runs out a spit of land of about a mile in length. The monastery is situated at the southermost extremity; and at a small distance north of it stands the village. On this island there is plenty of fish and fowl; but the air and soil are bad. There is not a tree on the island. The village, which stands on a rising ground, consists but of a few scattered houses, chiefly inhabited by fishermen; and it has two inns. The north and east coasts are formed of perpendicular rocks, the other sides sink by gradual slopes to the sands. There is a commodious harbour, defended by a block-house; which last was surprised and taken in 1715, but was soon invested and retaken.

Holy-island, though really part of Northumberland, belongs to Durham; and all civil disputes must be determined by the justices of that county. It was a very ancient episcopal seat. Aidan the first bishop, after presiding in it 14 years, died and was buried here A.D. 651. Finan, his successor, built a wooden church, thatched with reeds, but before the end of the century covered with lead by Bishop Eadbert. St Cuthbert, who from a poor shepherd became monk of Melrose 15 years, was prior here 12 more, when he retired to one of the barren Farne rocks, from whence he was called to this see, which he held only two years, and returned to his retirement, where he died, and was buried at the east end of his oratory, where his stone coffin is still shown. His body was found fresh 11 years after his death. Lindisfarne was ruined by the Danes, A.D. 793, when the monks carried his body about for seven years, and at last settled at Chester-le-street, whither the sea was translated, and where it continued many years. On a second destruction of the monastery by the Danes they were removing to Ripon, but stopped by a miracle at Durham, where the saint continued till the Reformation, when his body was found entire, and privately buried in a wooden coffin, as some pretend, near the clock, but more probably in the ground under where his shrine stood. The entrenches found among the rocks at Lindisfarne are called St Cuthbert's beds, and pretended to be made by him in the night. Eighteen bishops sat here till the removal of the see to Chester, which had eight more till the removal to Durham, A.D. 995. Lin-"
Lord Kames's grandfather, Henry Home, was a son of Sir John Home of Renton, who held the high office of lord justice- clerk, or chief criminal judge of Scotland, in the year 1663. He received the estate of Kames from his uncle George, who was lord justiclerk. The family of Renton is descended from that of the earls of Home, the representatives of the ancient princes of Northumberland, as appears from the records of the Lion Office.

The county of Berwick in Scotland has the honour of having given birth to this great and useful member of society. In early youth he was lively, and eager in the acquisition of knowledge. He never attended a public school; but was instructed in the ancient and modern languages, as well as in several branches of mathematics, and the arts necessarily connected with that science, by Mr Wingate, a man of considerable parts and learning, who spent many years as preceptor or private tutor to Mr Home.

After studying, with acuteness and diligence, at the university of Edinburgh, the civil law, and the municipal law of his own country, Mr Home early perceived that a knowledge of these alone is not sufficient to make an accomplished lawyer. An acquaintance with the forms and practical business of courts, and especially of the supreme court, as a member of which he was to seek for fame and emolument, he considered as essentially necessary to qualify him to be a complete barrister. He accordingly attended for some time the chamber of a writer to the signet, where he had an opportunity of learning the styles of legal deeds, and the modes of conducting different species of business. This wise step, independently of his great genius and unwearied application, procured him, after his admission to the bar, peculiar respect from the court, and proportional employment in his profession of an advocate. Whoever peruses the law-papers composed by Mr Home when a young man, will perceive an uncommon elegance of style, besides great ingenuity of reasoning, and a thorough knowledge of the law and constitution of his country. These qualifications, together with the strength and vivacity of his natural abilities, soon raised him to be an ornament to the Scottish bar; and, on the 2d day of February 1752, he was advanced to the bench as one of the judges of the court of session, under the title of Lord Kames.

Before this period, however, notwithstanding the unavoidable labours of his profession, Mr Home had favoured the world with several useful and ingenious works. In the year 1728, he published Remarkable Decisions of the Court of Session from 1716 to 1728, in one volume folio. In 1732 appeared Essays upon several subjects in law, viz. Justitia; Beneficium cedendorum actuum; Vinco Vincentius; and Prescription; in one volume 8vo. This first produced of his original genius, and of his extensive views, excited not only the attention, but the admiration of the judges, and of all the other members of the college of justice. This work was succeeded, in the year 1741, by Decisions of the Court of Session from its first institution to the year 1740, abridged and digested under proper heads, in a form of a Dictionary, in two volumes folio: a very laborious work, and of the greatest utility to every practical lawyer. In 1747 appeared Essays...
The year 1751 gave birth to the first fruits of his lordship's metaphysical studies, under the title of Essays on the Principles of Morality and Natural Religion, in two parts. Though a small volume, it was replete with ingenuity and acute reasoning, excited general attention, and gave rise to much controversy. It contained, in more explicit terms than perhaps any other work of a religious theist then known in Scotland, the doctrine which has of late made so much noise under the appellation of philosophical necessity. The same thing had indeed been taught by Hobbes, by Collins, and by the celebrated David Home, Esq., but as those authors either were profess'd infidels, or were supposed to be such, it excited, as coming from them, no wonder, and provoked for a time very little indignation. But when a writer, who exhibited no symptoms of extravagant scepticism, who insinuated nothing against the truth of revelation in general, and who inculcated with earnestness the great duties of morality and natural religion, advanced at the same time so uncommon a doctrine as that of necessity; a number of pens were immediately drawn against him, and for a while the work and its author were extremely obnoxious to a great part of the Scottish nation. On the other hand, there were some, and those not totally illiterates, who, confounding necessity with predestination, complimented Mr Home on his masterly defence of the established faith: and though between these two schemes there is no sort of resemblance, except that the future happiness or misery of all men is, according to both, certainly foreknown and appointed by God; yet we remember, that a professor in a dissenting academy so far mistook the one for the other, that he recommended to his pupils the Essays on Morality and Natural Religion, as containing a complete vindication of the doctrine of Calvin. For this mistake he was dismissed from his office, and excluded from the communion of the sect to which he belonged. Lord Kames, like many other great and good men, continued a necessary to the day of his death; but in a subsequent edition of the Essays, he exhibited a remarkable proof of his candour and liberality of sentiment, by altering the expressions, which, contrary to his intention, had given such general offence.

In 1761, he published an Introduction to the art of Thinking, in one volume 12mo. This small but valuable book was originally intended for the instruction of his own family. The plan of it is both curious, amusing, and highly calculated to catch the attention and to improve the minds of youth. It consists of maxims collected from Rochezofinault and many other authors. To illustrate these maxims, and to rivet the spirit and meaning in the minds of young persons, his lordship has added to most of them beautiful stories, fables, and historical anecdotes.

In the department of belles lettres, his Elements of Criticism appeared in 1762, in three volumes 8vo. This valuable work is the first, and a most successful attempt to shew, that the art of criticism is founded on the principles of human nature. Such a plan, it might be thought, should have produced a dry and phlegmatic performance. Lord Kames, on the contrary, from the sprightliness of his manner of treating every subject he handled, has rendered the Elements of Criticism not only highly instructive, but one of the most entertaining books in our language. Before this work...
he modestly gives the title of "Loose Hints upon Education, briefly concerning the culture of the heart." It was published in the year 1780, in one vol. 8vo, when the venerable and astonishing author was in the 89th year of his age. Though his lordship chose to call them "Loose Hints," the intelligent reader will perceive in this composition an uncommon activity of mind at an age so far advanced beyond the usual period of human life, and an earnest desire to form the minds of youth to honour, to virtue, to industry, and to a veneration of the Deity.

Besides the books we have enumerated, Lord Kames published many temporary and fugitive pieces in different periodical works. In the "Essays Physical and Literary," published by a society of gentlemen in Edinburgh, we find compositions of his lordship on "The Laws of Motion," "On the Advantages of Shallow Ploughing," and on "Evaporation"; all of which exhibit evident marks of genius and originality of thinking.

How a man employed through life in public business, and in business of the first importance, could find leisure for so many different pursuits, and excel in them (A), it is not easy for a meaner mind to form even a conception. Much, no doubt, is to be attributed to the superiority of his genius; but much must likewise have been the result of a proper distribution of his time. He rose early; when in the vigour of life at four o'clock, in old age at six; and studied all morning. When the court was sitting, the duties of his office employed him from eight or nine till twelve or one; after which, if the weather permitted, he walked for two hours with some literary friends, and then went home to dinner. Whilst he was on the bench, and we believe when he was at the bar, he neither gave nor accepted invitations to dinner during the term or session; and if any friend came uninvited to dinner with him, his lordship displayed his usual cheerfulness and hospitality, but always retired with his clerk as soon as he had drunk a very few glasses of wine, leaving his company to be entertained by his lady. The afternoon was spent as the morning had been, in study. In the evening he went to the theatre or the concert, from which he returned to the society of some men of learning, with whom he sat late, and displayed such talents for conversation as are not often found. It is observed by a late celebrated author, that "to read, write, and converse, in due proportions, is the business of a man of letters; and that he who hopes to look back hereafter with satisfaction upon past years, must learn to know the value of single minutes, and endeavour to let no particle of time fall useless to the ground." It was by practising these lessons that Lord Kames rose to literary eminence, in opposition to all the obstacles which the tumult of public business could place in his way.

To give a proper delineation of the public and pri-
HOM [ 580 ]

vate character of Lord Kames, would far exceed our limits. The writer of this article, however, who had the honour of an intimate acquaintance with this great and good man for more than twenty years, must be indulged in adding a few facts which fell under his own observation.

Lord Kames was remarkable for public spirit, to which he conjoined activity and great exertion. He for a long tract of time had the principal management of all the societies and boards for promoting the trade, fisheries, and manufactures, in Scotland. As conducive to those ends, he was a strenuous advocate for making and repairing turnpike roads through every part of the country. He had likewise a chief lead in the distribution and application of the funds arising from the estates in Scotland which had unfortunately been annexed to the crown. He was no less zealous in supporting, both by his writings and personal influence, literary associations. He was in some measure the parent of what was called the Physical and Literary Society. This society was afterwards incorporated into the Royal Society of Edinburgh, which received a charter from the crown, and which is daily producing marks of genius, as well as works of real utility.

As a private and domestic gentleman, Lord Kames was admired by both sexes. The vivacity of his wit, and of his animal spirits, even when advanced in years, rendered his company not only agreeable, but greatly solicited by the literati, and courted by ladies of the highest rank and accomplishments. He told very few stories; and rarely, if ever, repeated the same story to the same person. From the necessity of retelling anecdotes, the miserable refuge of those who, without genius, attempt to shine in conversation, the abundance of his own mind set him free; for his wit or his learning always suggested what the occasion required. He could with equal ease and readiness combat the opinions of a metaphysicist, unravel the intricacies of law, talk with a farmer on improvements in agriculture, or estimate with a lady the merits of the dress in fashion. Instead of being jealous of rivals, the characteristic of little minds, Lord Kames suffered and encouraged every symptom of merit that he could discover in the scholar, or in the lowest mechanic. Before he succeeded to the estate of Blair Drummond, his fortune was small. Notwithstanding this circumstance, he, in conjunction with Mrs. Drummond, his respectable and accomplished spouse, did much more service to the indigent than most families of greater opulence. If the present necessity was pressing, they gave money. They did more: When they discovered that male or female petitioners were capable of performing any art or labour, both parties exerted themselves in procuring that species of work which the poor people could perform. In cases of this kind, which were very frequent, the lady took charge of the women and his lordship of the men. From what has been said concerning the various and numerous productions of his genius, it is obvious that there could be few idle moments in his long protracted life. His mind was incessantly employed; either teeming with new ideas, or pursuing active and laborious occupations. At the same time, with all this intellectual ardour, one great feature in the character of Lord Kames, besides his literary talents and his public spirit, was a remarkable innocence of mind. He not only never indulged in distraction, but when any species of scandal was exhibited in his company, he either remained silent, or endeavoured to give a different turn to the conversation. As natural consequences of this amiable disposition, he never meddled with politics, even when parties ran to indecent lengths in this country; and what is still more remarkable, he never wrote a sentence, notwithstanding his numerous publications, without a direct and a manifest intention to benefit his fellow creatures. In his temper he was naturally warm, though kind and affectionate. In the friendships he formed, he was ardent, zealous, and sincere. So far from being inclined to irreligion, as some ignorant bigots insinuated, few men possessed a more devout habit of thought. A constant sense of Deity, and a veneration for Providence, dwelt upon his mind. From this source arose that propensity which appears in all his writings, of investigating final causes, and tracing the wisdom of the Supreme Author of nature. But here we must stop. Lord Kames, to the great regret of the public, died on the 27th day of December 1782. As he had no marked disease but the debility necessarily resulting from extreme old age, a few days before his death he went to the Court of Session, addressed all the judges separately, told them he was speedily to depart, and took a solemn and affectionate farewell.

HOME, John, a late eminent Scottish dramatic writer. See SUPPLEMENT.

HOMER, the prince of the Greek poets, flourished, according to Dr. Blair, about 900 B.C. according to Dr. Prestley 850, according to the Arundelian marbles 300, after the taking of Troy; and memorable to them all about 400 years before Plato and Aristotle. Seven cities disputed the glory of having given him birth, viz. Smyrna, Rhodes, Colophon, Salamis, Chios, Argos, and Athens.

-Smyrna,Rhodes,Colophon,Salamis,Chios,Argos,tt,Homer;
-Orbis de patria certe, Homere, tua.

We have nothing that is very certain in relation to the particulars of his life. The most regular account is that which goes under the name of Herodotus; and though it is generally supposed to be a spurious piece, yet as it is ancient, was made use of by Strabo, and exhibits that idea which the later Greeks, and the Romans in the age of Augustus, entertained of Homer, we must content ourselves with giving an abstract of it.

A man of Magnesia, whose name was Memalippus, went to settle at Cumae, where he married the daughter of a citizen called Homoros, and had by her a daughter called Crithis. The father and mother dying, the young woman was left under the tuition of Cenax her father's friend, and suffering herself to be deluded, was got with child. The guardian, though his care had not prevented the misfortune, was however willing to conceal it; and therefore sent Crithis to Smyrna, which was then building, 18 years after the founding of Cumae, and about 168 after the taking of Troy. Crithis being near her time, went one day to a festival which the town of Smyrna was celebrating on the banks of the river Males; where her pains coming upon her, she was delivered of Homer, whom she called Melitogenes, because he was born on the banks
Homer. banks of that river. Having nothing to maintain her,
she was forced to spin, and a man of Smyrna called
Phemius, who taught literature and music, having of-
ten seen Critheis, who lodged near him, and being
pleased with her housewifery, took her into his house
to spin the wool he received from his scholars for their
schooling. Here she behaved herself so modestly and
discreetly, that Phemius married her; and adopted her
son, in whom he discovered a wonderful genius, and
the best natural disposition in the world. After the
death of Phemius and Critheis, Homer succeeded to
his father-in-law's fortune and school; and was admis-
sed, not only by the inhabitants of Smyrna, but by
strangers, who resorted from all parts to that place of
trade. A shipmaster called Mentes, who was a man of
learning and a lover of poetry, was so taken with Ho-
er, that he persuaded him to leave his school, and to
travel with him. Homer, who had then begun his
poem of the Iliad, and thought it of great consequence
to see the places he should have occasion to treat of,
embraced the opportunity. He embarked with Mentes,
and during their several voyages never failed carefully
to note down all that he thought worth observing. He
travelled into Egypt, from whence he brought into
Greece the names of their gods, the chief ceremonies
of their worship, and a more improved knowledge in
the arts than what prevailed in his own country. He
visited Africa and Spain; in his return from whence
he touched at Ithaca, where he was much troubled
with a rheum falling upon his eyes. Mentes being in
haste to take a turn to Lesbos his native country,
left Homer well recommended to Mentor, one of the
chief men of the island of Ithaca, who took all possible
care of him. There Homer was informed of many
things relating to Ulysses, which he afterwards made
use of in composing his Odyssey. Mentes returning to
Ithaca, found Homer cured. They embarked together;
and after much time spent in visiting the coasts
of Peloponnesus and the islands, they arrived at Colo-
phon, where Homer was again troubled with the
defluxion upon his eyes, which proved so violent, that he
is said to have lost his sight. This misfortune made
him resolve to return to Smyrna, where he finished his
Iliad. Some time after, the ill posture of his affairs
obliged him to go to Cumae, where he hoped to have
found some relief. Here his poems were highly ap-
plauded: but when he proposed to immortalize their
town, if they would allow him a salary, he was answer-
ed, that "there would be no end of maintaining all
the "Omen", or blind men;" and hence got the name of
Homer. He afterwards wandered through several
places, and stopped at Chios, where he married, and
composed his Odyssey. Some time after, having added
many verses to his poems in praise of the cities of
Greece, especially of Athens and Argos, he went to
Samos, where he spent the winter, singing at the houses
of the great men, with a train of boys after him. From
Samos he went to Io, one of the Sporades, with a de-
sign to continue his voyage to Athens; but landing by
the way at Chios, he fell sick, died, and was buried on
the sea shore.

The only incontestable works which Homer has left
behind him are the Iliad and Odyssey. The Batracho-
mymosachia, or battle of the frogs and mice, has been
disputed. The hymns have been disputed also, and at-
tributed by the scholiasts to Cynethus the rhythmist: but
neither Thucydides, Lucian, nor Pausanias, have
scrupled to cite them as genuine. Many other pieces
are ascribed to him: epigrams, the Eastyges, the Ca-
cropeis, the destruction of Oschalia, of which only the
names are remaining.

Nothing was ever comparable to the cleanness and
majesty of Homer's style; to the sublimity of his
thoughts; to the strength and sweetness of his verses.
All his images are striking; his descriptions just
and exact; the passions so well expressed, and nature so justly
and finely painted, that he gives to every thing 
emotion, life, and action. But he more particularly excels
in invention, and in the different characters of his
heroes, which are so varied, that they affect us in an in-
expressible manner. In a word, the more he is read
by a person of good taste, the more he is admired.
Nor are his works to be esteemed merely as entertain-
ing poems, or as the monuments of a sublime and va-
ried genius. He was in general so accurate with re-
spect to costume, that he seldom mentioned persons or
things that we may not conclude to have been known
during the times of which he writes; and it was Mr
Pope's opinion, that his accuracy in the people, princes, and
countries, was purely historical, founded on the real
transactions of those times, and by far the most valuable
piece of history and geography left us concerning the
state of Greece in that early period. His geogra-
phical divisions of that country were thought so exact,
that we are told of many controversies concerning the
boundaries of Grecian cities which have been decided
upon the authority of his poems.

Achilles gave a rhetorician a box on the ear for
not having Homer's writings in his school. Alexander
was ravished with them, and commonly placed them
under his pillow with his sword: he inclosed the Iliad
in the precious casket that belonged to Darius; "in
order (said he to his courtiers) that the most perfect
production of the human mind might be inclosed in the
most valuable casket in the world." And one day sein-
ing the tomb of Achilles in Sigara, "Fortunate hero!
(cried he), thou hast had a Homer to sing thy victo-
ries!" Lycurgus, Solon, and the kings and princes of
Greece, set such a value on Homer's works, that they
took the utmost pains in procuring correct editions of
them, the most esteemed of which is that of Aristarchus.
Didymus was the first who wrote notes on Homer;
and Eustathius, archbishop of Thessalonica, in the 12th
century, is the most celebrated of his commentators.
Mr Pope has given an elegant translation of the Iliad,
adorned with the harmony of poetic numbers; and
Mad. Dacier has translated both the Iliad and Odyssey
in prose.

Those who desire to know the several editions of
Homer, and the writers who have employed themselves
on the works of that great poet, may consult Fabricius,
in the first volume of his Bibliotheca Graecae.

A very singular discovery, however, which was made
a few years ago in Russia, deserves to be here mention-
ed, together with the circumstances that attended it.
Christian Frederic Matthei, who had been educated by
the learned Ernesti, and did credit to the instructions
of that celebrated master by the great erudition that he
displayed, being invited to settle at Moscow, and to as-
sist in a plan of literature for which his abilities and ac-
quisions
HOMER. But though M. Rubenkenius is not inclined to attribute to Homer the hymn to Ceres, he yet acknowledges, that the structure of its language is founded on the model of that great poet, and he hesitates not to give it the honour of very high antiquity. He is of opinion, that it was written immediately after Homer, or at least in the age of Hesiod; and he congratulates the age on the discovery of so curious a poem, rescued by mere accident from the darkest retreats of oblivion, and perhaps but at a slight distance from inevitable perdition. He deems it to be an acquisition, not only calculated to gratify the curiosity of the connoisseurs in classic antiquity, or to entertain those lovers of Greek poetry whose studies are made subservient to a refined and elegant species of amusement, but he also esteems it to be of particular use to the critic, as it tends to illustrate some obscure passages both in the Greek and Latin poets.

HOMER, Homer, or Chomer, a Jewish measure, containing the tenth part of the ephah. See CORUS and MEASURE.

HOMESOKEN. See HAMESOKEN.

HOMICIDE, signifies in general the taking away of any person's life. It is of three kinds; justifiable, excusable, and felonious. The first has no share of guilt at all; the second very little; but the third is the highest crime against the law of nature that man is capable of committing.

I. Justifiable homicide is of divers kinds.

1. Such as is owing to some unavoidable necessity, without any will, intention, or desire, and without any inadvertence or negligence, in the party killing, and therefore without any shadow of blame; as, for instance, by virtue of such an office as obliges one, in the execution of public justice, to put a malefactor to death, who hath forfeited his life by the laws and verdict of his country. This is an act of necessity, and even of civil duty; and therefore not only justifiable but commendable, where the law requires it. But the law must require it, otherwise it is not justifiable: therefore wantonly to kill the greatest of malefactors, a felon, or a traitor, attainted or outlawed, deliberately, uncompelled, and extrajudicially, is murder. And farther, if judgment of death be given by a judge not authorized by lawful commission, and execution is done accordingly, the judge is guilty of murder. Also such judgment, when legal, must be executed by the proper officer, or his appointed deputy; for no one else is required by law to do it, which requisition it is that justifies the homicide. If another person doth it of his own head, it is held to be murder: even though it be the judge himself. It must farther be executed, servato juris ordine; it must pursue the sentence of the court. If an officer beheads one who is adjudged to be hanged, or vice versa, it is murder: for he is merely ministerial, and therefore only justified when he acts under the authority and compulsion of the law. But if a sheriff changes one kind of punishment for another, he then acts by his own authority, which extends not to the commission of homicide; and besides, this licence might occasion a very gross abuse of his power. The king indeed may remit part of a sentence, as in the case of treason, all but the beheading: but this is no change, no introduction of a new punishment; and in the case of
Hom. 583.

Homicide. In some cases homicide is justifiable, rather by permission, than by the absolute command of the law: either for the advancement of public justice, or in cases where the person killed was a criminal, or in cases where the person killing was acting in self-defense.

2. Homicides committed for the advancement of public justice, are: 1. Where an officer, in the execution of his office, either in a civil or criminal case, kills a person that resists him. 2. Where an officer, or any person assisting him, attempts to take a man charged with felony, and is resisted; and, in the endeavor to take him, kills him. 3. Where the prisoner in a gaol, or going to gaol, assault the gaoler or officer, and he in his defense kills any of them, it is justifiable, for the sake of preventing an escape. 4. Where trespassers in woods, parks, chases, or warrens, will not surrender themselves to the keepers, they may be slain; by virtue of the statute 21 Edward I. stat. 2. de malo factoribus in parcis, and 3 and 4 W. and M. c. 10.

But, in all these cases, there must be an apparent necessity on the officer's side; viz. that the party could not be arrested or apprehended, the riot could not be suppressed, the prisoners could not be kept in hold, the deer-stealers could not but escape, unless such homicide were committed; otherwise, without such absolute necessity, it is not justifiable. 6. If the champions in a trial by battle killed either of them the other, such homicide was justifiable, and was imputed to the just judgment of God, who was thereby presumed to have decided in favor of the truth.

In these instances of justifiable homicide, it may be observed, that the slayer is in no kind of fault whatsoever, not even in the minutest degree; and is therefore to be totally acquitted and discharged, with commendation rather than blame. But that is not quite the case in excusable homicide, the very name whereof imports some fault, some error, or omission; so trivial, however, that the law excuses it from the guilt of felony, though in strictness it judges it deserving of some little degree of punishment.

II. Excusable homicide is of two sorts; either per infortunium, by misadventure; or se defendendo, upon a principle of self-preservation. We will first see wherein these two species of homicide are distinct, and then wherein they agree.

1. Homicide per infortunium, or misadventure, is where a man, doing a lawful act, without any intention of hurt, unfortunately kills another; as where a man is at work with a hatchet, and the head thereof flies off and kills a stranger; or where a person, qualified to keep a gun, is shooting at a mark, and undesignedly kills a man: for the act is lawful, and the effect is merely accidental. So where a parent is moderately correcting his child, a master his apprentice or scholar, or an officer punishing a criminal, and happens to occasion his death, it is only misadventure; for the act of correction was lawful: but if he exceeds the bounds of moderation, either in the manner, the instrument, or the quantity of punishment, and death ensues, it is manslaughter at least, and in some cases (according to the circumstances) murder; for the act of immoderate correction is unlawful. Thus by an edict of the emperor Constantine, when the rigour of the Roman law with regard to slaves began to relax and soften, a master was allowed to chastise his slave with rods and imprisonment,

Homicide. imprisonment: and if death accidentally ensued, he was guilty of no crime; but if he struck him with a club or a stone, and thereby occasioned his death, or if in any other yet grosser manner immoderatè suo jure utatur, tun redi homicidii sit.

But to proceed. A tilt or tournament, the martial diversion of our ancestors, was however an unlawful act; and so are boxing and sword-playing, the succeeding amusement of their posterity: and therefore, if a knight in the former case, or a gladiator in the latter, be killed, such killing is felony of manslaughter. But if the king command or permit such diversion, it is said to be only misadventure; for then the act is lawful: in like manner as, by the laws both of Athens and Rome, he who killed another in the 

cranium, or public games, authorised or permitted by the state, was not held to be guilty of homicide. Likewise to whip another's horse, whereby he runs over a child and kills him, is held to be accidental in the rider, for he has done nothing unlawful; but manslaughter in the person who whipped him, for the act was a trespass, and at best a piece of idleness, of inevitably dangerous consequence. And in general, if death ensues in consequence of an idle, dangerous, and unlawful sport, as shooting or casting stones in a town, or the barbarous diversion of cock-throwing; in these and similar cases, the slayer is guilty of manslaughter, and not misadventure only; for these are unlawful acts.

2. Homicide in self-defence, or se defendendo, upon a sudden affray, is also excusable rather than justifiable, by the English law. This species of self-defence must be distinguished from that just now mentioned, as calculated to hinder the perpetration of a capital crime; which is not only a matter of excuse, but of justification. But the self-defence which we are now speaking of, is that whereby a man may protect himself from an assault, or the like, in the course of a sudden brawl or quarrel, by killing him who assaults him. And this is what the law expresses by the word chance-medley, or (as some rather choose to write it) chau-medley: the former of which in its etymology signifies a casual affair, the latter an affair in the heat of blood or passion: both of them of pretty much the same import; but the former is in common speech too often erroneously applied to any manner of homicide by misadventure; whereas it appears by the statute 24 Hen. VIII. c. 5. and our ancient books, that it is properly applied to such killing as happens in self-defence upon a sudden rencontre. The right of natural defence does not imply a right of attacking: for, instead of attacking one another for injuries past or impending, men need only have recourse to the proper tribunals of justice. They cannot therefore legally exercise this right of preventive defence, but in sudden and violent cases; when certain and immediate suffering would be the consequence of waiting for the assistance of the law. Wherefore, to excuse homicide by the plea of self-defence, it must appear that the slayer had no other possible means of escaping from his assailant.

In some cases this species of homicide (upon chance-medley in self-defence) differs but little from manslaughter, which also happens frequently upon chance-medley in the proper legal sense of the word. But the true criterion between them seems to be this: when both parties are actually combating at the time when the mortal stroke is given, the slayer is then guilty of man-slaughter; but if the slayer hath not begun to fight, or (having begun) endeavours to decline any farther struggle, and afterwards, being closely pressed by his antagonist, kills him to avoid his own destruction, this is homicide excusable by self-defence. For which reason the law requires, that the person, who kills another in his own defence, should have retreated as far as he conveniently or safely can, to avoid the violence of the assault, before he turns upon his assailant; and that not fictiously, or in order to watch his opportunity, but from a real tenderness of shedding his brother's blood. And though it may be cowardice in time of war between two independent nations, to flee from an enemy; yet between two fellow subjects, the law countenances no such point of honour: because the king and his courts are the vindices injuriarum, and will give to the party wronged all the satisfaction he deserves. In this the civil law also agrees with ours, or perhaps goes rather farther; "qui cum aliis tueri as non possint, domni culpam dedentur, innoxii sunt." The party assaulted must therefore flee as far as he conveniently can, either by reason of some wall, ditch, or other impediment; or as far as the fierceness of the assault will permit him; for it may be so fierce as not to permit him to yield a step, without manifest danger of his life, or enormous bodily harm; and then in his defence he may kill his assailant instantly. And this is the doctrine of universal justice, as well as of the municipal law.

And, as the manner of the defence, so is also the time to be considered: for if the person assaulted does not fall upon the aggressor till the affray is over, or when he is running away, this is revenge, and not defence. Neither, under the colour of self-defence, will the law permit a man to screen himself from the guilt of deliberate murder: for if two persons, A and B, agree to fight a duel, and A gives the first onset, and B retreats as far as he safely can, and then kills A, this is murder; because of the previous malice and concerted design. But if A upon a sudden quarrel assaults B first, and, upon B's returning the assault, A really and bona fide flies; and, being driven to the wall, turns again upon B and kills him; this may be 

se defendendo, according to some of our writers; though others have thought this opinion too favourable: inasmuch as the necessity, to which he is at last reduced, originally arose from his own fault. Under this excuse of self-defence, the principal civil and natural relations are comprehended: therefore, master and servant, parent and child, husband and wife, killing an assailant in the necessary defence of each other respectively, are excused; the act of the relation assisting being construed the same as the act of the party himself.

There is one species of homicide se defendendo, where the party slain is equally innocent as he who occasions his death: and yet this homicide is also excusable from the great universal principle of self-preservation, which prompts every man to save his own life preferable to that of another, where one of them must inevitably perish. As, among others, in that case mentioned by Lord Bacon, where two persons, being shipwrecked, and getting on the same plank, but finding it not possible to save them both, one of them thrusts the other from it.
Homicide, whereby he is drowned. He who thus preserves his own life at the expense of another man's, is excusable through unavoidable necessity, and the principle of self-defence; since their both remaining on the same weak plank is a mutual though innocent attempt upon, and an endangering of, each other's life.

Let us next take a view of those circumstances wherein these two species of homicide, by misadventure and self-defence, agree; and these are in their blame and punishment. For the law sets so high a value upon the life of a man, that it always intends some misbehaviour in the person who takes it away, unless by the command or express permission of the law. In the case of misadventure, it presumes negligence, or at least a want of sufficient caution, in him who was so unfortunate as to commit it; who therefore is not altogether faultless. And as to the necessity which excuses a man who kills another se defendendo, Lord Bacon intitles it necessitas culpabilis, and thereby distinguishes it from the former necessity of killing a thief or a malefactor. For the law intends that the quarrel or assault arose from some unknown wrong, or some provocation, either in word or deed; and since in quarrels both parties may be, and usually are, in some fault; and as it scarce can be tried who was originally in the wrong, the law will not hold the survivor entirely guiltless. But it is clear, in the other case, that where I kill a thief who breaks into my house, the original default can never be upon my side. The law besides may have a farther view, to make the crime of homicide more odious, and to caution men how they venture to kill another upon their own private judgment, by ordaining, that he who slays his neighbour, without an express warrant from the law so to do, shall in no case be absolutely free from guilt.

Nor is the law of England singular in this respect. Even the slaughter of enemies required a solemn purgation among the Jews; which implies, that the death of a man, however it happens, will leave some stain behind it. And the Mosical law appointed certain cities of refuge for him "who killed his neighbour unaware; as if a man goeth into the wood with his neighbour to hew wood, and his hand fetcheth a stroke with the ax to cut down a tree, and the head slippeth from the helve, and lighteth upon his neighbour that he die, he shall flee into one of those cities and live." But it seems he was not held wholly blameless, any more than in the English law; since the avenger of blood might slay him before he reached his asylum, or if he afterwards stirred out of it till the death of the high priest. In the imperial law likewise casual homicide was excused, by the indulgence of the emperor signed with his own sign manual, adnotatione principis; otherwise, the death of a man, however committed, was in some degree punishable. Among the Greeks, homicide by misfortune was expiated by voluntary banishment for a year. In Saxony, a fine is paid to the kindred of the slain; which also, among the western Goths, was little inferior to that of voluntary homicide; and in France, no person is ever absolved in cases of this nature, without a largess to the poor; and the charge of certain masses for the soul of the party killed.

The penalty inflicted by our laws is said by Sir Edward Coke to have been anciently no less than death; Vol. X. Part II.

which, however, is with reason denied by later and more accurate writers. It seems rather to have consisted in a forfeiture, some say of all the goods and chattels, others of only a part of them, by way of fine or weregild: which was probably disposed of, as in France, in pio usu, according to the humane superstition of the times, for the benefit of his soul who was thus suddenly sent to his account with all his imperfections on his head: But that reason having long ceased, and the penalty (especially if a total forfeiture) growing more severe than was intended, in proportion as personal property has become more considerable, the delinquent has now, and has had as early as our records will reach, a pardon and writ of restitution of his goods as a matter of course and right, only paying for suing out the same. And, indeed, to prevent this expense, in cases where the death has notoriously happened by misadventure or in self-defence, the judges will usually permit (if not direct) a general verdict of acquittal.

III. Felonious homicide is an act of a very different nature from the former, being the killing of a human creature, of any age or sex, without justification or excuse. This may be done either by killing one's self, or another man: for the consideration of which, see the articles SELF-MURDER, MURDER, and MANSLAUGHTER.

HOMILY, in ecclesiastical writers, a sermon or discourse upon some point of religion, delivered in a plain manner, so as to be easily understood by the common people. The word is Greek, ἡμιλία; formed of ἡμιλέω, catus, "assembly or council."

The Greek homily, says M. Fleury, signifies a familiar discourse, like the Latin sermo; and discourses delivered in the church took these denominations, to intimate, that they were not harangues or matters of ostentation and flourish, like those of profane orators, but familiar and useful discourses, as of a master to his disciples, or a father to his children.

All the homilies of the Greek and Latin fathers are composed by bishops. We have none of Tertullian, Clemens Alexandrinus, and many other learned persons; because, in the first ages, none but bishops were admitted to preach. The privilege was not ordinarily allowed to priests till toward the fifth century. St. Chrysostom was the first presbyter that preached stedly. Orig and St Augustine also preached; but it was by a peculiar license or privilege.

Photius distinguishes homily from sermon; in that the homily was performed in a more familiar manner, the prelate interrogating and talking to the people, and they in their turn answering and interrogating him, so that it was properly a conversation; whereas the sermon was delivered with more form, and in the pulpit, after the manner of the orators.

The practice of compiling homilies, which were to be committed to memory, and recited by ignorant or indolent priests, commenced towards the close of the 8th century, when Charlemagne ordered Paul Descon and Alcuin to form homilies or discourses upon the Gospels and Epistles, from the ancient doctors of the church. This gave rise to that famous collection entitled the Homiliarium of Charlemagne, and which being followed as a model by many productions of the same kind, composed by private persons, from a principle of
HOMINE REPLEYANDO, a writ for the bailing of a man out of prison when he is confined without commandment of the king or his judges, or for any cause that is repleivable. But this writ is now seldom used; a writ of habeas corpus being used on the necessary occasions.

HOMMOC, a name given by mariners to a hillock or small eminence of land, resembling the figure of a cone, and appearing on the sea coast of any country.

HOMO, MAN, is ranked by Linnæus under the order of primates; and characterised by having four parallel fore teeth both in the upper and lower jaw, and two mamme on the breast. This species, according to this author, are two, viz. the homo sapiens, and the homo troglodytes.

He subdivides the homo sapiens into five varieties, viz. the American, the European, the Asiatic, the African, and what he calls the monstrous. See MAN.

The troglodytes, or orang-outang, is a native of Ethiopia, Java, and Amboina. His body is white; he walks erect, and is about one-half the ordinary human size. He generally lives about 25 years. He conceals himself in caves during the day, and searches for his prey in the night. He is said to be exceedingly sagacious, but is not endowed with the faculty of speech. See TROGLODYTES and SIMIA, MAMMALIA INDEX.

HOMOGENEOUS, or HOMOGENEAL (composed of the Greek ὁμογενής, "like," and γένος, "kind"), is a term applied to various subjects, to denote, that they consist of similar parts, or of parts of the same nature and kind; in contradistinction to heterogeneous, where the parts are of different natures, &c.

HOMOLOGATION, in the civil law, the act of conferring or rendering a thing more valid and solemn, by publication, repetition, or recognition thereof. The word comes from the Greek ὁμολογία, "consent, assent;" formed of ὁμολογία, "like," and λογία, of λόγος, "to say;" q. d. to say the same thing; to consent, agree.

HOMOLOGOUS, in Geometry, an appellation given to the corresponding sides and angles of similar figures, as being proportional to each other.

HONAN, a province of China, bounded on the north by that of Petcheli and Chausi, on the west by Chami, on the south by Hongkong, and on the coast by Chantung. Every thing that can contribute to render a country delightful is found united in this province; the Chinese therefore call it Tong-hoa, or the middle flower: it is indeed situated almost in the centre of China. The ancient emperors, invited by the mildness of the climate and the beauty of the country, fixed their residence here for some time. The abundance of its fruits, pastures, and corn, the effeminacy of its inhabitants (who are accoutered extremely voluptuously), and lastly, the cheapness of provisions, have no doubt prevented trade from being so flourishing here as in the other provinces of the empire. The whole country is flat excepting towards the west, where there arises a long chain of mountains, covered with thick forests; and the land is in such a high state of cultivation, that those who travel through it imagine they are walking in an immense garden.—Besides the river Hoangho, which traverses this province, it is watered by a great number of springs and fountains; it has also a valuable lake, which invites to its banks a prodigious number of women, because its water has the property of communizing a lustre to silk, which cannot be imitated. Exclusive of forts, castles, and places of strength, this province contains eight fow cities or castles of the first class, and 102 of the second and third. In one of these cities, named Nanyang, is found a kind of serpent, the skin of which is marked with small white spots; the Chinese physicians steep it in wine, and use it afterwards as an excellent remedy against the palsy.

HONAN-FOU, a city of the above province, situated amidst mountains and between three rivers. The Chinese formerly believed this city to be the centre of the earth, because it was in the middle of their empire. Its jurisdiction is very extensive; for it comprehends one city of the second class and thirteen of the third: one of these cities named Teng-fong-hien, is famous on account of the tower erected by the celebrated Tcheon-kong for an observatory; there is still to be seen in it an instrument which he made use of to find the shadow at noon, in order to determine the latitude. This astronomer lived above a thousand years before the Christian era, and the Chinese pretend that he invented the mariners compass.

HONDEKOOTER, MELCHIOR, a famous Dutch painter, born at Utrecht, excelled in painting animals, and especially birds. His father and grandfather were of the same profession, and their subjects the same. He was trained up to the art by his father; but surpassed not only him, but even the best of his contemporaries, in a very high degree. Till he was seventeen years of age, he continued under the direction of his father, and accustomed himself to paint several sorts of birds; but particularly he was pleased to represent cocks, hens, ducks, chickens, and peacocks, which he described in an elegant variety of actions and attitudes. After his father's death, which happened in 1653, he received some instructions from his uncle John Baptist Weeninx; but his principal and best instructor was nature, which he studied with intense application.—His pencil was wonderfully neat and delicate; his touch light; his colouring exceedingly natural, lively, and remarkably transparent; and the feathers of his fowls were expressed with such a swelling softness, as might have readily and agreeably deceived the eye of any spectator.
Honey, considered as a medicine, is a very useful detergent and aperient, powerfully dissolving viscid juices, and promoting the expectoration of tough phlegm. In some particular constitutions it has an inconvenience of gripping, or of proving purgative, which is said to be in some measure prevented by previously boiling the honey. This, however, with all constitutions, is by no means effectual; and the circumstance mentioned has had so much weight with the Edinburgh college, that they do not now employ it in any preparation, and have entirely rejected the mella medicata, substituting syrups in their place: but there can be no doubt that honey is very useful in giving form to different articles, although there be some individuals with whom it may disagree. In order, however, to obtain the good effects of the honey itself, it must be used to a considerable extent, and as an article of diet. The following remarkable instances of the good effects of honey in some asthmatic cases, given by Mr. Monroe in his Medical and Pharmaceutical Chemistry, deserve to be here inserted.

"The late Dr. John Hume, one of the commissioners of the sick and hurt of the royal navy, was for many years violently afflicted with the asthma. Having taken many medicines without receiving relief, he at last resolved to try the effects of honey, having long had a great opinion of its virtues as a pectoral. For two or three years he ate some ounces of it daily, and got entirely free of his asthma, and likewise of a gravely complaint with which he had long been afflicted. About two years after he had recovered his health, when he was sitting one day in the office for the sick and hurt, a person labouring under a great difficulty of breathing, who looked as if he could not live many days, came to him, and asked him by what means he had been cured of his asthma? Dr. Hume told him the particulars of his own case, and mentioned to him the means by which he had found relief. For two years after he heard nothing of this person who was a stranger to him, and had seemed so bad that he did not imagine he could have lived many days, and therefore had not even asked him who he was; but at the end of that period, a man seemingly in good health, and decently dressed, came to the sick and hurt office, and returned him thanks for his cure, which he assured him he had been entirely brought about by the free use of honey."

Honey-dew, a sweet saccharine substance found on the leaves of certain trees, of which bees are very fond, by the husbandmen supposed to fall from the heavens like common dew. This opinion hath been refuted, and the true origin of this and other saccharine dens shown by the Abbé Boissier de Sauvages, in a memoir read before the Society of Sciences at Montpelier. "Chance (says the Abbé) afforded me an opportunity of seeing this juice in its primitive form on the leaves of the holm oak: these leaves were covered with thousands of small round globules or drops, which, without touching one another, seemed to point out the pores from whence each of them had proceeded. My taste informed me, that they were as sweet as honey; the honey-dew on the neighbouring bramble did not resemble the former, the drops having run to-
Honey-Dew.

Together, owing either to the moisture of the air which had diluted them, or to the heat which had expanded them. The dew was become more viscous, and lay in large drops, covering the leaves; in this form it is usually seen.

"The oak had at this time two sorts of leaves: the old, which were strong and firm; and the new, which were tender, and newly come forth. The honey-dew was found only on the old leaves, though these were covered by the new ones, and by that means sheltered from any moisture that could fall from above. I observed the same on the old leaves of the bramble, while the new leaves were quite free from it. Another proof that this dew proceeds from the leaves is, that other neighbouring trees not furnished with a juice of this kind had no moisture on them: and particularly the mulberry, which is a very particular circumstance, for this juice is a deadly poison to silk-worms. If this juice fell in the form of a dew, mist, or fog, it would wet all the leaves without distinction, and every part of the leaves, under as well as upper. Heat may have some share in its production: for though the common heat promotes only the transpiration of the more volatile and fluid juices, a sultry heat, especially if reflected by clouds, may so far dilate the vessel as to produce a more viscous juice, such as the honey-dew.

The second kind of honey-dew, which is the chief resource of bees after the spring flowers and dew by transpiration on leaves are past, owes its origin to a small insect called a vine-fetter; the excrement ejected with some force by this insect makes a part of the most delicate honey known in nature (see ApHS). These vine-fretters rest during several months on the barks of particular trees, and extract their food by piercing that bark, without hurting or deforming the tree. These insects also cause the leaves of some trees to curl up, and produce galls upon others. They settle on branches that are a year old. The juice, at first perhaps hard and crabbed, becomes, in the bowels of this insect, equal in sweetness to the honey obtained from the flowers and leaves of vegetables; excepting that the flowers may communicate some of their essential oil to the honey, and this may give it a peculiar flavour, as happened to myself by planting a hedge of rosemary near my bees at Sauvages; the honey has tasted of it since then, that shrub continuing long in flower.

I have observed two species of vine-fretters, which live unsheltered on the bark of young branches; a larger and a lesser. The lesser species is of the colour of the bark upon which it feeds, generally green. It is chiefly distinguished by two horns, or straight, immovable, fleshy substances, which rise perpendicularly from the lower sides of the belly, one on each side. This is the species which lives on the young branches of bramble and elder. The larger species is double the size of the other; is of a blackish colour; and instead of the horns which distinguish the other, has in the same part of the skin a small button, black and shining like jet.

The buzzing of bees in a tuft of holm-oak, made me suspect that something very interesting brought so many of them bither. I knew that it was not the season for expecting honey-dew, nor was it the place where it is usually found; and was surprised to find the tuft of leaves and branches covered with drops which the bees collected with a humming noise. The form of the drops drew my attention, and led me to the following discovery. Instead of being round like drops which had fallen, each formed a small longish oval. I soon perceived from whence they proceeded. The leaves covered with these drops of honey weresituated beneath a swarm of the larger black vine-fretters; and on observing these insects, I perceived them from time to time raise their bellies, at the extremity of which there then appeared a small drop of an amber colour, which they instantly ejected from them to the distance of some inches. I found by tasting some of these drops which I had caught on my hand that it had the same flavour with what had before fallen on the leaves. I afterwards saw the smaller species of vine-fretters eject their drops in the same manner. This ejection is so far from being a matter of indifference to these insects themselves, that it seems to have been wisely instituted for preserving each individual, as well as to preserve the whole swarm from destruction; for pressing as they do one upon another, they would otherwise soon be glued together, and rendered incapable of stirring. The drops thus spurted out fall upon the ground, if not intercepted by leaves or branches; and the spots they make on stones remain some time, unless washed off by rain. This is the only honey-dew that falls; and this never falls from a greater height than a branch where these insects can cluster.

It is now easy to account for a phenomenon which formerly puzzled me greatly. Walking under a lime-tree in the king's garden at Paris, I felt my hand wetted with little drops, which I at first took for small rain. The tree indeed should have sheltered me from the rain, but I escaped it by going from under the tree. A seat placed near the tree shone with these drops. And being then unacquainted with anything of this kind, except the honey-dew found on the leaves of some particular trees, I was at a loss to conceive how so glutinous a substance could fall from the leaves in such small drops: for I knew that rain could not overcome its natural attraction to the leaves till it became pretty large drops; but I have since found, that the lime-tree is very subject to these vine-fretters.

Bees are not the only insects that feast upon this honey; ants are equally fond of it. Led into this opinion by what naturalists have said, I at first believed that the horns in the lesser species of these vine-fretters had in their extremity a liquid which the ants went in search of; but I soon discovered that what drew the ants after them came from elsewhere, both in the larger and lesser species, and that no liquor is discharged by the horns. There are two species of ants which search for these insects. The large black ants follow those which live on the oaks and chestnut; the lesser ants attend those on the elder. But as the ants are not, like the bees, provided with the means of sucking up fluids; they place themselves near the vine-fretters, in order to seize the drop the moment they see it appear upon the anus; and as the drop remains some time on the small vine-fretters before they can cast it off, the ants have leisure to catch it, and thereby prevent the bees from having any share: but
HON

the vine-frettars of the oak and chestnut being stronger, and perhaps more plentifully supplied with juice, dart the drop instantly, so that the larger ants get very little of it.

"The vine-frettars finding the greatest plenty of juice in trees about the middle of summer, afford also at that time the greatest quantity of honey; and this lessens as the season advances, so that in the autumn the bees prefer to it the flowers then in season. Though these insects please the tree as the sap in a beautiful place, yet the trees do not seem to suffer at all from them, nor do the leaves lose the least of their verdure. The husbandman therefore acts injudiciously when he destroys them."

HONEY-GUIDE, a curious species of cuckow. See CUCULUS, ORNITHOLOGY INDEX.

HONEY-LOCUST, or Three-thorned Acoria. See GLYCISIA, BOTANY INDEX.

HONEY-SUCKLE. See Lonicera, BOTANY INDEX.

HONFLEUR, a considerable sea-port town of France, in the department of Calvados, with a good harbour, and trade in bone-lace, and with 9600 inhabitants. It is seated on the river Seine, in E. Long. 0. 19. N. Lat. 25. 49.

HONI SOIT QUI MAL Y PENSE, q. d. "Evil to him that thinks evil!" the motto of the most noble order of the knights of the Garter. See GARTER.

HONITON, a very pleasant market and borough town in Devonshire, situated 3 56 miles west of London, and 16 east of Exeter. It contained 2735 inhabitants in 1811. It has one church on a hill full half a mile from the town, and a chapel and free grammar school in the town. It is well paved and lighted, and lakes of water run through it. This place has suffered by fires greatly in 1747 and 1765. The market is on Saturday, and one fair in July; its manufactures are serge, and rich bone-lace and edgings. It was a corporation chartered by James II. but reverted to its old constitution on the revolution, and is now governed by a portreeve who is chosen annually. It first returned members the 28th Edw. I.

HONORIACI, in antiquity, an order of soldiery under the eastern empire, who introduced the Goths, Vandals, Alani, Suevi, &c. into Spain. Didymus and Verinaeas, two brothers, had, with great vigilance and valour, defended the passages of the Pyrenees against the Barbarians for some time, at their own expense; but being at length killed, the emperor Constantinus appointed the honoriaci to defend those passages, who, not contented to lay them open to all the nations of the north then ravaging the Gauls, joined themselves to them.

HONOURS, a testimony of esteem or submission, expressed by words, actions, and an exterior behaviour, by which we make known the veneration and respect we entertain for any one on account of his dignity or merit. The word honour is also used in general for the esteem due to virtue, glory, and reputation. It is also used for virtus and probity themselves, and for an exactness in performing whatever we have promised; and in this last sense we use the term, a man of honour. But honour is more particularly applied to two different kinds of virtue; bravery in men, and chastity in women.—Virtue and Honour were deified among the ancient Greeks and Romans, and had a joint temple consecrated to them at Rome; but afterwards each of them had separate temples, which were so placed that no one could enter the temple of Honour without passing through that of Virtue; by which the Romans were continually put in mind, that virtue is the only direct path to true glory. Plutarch tells us, that the Romans, contrary to their usual custom, sacrificed to Honour uncovered: perhaps to denote, that wherever honour is, it wants no covering, but shows itself openly to the world.

The Spanish historians relate an memorable instance of honour and regard to truth. A Spanish cavalier in a sudden quarrel slew a Moorish gentleman, and fled. His pursuer soon lost sight of him, for he had unperceived thrown himself over a garden wall. The owner, a Moor, happening to be in his garden, was addressed by the Spaniard on his knees, who acquainted him with his case, and implored concealment. "Eat this," said the Moor (giving him half a peach), "you now know that you may confide in my protection." He then locked him up in his garden apartment, telling him as soon as it was night he would provide for his escape to a place of greater safety. The Moor then went into his house, where he had but just seated himself, when a great crowd, with loud lamentations, came to his gate, bringing the corpse of his son, who had just been killed by a Spaniard. When the first shock of surprise was a little over, he learnt from the description given, that the fatal deed was done by the very person then in his power. He mentioned this to no one; but as soon as it was dark retired to his garden, as if to grieve alone, giving orders that none should follow him. Then accosting the Spaniard, he said, "Christian, the person you have killed is my son; his body is now in my house. You ought to suffer; but you have eaten with me, and I have given you my faith, which must not be broken." He then led the astonished Spaniard to his stables, mounted him on one of his steadiest horses, and said, "Fly far while the night can cover you; you will be safe in the morning. You are indeed guilty of my son's blood: but God is just and good; and I thank him I am innocent of yours, and that my faith given is preserved."

This point of honour is most religiously observed by the Arabs and Saracens, from whom it was adopted by the Moors of Africa, and by them was brought into Spain. The following instance of Spanish honour may still dwell in the memory of many living, and deserves to be handed down to the latest posterity. In the year 1746, when we were in hot war with Spain, the Elizabeth of London, Captain William Edwards, coming through the gulf from Jamaica, richly laden, met with a most violent storm, in which the ship sprang a leak, that obliged them, for the saving of their lives, to run into the Havana, a Spanish port. The captain went on shore, and directly waited on the governor, told the occasion of his putting in, and that he surrendered the ship as a prize, and himself and his men as prisoners of war, only requesting good quarter. "No, Sir," replied the Spanish governor, "if we had taken you in fair war at sea, or approaching our coast with hostile intentions, your ship would then have been a prize, and your people prisoners; but when, distressed by a tempest, you come into our ports for the safety of your lives, we, the enemies, being men, are bound...as such...by the laws of humanity to afford...
Honour: relief to distressed men who ask it of us. We cannot
men against our enemies take advantage of an act of
God. You have leave therefore to unload your ship,
if that be necessary, to stop the leak; you may send
her here, and traffic so far as shall be necessary to pay
the charges; you may then depart, and I will give
you a pass to be in force till you are beyond Bermuda:
if after that you are taken, you will then be a lawful
prize; but now you are only a stranger, and have a
stranger's right to safety and protection." The ship
accordingly departed, and arrived safe in London.

A remarkable instance of the like honour is record-
ed of a poor unenlightened African negro, in Captain
Snelgrave's account of his voyage to Guinea. A New
England sloop trading there in 1752, left a second
mate, William Murray, sick on shore, and sailed with-
out him. Murray was at the house of a black named
Cudjoe, with whom he had contracted an acquaintance
during their trade. He recovered; and the sloop be-
ing gone, he continued with his black friend till some
other opportunity should offer of his getting home.
In the mean time a Dutch ship came into the road,
and some of the blacks coming on board her were
treachrously seized and carried off as their slaves. The
relations and friends, transported with such passion,
rushed into the house of Cudjoe, to take revenge by kill-
ing Murray. Cudjoe stopt them at the door, and de-
manded what they wanted. "The white men," said
they, "have carried away our brothers and sons, and
we will kill all white men. Give us the white men you
have in your house, or we will kill him." "Nay,"
said Cudjoe, "the white men that carried away your
relations are bad men, kill them when you can take
them; but this white man is a good man, and you
must not kill him." "But he is a white man," they
cried: "and the white men are all bad men, we will
kill them all." "Nay," says he, "you must not kill a man that has done no harm, only for being white.
This man is my friend, my house is his post, I am his
soldier, and must fight for him; you must kill me be-
fore you can kill him. What good man will ever come
again under my roof, if I let my floor be stained with
a good man's blood?" The negroes seeing his resolu-
tion, and being convinced by his discourse that they
were wrong, went away ashamed. In a few days Mur-
ray ventured abroad again with his friend Cudjoe,
when several of them took him by the hand, and told
him, "They were glad they had not killed him; for
as he was a good (meaning innocent) man, their God
would have been very angry, and would have spoiled
their fishing."

Honour, in the beau mode, has a meaning materi-
ally different from the above, and which it is easier to
illustrate than define. It is, however, subject to a sys-
tem of rules, called the law of honour, constructed by
people of fashion, calculated to facilitate their inter-
course with one another, and for no other purpose.
Consequently, nothing is considered as inconsistent with
honour, but what tends to incommode this intercourse.
Hence, as Arohdesian Paley states the matter, pro-
faneness, neglect of public worship or private devotion,
scandal to servants, rigorous treatment of tenants or
other dependents, want of charity to the poor, inju-
rices done to tradesmen, insolveney or delay of pay-
ment, with numberless examples of the same kind, are
acquainted no breaches of honour; because a man is
not a less agreeable companion for these vices, nor
the worse to deal with in these cases, which are
usually transacted between one gentleman and another.

Again, the law of honour being constituted by
men occupied in the pursuit of pleasure, and for
the mutual conveniency of such men, will be found,
as might be expected from the character and de-
sign of the law-makers, to-be, in most instances, fa-
vourable to the licentious indulgence of the natural
passions. Thus it allows of fornication, adultery,
debauchery, prodigality, dwellings, and revenge in the
extreme; and lays no stress upon the virtues opposite
to these.

Honour or Rank.—The degrees of honour which
are observed in Britain may be comprehended under
these two heads, viz., nobles majoris, and noble-minors.
Those included under the first rank are, archbishops,
dukes, marquises, earls, viscount, bishops, and barons;
which are all distinguished by the respective ornaments
of their escutcheons; and those of the last are baronets,
knavies, esquires, and gentleman. There are some au-
thors who have baronets to be the last under the first
rank; and their reason is, because their honour is
beneficial and by patronage, as that of the nobility. See
Commonality and Nobility.

Honours of War, in a siege, is, when a governor,
having made a long and vigorous defence, is at last
obliged to surrender the place to the enemy for most
of men and provisions, and makes it one of his principal
articles to march out with the honours of war; that is,
with shouldered arms, drums beating, colours flying,
and all their baggage, &c.

Military Honours. All armies salute crowned heads
in the most respectful manner, drums beating a march,
colours and standards drooping, and officers saluting.
Their guards pay no compliment, except to the princes of
the blood; and even that by courtesy, in the absence
of the crowned head.

To the commander in chief the whole line turns out
without arms, and the camp-guards beat a march, and
salute. To generals of horse and foot, they beat a
march, and salute. Lieutenant-generals of ditto, three
ruffs, and salute. Major-generals of ditto, two ruffs,
and salute. Brigadiers of ditto, rested arms, one ruff,
and salute. Colonels of ditto, rested arms, and no be-
toing. Centinels rest their arms to all field-officers, and
shoulder to every officer. All governors, that are not
general officers, shall, in all places where they are go-
vernors, have one ruff, with rested arms; but for those
who have no commission as governors, no drum shall
beat. Lieutenant-governors shall have the main-guard
turned out to them with shouldered arms.

Prussian Honours of War, chiefly imitated by most
powers in Europe, are,

To the king, all guards beat the march, and all of-
icers salute. Field-marshals, received with the march,
and saluted in the king's absence. General of horse
or foot, four ruffs. But if he commands in chief, a
march and salute. Lieutenant-generals of horse or foot,
commanding or not, guards beat three ruffs. Major-
generals of horse and foot, two ruffs. Officers, when
their guards are under arms, and a general makes a sig-
nal, must rest to him, but not beat; when not-get
under arms, and a signal made, only stand by their arms.
Honour.

Village-guards go under arms only to the king, field-marshal, generals of horse and foot, and to the general of the day. Generals guard go under arms only to the king, field-marshal, and the general over whom they mount. Commanding officers of regiments and battalions, their own quarter and rear guards to turn out; but not to other field-officers, unless they are of the day. Generals in foreign service, the same.

Honours paid by Centinels. Field-marshal; two centinels with ordered firelocks, at their tent or quarter. Generals of horse or foot; two centinels, one with his firelock shouldered, the other ordered. Lieutenants-generals; one, with firelock ordered. Major-generals; one, with firelock shouldered.

The first battalion of guards go under arms to the king only; not to stand by, nor draw up in the rear of their arms to any other; nor to give centinels to foreigners. Second and third battalions draw up behind their arms to their princes, and to field-marshal; but when on grenadier guards or out-posts, they turn out, as other guards do, to the officers of the day. They give one centinel with shouldered arms to the princes of the blood, and to field-marshal when they lie alone in garrisons.

Court of Honour. See Court of Chivalry.

Fountain of Honour. The king is so styled, as being the source of honours, dignities, &c. See Prerogative.

It is impossible that government can be maintained without a due subordination of rank; that the people may know and distinguish such as are set over them, in order to yield them their due respect and obedience; and also that the officers themselves, being encouraged by emulation and the hopes of superiority, may the better discharge their functions; and the law supposes, that no one can be so good a judge of their several merits and services as the king himself who employs them. It has therefore entrusted him with the sole power of conferring dignities and honours, in confidence that he will bestow them upon none but such as deserve them. And therefore all degrees of nobility, of knighthood, and other titles, are received by immediate grant from the crown; either expressed in writing, by writs or letters patent, as in the creation of peers and baronets; or by incorporeal investiture, as in the creation of a simple knight.

From the same principle also arises the prerogative of erecting and disposing of offices; for honours and offices are in their nature convertible and synonymous. All offices under the crown carry in the eye of the law an honour along with them; because they imply a superiority of parts and abilities, being supposed to be always filled with those that are most able to execute them. And, on the other hand, all honours in their original had duties or offices annexed to them: an earl, comtes, was the conservator or governor of a county; and a knight, miles, was bound to attend the king in his wars. For the same reason therefore that honours are in the disposal of the king, offices ought to be so likewise; and as the king may create new titles, so may he create new offices; but with this restriction, that he cannot create new offices with new fees annexed to them, nor annex new fees to old offices; for this would be a tax upon the subject, which cannot be imposed but by act of parliament. Wherefore, in 13 Hen. IV. a new office being created by the king's letters patent for measuring cloths, with a new fee for the same, the letters patent were, on account of the new fee, revoked and declared void in parliament.

Upon the same or a like reason, the king has also the prerogative of conferring privileges upon private persons. Such as granting place or precedence to any of his subjects, as shall seem good to his royal wisdom: or such as converting aliens, or persons born out of the king's dominions, into denizens; whereby some very considerable privileges of natural-born subjects are conferred upon them. Such also is the prerogative of erecting corporations; whereby a number of private persons are united and knit together, and enjoy many liberties, powers, and immunities, in their political capacity, which they were utterly incapable of in their natural.

Maids of Honour, are young ladies in the queen's household, whose office is to attend the queen when she goes abroad, &c. In England they are six in number, and their salary 300l. per annum each.

Honour is particularly applied in our customs to the more noble kind of seignories or lordships, whereof other inferior lordships or manors hold or depend. As a manor consists of several tenements, services, customs, &c. so an honour contains divers manors, knights-fees, &c. It was also formerly called beneficium or royal fee, being always held of the king in capite.

Honour-Point, in Heraldry, is that next above the centre of the escutcheon, dividing the upper part into two equal portions.

Honorable, a title conferred on the younger sons of earls, the sons of viscounts and barons; as also on such persons as have the king's commission, and upon those who enjoy places of trust and honour.

Honorary, something done or conferred upon any one, to do him honour. See the article Honour.

Honorary is sometimes understood of a person who bears or possesses some post or title, only for the name's sake, without doing any thing of the functions belonging to it, or receiving any advantage from it: thus we say honorary counsellors, honorary fellows, &c.

Honourary is also used for a lawyer's fee, or a salary given to public professors in any art or science.

Hood, Robin, a famous outlaw, and deer-stealer, who chiefly harboured in Sherwood forest in Nottinghamshire. He was a man of family, which by his pedgree appears to have had some title to the earldom of Huntington; and played his pranks about the latter end of the 12th century. He was famous for archery and for his treatment of all travellers who came in his way: levyng contributions on the rich, and relieving the poor. Falling sick at last, and requiring to be bled, he is said to have been betrayed and bled to death. He died in 1247; and was buried at Kirkclee in Yorkshire, then a Benedictine monastery, where his grave-stone is still shown.

Hood. See Chaperon and Cowl.

Hood, in falconry, is a piece of leather, wherein the head of a hawk, falcon, or the like, is covered.

Hood Island, one of the Marquees Islands, in the South sea. It was discovered in April 1774 by Captain Cook, who gave it that name from the person who first
saw the land. It is the most northly of the cluster, and lies in S. Lat. 9. 26. W. Long. 139. 13.

HOOF, the horny substance that covers the feet of divers animals, as oxen, horses, &c.

HOOGRY-BOUND. See FARRIERY Index.

HOOGLY, the name of a province, city, and river of Hindostan. See HUGHLEY.

HOOGUSTRATEN, a town of the Netherlands, with 1360 inhabitants, 24 miles south-west from Brüle Duc, and 30 miles north-east from Antwerp.

HOOK, in angling, &c. See FISHING-HOOK.

HOOKS, in building, &c. are of various sorts; some of iron and others of brass, viz. 1. Armour-hooks, which are generally of brass, and are to lay up arms upon, as guns, muskets, half-pikes, pikes, javelins, &c. 2. Casement-hooks. 3. Chimney-hooks, which are made both of brass and iron, and of different fashions: their use is to set the tors and fire-shovel against. 4. Curtain-hooks. 5. Hooks for doors, gates, &c. 6. Double line-hooks, large and small. 7. Single line-hooks, large and small. 8. Tenter-hooks of various sorts. See TENTER.

HOOKS of a ship, are all those forked timbers which are placed directly upon the keel, as well in her run as in her rake.

CAB-HOOKS, those which being made fast to the end of a rope with a noose (like that which brewers use to sling or carry their barrels on), are made use of for slings.

FOOT-HOOKS, in a ship, the same with futtocks.

STOVE-HOOKS, a tackle with two hooks; one to hitch into a cringle of the main or fore-sail, in the bolt-rop at the leech of the sail by the clew; and the other is to hitch into a strap, which is spliced to the chest-tree.

Their use is to pull down the sail, and succour the tackles in a large sail and stiff gale, that all the stress may not bear upon the tack. It is also used when the tack is to be seized more secure, and to take off or put on a bonnet or drabler.

HOOK-PINS, in Architecture, are taper iron pins, only with a hook-head, to pin the frame of a roof or floor together.

HOOKAH, among the Arabs and other nations of the East, is a pipe of a singular and complicated construction, through which tobacco is smoked: out of a small vessel of a globular form, and nearly full of water, issue two tubes, one perpendicularly, on which is placed the tobacco; the other obliquely from the side of the vessel, and to the person that smokes applies his mouth; the smoke by this means being drawn through water, is cooled in its passage and rendered more grateful: one takes a whiff, draws up a large quantity of smoke, puffs it out of his nose and mouth in a dense cloud, and passes the hookah to his neighbour; and thus it goes round the whole circle. — The hookah is known and used throughout the east; but in those parts of it where the refinements of life prevail greatly, every one has his hookah sacred to himself; and it is frequently an implement of a very costly nature, being of silver, and set with precious stones; in the better kind, that tube which is applied to the mouth is very long and pliant; and for that reason is termed the snake: people who use it in a luxurious manner, fill the vessel through which the smoke is drawn with rose water, and it thereby receives some of the fragrant quality of that fluid.

HOOKE, ROBERT, a very eminent English mathematician and philosopher, was the son of Mr John Hooke minister of Freshwater, in the isle of Wight, where he was born in 1635. He very early discovered a genius for mechanics, by making curious toys with great art and dexterity. He was educated under Dr Bushby in Westminster school; where he not only acquired a competent share of Greek and Latin, together with an insight into Hebrew and some other Oriental languages, but also made himself master of a considerable part of Euclid's elements. About the year 1653, he went to Christ-Church in Oxford, and in 1655 was introduced to the Philosophical Society there; where, discovering his mechanical genius, he was first employed to assist Dr Willis in his operations in chemistry, and afterwards recommended to the honourable Robert Boyle, whom he served several years in the same capacity. He was also instructed in astronomy about this time by Dr Seth Ward, Savilian professor of that science; and from henceforward distinguished himself by many noble inventions and improvements of the mechanic kind. He invented several astronomical instruments, for making observations both at sea and land; and was particularly serviceable to Mr Boyle in completing the invention of the air-pump.

Sir John Cutler having founded a mechanic school in 1664, he settled an annual stipend on Mr Hooke for life, intrusting the president, council, and fellows, of the Royal Society to direct him with respect to the number and subjects of his lectures; and on the 8th of January 1664-5, he was elected by that society curator of experiments for life, with an additional salary. In 1666 he produced to the Royal Society a model for rebuilding the city of London destroyed by fire, with which the society was well pleased, but although the lord mayor and aldermen preferred it to that of the city surveyor, it was not carried into execution. It is said, by one part of this model of Mr Hooke's, it was designed to have all the chief streets, as from Leadenhall to Newgate, and the like, to lie in exact straight lines, and all the other cross streets turning out of them at right angles, with all the churches, public buildings, markets, &c. in proper and convenient places. The rebuilding of the city according to the act of parliament requiring an able person to set out the ground to the proprietors, Mr Hooke was appointed one of the surveyors; in which employment he got most part of his estate, as appeared pretty evident from a large iron chest of money found after his death, locked down with a key in it, and a date of the time, which showed it to have been so shut up above 30 years.— Mr Oldenburg, secretary to the Royal Society, dying in 1677, Mr Hooke was appointed to supply his place, and began to take minutes of the meeting in October, but did not publish the Transactions. In the beginning of the year 1678, his brother's daughter, Mrs Grace Hooke, who had lived with him several years, died; and he was so affected with grief at her death, that he hardly ever recovered it, but was observed from that time to become less active, more melancholy, and even more cynical than ever.
ever. At the same time, a chancery suit in which he was concerned with Sir John Cutler, on account of his salary for reading the Cutlerian lectures, made him very uneasy, and increased his disorder. In 1659, he was employed in forming the plan of the hospital near Hoxton, founded by Robert Ask alderman of London, who appointed Archbishop Tillotson one of his executors; and in December the same year, Hooke was created doctor of physic, by a warrant from that prelate. In June 1656, the chancery suit with Sir John Cutler was determined in his favour, to his inexpressible satisfaction. His joy on that occasion was found in the words of the prayer in the ordinary that is prefixed: DOMINE, DULCIS DOMINI. "I was born on this day of July 1635, and God hath given me a new birth: may I never forget his mercies to me! while he gives me breath may I praise him!"

In the same year 1666, an order was granted to him for repeating most of his experiments at the expense of the Royal Society, upon a promise of his finishing the accounts, observations, and deductions from them, and of perfecting the description of all the instruments contrived by him; but his increasing illness and general decay rendered him unable to perform it. He continued some years in this wasting condition; and thus languishing till he was quite emaciated, he died March 3d 1702, at his lodgings in Gresham college, and was buried in St Helen's church, Bishopsgate street; his corpse being attended by all the members of the Royal Society then in London.

Dr Hooke's character, in some respects, was not one of the most amiable. In his person he exhibited but a mean appearance, being short of stature, very crooked, pale, lean, and of a meagre aspect, with lank brown hair, which he wore very long, and hanging over his face. Suitable to his person, his temper was penurious, melancholy, mistrustful: and, though possessed of great philosophical knowledge, he had so much ambition, that he would be thought the only man who could invent or discover; and thus it has been asserted by some, that he frequently laid claim to the inventions and discoveries of others, while he boasted of many of his own which he never communicated. On the contrary his admirers have retorted the charge, and have blamed others with claiming the discoveries of this philosopher. Without deciding on this point, which seems at least somewhat doubtful, we shall leave our readers to judge for themselves, after recommending to their perusal the history of the inventions claimed by Dr Hooke at the end of this article, and the note under the article Watch, both drawn up, we believe, by Professor Robinson. In the religious part of his character he was so far exemplary, that he always expressed a great veneration for the Deity; and seldom received any remarkable benefit in life, or made any considerable discovery in nature, or invented any useful contrivance, or found out any difficult problem, without setting down his acknowledgement to God, as many places in his diary plainly show. He frequently studied the sacred writings in the original; for he was acquainted with the ancient languages, as well as with all parts of the mathematics. He wrote 1. Lectiones Cutlerianae, or Cutlerian Lectures. 2. Micrographia, or Descriptions of minute bodies made by magnifying glasses. 3. A de-

cription of helioscopes. 4. A description of some mechanical improvements of lamps and water-pois. quarta. 5. Philosophical collections. After his death were published, 6. Posthumous works collected from his papers by Richard Waller secretary to the Royal Society.

Chronological History of Inventions and Discoveries by Dr Hooke.

1656, Barometer, a weather-glass.
1657, A scapement, for maintaining the vibration of a pendulum. And not long after, the regulating or balance-spring for watches.
1658, The double barrelled air-pump. —The conical pendulum. —His first employment of the conical pendulum was no less ingenious and scientific than it was original. He employed it to represent the mutual gravitation of the planets; a fact which he had most systematically announced. He had shewn, that a force, perfectly analogous to gravity on this earth, operated on the surface of the moon and of Jupiter. Considering the numerous round pits on the surface of the moon, surrounded with a sort of wall, and having a little eminence in the middle, as the production of volcanoes, he inferred, that the ejected matter fell back again to the moon, as such matter falls back again to the earth. He saw Jupiter surrounded with an atmosphere, which accompanied him; and therefore pressed on him, as our air presses on the earth. —He inferred, that it was the same kind of power that maintained the sun and other planets in a round form. He inferred a force to the sun from the circulation round him, and he called it a gravitation; and said that it was not the earth which described the ellipse, but the centre of gravity of the earth and moon. He therefore made a conical pendulum, whose tendency to a vertical position represented the gravitation to the sun, and which was projected at right angles to the vertical plane; and shewed experimentally, how the different proportions of the projectile and centripetal tendencies produced various degrees of eccentricity in the orbit. He then added another pendulum, describing a cone round the first, while this described a cone round the vertical line, in order to see what point between them described the ellipse. The results of the experiment were intricate and unsatisfactory; but the thought was ingenious. He candidly acknowledged, that he had not discovered the true law of gravitation which would produce the description of an ellipse round the focus, owing to his want of due mathematical knowledge; and therefore left this investigation to his superiors. Sir Isaac Newton was the happy man who made the discovery, after having entertained the same notions of the forces which connected the bodies of the solar system, before he had any acquaintance with Dr Hooke, or knew of his speculations.

1660, The engine for cutting clock and watch-wheels. —The chief phenomena of capillary attraction. —The freezing of water at a fixed temperature.
1663, The method of supplying air to a diving bell. The number of vibrations made by a musical chord.
1664, His Micrographia was, by the council of the Royal Society, ordered to be printed; but in that work are many just notions respecting respiration, the com-
position of the atmosphere; and the nature of light, 
which were afterwards attributed as discoveries to Ma-
yow and others, who, though we are far from suppos-
ing that they stole their discoveries from Dr Hooke,
were certainly anticipated by him.
1666. The quadrant by reflection.
1667. The marine barometer.—The gage for sound-
ing unfathomable depths.
1668. The measurement of a degree of the meridi-
an, with a view to determine the figure of the earth,
by means of a zenith sector.
1669. The fact of the conservatio virium vivorum,
and that in all the productions and extinctions of
motion, the accumulated forces were as the squares of
the final or initial velocities. This doctrine he announces
in all its generality and importance, deducing from it
all the consequences which John Bernoulli values him-
self so highly upon, and which are the chief facts ad-
duced by Leibnitz in support of his doctrine of the
forces of bodies in motion. But Hooke was perfectly
aware of their entire correspondence with the Cartesian
or common doctrine, and was one of the first in apply-
ing the celebrated 39th proposition of Newton's Prin-
cipia to his former positions on this subject, as a ma-
thematical demonstration of them.
1673. That the catenaria was the best form of an
arch.
1674. Steam engine on Newcomen's principle.
1679. That the air was the sole source of heat in
burning: That combustion is the solution of the inflam-
mable vapour in air; and that in this solution the air
gets out its heat and light. That nitre explodes and
causes bodies to burn without air, because it consists
of this air accompanied by its heat and light, in a con-
densed or solid state, and air supports flame, because
it contains the same ingredients that gunpowder doth,
that is, a nitrous spirit: That this air dissolves some-
thing in the blood while it is exposed to it in the lungs
in a very expanded surface, and when saturated with
it, can no longer support life nor flame; but in the act
of solution, it produces animal heat: That the arterial
and venal blood differ on account of this something be-
ing wanting in one of them. In short, the fundamen-
tal doctrines of modern chemistry are systematically
delivered by Dr Hooke in his Micrographia, publish-
ed in 1664, and his Lampas, published in 1677.
1680. He first observed the secondary vibrations
of elastic bodies, and their connection with harmonic
sounds. A glass containing water, and excited by a
fiddletick, threw the water into undulations, which
were square, hexagonal, octagonal, &c. shewing that it
made vibrations subordinate to the total vibration; and
that the fundamental sound was accompanied by its
octave, its twelfth, &c.
1681. He exhibited musical tones by means of tooth-
ed wheels, whirled round and rubbed with a quill,
which dropped from tooth to tooth, and produced tones
proportioned to the frequency of the cracks or snaps.
1684. He read a paper before the Royal Society,
in which he affirms, that some years before that period
he had proposed a method of discovering at a distance,
not by sound but by sight. He then proceeds to de-
scribe a very accurate and complete telegraph, equal,
perhaps, in all respects to those now in use. But some
years previous to 1684, M. Amontons had not invent-
ed his telegraph; so that, though the marquis of War-
ner unquestionably gave the first hint of this instru-
ment, Dr Hooke appears to have first brought it to
perfection. See TELEGRAPH; and a book, published
1726, entitled Philosophical Experiments and Obser-
cations of the late eminent Dr Robert Hooke.
To him also we are indebted for many other disco-
very of lesser note; such as the wheel barometer, the
universal joint, the manometer, screw divided quadrant,
telescopic sights for astronomical instruments, represen-
tation of a muscular fibre by a chain of bladder, ex-
periments shewing the induction of light, and its at-
traction for solid bodies, the curvilinear path of light
through the atmosphere.
HOOKE, Nathaniel, author of an esteemed Roman
history and other performances. Of this learned gen-
tleman the earliest particulars to be met with are furn-
ishcd by himself, in the following modest but manly
deposition to the earl of Oxford, dated Oct. 7. 1722:
"My Lord, the first time I had the honour to wait
upon your Lordship since your coming to London,
and looking over your lordship had the goodness to ask me, what way
of life I was then engaged in? A certain man was
hindered me at that time from giving a direct
answer. The truth is, my lord, I cannot be said at
present to be in any form of life, but rather to live
tempestuoso. The late epidemical distemper seized me,
I endeavoured to be rich, imagined for a while that I
was, and am in some measure happy to find myself at
this instant but just worth nothing. If your lordship,
or any of your numerous friends, have need of a ser-
vant with the bare qualifications of being able to read
and write, and to be honest, I shall gladly undertake
any employments your lordship shall not think me
unworthy of. I have been taught, my lord, that nei-
er a man's natural pride, nor his self-love, is an equal
judge of what is fit for him; and I shall endeavour to
remember, that it is not the short part we act, but the
manner of our performance, which gains or loses us
the applause of Him who is finally to decide of all human
actions. My lord, I am just now employed in trans-
slating from the French, a History of the Life of the
late Archbishop of Cambry; and I was thinking to
beg the honour of your lordship's name to protect a
work which will have so much need of it. The origi-
nal is not yet published. 'Tis written by the author of
the Discourse upon Epic Poetry, in the new edi-
tion of Telemarchi. As there are some passages in
the book of a particular nature, I dare not solicit your
lordship to grant me the favour I have mentioned, till
you first have perused it. The whole is short, and
pretty fairly transcribed. If your lordship could find
a spare hour to look it over, I would wait upon your
lordship with it, as it may possibly be no unpleasing
entertainment. I should humbly ask your lordship's
pardon for so long an address in a season of so much
business. But when should I be able to find a time in
which your lordship's goodness is not employed? I am
with perfect respect and duty, my lord, your lordship's
most obliged, most faithful, and most obedient humble
servant, NATHANIEL HOOKE." The translation here
spoken of was afterwards printed in 12mo, 1723. From
this period till his death, Mr Hooke enjoyed the con-
fidence and patronage of men not less distinguished by
virtue than by titles. In 17 . . . he published a transla-

HOO

He revised a Translation of "The History of the Conquest of Mexico by the Spaniards, by Thomas Townsend, Esq." printed in 3 vols 8vo; and in the same year he published, in 4to, the first volume of "The Roman History, from the building of Rome to the ruin of the Commonwealth; illustrated with maps and other plates." In the dedication to this volume, Mr. Hooker took the opportunity of "publicly testifying his just esteem for a worthy friend, to whom he had been long and much obliged." By telling Mr. Pope, then, the story of the young man of his name at the head of those sheets was "like the hanging out a splendid sign, to catch the traveller's eye, and entice him to make trial of the entertainment the place affords." But, (he proceeds), when I can write under my sign, that Mr. Pope has been here, and was content, who will question the goodness of the house?" The volume is introduced by "Remarks on the History of the Seven Roman Kings, occasioned by Sir Isaac Newton's objections to the supposed 244 years duration of the royal state of Rome." His nervous pen was next employed in digesting "An Account of the conduct of the Dowager-duchess of Marlborough, from her first coming to court to the year 1710, in a Letter from herself to Lord — in 1742." 8vo. His reward on this occasion was considerable; and the reputation he acquired by the performance must be a great. The circumstances of this transaction are thus related by Dr. Maty, in his Memoirs of Lord Chesterfield, vol. i. p. 216. "The relict of the great duke of Marlborough, being desirous of submitting to posterity her political conduct, as well as her lord's, applied to the earl of Chesterfield for a proper person to receive her information, and put the memoir of her life into a proper dress. Mr. Hooker was recommended by him for that purpose. He accordingly waited upon the duchess, while she was still in bed, oppressed by the infirmities of age. But, knowing who he was, she immediately got herself lifted up, and continued speaking during six hours. She delivered to him, without any notes, her account in the most lively as well as the most connected manner. As she was not tired herself, she would have continued longer the business of this first sitting, had not she perceived that Mr. Hooker was quite exhausted, and wanted refreshment as well as rest. So eager was she for the completion of the work, that she insisted upon Mr. Hooker's not leaving her house till he had finished it. This was done in a short time; and her Grace was so well pleased with the performance, that she complimented the author with a present of 500l. a sum which far exceeded his expectations. As soon as he was free, and permitted to quit the house of his benefactress, he hastened to the earl, to thank him for his favour, and communicated to him his good fortune. The perturbation of mind he was under, occasioned by the strong sense of his obligation, plainly appeared in his stammering out his acknowledgments; and he, who had succeeded so well in the interpretation of Grace's sentiments, could scarcely utter his own." The second volume of the Roman History appeared in 1745; when Mr. Hooker embraced the fair occasion of congratulating his worthy friend the earl of Marchmont, on "that true glory, the consenting praise of the honest and the wise," which his lordship had so early acquired. To the second volume Mr. Hooker added "The Capitoline Marbles, or Consular Calendars, an ancient Monument accidentally discovered at Rome in the year 1545, during the Pontificate of Paul III." In 1758 Mr. Hooker published Observations on, I. The Answer of M. l'Abbé du Vertot to the earl of Stanhope's Inquiry concerning the Senate of ancient Rome; dated December 1716. II. A Dissertation upon the Constitution of the Roman Senate, by a Gentleman; published in 1743. III. A Treatise on the Roman Senate, by Dr. Coverley Middleton; published in 1747. IV. An Essay on the Roman Senate, by Dr. Thomas Chapman; published in 1750; which he wrote with great propriety inscribed to Mr. Speaker Osnow. The third volume of Mr. Hooker's Roman History to the end of the Gallic war, was printed under his inspection before his last illness; but did not appear till after his death, which happened in 1766. The fourth and last volume was published in 1771. Dr. Hooker left two sons; of whom one is a divine of the church of England; the other, a doctor of the Sorbonne, and professor of astronomy in that illustrious seminary.

HOOKER, John, alias Vowell, was born in Exeter, about the year 1524, the second son of Robert Hooker, who in 1539 was mayor of that city. He was instructed in grammar learning by Dr. Moreman, vicar of Menbinte in Cornwall, and thence removed to Oxford; but to what college is uncertain. Having left the university, he travelled to Germany, and resided some time at Cologne, where he kept exercises in law, and probably graduated. Thence he went to Strasburg, where he studied divinity under the famous Peter Martyr. He now returned to England, and soon after visited France, intending to proceed to Spain and Italy; but was prevented by a declaration of war. Returning therefore again to England, he fixed his residence in his native city, where, having married, he was in 1545 elected chamberlain, being the first person who held that office, and in 1571 represented his fellow citizens in parliament. He died in the year 1601, and was buried in the cathedral church at Exeter. He wrote, among other works, 1. Order and usage of keeping of parliaments in Ireland. 2. The events of comets or blazing stars, made upon the sight of the comet Pagonia, which appeared in November and December 1577. 3. An addition to the chronicles of Ireland from 1546 to 1568; in the second volume of Holinshed's chronicle. 4. A description of the city of Exeter, and of the sondrie assaults given to the same; Holinsh. Chron. vol. iii. 5. A book of ensigns. 6. Translation of the history of the conquest of Ireland from the Latin of Giraldo Cambrensis; in Holinsh. Chron. vol. ii. 7. Synopsis chorographica, or an historical record of the province of Devon; never printed.

HOOKER, Richard, a learned divine, was born at Heavy-tree, near Exeter, in the year 1533. Some of his ancestors were mayors of that city, and he was nephew to John Hooker, the historian. His uncle was first supported at the university of Oxford, with the addition of a small pension from Dr. Jewel, bishop of Salisbury, who in 1563 got him admitted one of the clerks of Corpus Christi college. In 1573 he was elected scholar. In 1577 he took the degree of master of
HOOPER. Hooker was admittted fellow the same year. In July 1579, he was appointed deputy professor of the Hebrew language. In October, in the same year, he was for some trivial misdemeanor expelled the college, but was immediately restored. In 1581 he took orders; and, being appointed to preach at St. Paul's cross, he came to London, where he was unfortunately drawn into a marriage with Joan Churchman, the termagant daughter of his hostess. Having thus lost his fellowship, he continued in the utmost distress till the year 1584, when he was presented by John Chey, Esq., of the manor of Dracon, Buckinghamshire. In this retirement he was visited by Mr. Edwin Sandys, and Mr. George Cranmer, his former pupils. They found him, with a Horace in his hand, tending some sheep in the common field, his servant having been ordered home by his sweet Xantippe. They attended him to his house; but were soon deprived of his company by an order, from his wife Joan, for him to come and rock the cradle. Mr. Sandys's representation to his father, of his tutor's situation, procured the master'ship of the Temple. In this situation he met with considerable molestation from one Travers, lecturer of the Temple, and a bigoted Puritan, who in the afternoon endeavoured to confute the doctrine delivered in the morning. From this disagreeable situation he solicited Archbishop Whitgift to remove him to some country retirement, where he might prosecute his studies in tranquillity. Accordingly in 1592, he obtained the rectory of Boscomb in Wiltshire, together with a prebend in the church of Salisbury, of which he was also made sub-dean. In 1594 he was presented to the rectory of Bishopsbourne in Kent, where he died in the year 1600. He was buried in his own parish-church, where a monument was erected to his memory by William Cooper, Esq. He was meek, pious, and learned divine. He wrote, 1. Ecclesiastical polity, in eight books folio. 2. A discourse of justification, &c. with two other sermons, Oxford 1612, 4to. Also several other sermons printed with the Ecclesiastical Polity. Hooker, in naval architecture, a vessel much used by the Dutch, built like a ship, but rigged and masted like a boat. Hookers will lie nearer a wind than vessels with cross-sails can do. They are from 50 to 200 tons burden, and with a few hands will sail to the East Indies.

HOOP, a piece of plant wood, or iron, bent into a circular form, commonly used for securing stakes, &c. Driving a Hoop, a boyish exercise, of good effect in rendering the limbs pliable, and for strengthening the nerves.

HOOPER, John, bishop of Worcester, and a martyr in the Protestant cause, was born in Somersetshire, and educated at Oxford, probably at Merton-college. In 1518 he took the degree of bachelor of arts, and afterwards became a Cistercian monk; but at length, disliking his fraternity, he returned to Oxford, and there became infected with Lutheranism. He was made chaplainKeyes to Sir John Arundel, who afterwards suffered with the protector in the reign of Edward VI. But that very catholic knight, as Wood calls him, discovering his chaplain to be a heretic, Hooper was obliged to leave the kingdom. After continuing some time in France, he returned to England, and lived with a gentleman called Seainlow; but being again discovered, he escaped in the habit of a sailor to Ireland; thence embarked for the continent, and fixed his abode in Switzerland.—When King Edward came to the crown, Mr. Hooper returned once more to his native country. In 1550, by his old patron Sir John Arundel's interest with the earl of Warwick, he was consecrated bishop of Gloucester; and in 1552 was nominated to the see of Worcester, which he held in commendam with the former. But Queen Mary had scarce ascended the throne, before his lordship was imprisoned, tried, and not found to recant, condemned to the flames. He suffered this terrible death at Gloucester, on the 6th of February 1554, being then near 60 years of age. He was an avowed enemy to the church of Rome, and not perfectly reconciled to what he thought remnants of Popery in the church of England. In the former reign he had been one of Bonner's accusers, which sufficiently accounts for his being one of Queen Mary's first sacrifices to the holy see. He was a person of good parts and learning, as may be found in Fox's Book of Martyrs.

HOOPER, George, a very learned writer, bishop of Bath and Wells, was well skilled in mathematics, and in the eastern learning and languages. He sat in these see above 25 years, often refused a seat in the privy council, and could not be prevailed upon to accept of the bishopric of London on the death of Bishop Compton. He wrote, 1. The church of England free from the imputation of Popery. 2. A discourse concerning Lent. 3. New danger of Presbytery. 4. An enquiry into the state of the ancient measures. 5. De Palestiniarum heresi confectura. 6. Several sermons; and other works.

HOOPING-COUGH. See Medicine Index. HOOPEO. See UPUSA, ORNITHOLOGY INDEX. HOP, in Botany. See HUMULUS, BOTANY INDEX. Hops were first brought into England from the Netherlands in the year 1524. They are first mentioned in the English statute book in the year 1552, viz. in the 5 and 6 of Edw. VI. cap. 5. And by an act of parliament of the first year of King James I. anno 1603, cap. 18. it appears, that hops were then produced in abundance in England. The hop being a plant of great importance in the article of brewing, we shall consider what relates to the culture and management of it, under the following heads:

Of Soil. As for the choice of their hop grounds, they esteem the richest and strongest grounds the most proper; and if it be rocky within two or three feet of the surface the hops will prosper well; but they will by no means thrive on a stiff clay or spongy wet land.

The Kentish planters account new land best for hops; they plant their hop gardens with apple-trees at a large distance, and with cherry-trees between; and when the land hath done its best for hops, which they reckon it will in about 7 years, the trees begin to bear. The cherry-trees last about 30 years; and by that time the apple-trees are large, they cut down the cherry-trees.

The Essex planters account a moory land the most proper for hops. As to the situation of a hop-ground, one that includes...
HOP

clines to the south or west is the most eligible; but if it be exposed to the north-east or south-west winds, there should be a shelter of some trees at a distance, because the north-east winds are apt to nip the tender shoots in the spring; and the south-west winds frequently break and blow down the poles at the latter end of the summer and very much endanger the hops.

In the winter-time provide your soil and manure for the hop-ground against the following spring.

If the dung be rotten, mix it with two or three parts of common earth, and let it incorporate together till you have occasion to make use of it in making your hop hills; but if it be new dung, then let it be mixed as before till the spring in the next year, for new dung is very injurious to hops.

Dung: of all sorts was formerly more commonly made use of than it is now, especially when rotten and turned to mould, and they who have no other manure must use it; which if they do, cows or hogs dung, or human ordure mixed with mud, may be a proper compost, because hops delight most in a manure that is cool and moist.

Planting. Hops require to be planted in a situation so open, that the air may freely pass round and between them, to dry up and dissipate the moisture, whereby they will not be subject to fire-blasts, which often destroy the middle stems of large plantations while the outsides remain unharmed.

As for the preparation of the ground for planting, it should, in the preceding winter, be ploughed and harrowed even; and then lay upon it in heaps a good quantity of fresh rich earth, or well rotten dung and earth mixed together, sufficient to put half a bushel in every hole to plant the hops in, unless the natural ground be very fresh and good.

The hills where the hops are to be planted should be eight or nine feet asunder, that the air may freely pass between them; for in close plantations they are very subject to what the hop-planters call the fire-blast.

If the ground is intended to be ploughed with horses between the hills, it will be best to plant them in squares chequerwise; but if the ground is so small that it may be done with the breast-plough or spade, the holes should be ranged in a quincunx form. Which way soever you make use of, a stake should be stuck down at all the places where the hills are to be made.

Persons ought to be very curious in the choice of the plants as to the kind of hop; for if the hop-garden be planted with a mixture of several sorts of hops that ripen at several times, it will cause a great deal of trouble, and be a great detriment to the owner.

The two best sorts are the white and the gray bind; the latter is a large square hop, more hardy, and is the more plentiful bearer, and ripens later than the former.

There is also another sort of the white bind, which ripens a week or ten days before the common; but this is tenderer, and a less plentiful bearer; but it has this advantage, that it comes first to market.

But if three grounds, or three distant parts of one ground, be planted with these three sorts, there will be this convenience, that they may be picked successively as they become ripe. The sets should be five or six inches long, with three or more joints and buds on them.

If there be a sort of hop you value, and would increase plants and sets from, the superfluous bind may be laid down when the hops are tied, cutting off the tops, and burying them in the hill; or when the hops are dressed, all the cuttings may be saved; for almost every part will grow, and become a good set the next spring.

As to the seasons of planting hops, the Kentish planters best approve the months of October and March, both which sometimes succeed very well; but the sets are not to be had in October, unless from some ground that is to be destroyed; and likewise there is some danger that the sets may be rotted, if the winter prove very wet; therefore the most usual time of procuring them is in March, when the hops are cut and dressed.

As to the manner of planting the sets, there should be five good sets planted in every hill, one in the middle, and the rest round about sloping, the tops meeting at the centre; they must stand even with the surface of the ground; let them be pressed close with the hand, and covered with fine earth, and a stick should be placed on each side the hill to secure it.

The ground being thus planted, all that is to be done more during that summer, is to keep the hills clean from weeds, and to dig up the ground about the month of May, and to raise a small hill round about the plants. In June you must twist the young bind or branches together into a bunch or knot; for if they are tied up to small poles in the first year, in order to have a few hops from them, it will not counteract the weakening of the plants.

A mixture of compost or dung being prepared for your hop-ground, the best time for laying it on, if the weather prove dry, is about Michaelmas, that the wheels of the dung-cart may not injure the hops, nor furrow the ground: if this be not done then, you must be obliged to wait till the frost has hardened the ground, so as to bear the dung-cart; and this is also the time to carry on your new poles, to recruit those that are decayed, and to be cast out every year.

If you have good store of dung, the best way will be to spread it in the alleys all over the ground, and to dig it in the winter following. The quantity they will require will be 40 loads to an acre, reckoning about 30 bushels to the load.

If you have not dung enough to cover all the ground in one year, you may lay it on one part one year, and on the rest in another, or a third; for there is no occasion to dung the ground after this manner often than once in three years.

Those who have but a small quantity of dung, usually content themselves with laying on about twenty loads upon an acre every year; this they lay only on the hills, either about November, or in the spring; which last some account the best time, when the hops are dressed, to cover them after they are cut; but if it be done at this time, the compost or dung ought to be very well rotted and fine.

Dressing. As to the dressing of the hops, when the hop-ground is dug in January or February, the earth about the hills, and very near them, ought to be taken away.
HOP

away with a spade, that you may come the more con-
veniently at the stock to cut it.

About the end of February, if the hops were planted
the stock before, or if the ground be weak, they
ought to be dressed in dry weather; but else, if the
ground be strong and in perfection, the middle of
March will be a good time: and the latter end of
March, if be apt to produce over-rank bindes, or
the beginning of April, may be soon enough.

Then having with an iron picker cleared away all the
earth out of the hills, so as to clear the stock to the
principal roots, with a sharp knife you must cut off all
the shoots which grew up with the bindes the last year;
and also all the young suckers, that none be left to run
in the alley, and weaken the hill. It will be proper
to cut one part of the stock lower than the other, and
also to cut that part low that was left highest the pre-
ceding year. By pursuing this method you may expect
to have stronger buds, and also keep the hill in good
order.

In dressing those hills that have been planted the
year before, you ought to cut off both the dead tops
and the young suckers which have sprung up from the
sets, and also to cover the stocks with fine earth a fin-
ger's length in thickness.

The poleing. About the middle of April the hops
are to be poled, when the shoots begin to sprout up;
the poles must be set to the hills deep into the ground,
with a square iron picker or crow, that they may the
better endure the winds; three poles are sufficient for
each hill. These should be placed as near the hill as
may be, with their bending tops turned outwards from the
hill, to prevent the bindes from entangling; and a space
between two poles ought to be left open to the south to
admit the sun-beams.

The poles ought to be in length 16 or 20 feet,
more or less according as the ground is in strength;
and great care must be taken not to overpole a young
or weak ground, for that will draw the stock too much
and weaken it. If a ground be overpole, you are not
to expect a good crop from it; for the branches which
bear the hops will grow very little till the bindes have
over-reached the poles, which they cannot do when the
poles are too long. Two small poles are sufficient for
a ground that is young.

If you wait till the sprouts or young bindes are grown
to the length of a foot, you will be able to make a bet-
ter judgment where to place the largest poles; but if
you stay till they are so long as to fall into the alleys,
it will be injurious to them, because they will entangle
one with another, and will not clasp about the pole
neatly.

Maple or aspen poles are accounted the best for
hops, on which they are thought to prosper best, be-
cause of their warmth; or else, because the climbing
of the hop is promoted by means of the roughness
of the bark. But for durability, ash or willow poles
are preferable; but chestnut poles are the most durable
of all.

If after the hops are grown up you find any of
them have been under-poled, taller poles may be pla-
ced near those that are too short to receive the bindes
from them.

The tying. As to the tying of hops, the buds that
do not clasp of themselves to the nearest pole when
they are grown to three or four feet high, must be
clasped by the hand, turning them to the sun,
whose course they will always follow. They must be
bound with withered rushes, but not so close as to hin-
der them from climbing up the pole.

This you must continue to do till all the poles are
furnished with bindes, of which two or three are enough
for a pole; and all the sprouts and bindes that you have
no occasion for are to be plucked up; but if the
bindes be young, then none of these useless bindes
should be plucked up, but should be wraught up to-
tgether in the middle of the hill.

When the bindes are grown beyond the reach of your
hands, if they forsake the poles, you should make use
of a stand-ladder in tying them up.

Towards the latter end of May, when you have
made an end of tying them, the ground must have the
summer dressing: this is done by casting up with
the spade some fine earth into every hill; and a month
after this is done, you must hoe the alleys with a
Dutch hoe, and make the hills up to a convenient
bigness.

Gathering. About the middle of July hops begin to
blow, and will be ready to gather about Bartholomew
Tide. A judgment may be made of their ripeness by
their strong scent, their hardness, and the brownish co-

our of their seed.

When by these tokens they appear to be ripe, they
must be picked with all the expedition possible; for if
at this time a storm of wind should come, it would do
them great damage by breaking the branches, and
bruising and discoloring the hops; and it is very well
known that hops, being picked green and bright, will
sell for a third part more than those which are discol-
oured and brown.

The most convenient way of picking them is into a
long square frame of wood, called a bin, with a cloth
hanging on tenter hooks within it, to receive the hops
as they are picked.

The frame is composed of four pieces of wood join-
ed together, supported by four legs, with a prop at
each end to bear up another long piece of wood plac-
ed at a convenient height over the middle of the bin;
this serves to lay the poles upon which are to be
picked.

The bin is commonly eight feet long, and three
feet broad; two poles may be laid on it at a time, and
six or eight persons may work at it, three or four on
each side.

It will be best to begin to pick the hops on the east
or north side of your ground, if you can do it conve-
niently; this will prevent the south-west wind from
breaking into the garden.

Having made choice of a spot of the ground con-
taining 12 hills square, place the bin upon the hill
which is in the centre, having five hills on each side;
and when these hills are picked, remove the bin into
another piece of ground of the same extent, and so pro-
ced till the whole hop-ground is finished.

When the poles are drawn up to be picked, you
must take great care not to cut the bindes too near the
hills, especially when the hops are green, because it will
make the sap to flow excessively.

The hops must be picked very clean, i.e. free from
leaves and stalks; and, as there shall be occasion, two
or
or three times in a day the bin must be emptied into a hop-bag made of coarse linen cloth, and carried immediately to the east or kiln in order to be dried; for if they should be long in the bin or bag, they will be apt to heat and be discoloured.

If the weather be hot, there should no more poles be drawn than can be picked in an hour, and they should be gathered in fair weather, if it can be, and when the hops are dry; this will save some expense in firing, and preserve their colour better when they are dried.

The crop of hops being thus bestowed, you are to take care of the poles against another year, which are best to be laid up in a shed, having first stripped off the balsam from them; but if you have not that convenience, set up three poles in the form of a triangle, or six poles (as you please) wide at bottom; and having set them into the ground, with an iron picker, and bound them together at the top, set the rest of your poles about them; and being thus disposed, none but those on the outside will be subject to the injuries of the weather, for all the inner poles will be kept dry, unless at the top; whereas, if they were on the ground, they would receive more damage in a fortnight than by their standing all the rest of the year.

Drying. The best method of drying hops is with charcoal on an east or kiln, covered with hair-cloth, of the same form and fashion that is used for drying malt. There is no need to give any particular directions for making these, since every carpenter or bricklayer in those countries where hops grow, or malt is made, knows how to build them.

The kiln ought to be square, and may be of 10, 12, 14, or 16 feet over at the top, where the hops are laid, as your plantation requires, and your room will allow. There ought to be a due proportion between the height and breadth of the kiln and the beguells of the steddle where the fire is kept, viz. if the kiln be 12 feet square on the top, it ought to be nine feet and a half square, and so proportionable in other dimensions.

The hops must be spread even upon the east a foot thick or more, if the depth of the curb will allow it; but care is to be taken not to overload the east if the hops be green or wet.

The east ought to be first warmed with a fire before the hops are laid on, and then an even steady fire must be kept under them; it must not be too fierce at first, lest it scorche the hops, nor must it be suffered to sink or slacken, but rather be increased till the hops be nearly dried, lest the moisture or sweat which the fire has raised fall back and discolor them. When they have lain about nine hours they must be turned, and in two or three hours more they may be taken off the east. It may be known when they are well dried by the brittleness of the stalks and the easy falling off of the hop leaves.

It is found by experience that the turning of hops, though it be after the most easy and best manner, is not only an injury to waste the hops, but also an expense of fuel and time, because they require as much fuel and as long a time to dry a small quantity, by turning them, as a large one. Now this may be prevented by having a cover (to be let down and raised at pleasure) to the upper bed whereon the hops lie.

This cover may also be tinned, by nailing single tin plates over the face of it; so that when the hops begin to dry, and are ready to burn, i.e., when the greatest part of their moisture is evaporated, then the cover may be let down within a foot or less of the hops (like a reverberatory), which will reflect the heat upon them, so that the top will soon be as dry as the lowermost, and every hop be equally dried.

Bagging. As soon as the hops are taken off the kiln, lay them in a room for three weeks or a month to cool, give and toughen; if they are bagged immediately they will powder, but if they lie a while (and the longer they lie the better, provided they be covered close with blankets to secure them from the air] they may be bagged with more safety, as not being liable to be broken to powder in treading; and this will make them bear treading the better, and the harder they are trodden the better they will keep.

The common method of bagging is as follows: they have a hole made in an upper floor, either round or square, large enough to receive a hop-bag, which consists of four ells and a half of ell-wide cloth, and also contains ordinarily two hundred and a half of hops; they tie a handful of hops in each lower corner of the bag to serve as handles to it; and they fasten the mouth of the bag, so placed that the hoop may rest upon the edges of the hole.

Then he that is to tread the hops down into the bag, treads the bag on every side, another person continually putting them in as he treads them till the bag is full; which being well filled and trodden, they unroll the fastening of the bag to the hops, and let it down, and close up the mouth of the bag, tying up a handful of hops in each corner of the mouth, as was done in the lower part.

Hops being thus packed, if they have been well dried, and laid up in a dry place, will keep good several years; but care must be taken that they be neither destroyed nor spoiled by the mice making their nests in them.

Produce. The charge of an acre of hop-ground in most parts of England where hops are cultivated, is computed thus: three pounds for the husbandry, four pounds for the wear of the poles, five pounds for picking and drying, one pound ten shillings for dung, one pound for rent, though in some places they pay four or five pounds an acre yearly for the rent of the land, and ten shillings for tythe; in all 5s. a year. The hop planters in England reckon that they have but a moderate return, when the produce of an acre of hops does not sell for more than 30l. They frequently have fifty, sixty, eighty, or a hundred pounds; and in a time of general scarcity considerably more: so that, upon the whole, if the total charge of an acre of hops is computed at fifteen pounds a-year, and its average produce at thirty pounds, the clear profit from an acre will be fifteen pounds a-year. But the plantation of hops has lately so much increased, and the average produce so much exceeded the consumption, that hops have been with many planters rather a losing than a very profitable article.

Uses. In the spring-time, while the bud is yet tender, the tops of the plant being cut off, and boiled, are ate like asparagus, and found very wholesome, and effectual to loosen the body; the heads and tendrils are
HOP [600]

Hops. good to purify the blood in the scurvy, and most cutaneous diseases; decorations of the flowers, and syrups thereof, are of use against pestilential fevers; juleps and aposomes are also prepared with hops for hypochondriacal and hysterical afflictions, and to promote the menses.

A pillow stuffed with hops and laid under the head, is said to procure sleep in fevers attended with a delirium. But the principal use of hops is in the brewery, for the preservation of malt liquors; which by the superaddition of this balsamic, aperient, and diuretic bitter, become less viscid, less apt to turn sour, more detergent, more disposed to pass off by urine, and in general more salubrious. They are said to contain an agreeable odoriferous principle, which promotes the vinous fermentation. When slightly boiled or infused in warm water, they increase its spirituality.

Laws relating to Hops. By 9 Anne, cap. 122, an additional duty of 3d. a pound is laid on all hops imported, over and above all other duties; and hops landed before entry and payment of duty, or without warrant for landing, shall be forfeited and burnt; the ship also shall be forfeited, and the person concerned in importing or landing shall forfeit 5l. a hundred weight; 7 Geo. II. cap. 19. By 9 Anne, cap. 12, there shall be paid a duty of 1d. for every pound of hops grown in Great Britain, and made fit for use, within six months after they are cured and bagged; and hop-grounds are required to be entered on pains of 40s. an acre. Places of curing and keeping are also to be entered, on pains of 50l. which may be visited by an officer at any time without obstruction, under the penalty of 20l. All hops shall, within six weeks after gathering, be brought to such places to be cured and bagged, on pain of 5s. a pound. The rebagging of foreign hops in British bagging for sale or exportation, incurs a forfeiture of 10l. a hundred weight; and defrauding the king of his duty by using twice or oftener the same bag, with the officer's mark upon it, is liable to a penalty of 40l. The removal of hops before they have been bagged and weighed, incurs a penalty of 50l. Concealment of hops subjects to the forfeiture of 20l. and the concealed hops; and any person who shall privately convey away any hops, with intent to defraud the king and owner, shall forfeit 5s. a pound. And the duties are required to be paid within six months after curing, bagging, and weighing, on pain of double duty, two-thirds to the king, and one-third to the informer. No common brewer, &c. shall use any bitter ingredient instead of hops, on pain of 20l. Hops which have paid the duty may be exported to Ireland; but by 6 Geo. II. cap. 1. there shall be no drawback; and by 7 Geo. II. cap. 19, no foreign hops shall be landed in Ireland. Notice of bagging and weighing shall be sent in writing to the officer, on pain of 50l. 6 Geo. cap. 21. And by 14 Geo. III. cap. 68, the officer shall on pain of 5l. weigh the bags or pockets, and mark on them the true weight or tare, the planter's name and place of abode, and the date of the year in which such hops were grown; and the altering or forging, or obliterating such mark, incurs a forfeiture of 10l. The owners of hops shall keep at their costs, &c. just weights and scales, and permit the officer to use them on pain of 20l. 6 Geo. cap. 21. And by 10 Geo. III. cap. 44, a penalty of 20l. is inflicted for false scales and weights. The owners are allowed to use casks instead of bags, under the same regulations. 6 Geo. cap. 21. If any person shall mix with hops any drug to alter the colour or scent, he shall forfeit 5l. a hundred weight. If any person shall unlawfully and maliciously cut hop bines growing on poles in any plantation, he shall be guilty of felony without benefit of clergy. 6 Geo. II. cap. 37.

HOPE, in Ethics, is the desire of some good, attended with a belief of the possibility at least, of obtaining it, and enlivened with joy, greater or less, according to the greater or less probability of our possessing the object of our hope. Alexander, preparing for his Asian expedition, distributed his hereditary dominions among his friends; allotting to some villages, to others boroughs, to others cities; and being asked what he had reserved for himself, replied, Hope.

Hope, Good, Cape of. See Good Hope.

HOPEA, a genus of plants belonging to the polydelphis class. See Botany Index.

HOPLITES, hoplite (formed of ἔλος, armouer), in antiquity, were such of the candidates at the Olympic and other sacred games as ran races in armour.

One of the finest pieces of the famous Parthian armours was a painting which represented two hoplites; the one running, and seeming to sweat large drops; the other laying his arms down, as quite spent and out of breath.

HOPLITODROMOS, (formed of ἔλος, armouer; and ὄρμον, I run), in the ancient gymnastic sports, a term applied to such persons as went through those toilsome and robust exercises in complete armour; by which the exercise became much more violent, and the wearing of armour in the time of battle much more easy.

HOPLOMACHI, ὁλομαχείς, (composed of ἔλος, armouer, and μαχέομαι, I fight), in antiquity, were a species of gladiators who fought in armour; either completely armed from head to foot, or only with a cask and cuirass.

HOPPER, a vessel in which seed-corn is carried at the time of sowing.

The word is also used for that wooden trough in a mill into which the corn is put to be ground.

HOR, a mountain, or mountainous tract of Arabia Petraea, situated in that circuit which the Israelites took to the south and south-east of Edom in their way to the borders of Moab: on this mountain Aaron died. The inhabitants were called Horites. This tract was also called Seir, either from a native Horite, or from Esau, by way of anticipation from his hairy habit of body; whose posterity drove out the Horites.

HORŒ. See Hours.

HORŒA, in antiquity, solemn sacrifices, consisting of fruits, &c. offered in spring, summer, autumn, and winter; that heaven might grant mild and temperate weather. These, according to Meursius, were offered to the goddesses called Ἐλευθερία, i.e. Hours, who were three in number, attended upon the Sun, presided over the four seasons of the year, and had divine worship paid them at Athens.

HORAPOLLO, or HORUS APOLLO, a grammarian of Panaplas in Egypt, according to Suidas, who first taught at Alexandria, and then at Constantinople under
HORATII, three Roman brothers, who, under the reign of Tullius Hostilius, fought against the three Curitii, who belonged to the Alban army. Two of the Horatii were first killed; but the third, his address, successively slew the three Curitii, and by this victory rendered the city of Alba subject to the Romans. See ROME.

HORATIUS, surnamed Cocles from his losing an eye in battle, was nephew to the consul Horatius Pulvillus, and descended from one of the three brothers who fought against the Curitii. Porssenna, laying siege to Rome, drove the Romans from Janiculum; and pursued them to the wooden bridge over the Tiber, which joined the city to Janiculum. Largius, Herminius, and Horatius Cocles, sustained the shock of the enemy on the bridge, and prevented their entering the city with the Romans; but Largius and Herminius having passed the bridge, Horatius Cocles was left alone, and repulsed the enemy till the bridge was broken under him; he then threw himself armed into the Tiber, swam across the river, and entered Rome in triumph.

HORATIUS, Quintus Flaccus, the most excellent of the Latin poets of the lyric and satirical kind, and the most judicious critic in the reign of Augustus, was the grandson of a freedman, and was born at Venusia 64 B.C. He had the best masters in Rome, after which he completed his education at Athens. Having taken up arms, he embraced the party of Brutus and Cassius, but left his shield at the battle of Philippi. Some time after he gave himself up entirely to the study of poëtic literature and poetry. His talents soon made him known to Augustus and Mecenas, who had a particular esteem for him, and loaded him with favours. Horace also contrived a strict friendship with Agrippa, Pollie, Virgil, and all the other great men of his time. He lived without ambition, and led a tranquil and agreeable life with his friends; but was subject to a delusion in his eyes. He died at the age of 57. There are still extant his Odes, Epistles, Satires, and Art of Poetry; of which there have been a great number of editions. The best are those of the Louvre, in 1642, folio; of Paris 1691, quarto; of Cambridge, 1699; and that with Bentley's emendations, printed at Cambridge in 1711.

HORD, in Geography, is used for a company of wandering people, which have no settled habitation, but strol about, dwelling in waggons or under tents, to be ready to shift as soon as the herbage, fruit, and the present province, is eaten bare: such are several tribes of the Tartars, particularly those who inhabit beyond the Wolga, in the kingdoms of Astracan and Bulgaria.

HORDEUM, BARLEY, a genus of plants belonging to the triandra class; and in the natural method ranking under the 4th order, Gramina. See BOTANY Index.

HORDICALIA, or HORDICIDIA, in antiquity, a religious feast held among the Romans, wherein they sacrificed cattle big with young. This feast fell on April 9th, on which day they sacrificed 30 cows with calf to the goddess Tellus or the earth; part of them were sacrificed in the temple of Jupiter. The calves taken out of their bellies were burnt to ashes at first by the pontiffs, afterwards by the eldest of the vestal virgins.

HOREB, or OREB, a mountain of Arabia Petraea, contiguous to and on the south side of Mount Sinai; the scene of many miraculous appearances.

HORESTI (Tacitus), a people of Britain, beyond Solway frith. Now Eskdale (Cameren).

HORITES, an ancient people, who at the beginning dwelt in the mountains of Seir beyond Jordan (Gen. xiv. 6.). They had princes, and were powerful, even before Ewau made a conquest of their country (id. xxxvi. 29—30.). The Horites, the descendants of Seir, and the Edomites, seem afterwards to have been confounded, and to have composed but one people (Deut. ii. 2. xxxiii. 2. and Judg. v. 4.). They dwelt in Arabia Petraea, and Arabia Deserta, to the south-east of the promised land. We find the Heb. word נוֹר, Chorah, which in the book of Genesis is translated Horites, to be used in an appellative sense in several other passages of scripture, and to signify nobles, or great and powerful men (1 Kings xxii. 11. and Neh. ii. 16. iv. 14. v. 7. vi. 7. vii. 5. xii. 17. 1 Cor. x. 17. Isa. xxxiv. 12. Jer. xxxvii. 20. xxxix. 6.). And it is very probable that the Greeks derived from hence their heroes, in like manner as they derived Anas, "a king," from the sons of Anak, the famous giant in Palestine.

HOREHOUND, the name of a plant. See MARUBIUM, BOTANY Index.

HORIZON, in Geography and Astronomy, a great circle of the sphere, dividing the world into two parts or hemispheres; the one upper and visible, the other lower and hid. The word is pure Greek, ἡρεῖον, which literally signifies "bounding or terminating the sight;" being formed of ἡρέω, termineo, define, "I bound, I limit;" whence it is also called finitor, "finisher." See ASTRONOMY and GEOGRAPHY.

The horizon is either rational or sensible.

Rational, true, or astronomical Horizon, which is also called simply and absolutely the horizon, is a great circle, whose plane passes through the centre of the earth, and whose poles are the zenith and nadir. It divides the sphere into two equal parts or hemispheres.

Sensible, visible, or apparent Horizon, is a lesser circle of the sphere, which divides the visible part of the sphere from the invisible. Its poles, too, are the zenith and nadir; and consequently the sensible horizon is parallel to the rational; and it is cut at right angles,
HOR [ 602 ]

HOR

and into two equal parts, by the verticals.—The sensible horizon is divided into eastern and western. The eastern or opposite horizon, is that portion of the horizon wherein the heavenly bodies rise. The western or opposite horizon, is that wherein the stars set. The altitude or elevation of any point of the sphere, is an arch of a vertical circle intercepted between it and the sensible horizon.

By sensible horizon is also frequently meant a circle, which determines the segment of the surface of the earth, over which the eye can reach; called also the physical horizon. In this sense we say, a spacious horizon, a narrow scanty horizon.

HORIZONTAL, something that relates to the horizon, is taken in the horizon, or on a level with the horizon.—We say, a horizontal plane, horizontal line, &c.

Horizontal Dial, is that drawn on a parallel to the horizon: having its guomon, or style, elevated according to the altitude of the pole of the place for which it is designed. Horizontal dials are, of all others, the most simple and easy. The manner of describing them, see under the article Dial.

Horizontal Line, in Perspective, is a right line drawn through the principal point, parallel to the horizon: or, it is the intersection of the horizontal and perspective planes. See Perspective.

horizontal Plane, is that which is parallel to the horizon of the place, or nothing inclined thereto.

The business of leveling is to find whether two points be in the horizontal plane; or how much the deviation is. See LEVELLING.

Horizontal Plane, in Perspective, is a plane parallel to the horizon, passing through the eye, and cutting the perspective plane at right angles.

 Horizontal Projection. See Geography Index.

Horizontal Range, or Level Range, of a piece of ordnance, is the line it describes, when directed parallel to the horizon or horizontal line. See GUNNERY, passim.

Horizontal Moon. See Moon, Astronomy Index.

Horizontal Speculum. See Speculum.

Horminum, clarx, a genus of plants belonging to the didynamia class; and in the natural method ranking under the 3rd order, Verticillata. See Botany Index.

Horn, in Physiology, a hard substance growing on the heads of divers animals, particularly the cloven-footed quadrupeds; and serving them both as weapons of offence and defence.

The horn of animals is of the same nature as their gelatinous matter; and is only that matter charged with a less quantity of water, and a larger quantity of earth, and sufficiently condensed to have a firm and solid consistence. By digesting horn with water in Papin’s digester, it may be entirely converted into jelly.

Horn is a perfectly animalised matter, and furnishes in distillation the same principles as all animal matters; that is, at first a pure phlegm, with a degree of heat not exceeding that of boiling water; then a volatile alkaline spirit, which becomes more and more penetrating and strong; a fetid, light, and thin oil; a concrete volatile salt, which forms ramifications upon the sides of the receiver; much air; fetid oil, which becomes more and more black and thick; and lastly, it leaves in the retort a considerable quantity of almost incombustible coal, from which, after its incineration, scarcely any fixed alkali can be obtained.

Animal oil, and particularly that which is drawn first in the distillation of horn, is susceptible of acquiring great thinness and volatility by repeated distillations, and is then called the oil of dippel.

The horns of stage, and of other animals of that kind, are the most proper to furnish the animal oil to be rectified in the manner of dippel; because they yield the largest quantity. These horns also differ from the horns of other animals in this, that they contain a larger quantity of the same kind of earth which is in bones; hence they seem to possess an intermediate nature between horns and bones.

Hart’s-Horn. See Hart’s-Horn.

Horns make a considerable article in the arts and manufactures. Balloons horns, softened by the fire, serve to make lanthorns, combs, knives, ink-horns, tobacco-boxes, &c.

Dyeing of Horn.—Black is performed by steeping brass in aquafortis till it be returned green: with this the horn is to be washed once or twice, and then put into a warmed decoction of logwood and water. Green is begun by boiling it, &c. in alum-water; then with verdigrise, ammoniac, and white-wine vinegar; keeping it hot therein till sufficiently green. Red is begun by boiling it in alum-water; and finished by decoction in a liquor compounded of quick-lime steeped in rain water, strained, and to every pint an ounce of Brazilwood added. In this decoction the bone, &c. is to be boiled till sufficiently red.

Dr. Laws informs us that horns receive a deep black stain from solution of silver. It ought to be diluted to such a degree as not sensibly to corrode the subject; and applied two or three times, if necessary, at considerable intervals, the matter being exposed as much as possible to the sun, to hasten the appearance and deepening of the colour.

Dyeing or staining Horn to imitate Tortoise-shell.—The horn to be dyed must be first pressed into proper plates, scales, or other flat form; and the following mixture prepared. Take of quick-lime two parts, and of litharge one part; temper them together to the consistence of a soft paste with soap-ley. Put this paste over all the parts of the horn, except such as are proper to be left transparent, in order to give it a nearer resemblance of the tortoise-shell. The horn must remain in this manner covered with the paste till it be thoroughly dry; when, the paste being brushed off, the horn will be found partly opaque and partly transparent, in the manner of tortoise-shell; and when put over a foil, of the kind of latten called assidue, will be scarcely distinguishable from it. It requires some degree of fancy and judgement to dispose of the paste in such a manner as to form a variety of transparent parts, of different magnitudes and figures, to look like the effect of nature: and it will be an improvement to add some transparent parts; which may be done by mixing whitening with some of the paste to weaken its operation in particular places; by which spots of a reddish brown will be produced, which if properly interspersed, especially on the edges of the dark parts, will greatly increase both the beauty of the work, and its similitude with the real tortoise-shell.

Horn.
Horn is also a sort of musical instrument of the wind kind; chiefly used in hunting, to animate and bring together the dogs and the hunters. The term anciently was, wind a horn; all horns being in those times compassed; but since straight horns are come in fashion, they say blow a horn, and sometimes sound a horn.

There are various lessons on a horn; as the recrheat, double recrheat, royal recrheat, running or farewell recrheat; &c. See Recrheat.

The French horn is no other than a wrested or contorted trumpet. It labours under the same defects as the trumpet itself; but these have of late been so palliated, as to require no particular selection of keys for this instrument. In the beginning of the year 1773, a foreigner, named Spandau, played in a concert at the opera-house a concerto, part whereof was in the key of C, with the minor-third; in the performance of which all the intervals seemed to be as perfect as in any wind-instrument. This improvement was effected by putting his right hand into the bottom or bell of the instrument, and attempering the sounds by the application of his fingers to different parts of the tube.

The Hebrews made use of horns, formed of rams horns, to proclaim the jubilee; whence the name Jubilee.

Cape Horn. See Terra del Fuego.

Horn-beam. See Carpinus, Botany Index.

Horn-Bill. See Bucerus, Ornithology Index.

Horn-Blende. A species of mineral. See Mineralogy Index.

Human Horns. In Dr Charles Leigh's natural history of Lancashire, Cheshire, and the Peak in Derbyshire, is the print of a woman with two horns on her head. When she was 28 years of age an excrecence grew upon her head like a wen, which continued 20 years, and then grew into two horns. After four years she cast them, and in their place grew two others. After four years she cast these also, and the horns which were on her head in 1668 (the time when the account was written) were then loose. Her picture and one of her horns are in Ashmole's museum. In the university library at Edinburgh is preserved a horn which was cut from the head of Elizabeth Love, in the 50th year of her age. It grew three inches above the ear, and was growing seven years.

Horn Distemper, a disease incident to horned cattle, affecting the internal substance of the horn commonly called the pith, which it insensibly wastes, and leaves the horn hollow. The pith is a spongy bone, the cells of which are filled with an unctuous matter. It is furnished with a great number of small blood vessels, is overspread with a thin membrane, and appears to be united by sutures with the bones of the head. According to an account of this distemper, published by Dr Tofts in the Memoirs of the American Academy, vol. 1, the said spongy bone is sometimes partly, and sometimes entirely wasted. The horn loses its natural bent, and a degree of coldness is felt upon handling it. The distemper, however, is seldom suspected without a particular acquaintance with the other symptoms, which are a dulness in the countenance of the beast, a sluggishness in moving, a failure of appetite, an inclination to lie down, and, when accompanied with an inflammation of brain, a giddiness and frequent tossing of the head. The limbs are sometimes affected with stiffness, as in a rheumatism; in cows the milk often fails, the udder is hard, and in almost all cases there is a sudden wasting of the flesh. As soon as the distemper is discovered, an opening into the diseased horn should be immediately made, which may be done with a gimlet of a moderate size, in such a part of the horn as is most favourable for the discharge. It is recommended as most prudent to bore at first two or three inches above the head. If it is found hollow, and the gimlet passes through to the opposite side, and no blood discharges from the aperture, it may be best to bore still lower, and as near the head as it shall be judged that the hollowness extends. This opening is affirmed to be a necessary measure, and often gives immediate relief. Care must be taken to keep it clear, as it is apt to be clogged by a thin fluid that gradually oozes out and fills up the passage. Some have practised sawing off the horn; but, according to the best observations, it succeeds no better than boring. From the cases Dr Tofts has seen, he is led to conclude that injections are in general unnecessary; that, when the distemper is early discovered, no more is required than a proper opening into the horn, keeping it sufficiently clear for the admission of fresh air, the removal of the compression, and the discharge of floating matter. But when the distemper has reached the brain, so as to produce great inflammation, it is much to be doubted whether any method of cure will succeed.

Horn-Fish, Gar-fish, or Sea-needle. See Esox, Ichthyology Index.

Horn-Work, in fortification, an outwork of two demi-bastions joined by a curtain. See Fortification.

Hornby, a town of England, in Lancashire, it had a castle, as the name imports; from the architecture of which, and the Roman coins that are sometimes dug up here, it is thought to have been a camp or station of the Romans. The town is well built, and is almost surrounded with water. It is a signory of 13 lordships, in which are several chapels. Horn-castle contained in 1811, 2622 inhabitants, who are principally occupied in the manufacture of leather. It has a market on Saturdays, and fairs in June and August.

Horne, George, an English prelate of great eminence, was born in the vicinity of Maidstone, in the county of Kent, in the year 1730. His father was rector of Oatham, and having for some time acted in the capacity of a tutor at Oxford, was well qualified to superintend the education of his son George. However, that he might not be spoiled by too long a residence at home, he was, by the advice of a friend, sent to Maidstone school at the age of 13, where he continued under an eminent teacher for two years, and acquired some knowledge of oriental literature, particularly the Hebrew, and went to Oxford in his 15th year. Here
be indefatigably laboured to store his mind with almost every branch of useful learning, and resolved to make polite literature subservient to the knowledge and illustration of the Scriptures. He studied the Hebrew more attentively, and was wisely exhorted to abandon the method of Buxtorf, so encumbered with that load of publish, the masoretic punctuation. The restraint of his conduct, and the vivacity of his conversation, gained him the esteem of every person with whom he was acquainted. In the year 1740 he was made B. A. and next year was elected to a fellowship in Magdalen college, without any solicitation upon his part.

About this time he became a prostrate to what are called mysteries of Hutchinsonianism, chiefly through the influence of Mr. William Jones. His mind, at the age of 19, was completely fettered by those doctrines, believing that it was the design of Sir Isaac Newton and Dr. Clarke, to subvert the theology of the Scriptures, and introduce the stoical anima mundi into the place of the God of the universe! Under the influence of such an infatuated whim, it is not astonishing that he should endeavour to discredit the system of Newton. He obtained the degree of M. A. in the year 1752, when he engaged in a controversy on the subject of the cherubim, in the Gentleman's Magazine, subscribing himself Ingenius. With a view to recommend the writings of Hutchinson, he published "A fair, candid, and impartial state of the case between Sir Isaac Newton and Mr. Hutchinson, in which it is shown, how far a system of physics is capable of mathematical demonstration; how far Sir Isaac's, in such a system, has that demonstration; and consequently, what regard Mr. Hutchinson's claim may deserve to have paid it." In the year 1753 Mr. Horne entered into holy orders, and acquired high reputation as a public speaker, as his compositions were excellent, and his eloquence graceful. While preaching before the university, he introduced some of his peculiar notions, which again led him into controversy. A piece made its appearance, entitled "A word to the Hutchisonians; or, remarks on three extraordinary sermons, lately preached before the university of Oxford, by Dr. Patten, Mr. Wetherell, and Mr. Horne." To this our author replied in his "Apoloogy for certain gentlemen in the university of Oxford, aspersed in a late anonymous pamphlet," &c. The vindication of the hint to the Hutchinsonians, was supposed to be the production of Dr. Kennicott, who became afterwards so famous for his labours in collating Hebrew manuscripts, and his valuable edition of the Hebrew Bible. He (Mr. Horne) was chosen proctor of the university in 1753, and on the honourable termination of his authority was created B. D. When Mr. (afterwards Dr.) Kennicott, gave the world proposals for collating the text of the Hebrew Bible, for the purpose of correcting the original, and preparing for a new translation, Mr. Horne was very much alarmed. He falsely apprehended that the adoption of such a measure would overwhelm the sacred text with licentious criticism; on which account he published, in 1760, "A view of Mr. Kennicott's method of correcting the Hebrew text, with three queries formed thereon, and humbly submitted to the consideration of the learned and Christian world." But an acquaintance which thus began in hostility was converted afterwards into genuine friendship, which continued through the whole of life.

In 1764, Mr. Horne was created D. D. although as yet advanced to no conspicuous station. On the death of Dr. Jenner, the president of Magdalen college, Dr. Horne was appointed to succeed him in a post at once honourable and valuable, in the beginning of 1768, after which we are informed that he exchanged a single for a married life. Next year he published "Considerations on the life and death of St. John the Baptist, being the substance of several sermons preached by him before the university." In 1771, he was chosen chaplain in ordinary to his majesty, which he held for ten years. In 1772, when a number of clergymen had formed the resolution of petitioning parliament for relief as to the subscribing the liturgy and thirty-nine articles, Dr. Horne determined, if possible, to defeat their object, for which purpose he published "Considerations on the projected reformation of the church of England, in a letter to Lord North."

He now set about the finishing of his greatest work, which had occupied his attention for almost 20 years. This was his "Commentary on the Book of Psalms," which appeared in 1776, in 2 vols. quarto. It exhibits profound erudition, a great genius, and fervent piety; and is perused with much pleasure and advantage by every judge of merit. In the same year he was chosen vice-chancellor of the university, which he held to the latter end of the year 1780. On the publication of Dr. Adam Smith's letter, containing an account of the death of Mr. David Hume, Dr. Horne, in the year 1777, publicly animadverted upon it, in "A letter to Adam Smith, L. L. D. on the life, death, and philosophy of his friend David Hume, Esq. by one of the people called Christians." In this work he exposes the absurdities of the Scotch philosopher's performance, to the contempt of the religious world, with clear and conclusive reasoning, and keen but good-humoured irony. In 1779, Dr. Horne published "Discourses on various subjects and occasions," in two volumes octavo, which have procured the approbation of all descriptions of readers.

As vice-chancellor of the university he became acquainted with Lord North, to whose interest, joined with that of Lord Hawkesbury, he was indebted, in 1781, for the deanship of Canterbury. His time was now divided between this city and Oxford, and the conscientious discharge of every part of his complex duty made him universally beloved. In 1784 he published letters on infidelity, similar to his reply to Dr. Adam Smith. The books against which he levelled his ridicule are, "An apology for the life and writings of David Hume, Esq.;" Hume's "Dialogues on natural religion;" an essay on suicide by the same author, and a treatise entitled "Doubts of the infidels." In the year 1790, when Dr. Basset was translated to the see of St. Asaph, Dr. Horne was appointed to succeed him in the see of Norwich. His last literary labours were "Observations on the case of the Protestant dissenters with reference to the corporation and test acts," 1790; and "A charge intended to have been delivered to the clergy of the diocese of Norwich," at his first visitation, 1791. When he was raised to the episcopal dignity, his health, always delicate, began rapidly to decline.
Hornsey, a town of Middlesex, five miles north of London. It is a long straggling place, situated in a low valley, but extremely pleasant, having the new river winding through it. Its church, of which Highgate is a hamlet, is supposed to be built with the stones that came from Lodge-Hill, the bishop of London’s hunting-seat in his park here; it having been his mansion from the most ancient times. About a mile nearer this is a copse of young trees, called Hornsey wood, at the entrance of which is a public-house, which commands a fine prospect, and is a great resort of the citizens of London. In 1811, Hornsey contained 3,349 inhabitants.

Hornpipe, a common instrument of music in Wales, consisting of a wooden pipe, with holes at stated distances, and a horn at each end: the one to collect the wind blown into it by the mouth, and the other to carry off the sounds as modulated by the performer.

Hornpipe is also the name of an English air, probably derived from the above instrument. The measure of this air is triple time, with six crotchets in a bar; four of which are to be beat with the hand, down and two up.

Horoography, the art of making or constructing dials; called also dialling, horology, graphology, guanomica, sciatherica, photosciathica, &c.

HoroLOGIUM, Ὄρωλογιον, (composed of ὀρός, hora, “time, hour,” and λέγομαι, “speech, discourse,”) a common name among ancient writers for any instrument or machine for measuring the hours; see Chronometer.——Such are our clocks, watches, sun-dials, &c. See Clock, Watch, Dial, and Clepsydra.

Modern inventions, and gradual improvements, have given birth to some new terms that come properly under this head, and annexed new meanings to others totally different from what they had originally. All chronometers that announced the hour by striking on a bell, were called clocks: thus, we read of pocket-clocks, though nothing could seem more absurd than to suppose that a clock, according to the modern idea, should be carried in the pocket. In like manner, all clocks that did not strike the hour were called watches or time-pieces; and the different parts of a striking clock were distinguished by the watch-part and the clock-part; the former meaning that part which measures the time, and the latter the part which proclaims the hours. In the report of Sir Isaac Newton to the house of commons, anno 1713, relative to the longitude act, he states the difficulties of ascertaining the longitude by means of a watch; yet it is obvious, from several circumstances, that his remarks were directly to be understood of a time-piece regulated by a pendulum; for his objections are founded on the known properties of the pendulum, some of which differ essentially from the properties of the balance and spring. It is also to be remembered, that all the attempts of Huygens for finding the longitude were by means of pendulum clocks that did not strike the hour, and consequently, according to the language of the times, were called watches. At this time such machines for measuring time as are fixed in their place are called clocks, if they strike the hour; if they do not strike the hour, they are called time-pieces; and when constructed with more care, for a more accurate measure of time, they

Hornet, a species of wasp. See Vespa, Entomology Index.

Horninig, in Scots Law, a writing issuing from the signet, in his majesty’s name, at the instance of a creditor against his debtor, commanding him to pay or perform within a certain time, under pain of being declared rebel, and by a caption put in prison.

Hornsey, a town in Yorkshire, 188 miles north from London, and 15 from Hull. It is almost surrounded by a small arm of the sea; and the church having a high steeple, is a noted sea-mark. Not many years ago there was a street here called Hornsey-beck, which was washed away by the sea, except a house or two. The inhabitants amounted to 704 in 1811.
Horology—Horses

are called regulators. Some artists of late have affected to call such watches as were constructed for astronomical and nautical observations by the name of time-pieces, probably to intimate that they possess the advantages of those constructed with a pendulum.

Mr. John Harrison first gave the name of time-keeper to his watch, for the performance of which he received from parliament the sum of 20,000L. See Longitude.

For the account of the principles of this machine, see Time-keeper. And for the chief improvements that have been made for the more accurate measure of time, see Pallets, Pendulum, and Scaepment.

Horopter, in Optics, is a right line drawn through the point where the two optic axes meet, parallel to that which joins the centres of the two eyes, or the two pupils.

Horoscope, in Astrology, the degree or point of the heavens rising above the eastern point of the horizon at any given time when a prediction is to be made of a future event: as, the fortune of a person then born, the success of a design then laid, the weather, &c. The word is composed of aequ, hora, "hour," and the verb causo, video, "I behold."

Such was at one time the infatuation concerning horoscopes, that Albertus Magnus, Cardan, and others, are said to have had the temerity to draw that of Jesus Christ.

Horoscope is also used for a scheme or figure of the twelve houses, i.e., the twelve signs of the zodiac, wherein is marked the disposition of the heavens for any given time. Thus we say, to draw a horoscope, construct a horoscope, &c. We call it, more peculiarly, calculating a nativity, when the life and fortune of a person are the subject of the prediction; for they draw horoscopes of cities, great enterprises, &c. See House.

Horoscoppy. See Divination, No. 2.

Horrea, in Roman antiquity, were public magazines of corn and salt-beef, out of which the soldiers were furnished on their march in the military roads of the empire. Horrea was also the name which they gave to their granaries.

Horrox, Jeremiah, an eminent English astronomer in the 17th century, was born at Textet near Liverpool in Lancashire in 1619. He died, to the great loss of that science and of the world, in the 23d year of his age, after he had just finished his Venus in Sole visa; which, with some other works, was published by Dr. Wallis, in quarto.

Horror, strictly signifies such an excess of fear as makes a person tremble. See Fear, Fright, and Terror. In medicine, it denotes a shivering and shaking of the whole body, coming by fits. It is common at the beginning of all fevers, but is particularly remarkable in those of the intermittent kind.

Horror of a Vacuo, was an imaginary principle among the ancient philosophers, to which they ascribed the ascent of water in pumps, and other similar phenomena, which are now known to be occasioned by the weight of the air.

Horse. See Equus, Mammalia Index.

Horses were very rare in Judaea till Solomon's time. Before him we find no horsemen mentioned in the armies of Israel. David having won a great battle against Hadadezer king of Shobah (2 Sam. viii. 4, 5.), took 1700 horses, and laded all belonging to the chariots of war, reserving only 100 chariots. The judges and princes of Israel used generally to ride on mules or asses. After David's time, horses were more common in the country of Judah, &c. Solomon is the first king of Judah who had a great number of horses, and he kept them rather for pomp than for war; for we do not read that he made any military expeditions. He had, says the Scripture (1 Kings iv. 25.), 40,000 stalls of horses for his chariots, and 12,000 horsemen distributed in his fortified places (1 Kings x. 26.). He had his horses from Egypt (ibid. ver. 28, 29.) and there was not a set which did not cost him more than 600 shekels, which make of our money about 90L. Moses had forbidden the king of the Hebrews to keep a great number of horses (Deut. xvii. 16.), lest at any time he should be inclined to carry the people back into Egypt.

We read in the second book of Kings (xxiii. 17.), that Josiah took away the horses which the kings of Judah his predecessors had consecrated to the sun. We know the sun was worshipped over all the east, and that the horse, the swiftest of tame beasts, was consecrated to this deity, who was represented as riding in a chariot drawn by the most beautiful and swiftest horses in the world, and performing every day his journey from east to west, in order to communicate his light to mankind. Xenophon describes a solemn sacrifice of horses, which was made with ceremony to the sun: they were all the finest steeds, and were led with a white chariot, crowned, and consecrated to the same god. We may believe that the horses which Josiah removed out of the court of the temple, were appointed for the like sacrifices. The rabbins inform us, that these horses were every morning put to the chariots dedicated to the sun, whereas there is mention made in the same book; and that the king, or some of his officers, got up and rode to meet the sun in its rising, as far as from the eastern gate of the temple to the suburbs of Jerusalem. Others are of opinion, that the horses mentioned in the book of Kings were of wood, stone, e., or metal, erected in the temple in honour of the sun; Others, that they were horses which none were permitted to ride or fasten to the yoke, but were free, and left to themselves, like those which Julius Caesar let loose and set at liberty after his passage of the Rubicon.

Horses were used both amongst the Greeks and Romans in war, but were not originally very numerous; for as each horseman provided his own horse, few would be able to bear the expense. Horses for a considerable time were managed by the voice alone, or by a switch, without bridle, saddle, or stirrups. Their harness was skins of beasts, or sometimes cloth. Both horses and men amongst the Greeks underwent a severe probation before their admission into the cavalry.—Horse-races were common amongst the Greeks and Romans, and the place where they ran or breathed their courser was called hippocormus.

Management of a Horse upon and after a Journey. See that his shoes be not too strait, or press his feet, but be exactly shaped; and let him be shod some days before you begin a journey, that they may be settled to his feet.

Observe that he is furnished with a bit proper for him,
him, and by no means too heavy, which may incline
him to carry low, or rest upon the hand when he
grows weary, which horsemen call making use of his
fifth leg.

The mouth of the bitt should rest upon his bars
about half a finger's-breadth from his tushes, so as not
to make him stumble his lips; the curb should rest in
the hollow of his beard a little above the chin; and if
it gall him, you must defend the place with a piece of
buff or other soft leather.

Take notice that the saddle do not rest upon his wi-
thers, reins, or back-bone, and that one part of it do
not press his back more than another.

Some riders gall a horse's sides below the saddle with
their stirrup-leathers, especially if he be lean; to hin-
der it, you should fix a leather strap between the points
of the fore and hind-bows of the saddle, and make the
stirrup-leather pass over them.

Begin your journey with short marches, especially
if your horse has not been exercised for a long time;
suffer him to stale as often as you find him inclined:
and not only so, but invite him to it; but do not ex-
cite your mares to stale, because their vigour will be
thereby diminished.

It is advisable to ride very softly, for a quarter or
half an hour before you arrive at the inn, that the
horse not being too warm, nor out of breath, when
put into the stable, you may unbridle him: but if your
business obliges you to put on sharply, you must then
(the weather being warm) let him be walked in a man's
hand, that he may cool by degrees; otherwise, if it be
very cold, let him be covered with cloths, and walked
up and down in some place free from wind; but in case
you have not the convenience of a sheltered walk,
stable him forthwith, and let his whole body be rubbed
dried with straw.

Although some people will have their horses' legs
rubbed down with straw as soon as they are brought
into the stable, thinking to supple them by that
means; yet it is one of the greatest errors that can be
committed, and produces no other effects than to draw
down into the legs those humours that are always stir-
red up by the fatigue of the journey; not that the
rubbing of horses' legs is to be disallowed; on the con-
trary, we highly approve of it, only would not have
it done at their first arrival, but when they are perfectly
cooled.

Being come to your inn, as soon as your horse is
partly dried, and ceases to beat in the flanks, let him
be unbridled, his bitt washed, cleansed, and wiped, and
let him eat his hay at pleasure.

If your horse be very dry, and you have not given
him water on the road, give him oats washed in good
mild ale.

The dust and sand will sometimes so dry the tongues
and mouths of horses, that they lose their appetites:
in such case, give them bran well moistened with wa-
ter to cool and refresh their mouths; or wash their
mouths and tongue with a wet sponge, to oblige them
to eat.

The foregoing directions are to be observed after
moderate riding; but if you have rode excessively hard,
unsaddle your horse, and scrape off the sweat with a
sweating-knife, or scraper, holding it with both hands,
and going always with the hair; then rub his head and
cars with a large hair-cloth, wipe him also between the
fore legs and hind legs; in the meanwhile, his body
should be rubbed all over with straw, especially under
his belly and beneath the saddle, till he is thoroughly
dried.

That done, set on the saddle again; cover him; and
if you have a warm place, let him be gently led up and
down in it for a quarter of an hour; but if not, let him
dry where he stands.

Or you may unsaddle him immediately; scrape off
the sweat; let the ostler take a little vinegar in his
mouth and squirt it into the horse's; then rub his
head, between the fore and hind legs, and his whole
body, till he is pretty dry; let him not drink till he is
thoroughly cool, and has eaten a few oats; for many,
by drinking too soon, have been spoiled. Set the
saddle in the sun or by a fire, in order to dry the
pannels.

When horses are arrived at an inn, a man should,
before they are unbridled, lift up their feet, to see
whether they want any of their shoes, or if those they
have do not rest upon their sides; afterwards he should
pick and clean them of the earth and gravel which may
be got betwixt their shoes and soles.

If you water them abroad, upon their return from
the river cause their feet to be stopped with cow-
dung, which will ease the pain therein; and if it be in
the evening, let the dung continue in their feet all
night, to keep them soft and in good condition; but if
your horse have brittle feet, it will be requisite to snout
the fore feet, at the on-setting of the hoofs, with but-
ter, oil, or hog's grease, before you water him in the
morning, and in dry weather they should be also greased
at noon.

Many horses, as soon as unbridled, instead of eat-
ing, lay themselves down to rest, by reason of the
great pain they have in their feet, so that a man is apt
to think them sick; but if he looks to their eyes, he
will see they are lively and good; and if he offers them
meat as they are lying, they will eat it very willingly;
yet if he handles their feet, he will find them extre-

dely hot, which discovers their suffering in that part.
You must therefore see if their shoes do not rest upon
their soles, which is somewhat difficult to be certain-
ly known without unshoeing them; but if you take off
their shoes, then look to the inside of them, and you
may perceive that those parts which rest upon the
soles are more smooth and shining than the others;
in this case you are to pare their feet in those parts,
and fix on their shoes again, anointing the hoofs, and
stopping the soles with scalding hot black pitch or

After a long day's journey, at night feel your horse's
back, if he be pinched, galled, or swelled (if you do
not immediately discover it, perhaps you may after sup-
ner), there is nothing better than to rub it with good
brandy and the white of an egg. If the galls are be-

between the legs, use the same remedy; but if the ostler

rubs him well between the legs, he will seldom be gal-

led in that part.

In order to preserve horses after travel, take these
few useful instructions. When you are arrived from a
journey, immediately draw the two heel-nails of the
fore feet; and, if it be a large shoe, then four: two
or three days after, you may blood him in the neck,
Horse. and feed him for 10 or 12 days only with wet bran, without giving him any oats; but keep him well littered.

The reason why you are to draw the heel-nails, is because the heels are apt to swell, and if they are not thus eased, the shoes would press and straiten them too much: it is also advisable to stop them with cow-dung for a while; but do not take the shoes off, nor pare the feet, because the humour is drawn down by that means.

The following bath will be very serviceable for preserving your horse’s legs. Take the dung of a cow or ox, and make it thin with vinegar, so as to be of the consistence of thick broth; and having added a handful of small salt, rub his fore legs from the knees, and the hind legs from the gammelors, chasing them well with and against the hair, that the remedy may sink in and stick to those parts, that they may be all covered over with it. Thus leave the horse till morning, not wetting his legs, but giving him his water that evening in a pail; next-morning lead him to the river, or wash his legs in well water, which is very good, and will keep them from swelling.

Those persons, who, to recover their horses feet, make a bore in them, which they fill with moistened cow-dung, and keep it in their fore feet during the space of a month, do very ill; because, though the continual moisture that issues from the dung occasions the growing of the hoof, yet it dries and shrinks it so excessively when out of that place, that it splits and breaks like glass, and the foot immediately straitens. For it is certain, that cow-dung (contrary to the opinion of many people) spoils a horse’s hoof: it does indeed moisten the sole, but it dries up the hoof, which is of a different nature from it. In order, therefore, to recover a horse’s feet, instead of cow-dung, fill a bore with blue wet clay, and make him keep his fore-feet in it for a month.

Most horses that are fatigued or over-rid, and made lean by long journeys, have their flanks altered without being purgy, especially vigorous horses that have worked too violently.

There is no method better to recover them, than to give each of them in the morning half a pound of honey very well mingled with scaled bran; and when they readily eat the half pound, give them the next time a whole one, and afterwards two pounds, every day, continuing this course till your horses are empty, and purge kindly with it; but as soon as you perceive that their purging ceases, forbear to give them any more honey.

You may administer powder of liquorice in the scaled bran for a considerable time; and to cool their blood, it will not be improper to let them have three or four glysters.

In case the horse be very lean, it is expedient to give him some wet bran, over and above his proportion of oats; and grass is also extraordinary beneficial, if he be not purgy.

If it be a mare, put her to a horse; and if she never had a foal before, it will enlarge her belly.

Sometimes excessive feeding may do horses more harm than good, by rendering them subject to the sarscy. You should therefore be cautious in giving them too great a quantity at a time, and take a little blood from them now and then.

When a horse begins to drink water heartily, it is a certain sign that he will recover in a short time. As to the method of giving him water during a journey, observe the following rules:

All the while you are upon a journey, let your horse drink of the first good water you come to, after seven o’clock in the morning if it be in summer-time, and after nine or ten in winter.

That is accounted good water which is neither too quick and piercing, nor too muddy and stinking.

This is to be done, unless you would have him gallop a long time after drinking; for so, you must forbear.

Though it is the custom in England to run and gallop horses after drinking, which we call watering-courses, to bring them (as they say) into wind; yet says M. de Bolseyel, it is the most pernicious practice that can be imagined for horses, by which many are rendered purgy.

While a horse is drinking, draw up his head five or six times, making him move a little between every draught; and notwithstanding he be warm, and sweat very much, yet if he be not quite out of breath, and you have still four or five miles to ride, he will be better after drinking a little, than if he had drank none at all: it is true, indeed, that if the horse is very warm, you should, at coming out of the water, redouble your pace, to make him go at a gentle trot, to warm the water in his belly.

You ought to let him drink after this manner during the whole time of your journey; because, if when you happen to bait him he be hot or sweaty, you must not let him drink for a long time, as it would endanger his life; and when his bridle is taken off, his excessive thirst will hinder him from eating, so that he will not offer to touch his meat for an hour or two, which perhaps your occasion will not allow you for a baiting time, and not to have any food will render him unfit for travel.

If you meet with any ford before you come to your inn, ride the horse through it two or three times, but not up to his belly: this will not only cleanse his legs, but the coldness of the water will bind up the humours, and prevent them from descending.

If your horse has been very warm, and you have not had the convenience of watering him upon the road, be will, when unbridled, eat but very little; therefore he should have his oats given him washed in ale or beer, or only some of them, if you intend to feed him again after he has drank.

Some are of opinion, that horses are often spoiled by giving them oats before their water; because they say the water makes the oats pass too soon, and out of the stomach undisgested. But M. de Bolseyel affirms, that though it be the common custom not to do it till after, yet it is proper to feed with oats both before and after, especially if the horse be warm, and has been hard rode; for he will be a great deal the better for it, and in no danger of becoming sick.

Breeding of Horses. When the stallion is chosen, and all the mares intended for him are collected togethert there must be another stone horse, to discover which
HOR

Hor. which of the mares are in heat, and, at the same time, contribute to inflame them. All the mares are to be brought successively to this stone-horse, which should also be inflamed, and suffered frequently to neigh. As he is for leaping every one, such as are not in heat keep him off, whilst those which are so suffer him to approach them. But instead of being allowed to satisfy his impotence, he must be led away, and the real stallion substituted in his stead. This step is necessary for ascertaining the true time of the mare's heat, especially of those which have not yet had a colt; for with regard to such as have recently foaled, the heat usually begins nine days after their delivery; and on that very day they may be led to the stallion to be covered; and nine days after, by the experiment above mentioned, it may be known whether they are still in heat. If they are, they must be covered a second time; and thus successively every ninth day while their heat continues: for when they are impregnated, their heat abates, and in a few days ceases entirely.

But that every thing may be done easily and conveniently, and at the same time with success and advantage, great attention, expence, and precaution, are requisite. The stud must be fixed in a good soil, and in a suitable place, proportioned to the number of mares and stallions intended to be used. This spot must be divided into several parts, inclosed with rails or ditches well fenced; in the part where the pasture is the richest, the mares in fold, and those with colts by their sides, are to be kept. Those which are not impregnated, or have not yet been covered, are to be separated, and kept with the fillies in another close, where the pasture is less rich, that they may not grow too fat, which would obstruct the progress of generation. Lastly, the young stone colts or geodings are to be kept in the driest part of the fields, and where the ground is most unequal; that by running over the uneven surface, they may acquire a freedom in the motion of their legs and shoulders. This close where the stone colts are kept, must be very carefully separated from the others, lest the young horses break their bounds, and enervate themselves with the mares. If the tract be so large as to allow of dividing each of these closes into two parts, for putting oxen and horses into them alternately, the pasture will last much longer than if continually eaten by horses: the ox improving the fertility, whereas the horse lessens it. In each of these closes should be a pond; standing water being better than running, which often gripes them; and if there are any trees in the ground, they should be left standing, their shade being very agreeable to the horses in great heats; but all stumps or stumps should be grubbed up, and all holes levelled, to prevent accidents. In these pastures your horses should feed during the summer; but in the winter the mares should be kept in the stable and fed with hay. The colts also must be housed, and never suffered to feed abroad in winter, except in very fine weather. Stallions that stand in the stable should be fed more with straw than hay; and moderately exercised till covering time, which will generally last from the beginning of April to the end of June. But during this season they should have no other exercise, and be plentifully fed, but with the same food as usual. Before the stallion is brought to the Vol. X. Part II.

mares, be should be dressed, as that will greatly increase his ardour. The mare must also be carried, and have no shoes on her hind feet, some of them being ticklish, and will kick the stallion. A person holds the mare by the halter, and two others lead the stallion by long reins; when he is in a proper situation, another assistant carefully directs the yard, pushing aside the mare's tail, as a single hair might hurt him dangerously. It sometimes happens that the stallion does not complete the work of generation, coming from the mare without making any injection; it should therefore be attentively observed, whether, in the last moments of the copulation the deck of the stallion's tail has a vibrating motion; for such a motion always accompanies the emission of the seminal lymph. If he has performed the act, he must on no consideration be suffered to repeat it; but be led away directly to the stable, and there kept two days. For, however able a good stallion may be of covering every day during the three months, it is much better to let him be led to a mare only every other day: his produce will be greater, and he himself less exhausted. During the first seven days, let four different mares be successively brought to him; and the ninth day let the first be again brought, and so successively while they continue in heat; but as soon as the heat of any one is over, a fresh mare is to be put in her place, and covered in her turn every nine days; and as several retain even at the first, second, or third time, it is computed that a stallion, by such management, may, during the three months, cover 15 or 16 mares, and beget 10 or 12 colts. These animals have a very large quantity of the seminal lymph; so that a considerable portion of it is shed during the emission. In the mares likewise is an emission, or rather distillation of the seminal lymph, during the whole time they are horning; ejecting a viscid whitish lymph, called the heats, which ceases on conception. This ichor the Greeks called hippocanpes; and pretended that phillæ was made of it, one remarkable effect of which was; to render a horse frantic with lust. This hippocanpes is very different from that found in the secundines of the foal, which M. Daubenton first discovered, and has so accurately described its nature, origin, and situation. The ejection of this liquor is the most certain sign of the mare's heat; but it is also known by the inflation of the lower part of the vulva, by her frequent neighings, and attempts to get to the horses. After being covered, nothing more is requisite than to lead her away to the field. The first foal of a mare is never so strongly formed as the succeeding; so that care should be taken to procure for her, the first time, a larger stallion, that the defect of the growth may be compensated by the largeness of the size. Particular regard should also be had to the difference or congruity of the fashion of the stallion and the mare; in order to correct the faults of the one by the perfections of the other: especially never to make any disproportionate copulations, as of a small horse with a large mare, or a large horse with a small mare; as the produce of such copulation would be small, or badly proportioned. It is by gradations that we must endeavour to arrive at natural beauty; for instance, to give to a mare a little too clumsy, a well-made horse and finely shaped; to a small mare, a horse
presented itself first, as in all other animals: at its coming out of the matrix, it breaks the secundines or integuments that inclose it, which is accompanied with a great flux of the lymph contained in them; and at the same time one or more solid lumps are discharged, formed by the sediment of the inappasite liquor of the allantoids. This lump, which the ancients called the hippocampus of the colt, is so far from being, as they imagined, a mass of flesh adhering to the head of the colt, that it is separated from it by a membrane called amnios. As soon as the colt is fallen, the mare licks it, but without touching the hippocampus, which points out another error of the ancients, who affirmed that she instantly devours it.

The general custom is to have a mare covered nine days after her foaling, that no time may be lost; but it is certain, that the mare having, by this means, both her present and future foal to nourish, her ability is divided, and she cannot supply both so largely as she might one only. It would therefore be better, in order to have excellent horses, to let the mares be covered only every other year; they would last the longer, and bring foals more certainly; for, in common studs, it is so far from being true that all mares which have been covered bring colts every year, that it is considered as a fortunate circumstance if half or at most two-thirds of them foal.

Mares, when pregnant, will, admit of copulation; but it is never attended with any superfeacion. They usually breed till they are 14 or 15 years of age; and the most vigorous till they are above 18. Stallions, when well managed, will engender till the age of 25, and even beyond; but it must be observed, that such horses as are soonest made stallions, are also the soonest incapable of generation: thus the large horses, which acquire strength sooner than the slender, and are therefore often used as stallions as soon as they are four years old, are incapable of generation after they are sixteen.

**Gelding of Horses.** See Castration, Farriery

**Index.**

_Draught-Horse_, in farming, a sort of coarse-made horse destined for the service of the cart or plough. In the choice of these horses for what is called the show draught, they are to be chosen of an ordinary height; for otherwise, when put into the cart, one draws unequally with the other. The draught-horse should be large bodied and strong jointed, and of such a disposition, as rather to be too dull than too brisk, and rather to crave the whip than to draw more than is needful. Mares are the fittest for this use for the farmer, as they will be kept cheap, and not only do the work, but keep breeding, and give a yearly increase of a foal. They should have a good head, neck, breast, and shoulders; for the rest of the shape, it is not of much consequence. Only, for breeding, the mare should have a large belly; for the more room a foal has in the dam, the better proportioned it will be. Draught-horses should be always kept to that employ. Some put them to the saddle on occasion, but it does them great harm, alters their pace, and spoils them for labour. The draught horse ought to have a large broad head, because horses of this shaped head are less subject than others to diseases of the eyes. The ears should be small,
HOR

Horse.

small, straight and upright; the nostrils large and open, that he may breathe with the more freedom. A horse with a full and bold eye always promises well. On the other hand, a sunken eye and an elevated brow are bad signs. The horse is esteemed fittest for this purpose also, that has a large and round button, which neither sinks down nor cuts. He must have a firm and strong tail, and the dock must be thick and well furnished with hair, and placed neither very high nor very low. The legs should be rather flat and broad than round; the roundness of the leg being a fault in a horse destined to labour that will soon ruin him. As to the binder legs, the thighs should be fleshly and long, and the whole muscle which shows itself on the outside of the thigh should be large and very thick. No country can bring a parallel to the size and strength of our horses destined for the draught. In London there are instances of single horses that are able to draw on a plain, for a small space, the weight of three tons, and which can with ease, and for continuance, draw half that weight. The pack horses of Yorkshire usually carry a burden of 420 lb. over the highest hills of the north, as well as the most level roads: but the most remarkable proof of the strength of our British horses is derived from that our mill horses; some of which will at one load carry 13 measures, which at a moderate computation of 70 lb. each, will amount to 910 lb. Nothing is so essential to the health of these serviceable creatures as cleanliness; if they are fed ever so well, and not kept clean, they will be subject to numerous diseases.

The servant who has the care of them ought to be up very early, and to clean the racks and mangers from all filth. The carriage of them ought to be carefully performed every morning, but not in the stable, for the dust to fall upon the other horses, as it is too often done. After the horses are dusted, they should daily twist a whip of straw hard up, and wetting it in water, rub the legs, shoulders, and body with it. Many of the diseases of draught-horses, which are not owing to nastiness, are owing to bad water; such as is too raw, too muddy, or too cold, being improper. If there be any running stream in the neighbourhood, they should always be led to that water every day in summer; but in winter, well-water is warm, and is better for them. If there be a necessity of giving them well-water in summer, it must be drawn up some hours before the time, and exposed to the sunbeams in tubs or troughs; marsh-water or that of lowland ditches is worst of all. When the labouring horse has drunk his water, he should have his oats given him, and these should be carefully sifted, and the manger dusted first. It is a common practice, as soon as a horse is come in from his work, to rub down his legs with a hard whip of hay; but the best judges of horses absolutely condemn this, and observe, that this rubbing of the legs after hard labour brings down humours into them, and makes them stiff.

The rubbing itself is wholesome, but the doing it when the creature is hot is the mischief; while a horse is in a sweat it is a great relief and refreshment to him to have his body rubbed down, but when he is cold is the proper time to rub his legs. The racks are to be well supplied with hay, and the horses should be left to rest and eat, about two hours, and then led to water; after this their oats should be given them, and they should then go to work again.

In the evening, when the labour of the day is over, the first thing to be done is to examine the feet, and see if any thing is amiss about the shoes; and what earth or gravel is lodged in the foot, between the shoe and the sole, is to be picked out, and some fresh cow-dung put in its place, which will cool and refresh the part.

A very material thing for the preservation of all sorts of cattle, but of none so much as draught-horses, is fresh and clean litter.

Horse-Chesnut. See Aesulus, Botany Index.
Horse-Guards. See Guards.
Horse-Hunting. See Hunter.
Horse-Measure. See a rod of box to slide out of a cane, with a square at the end, being divided into inches to measure the height of horses.
Horse-Muscle. See Mytilus, Conchology Index.
Horse-Radish. See Cochlearia, Botany Index.
Horse-Shoe, a cover or defence for the sole of a horse's foot. See Farriery Index.
Horse-Shoe-head, a disease in infants, wherein the sutures of the skull are too open, or too great a vacuity is left between them; so that the aperture shall not be totally closed up, or the cranium in that part not be so hard as the rest for some years after. This openness is found to be increased upon the child's catching cold. When the disease continues long, it is reputed a sign of weakness and short life. In this case it is usual to rub the head now and then with warm rum or brandy, mixed with the white of an egg and palm-oil. Sometimes the disorder arises from a collection of waters in the head called a hydrocephalus.

Stone-Horse. See Stallion.
Horse-Tail. See Equisetum, Botany Index.
Horse-Vetch. See Hippocrepis, Botany Index.
War-Horse. The proper rules for choosing a horse for service in war, are these: he should be tall in stature, with a comely head, and out-swelling forehead. His eye should be bright and sparkling, and the white part of it covered by the eye-brow. The ears should be small, thin, short, and pricking; or if long, they should be moveable with ease, and well carried. The neck should be deep, and the breast large and swelling; the ribs bending, the chine broad and straight, and the buttocks round and full. The tail should be high and broad, neither too thick nor too thin; the thigh swelling; the leg broad and flat, and the pastern short. When such a horse is chosen, he must be kept high during the time of his teaching, that he may be full of vigour. His food must be sweet hay, and good clean oats, or two parts of oats and one part of beans or pease, well dried and hardened. The quantity should be half a peck in the morning, and the same quantity at noon and in the evening. Upon his resting days he is to be dressed between five and six in the morning, and watered at seven or eight. In the evening he is to be dressed at four, and watered about five, and he must always have provender given him after watering; he must be littered about eight, and then must have food given him for all night. The night before he is ridden, all
Horse. His neck is to be taken away about nine o'clock, and he must have a handful or two of oats about four in the morning; when he has eaten these, he is to be turned upon the stable, and rubbed very well with dry clothes; then saddled, and made fit for his exercise. When he has performed this, he is to be brought sweating into the stable, and rubbed down with dry whips. When this has been done, the saddle is to be taken off, and he is to be rubbed down with dry cloths; the housing cloth is then to be laid on; and the saddle being again laid on, he is to be walked gently about till thoroughly cool. After this, he must stand without meat two or three hours; then he must be fed; and in the afternoon he is to be rubbed and dressed as before, and watered in the usual manner.

Horse-Worm, in Natural History, a species of fly-worm, called also bot, produced by eggs deposited by a two-winged fly of the shape and size of the humble bee in the intestines of horses. See Botry, Fabriery Index.

River-Horse. See Hippopotamus, Mammalia Index.

Horse is also used in the military language, to express the cavalry; or the body of soldiers who serve on horseback.

The horse includes horse guards, horse grenadiers, and troopers. Dragoons are also frequently comprehended under this name, though they fight on foot: of these there are now 18 regiments; besides three regiments of dragoon-guards raised in 1585. See Grenadiers, Dragoons, and Guards.

Master of the Horse. See Master.

Light-Horse, are regiments of cavalry, mounted on light swift horses, whose men are small and lightly accoutred. They were first raised in 1737. The denomination arose here, that anciently they were lightly armed, in comparison of the royal guards, which were armed at all points.

Hungarian Horse. See Hussars.

Horse is also a term used in various arts and manufactures, for something that helps to sustain their work from the ground, for the more commodius working at it.

The horse used by tanners and skinners, also called the leg, is a piece of wood cut hollow and roundish, four or five feet long, and placed above it, upon which they pare their skins to get off the dirt, hair, flesh, &c.

Horse is also used in carpentry, for a piece of wood jointed across two other perpendicular ones, to sustain the beams, planks, &c. which make bridges over small rivers; and on divers other occasions.

Horse, in Sanskrit language, is the name of a rope reaching from the middle of a yard to its extremity, or what is called the yard-arm, and depending about two or three feet under the yard, for the sailors to tread upon whilst they are lowering, reaching, or furling the sails, rigging out the studding-sail booms, &c. In order, therefore, to keep the horse more parallel to the yard, it is usually suspended to it at proper distances, by certain ropes called stirrups, which hang about two feet under the yard, having an eye in their lower ends through which the horse passes.

Horse is also a thick rope, extended in a perpendicular direction near the fore or after-side of a mast, for the purpose of hoisting or extending some sail upon it. When it is fixed before a mast, it is calculated for the use of a sail called the square-sail, whose yard being attached to the horse, by means of a traveller, or bull's eye, which slides up and down occasionally, is retained in a steady position, either when the sail is set, or whilst it is hoisting or lowering. When the horse is placed abaft or behind a mast, it is intended for the try-sail of a snow, and is accordingly very rarely fixed in this position, except in those sloops of war which occasionally assume the form of snows, in order to deceive the enemy.

Horse is also a cant name introduced into the management of lotteries, for the chance or benefit of a ticket or number for one or more days, upon condition, if it be drawn a prize within the time covenedanted for, of returning to the seller an undrawn ticket.—To determine the value of a horse; multiply the amount of the prizes in the lottery by the time the horse is hired for; and from the product subtract the amount of the number of prizes by the value of an undrawn ticket into the time of the horse: the remainder being divided by the number of tickets into the whole time of drawing, the quotient is the value of the horse. See Lottery.

Horse-Bread. See Bread.

Horse-Dung, in Gardening, is of great use in making hot beds, for the raising all sorts of early crops as salading, cucumbers, melons, asparagus, &c. for which purposes no other kind of dung will do so well. Horse-dung ferments the strongest; and if mixed with litter and sea-coal ashes in a due proportion, will continue its heat much longer than any other sort of dung whatsoever; and afterward, when rotted, becomes an excellent manure for most sorts of land: more especially for such as are of a cold nature. For still clayey land, horse-dung mixed with sea-coal ashes, and the cleansing of streets, will cause the parts to separate much sooner than any other compost; so that where it can be obtained in plenty, it is always to be recommended for such lands. See Dung.

Animated Horse-Hairs, a term used to express a sort of long and slender water-hair, of a blackish colour, and so much resembling a horse-hair, that it is generally by the vulgar supposed to be the hair fallen from a horse's mane into the water as he drinks, and there animated by some strange power. Dr Linser has at large confuted this absurd opinion, in the Philosophical Transactions.

Horse-Hair Worms. See Amphrema.

Horse-Hoeing Husbandry. See Agriculture, No 489.
HORSEMANSHIP;
Or, The Art of Riding, and of Training and Managing, Horses.

SECT. I. The Method of preparing Horses to be mounted.

THOUGH all horses are generally bought at an age when they have already been backed, they should be begun and prepared for the rider with the same care, gentleness, and caution, as if they had never been handled or backed; in order to prevent accidents, which might arise from skittishness or other causes: and as it is proper that they should be taught the figure of the ground they are to go upon when they are at first mounted, they should be previously trotted in a longe on circles, without any one upon them.

The manner of doing this is as follows: Put an easy girth upon the horse’s nose, and make him go forwards round you, standing quiet, and holding the longe; and let another man, if you find it necessary, follow him with a whip. All this must be done very gently, and but a little at a time: for more horses are spoiled by overmuch work, than by any other treatment whatever; and that by very contrary effects: for sometimes it drives them into vice, madness, and despair, and often stupifies and totally dispirits them.

The first obedience required in a horse is going forwards; till he perform this duty freely, never even think of making him rein back, which would inevitably make him restive: as soon as he goes forwards readily, stop and caress him. You must remember in this, and likewise in every other exercise, to use him to go equally well to the right and left; and when he obays, caress him and dismiss him immediately. If a horse that is very young takes fright andstands still, lead on another horse before him, which probably will induce him instantly to follow. Put a snaffle in his mouth; and when he goes freely, saddle him, girthing him at first very loose. Let the cord, which you hold, be long and loose; but not so much as to endanger the horse’s enangling his legs in it. It must be observed, that small circles, in the beginning, would constrain the horse too much, and put him upon defending himself. No bend must be required at first; never suffer him to gallop false; but whenever he attempts it, stop him without delay, and then set him off afresh. If he gallops of his own accord, and true, permit him to continue it; but if he does it not voluntarily, do not demand it of him at first. Should he fly and jump, shake the cord gently upon his nose without jerking it, and he will fall into his trot again. If he stands still, plunges, or rears, let the man who holds the whip make a noise with it; but never touch him till he be absolutely necessary to make him go on. When you change hands, stop and caress him, and entice him by fair means to come up to you; for by presenting yourself, as some do, on a sudden before horses, and frightening them to the other side, you run a great risk of giving them a shyness. If he keeps his head low, shake the converson to make him raise it; and in whatever the horse does, whether he walks, trots, or gallops, let it be a constant rule that the motion be determined, and really such as is intended, without the least shuffling, pacing, or any other irregular gait.

SECT. II. The Method of placing the Rider and rendering him firm on Horseback, with some occasional Instructions for Riders and the Horses.

It is necessary that the greatest attention, and the same gentleness that is used in teaching the horses, be observed likewise in teaching the rider, especially at the beginning. Every method and art must be practised to create and preserve, both in man and horse, all possible feeling and sensibility; contrary to the usage of most riding-masters, who seem industriously to labour at abolishing these principles both in the one and the other. As so many essential points depend upon the manner in which a man is at first placed on horseback, it ought to be considered and attended to with the strictest care and exactness.

The absurdity of putting a man, who perhaps has never before been upon a horse, on a rough trotting horse, on which he is obliged to stick with all the force of his arms and legs, is too obvious to need mentioning. This rough work, all at once, is plainly as detrimental at first, as it is excellent afterwards in proper time. No man can be either well or firmly seated on horseback, unless he be master of the balance of his body, quite unconstrained, with a full possession of himself, and at his ease; none of which requisites can be enjoyed, if his attention be otherwise engaged; as it must wholly be in a raw, unsupplied, and unprepared lad, who is put at once upon a rough horse; in such a distressful state, he is forced to keep himself on at any rate, by holding to the bridle (at the expense of the sensibility both of his own hand and the horse’s mouth), and by clinging with his legs, in danger of his life, and to the certain deprivation of a right feeling in the horse.

The first time a man is put on horseback, it ought to be upon a very gentle one. He never should be made to trot, till he is quite easy in the walk; nor gallop, till he is able to trot properly. The same must be observed in regard to horses; they should never be made to trot till they are obedient, and their mouths are well formed on a walk, nor be made to gallop, till the same be effected on a trot. When he is arrived at such a degree of firmness in his seat, the more he trots, and the more he rides rough horses, the better. This is not only the best method, but also the easiest and the shortest: by it a man is soon made sufficiently.
HORSEMANSHIP.

A soldier's right hand should be kept unemployed in riding; it carries the sword, which is sufficient business for it.

There remains one farther observation, that ought not to be omitted, about the hand, that it must be kept clear of the body; i.e., about two inches and a half forwards from it, with the nails turned opposite to the belly, and the wrist a little rounded with ease; a position not less graceful than ready for slackening, tightening, and moving the reins from one side to the other, as may be found necessary.

When the men are well placed, the more rough trotting they have without stirrups the better; but with a strict care always, that their position be preserved very exactly. In all cases, great care must be taken to hinder their clinging with their legs; in short, not sticking by hands or legs is ever to be allowed of at any time. If the motion of the horse be too rough, slacken it, till the rider grows by degrees more firm; and when he is quite firm and easy on his horse in every kind of motion, stirrups may be given him; but he must never leave off trotting often without any.

The stirrups must be neither short nor long; but of such a length, that when the rider, being well placed, puts his feet into them (about one-third of the length of each foot from the point of it), the points may be between two and three inches higher than the heels. The rider must not bear upon his stirrups, but only let the natural weight of his legs rest upon them: For if he bears upon them he would be raised above and out of his saddle; which he should never be, except in charging sword in hand, with the body inclined forwards at the very instant of attacking. Spurs may be given as soon as the rider is grown familiar with stirrups; or even long before, if his legs are well placed.

A hand should always be firm, but delicate: a horse's mouth should never be surprised by any sudden transition of it, either from slack to tight, or from tight to slack. Every thing in horsemanship must be effected by degrees, but at the same time with spirit and resolution. The hand which by giving and taking properly, gains its point with the least force, is the best; and the horse's mouth, under this same hand's directions, will also consequently be the best, supposing equal advantages in both from nature. This principle of gentleness should be observed upon all occasions in every branch of horsemanship. Sometimes the right hand may be necessary, upon some troublesome

Instruct.

ions con-

cerning

both Riders

and Horses.

some horses, to assist the left; but the seldomer this is done, the better; especially in a soldier, who has a sword to carry, and to make use of.

The snaffle must on all occasions be uppermost; that is to say, the reins of it must be above those of the bridle, whether the snaffle or the bit he used separately, or whether they be both used together. When the rider knows enough, and the horse is sufficiently prepared and settled to begin any work towards suppling, one rein must be shortened, and working on the sides worked by; but it must never be so much shortened, as to make the whole strength rest on that rein alone: for, not to mention that the work would be false and bad, one side of the horse's mouth would by that means be always deadened: whereas, on the contrary, it should always be kept fresh by its own play, and by the help of the opposite rein's acting delicately in a somewhat smaller degree of tension; the joint effect of which produces in a horse's mouth the proper, gentle, and easy, degree of appui or bearing.

A coward and a madman make alike bad riders, and are both alike discovered and confounded by the superior sense of the creature they are mounted upon, who is equally spoilt by both, though in very different ways. The coward, by suffering the animal to have his own way, not only confirms him in his bad habits, but creates new ones in him: and the madman, by false and violent motions and corrections, drives the horse, through despair, into every bad and vicious trick that rage can suggest.

It is very requisite in horsemanship, that the hand and legs should act in correspondence with each other in every thing: the latter always subservient and assistant to the former. Upon circles, in walking, trotting, or galloping, the outward leg is the only one to be used, and that only for a moment at a time, in order to set off the horse true, or put him right if he be false: and as soon as that is done, it must be taken away again immediately: but if the horse be lazy, or otherwise retains himself, both legs must be used and pressed to his sides at the same time together. The less the legs are used in general, the better. Very delicate good riders, with horses they have dressed themselves, will scarcely ever want their help. By the term outward is understood the side which is more remote from the centre; and by inward is meant the side next to the centre. In treading back, the rider should be careful not to use his legs, unless the horse backeth on his shoulders; in which case they must be both applied gently at the same time, and correspond with the hand. If the horse refuse to back at all, the rider's legs must be gently approached, till the horse lifts up a leg, as if to go forwards; at which time, when that leg is in the air, the rein of the same side with that leg which is lifted up will easily bring that same leg backwards, and accordingly oblige the horse to back; but if the horse offers to rear, the legs must be instantly removed away. The inward rein must be tighter on circles, so that the horse may bend and look inwards; and the outward one crossed over a little towards it; and both held in the left hand.

Let the man and horse begin on very slow motions, that they may have time to understand and reflect on what is taught them; and in proportion as the effects of the reins are better comprehended, and the manner of working becomes more familiar, the quickness of motion must be increased. Every rider must learn to feel, without the help of the eye, when a horse goes false, and remedy the fault accordingly: this is an intelligence, which nothing but practice, application, and attention, can give, in the beginning on slow motions. A horse may not only gallop false, but also trot and walk false. If a horse gallops false, that is to say, if going to the right he leads with the left leg, or if going to the left he leads with the right; or in case he is disunited, i.e. if he leads with the opposite leg behind to that which he leads with before; stop him immediately, and put him off again properly. The method of effecting this, is by approaching your outward leg, and putting your hand outwards; still keeping the inward rein the shorter, and the horse's head inwards, if possible; and if he should still resist, then bend and pull his head outwards also; but replace it again, bent properly inwards, the moment he goes off true. A horse is said to be disunited to the right, when going to the right, and consequently leading with the right leg before, he leads with the left behind; and is said to be disunited to the left, when going to the left, and consequently leading with the left leg before, he leads with the right behind. A horse may at the same time be both false and disunited; in correcting both which faults, the same method must be used. He is both false and disunited to the right, when in going to the right he leads with the left leg before, and the right behind; notwithstanding that hinder leg be with propriety more forward under his belly than the left, because the horse is working to the right: And he is false and disunited to the left, when in going to the left he leads with the right leg before and the left behind; notwithstanding, as above, that hinder leg be with propriety more forward under his belly than the right, because the horse is working to the left.

In teaching men a right seat on horseback, the greatest attention must be given to prevent stiffness, and sticking by force in any manner upon any occasion: stiffness disgraces every right work; and sticking serves only to throw a man (when displaced) a great distance from his horse by the spring he must go off with; whereas by a proper equilibrating position of the body, and by the natural weight only of the thighs, he cannot but be firm and secure in his seat.

As the men become more firm, and the horses more supple, it is proper to make the circles less, but not too much so, for fear of throwing the horses forwards upon their shoulders.

Some horses, when first the bit is put into their mouths, if great care be not taken, will put their heads very low. With such horses, raise your right hand with the bridoons in it, and play at the same time with the bit in the left hand, giving and taking.

On circles, the rider must lean his body inwards; unless great attention be given to make him do it, he will be perpetually losing his seat outwards. If at all scarce possible for him to be displaced, if he leans his body properly inwards.
HORSEMANSHIP.

Sect. III.

The Method of suppling Horses with Men upon them, by the EPAULE en dedans, &c. with and without a Longe, on Circles and on straight Lines.

When a horse is well prepared and settled in all his motions, and the rider firm, it will be proper then to proceed on towards a farther suppling and teaching of both.

In setting out upon this new work, begin by bringing the horse's head a little more inwards than before, pressing the inward rein gently to you by degrees. When this is done, try to gain a little on the shoulders, by keeping the inward rein the shorter, as before, and the outward one crossed over towards the inward one. The intention of these operations is this: The inward rein serves to bring in the head, and procures the bend; whilst the outward one, that is a little crossed, tends to make that bend perpendicular and as it should be, that is to say, to reduce the nose and the forehead to be in a perpendicular line with each other; it also serves, if put forwards, as well as also crossed, to put the horse forwards, if found necessary; which is often requisite, many horses being apt in this and other works rather to lose their ground backwards than otherwise, when they should rather advance; if the nose were drawn in towards the breast beyond the perpendicular, it would confine the motion of the shoulders, and have other bad effects. All other bends, besides what are above specified, are false. The outward rein, being crossed, not in a forward sense, but rather a little backwards, serves also to prevent the outward shoulder from getting too forwards, and makes it approach the inward one; which facilitates the inward leg's crossing over the outward one, which is the motion that so admirably supplies the shoulders. Care must be taken, that the inward leg pass over the outward one, without touching it: thus inwardly crossing over must be helped also by the inward rein, which you must count cross-ways, and over the outward rein every time the outward leg comes to the ground, in order to lift and help the inward leg over it: at any other time, but just when the outward leg comes to the ground, it would be wrong to cross the inward rein, or to attempt to lift up the inward leg by it; nay, it would be demanding an absolute impossibility, and lugging about the reins and horse to no purpose: because in this case, a very great part of the horse's weight resting then upon that leg, would render such an attempt not only fruitless, but also prejudicial to the sensibility of the mouth, and probably oblige him to defend himself; and, moreover, it would put the horse under a necessity of straddling before, and also of leading with the wrong leg, without being productive of any suppling motion whatsoever.

When the horse is thus far familiarly accustomed to what you have required of him, then proceed to effect by degrees the same crossing in his hinder legs. By bringing in the fore legs more, you will of course engage the hinder ones in the same work; if they resist, the rider must bring both reins more inward: and, if necessary, put back also, and approach his inward leg to the horse; and if the horse throws out his croup too far, the rider must bring both reins outwards, and, if absolutely necessary, he must also make use of his outward leg, in order to replace the horse properly: observing that the croup should always be considerably behind the shoulders, which in all actions must go first; and the moment that the horse obeys, the rider must put his hand and leg again in their usual position.

Nothing is more ungraceful in itself, more detrimental to a man's seat, or more destructive of the sensibility of a horse's sides, than a continual wriggling unsettledness in a horseman's legs, which prevents the horse from ever going a moment together true, steady, or determined.

A horse should never be turned, without first moving a step forwards: and when it is doing, the rider must not lift his elbow, and displace himself; a motion only of the hand from the one side to the other being sufficient for that purpose. It must also be a constant rule, never to suffer a horse to be stopped, mounted, or dismounted, but when he is well placed. The slower the motions are when a man or horse is taught anything, the better.

At first, the figures worked upon must be great, and afterwards made less by degrees, according to the improvement which the man and horse make; and the cadenced pace also, which they work in, must be accordingly augmented. The changes from one side to the other must be in a bold determined trot, and at first quite straight forwards, without demanding any side-motion on two pistes, which is very necessary to require afterwards when the horse is sufficiently supped. By two pistes is meant, when the fore parts and hinder parts do not follow, but describe two different lines.

In the beginning, a longe is used on circles, and also on straight lines, to help both the rider and the horse; but afterwards, when they are grown more intelligent, they should go alone. At the end of the lesson, rein back; then put the horse, by a little at a time, forwards, by approaching both legs gently to his sides, and playing with the bridle: if he resists, push him out immediately into a full trot. Shaking theersion on the horse's nose, and also putting one's self before him and rather near to him, will generally make him back, though he otherwise refuse to do it: and moreover a slight use and approaching of the rider's legs will sometimes be necessary in backing, in order to prevent the horse from doing it too much upon his shoulders; but the pressure of the legs ought to be very small, and taken quite away the moment that he puts himself enough upon his haunches. If the horse does not back upon a straight line properly, the rider must not be permitted to have recourse immediately to his leg, and so distort himself by it; but first try, if crossing over his hand and reins to which ever side may be necessary, it will not alone sufficient: which most frequently it will; if not, then employ the leg.

After a horse is well prepared and settled, and goes freely on in all his several paces, he ought to be in all his works kept, to a proper degree, upon his haunches, with his hinder legs well placed under him: whereby he will be always pleasant to himself and his rider, will be light in hand, and ready to execute whatever may be demanded of him, with facility, vigour, and quickness.

The common method that is used of forcing a horse sidewise,
HORSEMANSHIP.

Of the Head to the to the animal in its consequences; for, instead of suppling him, it obliges him to stiffen and defend himself, and often makes a creature that is naturally benevolent, resolute, frightened, and vicious.

For horses who have very high and long fore-hands, and who poke out their noses, a running snaffle is of excellent use; but for such as bore and keep their heads low, a common one is preferable; though any horse's head indeed may be kept up also with a running one, by the rider's keeping his hands very high and forwards: but whenever either is used alone without a bridle upon horses that carry their heads low and that bore, it must be sawed about from one side to the other.

This lesson of the epaule en dedans should be taught to such people as are likely to become useful in helping to teach men and to break horses; and the more of such that can be found the better; none others should ever be suffered upon any occasion to let their horses look any way besides the way they are going. But all horses whatever, as likewise all men who are designed for the teaching others, must go thoroughly and perfectly through this excellent lesson, under the directions of intelligent instructors, and often practice it too afterwards; and when that is done, proceed to and be finished by the lessons of head and tail to the wall.

SECT. IV. Of the Head to the Wall, and of the Croup to the Wall.

This lesson should be practised immediately after that of the epaule en dedans, in order to place the horse properly the way he goes, &c. The difference between the head to the wall, and the croup to the wall, consists in this: in the former, the fore-parts are more remote from the centre, and go over more ground; in the latter, the hinder parts are more remote from the centre, and consequently go over more ground; in both, as likewise in all other lessons, the shoulders must go first. In riding-horses, the head to the wall is the easier lesson of the two at first, the line to be worked upon being marked by the wall, not far from his head.

The motion of the legs to the right is the same as that of the epaule en dedans to the left, and so vice versa; but the head is always bent and turned differently: in the epaule en dedans, the horse looks the contrary way to that which he goes in this, he looks the way he is going.

In the beginning, very little bend must be required: too much at once would astonish the horse, and make him defend himself: it is to be augmented by degrees. If the horse absolutely refuses to obey, it is a sign that either he or his rider has not been sufficiently prepared by previous lessons. It may happen that weakness or a hurt in some part of the body, or sometimes temper, though seldom, may be the cause of the horse's defending himself: it is the rider's business to find out from whence the obstacle arises; and if he finds it to be from the first-mentioned cause, the previous lessons must be resumed again for some time; if from the second, proper remedies must be applied; and if from

the last cause, when all fair means that can be tried have failed, proper corrections with coolness and judgement must be used.

In practising this lesson to the right, bend the horse to the right with the right rein; helping the left leg over the right (at the time when the right leg is just come to the ground), with the left rein crossed towards the right, and keeping the right shoulder back with the right rein towards your body, in order to facilitate the left leg's crossing over the right; and so likewise vice versa to the left, each rein helping the other by their properly mixed effects. In working to the right, the rider's left leg helps the hinder parts on to the right, and his right leg stops them if they get too forwards; and so vice versa to the left: but neither ought to be used, till the hand being employed in a proper manner has failed, or finds that a greater force is necessary to bring about what is required than it can effect alone: for the legs should not only be corresponding with, but also subservient to, the hand; and all unnecessary aids, as well as all force, ought always to be avoided as much as possible.

In the execution of all lessons, the equilibre of the rider's body is of great use to the horse; it ought always to go with and accompany every motion of the animal; when to the right, to the right; and when to the left, to the left.

Upon all horses, in every lesson and action, it must be observed, that there is no horse but has his own peculiar appui or degree of bearing, and also a sensibility of mouth, as likewise a rate of his own, which it is absolutely necessary for the rider to discover and make himself acquainted with. A bad rider always takes off at least the delicacy of both, if not absolutely destroys it. The horse will inform his rider when he has got his proper bearing in the mouth, by playing pleasantly and steadily with his bit, and by the spray about his chaps. A delicate and good hand will not only always preserve a light appui, or bearing, in its sensibility; but also of a heavy one, whether naturally so or acquired, make a light one. The lighter this appui can be made, the better; provided that the rider's hand corresponds with it; if it does not, the more the horse is properly prepared, so much the worse. Instances of this inconvenience of the best of appuis, when the rider is not equally taught with the horse, may be seen every day in some gentlemen, who try to get their horses bitted as they call it, without being suitably prepared themselves for riding them: the consequence of which is, that they ride in danger of breaking their necks; till at length, after much hauling about, and by the joint insensibility and ignorance of themselves and their grooms, the poor animals gradually become mere senseless unfeeling posts; and thereby grow, what they call, settled. When the proper appui is found, and made of course as light as possible, it must not be kept duly fixed without variation, but be played with; otherwise one equally continued tension of reins would render both the rider's hand and the horse's mouth very dull. The slightest and frequent giving and taking is therefore necessary to keep both perfect.

Whatever pace or degree of quickness you work in,
To make
Horses

and
Sect. VI.

HORSEMANSIP.

be very small ones; the riders must keep their bodies back, raise their hands a little in order to help the fore-parts of the horse up, and be very attentive to the equilibrium. It is best to begin at a low bar covered with furze, which prickings the horse's legs, if he does not raise himself sufficiently, prevents his contracting a sluggish and dangerous habit of touching, as he goes over, which any thing yielding and not prickings would give him a custom of doing. Let the ditches you first bring horses to be narrow; and in this, as in every thing else, let the increase be made by degrees. Acquaint them to come up to every thing which they are to leap over, and to stand coolly at it for some time; and then to raise themselves gently up in order to form to themselves an idea of the distance. When they leap well standing, then use them to walk gently up to the leap, and to go over it without first halting at it; and after that practice is familiar to them, repeat the like in a gentle trot, and so by degrees faster and faster, till at length it is as familiar to them to leap flying on a full gallop as any other way: all which is to be acquired with great facility by calm and soft means, without any hurry.

As horses are naturally apt to be frightened at the sight and smell of dead horses, it is advisable to habituate them to walk over and leap over carcasses of dead horses: and as they are particularly terrified at this sight, the greater gentleness ought consequently to be used.

Horses should also be accustomed to swim, which often may be necessary upon service; and if the men and horses both are not used to it, both may be frequently liable to perish in the water. A very small portion of strength is sufficient to guide a horse anywhere indeed, but particularly in the water, where they must be permitted to have their heads, and be no ways constrained in any shape.

The unreasonable rage in Britain of cutting off all extremities from horses, is in all cases a very pernicious custom. It is particularly so in regard to a trooper's tail. It is almost incredible, how much they suffer at the pint for want of it: constantly fretting, and sweating, kicking about and hamming one another, tormented, and sting off their meat, miserable, and helpless; while other horses, with their tails on, brush off all flies, are cool and at their ease, and mend daily; whilst the docked ones grow every hour more and more out of condition.

Sect. VI. The Method of reining back,—and of moving forwards immediately after—of Pissing, of Pillors, &c.

NEVER finish your work by reining back with horses that have any disposition towards retaining themselves; but always move them forwards, and a little upon the haunches also, after it, before you dismount, (unless they retain themselves very much indeed, in which case nothing at all must be demanded from the haunches). This lesson of reining back, and pissing, is excellent to conclude with, and puts a horse well and properly upon the haunches: It may be done, according as horses are more or less supplied, either going forwards, backing, or in the same place: if it is done well advancing, or at most on the same spot, it is fully sufficient for a soldier's

be very small ones; the riders must keep their bodies back, raise their hands a little in order to help the fore-parts of the horse up, and be very attentive to the equilibrium. Sect. VI. The Method of reining back,—and of moving forwards immediately after—of Pissing, of Pillors, &c.

NEVER finish your work by reining back with horses that have any disposition towards retaining themselves; but always move them forwards, and a little upon the haunches also, after it, before you dismount, (unless they retain themselves very much indeed, in which case nothing at all must be demanded from the haunches). This lesson of reining back, and pissing, is excellent to conclude with, and puts a horse well and properly upon the haunches: It may be done, according as horses are more or less supplied, either going forwards, backing, or in the same place: if it is done well advancing, or at most on the same spot, it is fully sufficient for a soldier's
HORSEMANSHIP.

Of caring for a horse. For to piaffe in backing, is rather too much to be expected in the hurry which cannot but attend such numbers both of men and horses as must be taught together in regiments. This lesson must never be attempted at all, till horses are very well supplied, and somewhat accustomed to be put together; otherwise it will have very bad consequences, and create restiveness. If they refuse to back, and stand motionless, the rider’s legs must approach with the greatest gentleness to the horse’s sides; at the same time that the hand is acting on the reins to solicit the horse’s backing. This seldom fails of procuring the desired effect, by raising one of the horse’s fore-legs, which being in the air, has no weight upon it, and is consequently very easily brought backwards by a small degree of tension in the reins. When this lesson is well performed, it is very noble and useful, and has a pleasing air; it is an excellent one to begin teaching scholars with.

The lesson is particularly serviceable in the pillers, for placing scholars well at first. Very few regimental riding-houses have pillers, and it is fortunate they have not; for though, when properly made use of with skill, they are one of the greatest and best discoveries in horsemanship; they must be allowed to be very dangerous and pernicious, when they are not under the direction of a very knowing person.

WHENEVER a horse makes resistance, one ought, before remedy or correction is thought of, to examine very minutely all the tackle about him, if any thing hurts or tickles him, whether he has any natural or accidental weakness, or in short any the least impediment in any part. For want of this precaution, many fatal disasters happen: the poor dumb animal is frequently accused falsely of being restive and vicious; is used ill without reason; and, being forced into despair, is in a manner obliged to act accordingly, be his temper and inclination ever so well disposed. It is very seldom the case, that a horse is really and by nature vicious; but if such be found, he will despise all careesses, and then chastisements become necessary.

Correction, according as you use it, throws a horse into more or less violent action, which, if he be weak, he cannot support: but a vicious strong horse is to be considered in a very different light, being able both to undergo and consequently to profit by all lessons; and is far preferable to the best natured weak one upon earth. Patience and attention are never failing means to reclaim such a horse: in whatsoever manner he defends himself, bring him back frequently with gentleness (not however without having given him proper chastisement if necessary) to the lesson which he seems most averse to. Horses are by degrees made obedient, through the hope of recompense and the fear of punishment: how to mix these two motives judiciously together, is a very difficult matter; it requires much thought and practice; and not only a good head, but a good heart likewise. The coolest and best natured rider will always succeed best. By a dexterous use of the incitements above mentioned, you will gradually bring the horse to temper and obedience; more force, and want of skill and coolness, would only tend to confirm him in bad tricks. If he be impatient or choleric, never strike him, unless he absolutely refuse to go forward; which you must resolutely oblige him to do, and which will be of itself a correction, by preventing his having time to meditate and put in execution any defence by retaining himself. Resistance in horses, you must consider, is sometimes a mark of strength and vigour, and proceeds from spirit, as well as sometimes from vice and weakness. Weakness frequently drives horses into viciousness, when any thing wherein strength is necessary is demanded from them; nay, it inevitably must: great care therefore should always be taken to distinguish from which of these two causes any remedy or punishment is thought of. It may sometimes be a bad sign when horses do not at all defend themselves, and proceed from a sluggish disposition, a want of spirit, and of a proper sensibility. Whenever one is so fortunate as to meet with a horse of just the right spirit, activity, delicacy of feeling, with strength and good nature, he cannot be cherished too much; for such a one is a rare and inestimable jewel, and, if properly treated, will in a manner do every thing of himself. Horses are often spoilt by having too much done to them, and by attempts to dress them in too great an hurry, than by any other treatment.

If after a horse has been well supplied, and there are no impediments, either natural or accidental, if he still persist to defend himself, chastisements then become necessary: but whenever this is the case, they must not be frequent but always firm, though always as little violent as possible; for they are both dangerous and very prejudicial when frequently or slightly played with, and still more so when used too violently.

It is impossible, in general, to be too circumspect in lessons of all kinds, in aids, careesses, and caresses. Soon have quicker parts, and more cunning, than others. Many will imperceptibly gain a little every day on the rider. Various, in short, are their dispositions and capacities. It is the rider’s business to find out their different qualities, and to make them sensible how much he loves them, and desires to be loved by them; but at the same time that he does not fear them, and will be master.

Plunging is a very common defence among restive and vicious horses: if they do it in the same place, or backing, they must, by the rider’s legs and spurs firmly applied, be obliged to go forwards, and their heads kept up high. But if they do it flying forwards, keep them back, and ride them gently and very slow for a good while together. Of all bad tempers and qualities in horses, those which are occasioned by harsh treatment and ignorant riders are the worst.

Rearing is a bad vice, and, in weak horses especially, a very dangerous one. Whilst the horse is up, the rider must yield his hand; and when the horse is descending, he must vigorously determine him forwards: if this be done at any other time but whilst the horse is coming down, it may add a spring to his rearing, and make him fall backwards. With a good hand on them, horses seldom persist in this vice; for they are themselves naturally much afraid of falling backwards. If
Rules for Bad Horsemen.

HORSEMANSHP.

In the first place, every horse should be accustomed to stand still when he is mounted. One would imagine this might be readily granted; yet we see how much the contrary is practised. When a gentleman mounts at a livery-stable, the groom takes the horse by the bit, which he bends tight round his under jaw: the horse striving to go on, is forced back; advancing again, he frets, as he is again stopped short, and hurt by the manner of holding him. The rider, in the mean time, mounting without the bridle, or at least holding it but slightly, is helped to it by the groom, who being thoroughly employed by the horse’s fluttering, has at the same time both bridle and stirrup to give. This confusion would be prevented, if every horse was taught to stand still when he is mounted. Forbid your groom, therefore, when he rides your horse to water, to throw himself over him from a horse-block, and kick him with his leg, even before he is fairly upon him. This wrong manner of mounting is what chiefly teaches your horse the vicious habit against which we are here warning. On the other hand, a constant practice of mounting in the proper manner, is all that is necessary to prevent a horse’s going on till the rider is quite adjusted in the saddle.

The next thing necessary therefore is, that the rider should mount properly. The common method is to stand near the croup or hinder part of the horse, with the bridle held very long in the right hand. By this manner of holding the bridle before you mount, you are liable to be kicked; and when you are mounted, your horse may go on some time, or play what gambols he pleases, before the rein is short enough in your hand to prevent him. It is common likewise for an awkward rider, as soon as his foot is in the stirrup, to throw himself with all his force to gain his seat; which he cannot do, till he has first overbalanced himself on one side or the other: he will then wriggle into it by degrees. The way to mount with ease and safety is, to stand rather before than behind the stirrup. In this posture take the bridle short, and the mane together in your left hand, helping yourself to the stirrup with your right, so that your toe may not touch the horse in mounting. While your left foot is in the stirrup, move on your right, till you face the side of the horse, looking across over the saddle. Then with your right hand grasp the hinder part of the saddle; and with that and your left, which holds the mane and bridle, lift yourself upright on your left foot. Remain thus a mere instant on your stirrup, only so as to divide the action into two motions. While you are in this posture, you have a sure hold with both hands, and are at liberty, either to get safely down, or to throw your leg over and gain your seat. By this deliberate motion, likewise, you avoid, what every good horseman would endeavour to avoid, putting your horse into a flutter.

When you dismount, hold the bridle and mane together in your left hand, as when you mounted; put your right hand on the pommel of the saddle, to raise yourself; throw your leg back over the horse, grasp the hinder part of the saddle with your right hand, remain a moment on your stirrup, and in every respect dismount as you mounted; only what was your first motion when you mounted, becomes the last in dismounting. Remember not to bend your right knee in dismounting, lest your spur should rub against the horse.

It may be next recommended to hold your bridle at a convenient length. Sit square, and let not the purchase of the bridle pull forward your shoulder; but keep your body even, as it would be if each hand held a rein. Hold your reins with the whole grasp of your hand, dividing them with your little finger. Let your hand be perpendicular; your thumb will then be uppermost, and placed on the bridle. Bend your wrist a little outward: and when you pull the bridle, raise your hand toward your breast, and the lower part of the palm rather more than the upper. Let the bridle be at such a length in your hand, as, if the horse should stumble, you may be able to raise his head, and support it by the strength of your arms, and the weight of your body thrown backward. If you hold the rein too long, you are subject to fall backward as your horse rises.

If, knowing your horse perfectly well, you think a tight rein unnecessary, advance your arm a little (but not your shoulder) towards the horse’s head, and keep your usual length of rein. By this means, you have a check upon your horse, while you indulge him.

If you ride with a curb, make it a rule to hook on the chain yourself; the most quiet horse may bring his rider into danger, should the curb hurt him. If, in fixing the curb, you turn the chain to the right, the
the links will unfold themselves, and then oppose a
further turning. Put on the chain loose enough to
hang down on the horse's under lip, so that it may not
rise and press his jaw, till the reins of the bridle are
moderately pulled.

If your horse has been used to stand still when he is
mounted, there will be no occasion for a groom to hold
him; but if he does, suffer him not to touch the reins,
but that part of the bridle which comes down the
cheek of the horse. He cannot then interfere with
the management of the reins, which belongs to the
rider only; and holding a horse by the curb (which is
ever painful to him) is evidently improper when he is
to stand still.

Another thing to be remembered is, not to ride
with your arms and elbows as high as your shoulders;
but let them shake up and down with the motion of
the horse. The posture is unbecoming, and the weight
of the arms and of the body too if the rider does not
sit still) acts in continual jerks on the jaw of the
horse, which must give him pain, and make him unquiet, if
he has a tender mouth or any spirit.

Bad riders wonder why horses are gentle as soon as
they are mounted by skilful ones, though their skill
seems unemployed: the reason is, the horse goes at
his ease, yet finds all his motions watched; which
has sagacity enough to discover. Such a rider
hides his whip, if he finds his horse is afraid of it;
and keeps his legs from his sides, if he finds he dreads
the spur.

Avoid the ungraceful custom of letting your legs
shake against the sides of the horse: and as you are not
to keep your arms and elbows high, and in motion;
so you are not to rivet them to your sides, but let them
fall easy. One may, at a distance, distinguish a gen-
tenl horseman from an awkward one the first sits still,
and appears of a piece with his horse; the latter seems
flying off at all points.

It is often said with emphasis, that such a one has
no seat on horseback; and it means, not only that he
does not ride well, but that he does not sit on the right
part of the horse. To have a good seat, is to sit on
that part of the horse, which, as be springs, is the
centre of motion; and from which, of course, any
weight would be with most difficulty shaken. As in
the rising and falling of a board placed in
equilibrio, the centre will be always most at rest; the true seat
will be found in that part of your saddle, into which
your body would naturally slide, if you rode without
stirrups: and is only to be preserved by a proper poise
of the body, though the generality of riders imagine
it is to be done by the grasp of the thighs and knees.
The rider should consider himself as united to his horse
in this point; and when shaken from it, endeavour
to restore the balance.

Perhaps the mention of the two extremes of a bad
seat may help to describe the true one. The one is,
when the rider sits very far back on the saddle, so that
his weight presses the loins of the horse: the other,
when his body hangs forward over the pommel of
the saddle. The first may be seen practised by grooms,
when they ride with their stirrups affectedly short; the
latter, by fearful horsemen on the least flatter of the
horse. Every good rider, has, even on the hunting
saddle, as determined a place for his thighs, as can be
determined for him by the bars of a demi-peak. In-
deed there is no difference between the seat of either:
only, as in the first you ride with shorter stirrups,
your body will be consequently more behind your
knees.

To have a good seat yourself, your saddle must sit
well. To fix a precise rule might be difficult: it may
be a direction, to have your saddle press as nearly as
possible on that part which we have described as the
point of union between the man and horse; however,
not as to obstruct the motion of the horse's shoul-
ders. Place yourself in the middle or lowest part of
it: sit erect; but with as little constraint as in your
ordinary sitting. The ease of action marks the gentle-
man: you may repose yourself, but not lounge. The
set and studied erectness acquired in the riding-house,
by whose deportment is not easy, appears ungen-
tele and unnatural.

If your horse stops short, or endeavours by rising
and kicking to unseat you, bend not your body for-
ward, as many do in these circumstances: that motion
throws the breech backward, and you off your fork or
twist, and out of your seat; whereas, the advancing
the lower part of your body, and bending back the
upper part and shoulders, is the method both to keep
your seat, and to recover it when lost. The bending
your body back, and that in a great degree, is the
greatest security in flying leaps; it is a security too,
when your horse leaps standing. The horse's rising
does not try the rider's seat; the lash of his hind legs
is what ought chiefly to be guarded against, and is best
done by the body's being greatly inclined back. Stif-
fen not your legs or thighs; and let your body be pli-
able in the loins, like the coachman's on his box. This
loose manner of sitting will elude every rough motion
of the horse; whereas the fixture of the knees, so com-
monly laid a stress on, will in great shocks conduct to
the violence of the fall.

Was the cricket-player, when the ball is struck with
the greatest velocity, to hold his hand firm and fixed
when he receives it, the hand would be bruised, or per-
haps the bones fractured by the resistance. To ob-
viate this accident, he therefore gradually yields his
hand to the motion of the ball for a certain distance;
and thus by a due mixture of opposition and obedience,
catches it without sustaining the least injury. The case
is exactly the same in riding: the skilful horseman will
recover his poise by giving some way to the motion;
and the ignorant horseman will be flung out of his seat
by endeavouring to be fixed.

Stretch not out your legs before you; this will push
you against the back of the saddle; neither gather up
your knees like a man riding on a pack: this throws
your thighs upwards: each practice unseats you. Keep
your legs straight down; and sit not on the most fleshy
part of the thighs, but turn them inwards, so as to bring
in your knees and toes: and it is more safe to ride with
the ball of the foot pressing on the stirrup, than with
the stirrup as far back as the heel: for the pressure of
the heel being in that case behind the stirrup, keeps
the thighs down.

When you find your thighs thrown upwards, widen
your knees to get them and the upper part of your
fork lower down on the horse. Grasp the saddle with
the hollow or inner part of your thighs, but not more
than
HORSEMANSHIP

Sect. VIII.

than just to assist the balance of your body: this will also enable you to keep your spurs from the horse's sides, and to bring your toes in, without that affected and useless manner of bringing them in practised by many. Sink your heels straight down; for while your heels and thighs keep down, you cannot fall: this (sided with the bend of the back) gives the security of a seat, to those who bear themselves up in their stirrups in a swift gallop, or in the alternate rising and falling in a full trot.

Let your seat determine the length of your stirrups, rather than the stirrups your seat. If more precision is requisite, let your stirrups (in the hunting saddle) be of such a length, as that, when you stand in them, there may be the breadth of four fingers between your seat and the saddle.

It would greatly assist a learner, if he would practise riding in a large circle, as directed sect. i., without stirrups; keeping his face looking on the outward part of the circle so as not to have a full view of the horse's head, but just of that ear which is on the outward part of the circle; and his shoulder, which is towards the centre of the circle, very forward. By this means you learn to balance your body, and keep a true seat, independent of your stirrups: you may probably likewise escape a fall, should you at any time lose them by being accidentally shaken from your seat.

As the seat in some measure depends on the saddle, it may not be amiss to observe, that because a saddle with a high pommel is thought dangerous, the other extreme prevails, and the pommel is scarce allowed to be higher than the middle of the saddle. The saddle should lie as near the back-bone as can be, without hurting the horse; for the nearer you sit to his back, the better seat you have. If it does so, it is plain the pommel must rise enough to secure the withers from pressure: therefore, a horse whose withers are higher than common, requires a higher pommel. If, to avoid this, you make the saddle of a more straight line, the inconvenience spoken of follows; you sit too much above the horse's back, nor can the saddle form a proper seat. There should be no ridge from the button at the side of the pommel, to the back part of the saddle. That line also should be a little concave, for your thighs to lie at ease. In short, a saddle ought to be, as nearly as possible, as if cut out of the horse.

When you want your horse to move forward, raise his head a little, and touch him gently with your whip; or else, press the calves of your legs against his sides. If he does not move fast enough, press them with more force, and so till the spur just touches him. By this practice he will (if he has any spirit) move upon the least pressure of the leg. Never spur him by a kick; but if it be necessary to spur him briskly, keep your heels close to his sides, and slacken their force as he becomes obedient.

When your horse attempts to be vicious, take each rein separate, one in each hand, and advancing your arms forward, hold him very short. In this case, it is common for the rider to pull him hard, with his arms low. But the horse by this means having his head low too, has it more in his power to throw out his heels: whereas, if his head be raised very high, and his nose thrown out a little, which is consequent, he can neither rise before nor behind; because he can give himself neither of those motions, without having his head at liberty. A plank placed in aquilibrrio, cannot rise at one end unless it sinks at the other.

If your horse is headstrong, pull not with one continued pull, but stop, and back him often, just shaking the reins, and making little repeated pulls till he obeys. Horses are so accustomed to bear on the bit when they go forward, that they are discouraged if the rider will not let them do so.

If a horse is loose-necked, he will throw up his head at a continued pull; in which situation, the rider, seeing the front of his face, can have no power over him. When your horse does thus, drop your hand and give the bridle play, and he will of course drop his head again into its proper place: while it is coming down, make a second gentle pull, and you will find his mouth. With a little practice, this is done almost instantaneously; and this method will stop, in the distance of a few yards, a horse, which will run away with those who pull at him with all their might.

Almost every one must have observed, that when a horse feels himself pulled with the bridle, even when he is going gently, he often mistakes what was designed to stop him, as a direction to bear on the bit and go faster.

Keep your horse's head high, that you may raise his neck and crest; play a little with the rein, and move the bit in his mouth, that he may not press on it in one constant and continued manner: be not afraid of raising his head too high; he will naturally be too ready to bring it down, and tire your arms with its weight, on the least abatement of his mettle. When you feel him heavy, stop him, and make him go back a few paces: thus you break by degrees his propensity to press on his bridle.

You ought not to be pleased (though many are) with a round neck, and a head drawn in towards his breast: let your horse carry his head bridding in, provided he carries it high, and his neck arching upwards; but if his neck bends downwards, his figure is bad, his sight is too near his toes, he leans on the bridle, and you have no command over him. If he goes pressing but lightly on the bridle, he is the more sure-footed, and goes pleasanter; as your wrist only may guide him. If he hangs down his head, and makes your support the weight of that and his neck with your arms bearing on his fore-legs, (which is called being on his shoulders), he will strike his toes against the ground, and stumble.

If your horse is heavy upon the bit, tie him every day, for an hour or two, with his tail to the manger, and his head as high as you can make him lift it, by a rein on each post of the stall, tied to each ring of the snaffle bit.

Horse-breakers and grooms have a great propensity to bring a horse's head down, and seem to have no seat without a strong hold by the bridle. They know indeed, that the head should yield to the reins, and the neck form an arch; but do not take the proper pains to make it an arch upward. A temporary effect of attempting to raise a horse's head, may perhaps be making him push out his nose. They will bare tell you, that his head is too high already; whereas it is not the distance from his nose, but from the top of his head.
head to the ground, which determines the head to be high or low. Besides, although the fault is said to be in the manner of carrying the head, it should rather be said to be in that of the neck; for if the neck was raised, the head would be more in the position of one set on a well formed neck.

The design therefore of lifting up the head, is to raise the neck, and thereby bring in the head; for even while the bridle makes the same line from the rider's hand to the bit, the horse's nose may be either drawn in, or thrust out, according as his neck is raised or depressed. Instead of what has been here recommended, we usually see colts broke with their heads cavedon very low, their necks stiff, and not in the least supplied. When the breaking-tackle is left off, and they are mounted for the road, having more food and rest, they frequently plunge, and a second breaking becomes necessary. Then, as few gentlemen can manage their own horses, they are put into the hands of grooms, from whom they learn a variety of bad habits.

If, on the other hand, your horse carries his head (or rather his nose) too high, he generally makes some amends by moving his shoulders lightly, and going safely. Attend to the cause of this fault. Some horses have their necks set so low on their shoulders, that they bend first down, then upwards, like a stag's. Some have the upper line of their necks, from their ears to their withers, too short. A head of this sort cannot possibly bend inwards and form an arch, because the vertebrae (or neck bones) are too short to admit of flexure; for in long and short-necked horses the number of the vertebrae is the same. In some, the jaw is so thick, that it meets the neck, and the head by this means has not room to bend. On the other hand, some have the under line from the jaw to the breast so short, that the neck cannot rise.

In all these cases you may gain a little by a nice hand with an easy bit; but no curb, martingale, or other forcible method, will teach a horse to carry his head or neck in a posture which nature has made uneasy to him. By trying to pull in his nose farther than he can bear, you will add a bad habit to nature. You could not indeed contrive a more effectual method to make him continuously toss his nose up, and throw his foam over you.

The rule already given to ride a loose-necked horse, will be a proper one for all light-moutheed horses; one caution being added, which is, always to search whether his saddle or girths may not in some way pinch him; and whether the bit may not hurt his lip by being too high in his mouth: because, whenever he frets from either of these causes, his head will not be steady.

It is a common custom to be always pulling at the bridle, as if to set off to advantage either the spirit of the horse, or the skill of the rider. Our horses therefore are taught to hold their heads low, and pull so as to bear up the rider from the saddle standing in his stirrups, even in the gentlest gallop; how very improper this is, we are experimentally convinced, when we happen to meet with a horse which gallops otherwise. We immediately say, he canters excellently, and find the ease and pleasure of his motion. When horses are designed for the race, and swiftness is the only thing considered, the method may be a good one.

It is not to be wondered that dealers are always pulling at their horses, that they have the spur constantly in their sides, and are at the same time continually checking the rein: by this means they make them bound, and champ the bit, while their rage has the appearance of spirit. These people ride with their arms spread, and very low on the shoulders of their horses: this method makes them stretch their necks, and gives a better appearance to their fore-hands; it conceals also a thick jaw, which, if the head was up, would prevent its yielding to the bit; it hides likewise the ewe-neck, which would otherwise show itself. Indeed, if you have a horse unsteady to the bit, formed with a natural heavy head, or one which carries his nose obstinately in the air, you must find his mouth where you can, and make the best of him.

Many horses are taught to start, by whipping them for starting. How is it possible they can know it is designed as a punishment? In the riding-house, you teach your horse to rise up before, and to spring and lass out his hinder legs, by whipping him when tied between two pillars, with his head a little at liberty. If he understood this to be a punishment for doing so, he would not by that method learn to do it. He seems to be in the same manner taught to spring and fly when he is frightened. Most horses would go quietly past an object they were beginning to fly from, if their riders, instead of gathering up their bridles, and showing themselves so ready, should throw the reins loose upon their necks.

When a horse starts at any thing on one side, most riders turn him out of the road, to make him go up to what he starts at: if he does not get the better of his fear, or readily comply, he generally goes past the object, making with his hinder parts, or croup, a great circle out of the road; whereas, he should learn to keep straight on, without minding objects on either side.

If he starts at any thing on the left, hold his head high, and keep it straight in the road, pulling it from looking at the thing he starts at, and keeping your right leg hard pressed against his side, towards his flank: he will then go straight along the road. By this method, and by turning his head a little more, he may be forced with his croup close up to what frightened him; for as his head is pulled one way, his croup necessarily turns the other. Always avoid a quarrel with your horse, if you can: if he is apt to start, you will find occasions enough to exercise his obedience, when what he starts at lies directly in his way, and you must make him pass; if he is not subject to start, you should not quarrel with him about a trifle.

It must be observed, however, that this rule in going past an object may perhaps be a little irregular in a managed horse, which will always obey the leg: but even such a horse, if he is really afraid, and not revolting, it may not be amiss to make look another way; unless the object be something you would particularly accustom him to the sight of.

The case will also be different with a horse whose fear is owing to his being not used to objects; but
such a one is not to be rode by any horseman to whom these rules are directed: the starting here meant arises merely from the horse's being pampered, and springing through liveliness.

The notion of the necessity of making a horse go immediately up to everything he is afraid of, and not suffering him to become master of his rider, seems to be in general carried too far. It is an approved and good method to conquer a horse's fear of the sound of a drum, by beating one near to him at the time of feeding him: this not only familiarizes the noise to him, but makes it pleasant, as a fore-runner of his meat; whereas, if he was whipped up to it, he might perhaps start at it as long as he lived. Might not this be applied to his starting at other things, and show that it would be better to suffer him (provided he does not turn back) to go a little from and avoid an object he has a dislike to, and to accustom him to it by degrees, convincing him, as it were, that it will not hurt him; than to punish him, quarrel with him, and perhaps submit to his will at last, while you insist on his overcoming his fear in an instant? If he sees a like object again, it is probable he will recollect his dread, and arm himself to be disobedient.

We are apt to suppose that a horse fears nothing so much as his rider; but may he not, in many circumstances, be afraid of instant destruction? of being crushed? of being drowned? of falling down a precipice? Is it a wonder that a horse should be afraid of a loaded waggon? may not the hanging load seem to threaten the falling on him? There cannot be a rule more general, than to make him used to such a case, to show him there is room for him to pass. This is done by turning his head a very little from the carriage, and pressing your leg, which is farthest from it, against his side.

A horse is not to stop without a sign from his rider. —Is it not then probable, that when driven up to a carriage he starts at it, he conceives himself obliged either to attack or run against it? Can he understand the rider's spurring him with his face directed to it, as a sign for him to pass it? That a horse is easily alarmed for his face and eyes (he will even catch back his head from a hand going to caress him); that he will not go with any force, face to face, even to another horse (if in his power to stop); and that he sees perfectly sideways,—may be useful hints for the treatment of horses with regard to starting.

Though you ought not to whip a horse for starting, there can be no good effect from clapping his neck with your hand to encourage him. If one took any notice of his starting, it should be rather with some tone of voice which he usually understood as an expression of dislike to what he is doing; for there is opposition mixed with his starting, and a horse will ever repeat what he finds has failed his rider.

Notwithstanding the directions above given, of not pressing a horse up to a carriage he starts at; yet if one which you apprehend will frighten him meets you at a narrow part of the road, when you have once let him know he is to pass it, be sure you remain determined, and press him on. Do this more especially when part of the carriage has already passed you: for if, when he is frightened, he is accustomed to go back, and turn round, he will certainly do it if he finds, by your hand slackening, and legs not pressing, that you are irresolute; and this at the most dangerous point of time, when the wheels of the carriage take him as he turns. Remember not to touch the curb rein at these times; it will certainly check him. It is not known to every one, that the person who would lead a horse by the bridle, should not turn his face to him when he refuses to follow him: if, besides this, he raises his arms, shows his whip, or pulls the bridle with jerks, he frightens the horse, instead of persuading him to follow; which a little patience may bring about.

Ride with a snaffle; and use your curb, if you have one, only occasionally. Choose your snaffle full and thick in the mouth, especially at the ends to which the reins are fastened. Most of them are made too small and long; they cut the horse's mouth, and bend back over the bars of his jaw, working like pincers.

The management of the curb is too nice a matter to enter on here, farther than to prescribe great caution in the use of it: a turn of the wrist, rather than the weight of your arm, should be applied to it. The elasticity of a rod, when it hath hooked a fish, may give you some idea of the proper play of a horse's head on his bridle; his spirit and his pliability are both marked by it.

A horse should never be put to do anything in a curb which he is not ready at: you may force him, or pull his head any way with a snaffle; but a curb acts only in a straight line. It is true, that a horse will be turned out of one track into another by a curb, but it is because he knows it as a signal. When he is put to draw a chair and does not understand the necessity he is then under of taking a larger sweep when he turns, you frequently see him resist, as it is then called: but put him on a snaffle, or buckle the rein to that part of the bit which does not curb him; and the horse submits to be pulled about, till he understands what is desired of him. These directions suppose your horse to have spirit, and a good mouth; if he has not, you must take him as he is, and ride him with such a bit as you find most easy to yourself.

When you ride a journey, be not so attentive to your horse's nice carriage of himself, as to your encouragement of him, and keep him in good humour. Raise his head; but if he flags, you may indulge him with bearing a little more upon the bit than you would suffer in an airing. If a horse is lame, tender-footed, or tired, he naturally hangs upon his bridle. On a journey, therefore, his mouth will depend greatly on his strength and the goodness of his feet. Be then very careful about his feet, and let not a farrier spoil them. You will be enabled to keep them from danger, by the directions given under the article Farriery.

Very few, although practised in riding, know they have any power over a horse but by the bridle; or any use for the spur, except to make him go forward. A little experience will teach them a farther use. If the left spur touches him (and he is at the same time prevented from going forward), he has a sign, which he will soon understand, to move sidewise to the right. In the same manner to the left, if the right spur is closed to him: he afterwards, through fear of the spur,
HORSEMANSHIP.

Horsemen.

Sect. VIII.

SPUR, obeys a touch of the leg; in the same manner as a horse moves his croup from one side of the stall to the other, when any one strikes him with his hand. In short, his croup is guided by the leg, as his head is by the bridle. He will never disobey the leg, unless he becomes restive. By this means you will have a far greater power over him; he will move sidewise, if you close one leg to him; and straight forward, if both: even when he stands still, your legs held near him will keep him on the watch; and with the slightest unseen motion of the bridle upwards, he will raise his head, and show his forehand to advantage.

On this use of the legs of the rider, and guidance of the croup of the horse, are founded all the airs (as the riding-masters express themselves) which are taught in the manege; the passage, or side-motion of troopers to close or open their files, and indeed all their evolutions. But the convenience of some degree of this discipline for common use is the reason of mentioning it here. It is useful if a horse is apt to stumble or start. If to the first, by pressing your legs to his flank, and keeping up his head, he is made to go light on his fore-legs, which is aiding and supporting him; and the same if he does actually stumble, by helping him at the very instant to exert himself, while as yet any part of him remains not irrecoverably impressed with the precipitate motion. Hence this use of the hand and legs of the rider is called giving aids to a horse; for, as to holding up the weight of a heavy unactive horse, by mere pulling, it is as impossible as to recover him when falling down a precipice.

A horse is supported and helped by the hands and legs of his rider in every action they require of him; hence he is said to perform his airs by the aids from his rider.

The same manner is useful if a horse starts. For if when he is beginning to fly to one side, you leg on the side he is flying to, he stops his spring immediately. He goes past what he started at, keeping straight on, or as you choose to direct him; and he will not fly back from any thing if you press him with both legs. You keep his baunches under him, going down a hill; help him on the side of a bank; more easily avoid the wheel of a carriage; and approach more gracefully and nearer to the side of a coach or horseman. When a pampered horse curvets irregularly, and twists his body to and fro, turn his head either to the right or left, or both alternately (but without letting him move out of the track), and press your leg to the opposite side: your horse cannot then spring on his hind-legs to one side, because your leg prevents him; nor to the other, because his head looks that way, and a horse does not start and spring to the side on which he looks. Here it may not be amiss to observe the impropriety of the habit which many riders have, of letting their legs shake against the sides of the horse: if a horse is taught, they are then continually pressing him to violent action; and if he is not, they render him insensible and incapable of being taught. The fretting of a hot horse will hence be excessive, as it can no otherwise be moderated than by the utmost stillness of the seat, hands, and legs of the rider.

Colts at first are taught to bear a bit, and by degrees to pull at it. If they did not press it, they could not be guided by it. By degrees they find their necks stronger than the arms of a man; and that they are capable of making great opposition, and often of foiling their riders. Then is the time to make them support and plant in every part. The part which of all others requires most this pliancy is the neck. Hence the metaphor of stiff-necked for disobedient. A horse cannot move his head but with the muscles of his neck; this may be called his helm; it guides his course, changes and directs his motion.

The use of this pliancy in the different parts and limbs of a horse has been already shown in a former section. The present section being directed to the inexperienced horseman, it may suffice to add that his idea of suppleness need only be, that of an ability and readiness in a horse to move every limb, on a sign given him by the hands or legs of his rider; as also to bend his body, and move in a short compass, quick and collected within himself, so as instantly to be able to perform any other motion.

HORSHAM, a town of Sussex, seated near St Leonard's forest, 38 miles from London. It has its name from Horsa, brother to Hengist the Saxon; and is one of the largest towns in the county. It has sent members to parliament ever since the 80th of Edw. I. and is the place where the county-gaol is held, and often the assizes. It is a borough by prescription, with the title of two bailiffs and burgageholders within and without the borough, &c. who elect the members of parliament, and they are returned by the bailiffs chosen yearly by a court-leet of the lord of the manor, who return four candidates to the steward, and he nominates two of them for the office. Here is a very fine church, and a well endowed free-school. Great store of poultry is bought up for London at its market on Saturday, and it has a patent also for a monthly market. In 1811, the number of inhabitants was 3899.

HORTALIGERS, in the grand signior's court, upholsterers, or tapestry-hangers, who go always a day's journey before the grand signior, to fix upon a proper place for his tent, which they prepare first; and afterwards those of the officers, according to their rank.

HORTENSIR, QUINTUS, a celebrated Roman orator, the contemporary of Cicero, pleaded with universal applause at 19 years of age, and continued the same profession during 48 years. But being at last eclipsed by Cicero, he quitted the bar, and embraced a military life: became a military tribune, praetor, and afterwards consul about 80 B.C. Cicero speaks of him in such a manner as makes us regret the loss.
HOR. [ 626 ] HOR.

Hortensius, of his orations. Hortensius had a wonderful memory, and delivered his orations without writing down a single word, or forgetting one particular that had been advanced by his adversaries. He died very rich, a little before the civil war, which he had endeavoured by all possible means to prevent.

HORTICULTURE, the art of cultivating fruits, flowers, and various esculent plants, being the same as gardening. See Supplement.

HORTUS SICcus, a Dry Garden; an appellation given to a collection of specimens of plants, carefully dried and preserved.

The value of such a collection is evident, since a thousand minutes may be preserved in well-dried specimens of plants, which the most accurate engraver would overlook. We shall therefore give two methods of drying and preserving a hortus siccus; the first by Sir Robert Southwell in the Philosophical Transactions, No. 237; and the other by Dr Hill, in his review of the works of the Royal Society, with his objections to Sir Robert's method.

According to the former gentleman, the plants are to be laid flat between papers, and then put between two smooth plates of iron, screwed together at the corners; and in this condition committed to a baker's oven for two hours. When taken out, they are to be rubbed over with a mixture of equal parts of aquafortis and brandy; and after this to be fastened down on paper with a solution of the quantity of a walnut of gum tragacanth dissolved in a pint of water. See Herbal.

To this the Doctor objects, that the heat of an oven is much too uncertain to be employed in so nice an operation; and that the space of time ordered for containing the plants in it is of no information, unless the degree of heat, and even the different nature of the plant as to its succulence and the firmness or tenderness of its fibres, be attended to; there being scarcely any two plants alike in these particulars: consequently the degree and duration of heat sufficient for one plant would destroy another. Besides which, the acid used destroys the colour of many plants; and never recovers that of others lost in the drying; and frequently after the plant is fixed down, rots both the paper it is fixed to, and that which falls over it. Dr Hill's method is as follows: Take a specimen of a plant in flower, and with it one of its bottom leaves if it have any; bruise the stalk if too rigid, or slit it if too thick: spread out the leaves and flowers on paper, cover it with more paper, and lay a weight over all. At the end of 18 hours take out the plants, now perfectly flatteneD, and lay them on a bed of dry common sand; sift more dry sand over them to the depth of two inches, and thus let them lie about three weeks: the less succulent dry much sooner, but they take no harm afterward. If the floor of a garret be covered in spring with sand two inches deep, leaving space for walking to the several parts, it will receive the collection of a whole summer; the covering of sand being sifted over every parcel as laid in, they need no farther care from the time of laying them till they are taken up to be stuck on paper. The cement used by the Doctor is thus prepared: early in the spring, put two ounces of camphor into three quarts of water in a large bottle; shake it from time to time, and when the first collected plants are ready for the fastening down, put into a pint of the water, poured off into an earthen vessel that will bear the fire, two ounces of common glue, such as is used by the carpenters, and the same quantity of ichthyocolla beat to shreds; let them stand 36 hours, then gently boil the whole a few moments, and strain it off through a coarse cloth: this is to be warmed over a gentle heat when it is to be used, and the back of the plants smeared over with a painter's brush; after this lay them on paper, and gently press them for a few minutes, then expose them to the air a little; and finally lay them under a small weight between quires of paper to be equally dried.

It is scarce to be conceived how strongly the water becomes impregnated with the camphor by this simple process: a part of it indeed flies off in the making of the cement and the using of it; but enough remains with the plants to prevent the breeding of insects in it. He farther observes, that plants may be dried very well without sand, by only putting them frequently into fresh quires of paper, or a few, by only pressing them between the leaves of a book: but the sand method preserves the colour best, and is done with least trouble.

Another method much better than that of the oven is the flattening and drying the plant by passing a common smoothing iron for linen over the papers between which it is laid; but for nice things the most perfect of all methods is that by a common sand heat, such as is used for chemical purposes. The cold sand is to be spread smooth upon this occasion, the plant laid on it carefully flattened, and a thick bed of sand sifted over: the fire is then to be made, and the whole process carefully watched until by a very gentle heat the plant be carefully dried. The colour of the tenderest herb may by this manner be preserved; and flowers, that can no way else be preserved, may be managed perfectly well thus.

HORUS, a renowned deity of ancient Egypt. He was an emblem of the sun. Plutarch (in his treatise de Isis et Osiride) says, "that virtue which presides over the sun, whilst he is moving through space, the Egyptians called Horus and the Greeks Apollo." Job also calls Ur or Orus the sun—" If I gazed upon the sun (Ur, Orus) when he was shining, or on (Jôrêchâ) the moon walking in brightness, and my heart hath been secretly enticed (i. e. to worship), or my mouth hath kissed my hand; this also were an iniquity to be punished by the judge, for I should have denied the God who is above." Chap. xxxi. ver. 26, 27, 28.

The interpretation left by Hermæpin of the hieroglyphics engraved on the obelisk of Heliopolis (according to Ammianus Marcellinus), offers these remarkable words: "Horus is the supreme lord and author of time." These qualities, it is known, were chiefly attributed to Osiris: that they may apply, therefore, to Horus, he must necessarily denote the star of the day in certain circumstances; and this is what is explained to us by the oracle of Apollo of Claros:

Learn that the first of the gods is Jao.
He is called invisible in winter, Jupiter in the spring.
The sun in summer, and towards the end of autumn the tender Jao.

The star of the day, on attaining the summer solstice, and called per excellens the Sun, is the same as Horus.
HORUS [ 627 ]

HORS., In fact, the Egyptians represented him borne on lions, which signified his entrance into the sign of the lion. They who presided over the divine institutions, then placed sphynxes at the head of the canals and sacred fountains, to warn the people of the approaching inundation. Macrobius *, who informs us why the Greeks gave Horus the name of Apollo, confirms this sentiment: "In the mysteries (says he) they discover as a secret, which ought to be inviolable, that the sun arrived in the upper hemisphere, is called Apollo." These testimonies concur in proving, that this emblematical deity was no other than the star of day, passing through the signs of summer.

These lights may lead us to the explication of the sacred fable, which the priests published on the subject of Horus; for they enveloped in mystery every point of their religion. Plutarch gives it at length in his treatise of Isis and Osiris: The following are the principal traits. They said that he was the son of Osiris and of Isis; that Typhon, after killing his brother Osiris, took possession of the kingdom; that Horus, leaguing himself with Isis, avenged the death of his father, expelled the tyrant from his throne without depriving him of life, and reigned gloriously in Egypt. A person who has travelled so little in Egypt easily discovers natural phenomena hid under the veil of fable. In the spring, the wind khamain frequently makes great ravages there. It raises whirlwinds of burning sand, which suffocate travellers, darken the air, and cover the face of the sun in such a manner as to leave the earth in perfect obscurity. Here is the death of Osiris and the reign of Typhon. These hurricanes break out usually in the months of February, March, and April. When the sun approaches the sign of the lion, he changes the state of the atmosphere, disperses these tempests, and restores the northerly winds, which drive before them the malignant vapours, and preserve in Egypt coolness and salubrity under a burning sky. This is the triumph of Horus over Typhon, and his glorious reign. As the natural philosophers acknowledge the influence of the moon over the state of the atmosphere, they united her with this god, to drive the usurper from the throne. The priests considering Osiris as the father of time, might bestow the name of his son on Horus, who reigned three months in the year. This, according to Mr Savary †, is the natural explication of this allegory. And all enlightened men, he thinks, must have understood this language, which was familiar to them. The people only, whose feeble sight extends no farther than the exterior, without diving into the true meaning of things, might regard these allegorical personages as real gods, and decree prayers and offerings to them.

Jablonski, who has interpreted the epithet of Auru, which the Egyptians gave to Horus, pretends that it signifies efficacius virtus. These expressions perfectly characterise the phenomena which happened during the reign of this god. It is in summer, in fact, that the sun manifests all its power in Egypt. It is then that he washes the waters of the rivers with rains exhaled by him in the air, and driven against the summits of the Abyssinian mountains; it is then that the husbandman reckons on the treasures of agriculture. It was natural for them to honour him with the name of Auru, or efficacious virtue, to mark these auspicious effects.

HOSANNA, in the Hebrew ceremonies, a prayer which they rehearsed on the several days of the feast of tabernacles. It was thus called, because there was frequent repetition therein of the word Hosanna, save us, &c. Some are rehearsed on the first day, others on the second, &c. which they called hosanna of the first day, hosanna of the second day, &c.

Hosanna Rabba, or Grand Hosanna, is a name they give to their feast of tabernacles, which lasts eight days; because during the course thereof, they are frequently calling for the assistance of God, the forgiveness of their sins, and his blessing on the new year; and to that purpose they make great use of the hosanna, or prayers above mentioned. The Jews also applied the term hosanna rabba, in a more peculiar manner, to the seventh day of the feast of tabernacles; because they apply themselves more immediately on that day to invoke the divine blessing, &c.

HOSE, from the Saxon Hose, a stocking. See Stocking.

HOSEA, the first in number of the minor Hebrew prophets, as arranged in the Hebrew and Greek bibles, although probably the third in a chronological sense. He was the son of Beeri, but it is uncertain to what tribe he belonged. He prophesied in the reigns of Uzziah, Jotham, Ahaz, and Hezekiah, kings of Judah, and in the time of Jeroboam, who was king of Israel. If he uttered predictions during 66 years, between 750 and 724 before Christ, then he discharged the office of a sacred seer eighty years during the reign of Jeroboam II. 23 in the reign of Uzziah, the entire reign of Jotham and Ahaz, and three years in the reign of Hezekiah; but could not have survived the taking of Samaria. He reproved the vices of kings as well as their subjects, mixing threatenings of divine vengeance with promises of pardon in consequence of repentance. His style is concise, sententious, and abrupt. His short and lively comparisons are numerous. He is sometimes distinguished by great force of expression, has many beautiful passages, and in some parts is truly sublime. Dr Newcome was of opinion that the chief difficulty in understanding this prophet is owing to the corrupt readings which disfigure the printed text, and these he freely corrected from the collations of Dr Kennicott. On the other hand, Dr Horsley protests earnestly against Dr Newcome's opinion, declaring that the corruptions can be no cause of obscurity; but we must leave it to our readers to determine which of these two great men is in the right, from an attentive perusal of their own works, assured that they will decide in favour of him who furnishes the best helps for understanding this prophet.

HOSPINIAN, BODOLPHUS, one of the greatest writers that Switzerland has given birth to. He was born in 1547, at Altorf near Zurich; obtained the freedom of Zurich; and was made provost of the abbey-school. Notwithstanding this employment, he undertook a noble work of vast extent, which was a History of the Errors of Popery. Though he could not
not complete this work according to his plan, he published some considerable parts of it: what he published on the Eucharist, and another work called Concordia Disceors, exceedingly exasperated the Lutherans. He did not reply to them; but turning his arms against the Jesuits, published Historia Jemutina, &c. These writings gained him preferment; he being appointed archdeacon of Caroline church, and then minister of the abbey-church. He died in 1626; and there was an edition of his works published at Geneva 1681, in seven volumes in folio.

HOSPITAL, popularly Spital, a place or building erected, out of charity, for the reception and support of the poor, aged, infirm, sick, and otherwise helpless. The word is formed of the Latin hospes, "host, stranger." See Host.

In the early ages of the church, the bishop had the immediate charge of all the poor, both sound and diseased, as also of widows, orphans, strangers, &c. — When the churches came to have fixed revenues allotted them, it was decreed, that at least one-fourth part thereof should go to the relief of the poor; and to provide for them the more commodiously, divers houses of charity were built, which are since denominated hospitals. They were governed wholly by the priests and deacons, under the inspection of the bishop. In course of time, separate revenues were assigned for the hospitals; and particular persons, out of motives of piety and charity, gave lands and money for erecting of hospitals. When the church discipline began to relax, the priests, who till then had been the administrators of hospitals, converted them into a sort of benefices, which they held at pleasure, without giving account thereof to any body; reserving the greatest part of the income to their own use; so that the intentions of the founders were frustrated. — To remove this abuse, the council of Vienne expressly prohibited the giving any hospital to secular priests in the way of a benefice; and directed the administration thereof to be given to sufficient and responsible laymen, who should take an oath, like that of tutors, for the faithful discharge thereof, and be accountable to the ordinaries. — This decree was executed and confirmed by the council of Trent.

In Britain, hospitals are buildings properly endowed, or otherwise supported by charitable contributions, for the reception and support of the poor, aged, infirm, sick, or helpless.

A charitable foundation laid thus for the sustenance and relief of the poor is to continue for ever. Any person seized of an estate in fee, may, by deed involved in chancery, erect and found an hospital, and nominate such heads and governors therein as he shall think fit; and this charitable foundation shall be incorporated, and subject to the inspection and guidance of the heads and visitors nominated by the founder. Likewise such corporations shall have, take, and purchase lands, so as not to exceed 200l. a year, provided the same be not held of the king; and to make leases, reserving the accustomed yearly rent. See Corporation.

HOSPITAL, Michael de L'., chancellor of France in the 16th century, was one of the greatest men of his age, and had raised himself by degrees. He agreed to an edict much severer against the Protestants than he could have wished, to prevent the introduction of Hospital the inquisition. It was that of Romorantin. The Hospital's speeches he made, in order to inspire a spirit of toleration, made him much suspected by the Roman Catholics, and extremely odious to the court of Rome. The missions of state upon which he regulated himself were of great advantage to France, since he formed some disciples who opposed, in proper time, the pernicious attempts of the leaguer, and rendered them abortive. His pacific views being disliked by Catharine de Medicis, who had contributed to his advancement, she excluded him from the council of war, and occasioned his disgrace. He retired, however, of his own accord, in 1568; and spent the rest of his life at his country-seat at Vignai, where he died in 1573, aged 68. His poems are esteemed. He also published some excellent speeches and memoirs.

HOSPITAL, William-Francis-Antony, Marquis of, a great mathematician of France, was born of an ancient family in 1661. He was a geometrical almost from his infancy; for one day being at the duke of Rohan's, where some able mathematicians were speaking of a problem of Paschal's which appeared to them extremely difficult, he ventured to say, that he believed he could solve it. They were amazed at such presumption in a boy of 15, for he was then no more; nevertheless, in a few days he sent them the solution. He entered early into the army, and was a captain of horse; but being extremely short-sighted, and exposed on that account to perpetual inconveniences and errors, he at length quitted the army, and applied himself entirely to his favourite amusement. He contracted a friendship with Malebranche, and took his opinion upon all occasions. In 1693, he was received an honorary member of the academy of sciences at Paris; and he published a work upon Sir Isaac Newton's calculations, entitled, L'Analyse des infiniment petits. He was the first in France who wrote upon this subject; and on this account was regarded almost as a prodigy. He engaged afterwards in another work of the mathematical kind, in which he included Les Sections Coniques, les Lieux Geometriques, la Construction des Equations, et Une Theorie des Courbes Mechaniques: but a little before he had finished it, he was seized with a fever, of which he died Feb. 2. 1704, aged 43. It was published after his death.

HOSPITALITY, the practice of entertaining strangers. Dr Robertson, speaking of the middle ages, says, "Among people whose manners are simple, and who are seldom visited by strangers, hospitality is a virtue of the first rank. This duty of hospitality was so necessary in that state of society which took place during the middle ages, that it was not considered as one of those virtues which men may practise or not, according to the temper of their minds and the generosity of their hearts. Hospitality was enforced by statutes, and those who neglected the duty were liable to punishment. The laws of the Salii ordained that the moveables of an inhospitable person should be confiscated, and his house burnt. They were even so solicitous for the entertainment of strangers, that they permitted the landlord to steal for the support of his guest."

The hospitality of our British ancestors, particularly of the great and opulent barons, hath been much admired,
Hospitality, mired, and considered as a certain proof of the nobleness and generosity of their spirits. The fact is well attested. The castles of the powerful barons were capacious palaces, daily crowded with their numerous retainers, who were always welcome to their plentiful tables. They had their privy councillors, their treasurers, marshals, constables, stewards, secretaries, chaplains, heralds, pursuivants, pages, henchmen or guards, trumpeters, minstrels, and in a word all the officers of a royal court. The etiquette of their families was an exact copy of that of the royal household; and some of them lived in a degree of pomp and splendour little inferior to that of the greatest kings. Richard Neville, earl of Warwick, we are told, "was ever had in great favour of the commons of the land, because of the exceeding household which he daily kept in all countries wherever he sojourned or lay: and when he came to London, he held such an house, that six oxen were eaten at a breakfast; and every tavern was full of his meat." The earls of Douglas in Scotland, before the fall of that great family, rivalled or rather exceeded their sovereigns in pomp and profuse hospitality. But to this manner of living it is highly probable these great chief-tains were prompted by a desire of increasing the number and attachment of their retainers, on which, in those turbulent times, their dignity, and even their safety, depended, as much as to the innate generosity of their tempers. Those retainers did not constantly reside in the families of their lords; but they wore their livery and badges, frequently feasted in their halls, swelled their retinues on all great solemnities, attended them in their journeys, and followed them into the field of battle. Some powerful chief-tains had so great a number of these retainers constantly at their command, that they set the laws at defiance, were formidable to their sovereigns, and terrible to their fellow-subjects; and several laws were made against giving and receiving liversies. But these laws produced little effect in this period.

Hospitality was not confined to the great and opulent, but was practised rather more than it is at present by persons in the middle and lower ranks of life. But this was owing to necessity, arising from the scarcity of inns, which obliged travellers and strangers to apply to private persons for lodging and entertainment; and those who received them hospitably acquired a right to a similar reception. This was evidently the case in Scotland in the first part of this period. James I. A.D. 1434, procured the following act of parliament. "It is ordainit, That in all burrow towns, and throughhairs quhilk common passages are, that the be ordainit hostillaries and resesets, havand stables and chalmers; and that men find with thame bread and all, and all uther fude, alsweil for horse as men, for rasonable price." But travellers had been so long accustomed to lodge in private houses, that these public inns were quite neglected; and those who kept them presented a petition to parliament, complaining, "That the liegis travalland in the realme, quhen they cum to burrowis and throughhairs, berebes thame not in hostillaries, but with their acquaintance and freidis," This produced an act prohibiting travellers to lodge in private houses where there were hostillaries, under the penalty of 40s. and subjecting those who lodged them to the same penalty.

The inhabitants of the Highlands and the Western Isles were remarkable for their hospitality and kindness to strangers, and still retain the same disposition. See Highlanders.

HOSPITALLERS, HOSPITALARIS, an order of religious knights, who built an hospital at Jerusalem, wherein pilgrims were received. To these Pope Clement V. transferred the effects and revenues of the Templars, whom, by a council held at Vienne, he suppressed for their many and great misdemeanours. These hospitallers were otherwise called Knights of St. John of Jerusalem; and are the same with those whom we now call Knights of Malta.

HOSPITIUM, a term used in old writers either for an inn or a monastery, built for the reception of strangers and travellers. See inn and monastery.

HOSPODAR, a title borne by the princes of Walachia and Moldavia, who receive the investiture of their principalities from the grand signior. He gives them a vest and standard; they are under his protection, and obliged to serve him, and he even sometimes deposits them; but in other respects they are absolute sovereigns within their own dominions.

HOST, HOSPE, a term of mutual relation, applied both to a person who lodges and entertains another, and to the person thus lodged, &c. —The word is formed of the Latin hospes, which some will have thus called quasi hostium or ostium peces; for ostium was anciently written with an aspirate. —Thus the inn-keeper says, he has a good host, in speaking of the traveller who lodges with him: and the traveller, again, says, he has a kind host, in speaking of his landlord.

must be observed then, that it was the custom among the ancients, when any stranger asked for lodging, for the master of the house, and the stranger, each of them to set a foot on their own side of the threshold, and swear they would neither of them do any harm to the other. It was this ceremony that raised so much horror against those who violated the law or right of hospitality on either side; inasmuch as they were looked on as perjured.

Instead of hospes, the ancient Latins called it hostis; as Cicero himself informs us: though, in course of time, hostis came to signify an enemy; so much was the notion of hospitality altered.

Host is also used by way of abbreviation for hostia, a victim or sacrifice offered to the Deity. In this sense, host is more immediately understood of the person of the Word incarnate, who was offered up an host or hostia to the Father on the cross for the sins of mankind. See Hostia.

Host, in the church of Rome, a name given to the elements used in the eucharist, or rather to the consecrated wafer; which they pretend to offer up every day a new host or sacrifice for the sins of mankind. —They pay adoration to the host, upon a false presumption that the elements are no longer bread and wine, but transubstantiated into the real body and blood of Christ. See transubstantiation.

HOSTAGE,
HOSTAGE, a person given up to an enemy as a security for the performance of the articles of a treaty.

HOSTIA, Host, in antiquity, a victim offered in sacrifice to a deity. The word is formed from hostia, “enemy;” it being the custom to offer up a sacrifice before they joined battle, to render the gods propitious; or, after the battle was over, to give them thanks. Some choose to derive the word from hostio, q. d. ferio, “I strike.” Isidore on this word remarks, that the name hostia was given to those sacrifices which they offered before they marched to attack an enemy, (antiquam ad hostem pergerent): in contradistinction from victima, which were properly those offered after the victory.

Hostia also signified the lesser sorts of sacrifice, and victima the larger. A. Cellius says, that every priest, indifferently, might sacrifice the hostia, but that the victima could be offered by none but the conqueror himself. But, after all, we find these two words promiscuously used one for the other by ancient writers. We read of many kinds of hostiae: as hostiae purae, which were pigs or lambs ten days old; hostiae procidences, sacrifices offered the day before a solemn feast; hostiae bidentias, sacrifices of sheep or other animals of two years old; hostiae eximiae, a sacrifice of the flower of the flock; hostiae sucedences, sacrifices offered after others which had exhibited some ill omen; hostiae ambrosiales, victims sacrificed after having been solemnly led round the fields at the ambrosiales; hostiae ambisciales, victims slain after the ambisciales; hostiae cencareae or caviareae, victims sacrificed every fifth year by the college of postilias, in which they offered the part of the tail called caviar; hostiae prodigiae, sacrifices in which the fire consumed all, and left nothing for the priests; hostiae piscariae, expiatory sacrifices; hostiae ambiegnae or ambiegnae, sacrifices of cows or sheep that had brought forth twins; hostiae harugas, victims offered to predict future events from; hostiae mediocres, black victims offered at noon.

HOSTILITY, the action of an enemy, or a state of warfare. The word is Latin, hostilitas, formed of the primitive hostis, which signifies “enemy;” and which anciently signified “stranger,” hospes.

HOT-BEDS, in Gardening, beds made with fresh horse-dung, or tanners bark, and covered with glasses to defend them from cold winds. By the skilful management of hot-beds, we may imitate the temperature of warmer climates; by which means, the seeds of plants brought from any of the countries within the torrid zone may be made to flourish even under the poles.

The hot-beds commonly used in kitchen-gardens are made with new horse-dung mixed with the litter of a stable, and a few sea-coal ashes, which last are of service in continuing the heat of the dung. This should remain six or seven days in a heap; and being then turned over, and the parts mixed well together, it should be again cast into a heap; where it may continue five or six days longer, by which time it will have acquired a due heat. These hot-beds are made in the following manner: In some sheltered part of the garden, dig out a trench of a length and width proportionable to the frames you intend it for; and if the ground be dry, about a foot or a foot and a half deep; but if it be wet, not above six inches; then wheel the dung into the opening, observing to stir every part of it with a fork, and to lay it exactly even and smooth on every part of the bed, laying the bottom part of the heap, which is commonly free from litter, upon the surface of the bed: and if it be designed for a bed to plant out cucumbers to remain for good, you must make a hole in the middle of the place designed for each light about ten inches over, and six deep, which should be filled with good fresh earth, thrusting in a stick to show the places where the holes are; then cover the bed all over with the earth that was taken out of the trench about four inches thick, and put on the frame, letting it remain till the earth be warm, which commonly happens in three or four days after the bed is made, and then the plants may be placed in it. But if your hot-bed be designed for other plants, there need be no holes made in the dung; but after having smoothed the surface with a spade, you should cover the dung about three or four inches thick with good earth, putting on the frames and glasses as before. In making these beds, care must be taken to settle the dung close with a fork; and if it be pretty full of long litter, it should be trod down equally on every part. During the first week or ten days after the bed is made, you should cover the glasses but slightly in the night, and in the day-time carefully raise them, to let out the steam: but as the heat abates, the covering should be increased; and as the bed grows cold, new hot dung should be added round the sides of it.

The hot-bed made with tanners bark is, however, much preferable to that described above, especially for all tender exotic plants and fruits, which require an even degree of warmth to be continued for several months, which cannot be effected with horse-dung. The manner of making them is as follows: Dig a trench about three feet deep, if the ground be dry; but if wet, it must not be above a foot deep at most, and must be raised two feet above the ground. The length must be proportioned to the frames intended to cover it; but it should never be less than ten or twelve feet, and the width not less than six. The trench should be bricked up round the sides to the above-mentioned height of three feet, and filled in the spring with fresh tanners bark that has been lately drawn out of their vats, and has lain in a round heap, for the moisture to drain out of it, only three or four days: as it is put in, gently beat it down equally with a dung-fork; but it must not be trodden, which would prevent its heating, by setting it too close: then put on the frame, covering it with glasses; and in about ten days or a fortnight it will begin to heat; at which time plunge your pots of plants or seeds into it, observing not to tread down the bark in doing it. These beds will continue three or four months in a good temper of heat; and if you stir up the bark pretty deep, and mix a load or two of fresh bark with the old when you find the warmth decline, you will preserve its heat two or three months longer. Many lay some hot horse-dung in the bottom of the trench under the bark; but this ought never to be practised unless the bed is wanted sooner than the bark would heat of itself, and even then there ought only to be a small quantity of dung at the bottom.
The frames which cover these beds should be proportioned to the several plants they are designed to contain. If they are to cover the annas or pineapple, the back part should be three feet high, and the lower part 14 inches: if the bed be intended for taller plants, the frame must be made of a depth proportionable to them; but if it be for sowing of seeds, the frame need not be above 14 inches high at the back, and 7 in the front; by which means the heat will be much greater.

Hot-House. See Stove and Hypocaustum.

HOTEL, a French term, anciently signifying a house or dwelling place.—It is now more commonly used for the palaces or houses of the king, princes, and great lords. In this sense they say, the hotel de Conde, hotel de Conti, hotel du Louvre, &c.

The grand presint de l'hôtel, is the first judge of the officers of the king's household. His jurisdiction is much like that of lord steward of the household of the king of England.

The hotel de ville is what we call a town-house or town-hall.

HOTEL, is likewise used for a large inn, also for a large lodging-house ready furnished.

HOTTENTOTS, a people in the southern part of Africa, whose country extends north by west from the Cape of Good Hope beyond the mouth of Orange river, and from that cape in east-north-east direction to the mouth of the great Fish river, which parts it from Caffararia. According to Sanaus, this coast, beginning at the Mountains of the Moon under the tropic of Capricorn in 23° S. Extends north beyond the Cape to the coast of Zanguebar, having the Indian sea on the east, the Ethiopic on the west, the southern ocean on the south; and on the north the kingdoms of Mattatan, Monomotapa, and the coast of Zanguebar, or rather the Mountains of the Moon, which divide it from the rest of the continent.

The Europeans first became acquainted with this country in the year 1493, when Bartholomew Diaz, a Portuguese admiral, discovered the most southerly point of Africa, now called the Cape of Good Hope, but by him Cabos dos totos tormentos, or Cape of all Plagues, on account of the storms be met with in the neighbourhood; but John, then king of Portugal, having from the account of Diaz concluded that a passage to the East Indies was now discovered, changed the name to that of the Cape of Good Hope, which it still retains. In 1497, it was circumnavigated by Vasco de Gama, who made a voyage to India that way; however, it remained useless to Europeans till the year 1650, when Van Riebeck a Dutch surgeon first saw the advantages that would accrue to the East India company in Holland from a settlement at such a convenient distance both from home and from India. The colony which he planted has ever since continued in the hands of the Dutch, has greatly increased in value, and is visited by all the European ships trading to the East Indies. See Good-Hope.

The country now possessed by the Dutch is of pretty considerable extent, and comprehends part of the African coast on the west called Terra de Natal. It is naturally barren and mountainsous; but the industry of the Dutch hath overcome all natural difficulties, and it now produces not only a sufficiency of all necessities of life for the inhabitants, but also for the refreshment of all the Europeans who pass and repass that way.

The coast abounds in capes, bays, and roads. Thirty leagues to the east of the Cape of Good Hope, in S. Lat. 34° 21′, is another cape which runs out beyond 35°, called by the Portuguese, who first doubled it, Cabo dos Agulhas, or the Cape of Needles, on account of some strange variations in the magnetic needle observed as they came near it. Near this cape is a flat shore, with plenty of fish: it begins in the west near a fresh-water river, and, extending 15 leagues in the main sea, ends in the east near Fish-bay. Cabo Falso, so called by the Portuguese, who returning from India mistook it for the Cape of Good Hope, lies to the eastward between these two capes, about eight or nine leagues beyond that of Good Hope. Along the coasts, on both sides of the Cape of Good Hope, are many fine bays. Twenty-seven leagues to the north-west is Saldanha bay, so named from a Portuguese captain shipwrecked on the coast. The largest and most commodious is Table Bay, on the south, and near the mountain of that name, six leagues in circumference, with four fathoms water close to the beach. Opposite to this bay is Robu Elan, or the island of Rabbits in 34° 30′ S. Lat. 67° 30′ east from the Cape of Good Hope. Peter Both, in 1661, discovered a bay, which he named Uletest, sheltered only from north winds, in which is a small island, and on the west a rivulet of fresh water extremely convenient for European mariners. Twenty-five or thirty leagues farther east Both discovered Marshal Bay, afterwards named by the Portuguese Seno Formoso. Next to this is Seno de Lago, from its resemblance to a lake. There are several roads in this bay, and an island called Ilha dos Cois. Cabo de S. Francisco, and Cabo das Serras, are marked upon charts between these two bays. Near the latter of these capes is Cabo de Arecito, and the island Contento; and something more north-east is St Christopher's river, called San Christovam by the Portuguese, and by the Hottentots Nagod. The country beyond this river was called by the Portuguese, who discovered it on the day of our Lord's nativity, Terra de Natal. Between the Cape of Good Hope and Cabo dos Agulhas are the Sweet, Salt, and Jagulina rivers, which run into the sea, and sweet-water river flows from the Table-mountain.

The most remarkable mountains in this country are, Table-mountain, Devil's Tower, Lion's Head, and the Tiger hills. The three first lie near Table-bay, and surround Table-valley, where the Cape-town stands. (See the article Good-Hope.) Mr Forster, in his voyage, informs us, that the extremity of Africa towards the south is a mass of high mountains, of which the outermost are craggy, black, and barren, consisting of a coarse granite, which contains no heterogeneous parts, such as petrified shells, &c. nor any volcanic productions. The ground gradually rises on all sides towards these mountains which lie beyond the Table bay, keeping low and level only near the sea-side, and growing somewhat marshy in the isthmus between False and Table bays, where a salt rivulet falls into the latter. The marshy part has some verdure, but intermixed...
Hottentots mixed with a great deal of sand. The higher
grounds, which, from the sea side, have a parched
and dreary appearance, are, however, covered with
an immense variety of plants, among which are a
prodigious number of shrubs, but scarce one or two
species that deserve the name of trees. There are also
a few small plantations wherever a little run of wa-
ter moistens the ground. The ascent of Table-mount
is very steep and difficult, on account of the number of
loose stones which roll away under the feet of the
traveller. About the middle of the mountain is a bold,
grand chasm, whose walls are perpendicular, and often
impending rocks piled up in strata. Some rolls of
water ooze out of crevices, or fall from precipices in
drops, giving life to hundreds of plants and low
shrubs in the chasm. The summit of the mountain is
nearly level, very barren, and bare of soil; several
cavities, however, are filled with rain water, or contain
a small quantity of vegetable earth, from whence a
few odoriferous plants draw their nourishment. Some
antelopes, bowing baboons, solitary vultures, and toads,
are sometimes to be met with on the mountain. The
view from thence is very extensive and picturesque.

The bay seems a little pond or basin, and the ships in it
dwindled to little boats; the town under our feet,
and the regular compartments of its gardens, look like the
work of children.

Most accounts of this country that have been pub-
lished mention a surprising phenomenon which is an-
ually to be seen on the top of Table-hill from Sep-
tember to March; namely, a white cloud hovering on
its top, and called by sailors the Devil's table-cloth. (See
the article Good-Hope). This cloud is said by some
to appear at first no bigger than a barley-corn; then
increases to the size of a walnut, and soon after cov-
cers the whole top of the mountain. But, according
to Mr Kolben, it is never less, even on its first appear-
ance, than the size of a large ox, often bigger. It
hangs in several fleeces over the Table-hill and the
Wind or Devil's hill; which fleeces, at last uniting,
form a large cloud that covers the summits of these
two hills. After this has rested for some time with-
out change or motion, the wind bursts out suddenly
from it with the utmost fury. The skirts of the cloud
are white, but seem much more compact than the cur-
tor of common clouds; the upper parts are of a leaden
colour. No rain falls from it, but sometimes it dis-
covers a great deal of humidity; at which times it is
of a darker colour, and the wind issuing from it is broken,
raging by fits of short continuance. In its usual state,
the wind keeps up its first fury unabated for one, two,
three, or eight days; and sometimes for a whole month
together. The cloud seems all the while undiminished,
though little fleeces are from time to time detached
from it, and hurried down the sides of the hills, vanis-
hing when they reach the bottom, so that during the
storm the cloud seems to be supplied with new matter.
When the cloud begins to brighten up, these supplies
fail, and the wind proportionately abates. At length,
the cloud growing transparent, the wind ceases. Du-
ing the continuance of these south-east winds, the
Table-valley is torn by furious whirlwinds. If they
blow warm, they are generally of short duration; and
in this case the cloud soon disappears. This wind
rarely blows till after sunset, and never longer than till
towards midnight, though the cloud remains; but then
it is thin and clear; but when the wind blows cold, it
is a sure sign, that it will last for some time, an hour
at noon and midnight excepted; when it seems to
lie still to recover itself, and then lets loose its fury
again.

The Europeans at the Cape consider the year as di-
vided into two seasons, which they term monsoons; the
wet monsoon or winter, and the dry one or summer.
The first begins with our spring in March; the latter
with September, when our summer ends. In the sum-
mer monsoon reign the south-east winds already men-
tioned; which though they clear and render the air
more healthy, yet make it difficult for ships outward
bound to enter Table-bay. In the bad season, the
Cape is much subject to fogs; and the north-west
winds and rain make the inhabitants stay much at
home. But there are frequent intermissions and many
clear days till June and July; when it rains almost con-
tinually, and from thence till summer. The weather
in winter is cold, raw and unpleasant; but never more
rigorous than autumn in Germany. Water nev-
er freezes to above the thickness of half a crown; and
as soon as the sun appears the ice is dissolved. The
Cape is rarely visited with thunder and lightning, ex-
cpting a little near the turn of the seasons, which nev-
er does any hurt. During the continuance of the
south-east winds which rage in summer, the sky is free
of all clouds except that on the Table and Wind Hills,
already mentioned; but during the north-west winds,
the air is thick, and loaded with heavy clouds big with
rain. If the south-east winds should cease for any
length of time, the air becomes sickly by reason of the
sea weeds driving ashore and rotting; hence the Eu-
ropians are at such times affected with headaches and
other disorders: but, on the other hand, the violence
of those winds subjects them to inflammation of their
eyes, &c.

The natives of this country are called Hottentots, in
their own language; a word of which it is vain to in-
quire the meaning, since the language of this country
can scarce be learned by any other nation. The Hot-
tot language is indeed said to be a composition of the
most strange and disagreeable sounds, deemed by
many the disgrace of speech, without human sound or
articulation, resembling rather the noise of irritated
turkeys, the chattering of magpies, hooting of owls, and
depending on extraordinary vibrations, inflections, and
clashings of the tongue against the palate.—If this ac-
count is true, however, it is obvious, that all the re-
lations we have concerning the religion, &c. of the
Hottentots derived from themselves, must fail to the
ground, as nobody can pretend to understand a lan-
guage in itself unintelligible. The manners and cus-
toms of those people, however, are easily observable,
whether they themselves give the relation or not; and
if their language is conflagrable to them, it is no doubt
of a nature sufficiently wonderful.

Many accounts have been published concerning the
extreme nastiness and filthy customs of the Hottentots;
but from the observations of late travellers it appears,
that these have either been exaggerated, or that the
Hottentots (which is not improbable) have in some
measure laid aside their former manners. Dr Sparrman
describes them in much less dishonorable terms, and M.
Valliant
HOT

Hottentots. Vaillant seems to have been charmed with their innocence and simplicity. According to the doctor, these people are as tall as the generality of Europeans, though more slender in their persons, which he attributes to their scanty supply of food, and not acquainting themselves to hard labour. The characteristic of the nation, however, and which he thinks has not been observed by any one before, is, that they have small hands and feet in proportion to the other parts of their body. The distance between the eyes appears greater than in Europeans, by reason of the root of the nose being very low. The tip is pretty flat, and the iris of the eye has generally a dark-brown cast, sometimes approaching to black. Their skin is of a yellowish brown, something like that of an European who has the jaundice in a high degree; though this colour does not in the least appear in the whites of the eyes. Their lips are thinner than those of their neighbours the Negroes, Cafrres, or Mozambique.

In fine (says our author), their mouths are of a middling size, and almost always furnished with a set of the finest teeth that can be seen; and, taken together with the rest of their features, as well as their carriage, shape, and every motion, in short their tout ensemble indicates health and delight, or at least an air of sans souci. This carefree mien, however, discovers marks at the same time both of alacrity and resolution; qualities which the Hottentots, in fact, can show upon occasion. The hair of the head is black and frizzled, though not very close; and has so much the appearance of wool, that it would be taken for it, were it not for its harshness. They have but seldom any appearance of a beard, or hair upon other parts of their bodies. In the first place, any thing of this kind happens to be visible, it is always very slight.

A general opinion has prevailed, that the Hottentot women have a kind of natural veil which covers the sexual parts; but this is denied by our author. "The women (says he) have no parts uncommon to the rest of their sex: but the clitoris and nympha, particularly of those who are past their youth, are pretty much elongated; a peculiarity which has undoubtedly got footing in this nation in consequence of the relaxation necessarily produced by the method they have of besmearing their bodies, their slothfulness, and the warmth of the climate."

The Hottentots besmear all their bodies copiously with fat mixed up with a little soot. "This (says our author) is never wiped off; on the contrary, I never saw them use any thing to clean their skins, excepting that when in greasing the wheels of their wagons their hands were besmeared with tar and pitch, they used to get it off very easily with cow-dung, at the same time rubbing their arms into the bagains up to the shoulders, with this substance; so that as the dust and other filth, together with their sooty ointment, and the sweat of their bodies, most necessarily, notwithstanding it is continually wearing off, in some measure adhere to the skin, it contributes not a little to conceal the natural hue of the latter, and at the same time to change it from a bright amber-brown to a brownish yellow colour, obscured with filth and nastiness."—The doctor was enabled to discover the natural colour of the Hottentot by means of the ninety or so Dutch farmers' wives, who had made their Hottentot girls wash and soothe their skins, that they might be less filthy in looking after the children, or Hottentots, doing any other work that required cleanliness. Many of the colonists, however, are of opinion, that this operation of washing is no improvement to the look of a Hottentot; but that their natural yellow is fully as disagreeable as the black or brown colour of the ointment; and that the washed skin of a native of this country seems to be deficient in dress, like shoes that want blacking. This the doctor does not pretend to determine; though, whatever may be supposed deficient in look, we should think must be made up in cleanliness. The Hottentots perfume their bodies, by daubing them all over with the powder of an herb, the smell of which is at once rank and aromatic, approaching to that of the poppy mixed with spices. For this purpose they use various species of the dlosma, called by them bucku, and which they imagine to be very efficacious in the cure of disorders. One species of this plant, growing about Goud's river, is said to be so valuable, that no more than a thimble-full of its powder is given in exchange for a lamb.

By the ointment of soot and grease stuck full of the powder of bucku, a paste is formed which defends the bodies of the Hottentots in a great measure from the action of the air; so that they require very few clothes, and in fact go almost quite naked. The only covering of the men consists of two leather straps, which generally hang down the back from the chinie to the thighs, each of them in the form of an isosceles triangle, their points uppermost, and fastened to a belt which goes round their waist, their bases not being above three fingers broad, so that the covering they form is extremely trifling. These straps have very little dressing bestowed upon them, so that they make a rattling noise as the Hottentot runs along; and our author supposes that they may produce an agreeable coolness by fanning him. Besides this, the men have a bag or flap made of skin which hangs down before, and is fastened to the belt already mentioned. The hollow part of this seems designed to receive that which with us modesty requires to be concealed; but being only fastened by a small part of its upper end to a narrow belt, in other respects hanging quite loose, it is but a very imperfect concealment; and when the wearer is walking, or otherwise in motion, it is none at all. They call this purse by the Dutch name of jackall, it being always prepared of the skin of that animal, with the hairy side turned outwards.

The women cover themselves much more scrupulously than the men, having always two, and very often three coverings like aprons; though even these seem to be abundantly small for what we would term decency in this country. The outermost of these, which is the largest, measures only from about six inches to a foot in breadth. All of them are made of a skin well prepared and greased, the outermost being adorned with glass beads strung in different figures. The outermost reaches about half-way down the thighs, the middle about a third or one half less, and the third scarcely exceeds the breadth of the hand. The first is said to be designed for ornament, the second as a defence for modesty, and the third to be useful on certain occasions, which, however, are much less troublesome to the Hottentot than to the European females.

Our author,
Hottentot, with great probability, supposes that it was the sight of this innermost apron which misled the reverend Jesuit Tackard, who, on his return to Europe, first propagated the stories concerning the natural veils or excrecences of the Hottentots. A story was likewise commonly believed, that the men in general had but one testicle, and that such as were not naturally formed in this manner were artificially made so. But this our author likewise denies; and though he says that such an operation might have been formerly performed upon the males, yet it is not so now.

The other garments worn by the Hottentots are formed of a sheep's skin with the woolly side turned inwards; thus forming a kind of cloak, which is tied forwards over the breast: though sometimes, instead of a sheep's skin, some smaller kind of fur is used as a material. In warm weather they let this cloak hang carelessly over their shoulders, so that it reaches down to the calves of the legs, leaving the lower part of the breast, stomach, and fore part of the legs and thighs bare; but in cold weather they wrap it round them; so that the fore part of the body is likewise pretty well covered by it as far as the knees. But as one sheep-skin is not sufficient for this purpose, they sew on a piece on the top at each side with a thong or catquis. In warm weather they sometimes wear the woolly side outwards, but more frequently take off the cloak altogether, and carry it under their arm. This cloak or kroos serves them not only for clothes, but bedding also; and in this they lie on the bare ground, drawing up their bodies so close, that the cloak is abundantly sufficient to cover them. The cloaks used by the women differ little from those already described, excepting only that they have a long peak on them, which they turn up; forming with it a little hood or pouch, with the hairy side inwards. In this they carry their little children, to which the mother's breasts are now and then thrown over the shoulders; a custom common among some other nations, where the breasts of the females, by continual want of support, grow to an enormous length. The men commonly wear no covering on their heads, though our author says he has seen one or two who wore a greasy night-cap made of skin with the hair taken off. Those who live nearest the colonists have taken a liking to the European hats, and wear them slouched all round, or with only one side turned up. The women also frequently go bare-headed; though they sometimes wear a cap made in the shape of a short truncated cone. This appears to be the section of some animal's stomach, and is perfectly blacked by soot and fat mixed up together. These caps are frequently prepared in such a manner as to look shaggy; others have the appearance of velvet; and in our author's apprehension are not inelegant. Over this they sometimes wear an oval wreath or kind of crown made of a buffalo's hide, with the hair outermost. It is about four fingers' breadth in height, and surrounds the head so as to go a little way down upon the forehead, and the same depth on the neck behind, without covering the upper part of the cap above described. The edges of this wreath, both upper and under, are always smooth and even; each of them set with a row of small shells of the cyprue kind, to the number of more than 30, in such a manner, that, being placed quite close to one another, their beautiful white enamel, together with their mouths, are turned outwards. Between two rows of these shells run two others parallel, or else waved and interlaced in various ways. The Hottentots never pluck their ears or noses as other savages do: though the latter are sometimes marked with a black streak of soot; at others, though more rarely, with a large spot of red lead; of which last, on festivals and holidays, they likewise put a little on their cheeks. The necks of the men are bare, but those of the women are ornamented with a thong of undressed leather, upon which are strung eight or ten shells. These, which are about the size of beans, have a white ground, with large black spots of different sizes: but as they are always made use of in a barnished state, the doctor is uncertain whether they be of that kind which is described in the Systema Naturae under the name of nerita olbircilla, or exuiva. These shells are sold at an enormous price, no less than a sheep for each; as it is said that they come from the more distant coast of Caffraria. Both men and women are very fond of European beads, particularly the blue and white ones of the size of a pea; of which they tie several rows round the middle, and next to the girdles which hold the coverings above mentioned. Besides these ornaments, they use rings on their arms and legs, most of them made of thick leather straps generally cut in a circular shape; which, by being beat and held over the fire, are rendered tough enough to retain the curvature that is given them. From these rings it has been almost universally believed, that the Hottentots wrap guts about their legs in order to eat them occasionally. The men wear from one to five or six of these rings on their arms, just above the wrist, but seldom on their legs. The matrons of a higher rank have frequently a considerable number of them both on their arms and legs, especially on the latter: so that they are covered with them from the feet up to the knees. These rings are of various thicknesses, from that of a goose-quill to two or three times that size. Sometimes they are made of pieces of leather forming one entire ring; so that the arms and feet must be put through them when the wearer wishes to put them on. They are strung upon the legs, small and great, without any nicety; but are so large, that they shake and get twisted when the person walks. Rings of iron or copper, but especially of brass, of the size of a goose-quill, are considered as more genteel than those of leather. However, they are sometimes worn along with the latter, to the number of six or eight at a time, particularly on the arms. The girls are not allowed to use any rings till they are marriageable. The Hottentots seldom wear any shoes; but such as they do make use of are of the same form with those worn by the African peasants, by the Esthonians, and Livonians, as well as by some Finlanders; so that it is impossible to say whether they are the invention of the Dutch or the Hottentots themselves. They are made of undressed leather, with the hairy side outward; without any other preparation than that of being beat and moistened. If it be a thick and stout hide, as that of a buffalo, it is kept for some hours in cow dung, which renders it besides very soft and pliable. Some kind of grease is afterwards used for the same purpose. The shoes are then made in the following manner. They take a piece of leather of a rectangu-
HOT [ 635 ] HOT

Hottentots, lar form, something longer and broader than the foot of the person for whom the shoes are intended; the two foremost corners are doubled up together, and sewed down, so as to cover the fore-part of the foot; but this seam may be avoided, and the shoes made much nearer at the toes, by fitting immediately over them a cap taken from the membrane in the knee-joint of the hind-leg of some animal. In order to make this piece of skin or leather rise up to the height of an inch on both sides of the foot, and close it in neatly, it is pierced with holes at small distances all round the edge, as far as the hind-quarters; and through these holes is passed a thong, by which the rim is drawn up into gatters. In order to make strong hind-quarters, the back part of the piece of leather is doubled inwards, and then raised up and pressed along the heel. The ends of the thong or gathering string are then threaded on both sides through the upper edge of the hind-quarters, to the height of about two inches; they are then carried forwards in order to be drawn through two of the above-mentioned holes on the inside of each rim. Lastly, they are tied over the instep, or if it be thought necessary to tie the shoe still faster, they are carried crosswise over the instep, and so downwards under the thong, which comes out from the hind quarters; then again upward over the ankle, and even round the leg itself if the wearer chooses. Shoes of this kind are not without their advantages; they sit as neat upon the foot as a stocking, and at the same time preserve their form. They are easily kept soft and pliable by constantly wearing them; or if at any time they should become somewhat hard, this is easily remedied by beating and greasing them. They are extremely light and cool, by reason that they do not cover so much of the foot as a common shoe. They wear very well, as they are without any seam, and the soles of the shoes are both tough and yielding. These field shoes, as they are called, being made of almost raw leather, are much more durable than those of tanned leather, which are burnt up by the African sands, and slip and roll about in them; being also very ready to be torn in a rocky soil, which is not the case with the others. The doctor is of opinion, that these shoes would be particularly useful to sailors.

The huts of the Hottentots are built exactly alike; and we may readily give credit to our author when he tells us, that they are done in a style of architecture which does not a little contribute to keep envy from insinuating itself under the roofs. Some of these huts are circular, and others of an oblong shape, resembling a round beehive or vault; the ground-plot being from 18 to 24 feet in diameter. The highest are so low, that it is scarce ever possible for a middle-sized man to stand upright even in the centre of the arch; "but (says our author) neither the lowness thereof, nor that of the door, which is but just three feet high, can perhaps be considered as any inconvenience to a Hottentot, who finds no difficulty in stooping and crawling upon all fours, and is at any time more inclined to lie down than to stand. The fire-place is in the middle of each hut, by which means the walls are not so much exposed to danger from fire. From this situation of the fire-place also the Hottentots derive this additional advantage, that they can all sit or lie in a circle round it, enjoying equally the warmth of the fire. The door, low as it is, alone lets in day-light or Hottentots let out the smoke: and so much are these people accustomed to live in such smoky mansions, that their eyes are never affected by it in the least, nor even by the mephitic vapour of the fuel, which to Europeans would be certain death.

The frame of the arched roof is composed of slender rods or sprays of trees. These being previously bent into a proper form, are laid, either whole or pieced, some parallel to one another, others crosswise; after which they are strengthened by binding others round them in a circular form with withies. All these are taken principally from the clifortia conoides, which grows plentifully in this country near the rivers. Large mats are then placed very neatly over this lattice work, so as perfectly to cover the whole. The aperture which is left for the door is closed occasionally by a skin or piece of matting. These mats are made of a kind of cane or reed in the following manner. The reeds being laid parallel to one another, are fastened together with sinews or catgut, or some kind of catgut which they have had an opportunity of getting from the Europeans; so that they have it in their power to make them as long as they please, and as broad as the length of the reeds, which is from six to ten feet. The colonists make use of the same kind of matting, next to the tilts of their waggons, to prevent the sail-cloth from being rubbed and worn, and likewise to help to keep out the rain.

In a kraal, or Hottentot village, the huts are most commonly disposed in a circle, with the doors inwards; by which means a kind of court-yard is formed, where the cattle are kept at nights. The milk, as soon as taken from the cow, is put to other milk which is curdled, and kept in a leather sack with the hairy side inwards, as being the more cleanly; so that thus the milk is never drunk sweet. In some northern districts, where the land is dry and parched, both Hottentots and colonists are shepherds. When a Hottentot has a mind to shift his dwelling, he lays all the mate, skins, and rods, of which it is composed, on the backs of his cattle, which, to a stranger, makes a monstrous, unwieldy, and even ridiculous appearance.

There is a species of Hottentots named Bushmen, who dwell in the woody and mountainous parts, and subsist entirely by plunder. They use poisoned arrows, which they shoot from bows about a yard long and an inch in thickness in the middle, very much pointed at both ends. Dr Sparrman does not know the wood of which they are made, but thinks that it is not very elastic. The strings were made, some of sinews, and others of a kind of hemp, or in a inner bark of some vegetable, but most of them in a very slovenly manner. The arrows are about a foot and a half long, headed with bone and a triangular bit of iron; having also a piece of quill bound on very strongly with sinews, about an inch and a half from the top, in order to prevent it from being easily drawn out of the flesh. The whole is lastly covered over with a very deadly poison of the consistency of an extract. Their quivers are two feet long and four inches in diameter; and are supposed by our author to be made of the branch of a tree hollowed out, or more probably of the bark of one of the branches taken off whole, the bottom and cover being made of leather.

4 L 2
It is dashed on the outside with a pungent substance which grows hard when dry, and is lined about the aperture with the skin of the yellow serpent, supposed to be the most deadly in all that part of the world. The poison they make use of is taken from the most venomous serpents; and, ignorant as the Hottentots are, they all know that the poison of serpents may be swallowed with safety. See the article Boshiesmen.

In the year 1779, Lieutenant William Paterson, who took a long and dangerous excursion from the Cape along the western side of the continent, discovered a new tribe of Hottentots, whose living, he says, is in the highest degree wretched, and who are apparently the dirtiest of all the Hottentot tribes. Their dress is composed of the skins of seals and jackals, the flesh of which animals they feed upon. If a grampus happens to be cast ashore, they remove their huts to the place, and feed upon the carcass as long as it lasts, though perhaps it may be half roasted by the heat of the weather. They besmear their skins with the oil; by which means they smell so exceedingly rank that their approach may be thus perceived before they come in sight. Their huts, however, are much superior to those of the southern Hottentots already described; being higher, thatched with grass, and furnished with stools made of the back bones of the grampus. They dry their fish in the sun; as the lieutenant found several kinds of fish near their huts suspended from poles, probably for this purpose. He found also several aromatic plants which they had been drying.

With respect to the religion of the Hottentots, it does not appear that they have any. On being questioned on the subject of a Creator and Governor of the universe, they answer that they know nothing of the matter; nor do they seem willing to receive any instruction. All of them, however, have the most firm belief in the powers of magic; from whence it might be inferred that they believe in an evil being analogous to what we call the devil; but they pay no religious worship to him, though from this source they derive all the evil that happens, and among these evils they reckon cold, rain, and thunder. So monstrously ignorant are they, that many of the colonists assured Dr Sparrman, that their Boshiesmen would abuse the thunder with many opprobrious epithets, and threaten to assault the flashes of lightning with old shoes, or any thing that comes first to hand. Even the most intelligent among them could not be convinced by all the arguments our author could use, that rain was not always an evil, and that it would be an unhappy circumstance if it were never to rain. “A maxim (says he), from a race of men in other respects really endowed with some sense, and frequently with no small degree of penetration and cunning, ought, methinks to be considered as an indelible religious or superstitious notion entertained by them from their infancy, rather than as an idea taken up on due deliberation and consequent conviction.”

As the Hottentots have so strong a belief in the powers of magic, it is no wonder that they have abundance of witches and conjurers among them. These will readily undertake any thing, even to put a stop to thunder and rain, provided they be well paid for their pains; and if it happen to thunder or rain longer than the time they promised, they have always for an excuse, that a more powerful conjurer has put a stop to their incantations. Many of the Hottentots believe that all disorders incident to the human body are cured by magic. The wizards are fond of encouraging this idea: but at the same time take care to employ both external and internal remedies. Among the former may be reckoned a cure performed upon Captain Cook in some of the South-sea islands, viz. that of pinching, cutting, and kneading the whole body of the patient. To this, however, the Hottentot physicians add that of pretending to suck out a bone from some part of the patient’s body. After this it sometimes happens that the sick person is relieved, and sometimes not. In the latter case the operation is repeated; and if he dies, his friends lament that he was bewitched beyond the power of any one to assist him. These conjurers appear to be possessed of considerable slight of hand. Our author was informed by a colonist, that when he was a child, and playing with a bone of an ox which he drew as a cart, it appeared to his great astonishment to be sucked out of a sick person’s back by a wizard; and as far as he could remember, the patient recovered soon after. These pretensions of the wizards sometimes resulted in the like to persecutions; and there is an instance of a chief named Paba, who ordered a general massacre among them, in hopes of cutting off the person who he believed had bewitched himself, and afflicted him with sore eyes.

The superstition of the Hottentots never operates in the way of making them afraid in the dark. They seem, however, to have some ideas of a future state, as they reproach their friends, when dead, with leaving them so soon: at the same time adumbrating them from henceforth to demean themselves properly; by which they mean, that their deceased friends should not come back again and haunt them, nor allow themselves to be made use of by wizards to bring any mischief on those that survive them.

There is a genus of insects (the mantis) which, it has been generally thought, the Hottentots worship; but our author is so far from being of this opinion, that he tells us they have more than once exalted several of them for him, and assisted him in sticking pins through them as he did through other insects. “There is (says he), however, a diminutive species of this insect, which some think it would be a crime, as well as very dangerous to do any harm to: but this we have no more reason to look upon as any kind of religious worship, than we have to consider in the same light a certain superstitious notion prevalent among many of the more simple people in our own country (Sweden), who imagine that their sins will be forgiven them, if they set a cock-chafier on its feet that has happened to fall upon its back. The moon, according to Kolbe, receives a kind of adoration from the Hottentots; but the fact is, that they merely take the opportunity of her beams, and at the same time of the coolness of the night, to amuse themselves with dancing, and consequently have no more thoughts of worshipping her than the Christian colonists who are seen at that time strolling in great numbers about the streets, and parading on the stone steps with which their houses are usually encircled. The conjurers themselves, according to our author, are generally freethinkers, who have neither religion nor superstition of any kind.

Lieutenant
Hottentots. Lieutenant Paterson has given the following account of the Cafires, a nation whom no European but himself had then seen, and who inhabit the country to the north-east of the Cape as far down as 31° south latitude.

The men are from five feet ten inches to six feet high, and well proportioned; and in general as valiant fighting men as can be found; and of all the nations of the same continent. The nation, at the time he visited them, was divided into two parties, one to the northward, commanded by a chief named *Cha Cha Bea*, or *Tambushie*, and another named *D mostra*, who claimed the same authority on account of his mother being of the Cafire nation. This occasioned a contest between the two brothers, in the course of which *Cha Cha Bea* was driven out of his territories with a great number of his party; after which he took up his residence at a place named *Khoeta*, where he had an opportunity of entering into an alliance with the Bohisemen. — The Cafires are of a jet black colour, their eyes large, and their teeth as white as ivory. The clothing of both sexes is nearly the same; consisting entirely of the hides of oxen, which are made as plaited as cloth. The men wear tails of different animals tied round their thighs, pieces of brass in their hair, and large rings of ivory on their arms; they are likewise adorned with the hair of lions, feathers fastened on their heads, &c. They use the ceremony of circumcision, which is usually performed upon them when they are nine years of age. They are very fond of dogs, which they exchange for cattle, and will even give two bullocks in exchange for one dog which pleases them. They are expert in throwing lances, and in time of war use shields made of the hides of oxen. Throughout the day the men occupy themselves in hunting, fighting, or dancing; the women being employed in the cultivation of their gardens and corn. They seem not to be destitute of the knowledge of agriculture, as they cultivate several vegetables which do not naturally grow in their own country, viz. tobacco, watermelons, a small kind of kidney-beans, and hemp. The women also make their baskets, and the mats on which they lie. The men are very fond of their cattle, and cut their horns in such a manner as to be able to turn them into any shape they please, and teach them to answer to a whistle.

Mr. Forster is of opinion, that the country they inhabit is greatly superior to any part of Africa.

Of the Dutch settlements and policy at the Cape, Mr. Forster gives the following account.

"The income of the governor here is very considerable: for, besides a fixed appointment, and the use of houses, gardens, proper furniture, and every thing that belongs to his table, he receives about $10 dollars for every lea of wine which the company buy of the farmer in order to be exported to Batavia. The company allows the sum of $40 dollars for each lea, of which the farmer receives but $24: what remains is shared between the governor and second or deputy; the former taking two-thirds, which sometimes are said to amount to $4000 dollars per annum. The deputy-governor has the direction of the company's whole commerce here, and signs all orders to the different departments under him, as well as the governor to others. He and the fiscal have the rank of upper koopman. The fiscal is at the head of the police, and sees the penal laws put in execution: his income consists of fines, and the duties laid on certain articles of commerce; but if he be strict in exacting them, he is universally decried. The sound policy of the Dutch has likewise found it necessary to give the fiscal as a check, to overawe the other officers of the company, that they may not counteract the interests of their masters, or infringe the laws of the mother-country. He is, to that end, commonly well versed in juridical affairs, and depends solely upon the mother-country. The major (at present Mr. Von Frhnu, who received us with great politeness) has the rank of koopman or merchant: this circumstance surprises a stranger, who, in all other European states, is used to see military honours confer distinction and precedence; and appears still more singular to one who knows the contrast in this particular between Holland and Russia, where the idea of military rank is annexed to every place, even that of a professor at the university. The number of regular soldiers at this colony amounts to about 700, of which 400 form the garrison of the fort, near the Cape-town. The inhabitants capable of bearing arms form a militia of 4000 men, of whom a considerable part may be assembled in a few hours, by means of signals made from alarm-posts in different parts of the country. We may from hence make some estimate of the number of white people in this colony, which is at present so extensive, that the distant settlements are above a month's journey from the Cape: but these remote parts lie sometimes more than a day's journey from each other, are surrounded by various nations of Hottentots, and too frequently feel the want of protection from their own government at that distance. The slaves in this colony are at least in the proportion of five or more to one white person. The principal inhabitants at the Cape have sometimes from 20 to 30 slaves, who are in general treated with great lenity, and sometimes become great favourites with their masters, who give them very good clothing, but oblige them to wear neither shoes nor stockings, reserving these articles to themselves. The slaves are chiefly brought from Madagascar, and a little vessel annually goes from the Cape thither on that trade: there are, however, besides them, a number of Malays and Bengalese, and some negroes. The colonists themselves are for the greatest part Germans, with some families of Dutch and some of French Protestants.

The character of the inhabitants of the town is noted. They are industrious, but fond of good living, hospitable, and social, though accustomed to hire their apartments to strangers for the time they touch at this settlement, and used to be complimented with rich presents of stuffs, &c. by the officers of merchant ships. They have no great opportunities of acquiring knowledge, there being no public schools of note at the Cape; their young men are therefore commonly sent to Holland for improvement, and their female education is too much neglected. A kind of dislike to reading, and the want of public amusements, make their conversation uninteresting, and too frequently turn it upon scandal."
HOT [638] HOT

Hottentots, scandal, which is commonly carried to a degree of in-
veteracy peculiar to little towns. The French, English, Portu-
guese, and Malay languages, are very commonly spoken, and many of the ladies have acquired them. This circumstance, together with the accomplish-
ments of singing, dancing, and playing a tune on the lute, frequently united in an agreeable person, make amends for the want of refined manners and deli-
cacy of sentiment. There are, however, among the principal inhabitants, persons of both sexes, whose whole deportment, extensive reading, and well-culti-
vated understanding, would be admired and distinguished even in Europe. Their circumstances are in general easy, and very often affluent, on account of the cheap rate at which the necessaries of life are to be pro-
cured: but they seldom amass such prodigious riches here as at Batavia; and I was told the greatest private fortune at the Cape did not exceed 100,000 dollars, or about 25,000l. sterling.

"The farmers in the country are very plain hospita-
table people; but those who dwell in the remotest settlements seldom come to town, and are said to be very ignorant. This may easily be conceived, because they have no better company than Hottentots, their dwellings being often several days journey asunder, which must in a great measure preclude all intercourse. The vine is cultivated in plantations within the compass of a few days journey from the town; which were established by the first colonists, and of which the ground was given in perpetual property to them and their heirs. The company at present never part with the property of the ground, but let the surface to the farmer for an annual rent, which, though extremely moderate, being only 25 dollars for 60 acres, yet does not give sufficient encouragement to plant vineyards. The distant settlements, therefore, chiefly raise corn and rear cattle; nay, many of the settlers entirely follow the latter branch of rustic employment, and some have very numerous flocks. We were told there were two farmers who had each 15,000 sheep, and oxen in proportion; and several who possessed 6000 or 8000 sheep, of which they drive great droves to town every year; but lions and buffaloes, and the fati-
gue of the journey, destroy numbers of their cattle before they can bring them so far. They commonly take their families with them in large waggons covered with linen or leather, spread over hoops, and drawn by 8, 10, and sometimes 12 pair of oxen. They bring butter, mutton-tallow, the flesh and skins of river-horses (Hippopotamus), together with lion and rhinoceros skins, to sell. They have several slaves, and commonly en-
gage in their service several Hottentots of the poorest sort, and (as we are told) of the tribe called Boskies-
men, Bothchamans, or Bushmen, who have no cattle of their own, but commonly subsist by hunting, or by committing depredations on their neighbours. The opulent farmers set up a young beginner by intrusting to his care a flock of 400 or 500 sheep, which he leads to a distant spot, where he finds plenty of good grass and water; the one-half of all the lambs which are yeaned fall to his share, by which means he soon be-
comes as rich as his benefactor.

"Though the Dutch company seem evidently to dis-
courage all new settlers, by granting no lands in private property; yet the products of the country have of late years sufficed not only to supply the isles of Hottentots, France and Bourbon with corn, but likewise to furnish Hottiger, the mother-country with several ship loads. These ex-
ports would certainly be made at an easier rate than at present, if the settlements did not extend so far into the country, from whence the products must be brought to the Table-bay by land-carriage, on roads which are al-
most impassable. The intermediate spaces of unculti-
vated land between the different settlements are very extensive, and contain many spots fit for agriculture; but one of the chief reasons why the colonists are so much divided and scattered throughout the country, is to be met with in another regulation of the company, which forbids every new settler to establish himself with-
in a mile of another. It is evident, that if this settle-
ment were in the hands of the commonwealth, it would have attained to a great population, and a degree of opulence and splendour of which it has not the least hopes at present; but a private company of East India merchants find their account much better in keeping all the landed property to themselves, and tying down the colonist, lest he should become too great and power-
ful.

"The wines made at the Cape are of the greatest variety possible. The best, which is made at M. Vander Byp's plantation of Constantia, is spoken of in Europe, far more by report than from real knowledge: 30 leagues (or pipes) at the utmost are annually raised of this kind, and each league sells for about 50l. on the spot. The wines from which it is made were originally brought from Shiraz in Persia. Several other sorts grow in the neighbourhood of that plantation, which produce a sweet rich wine, that generally passes for genuine Con-
stantia in Europe. French plants of burgundy, mus-
cade, and frontignan, have likewise been tried, and have succeeded extremely well, sometimes producing wines superior to those of the original soil. An ex-
cellent dry wine, which has a slight agreeable tawness, is commonly drank in the principal families, and is made of Madeira vines transplanted to the Cape. Se-
veral low sorts, not entirely disagreeable, are raised in great plenty, and sold at a very cheap rate; so that the sailors of the East India ships commonly indulge themselves very plentifully in them whenever they come ashore.

"The products of the country supply with provisions the ships of all nations which touch at the Cape. Corn, flour, biscuit, salted beef, brandy, and wine, are to be had in abundance, and at moderate prices; and their fresh greens, fine fruits, good mutton and beef, are ex-
cellent restoratives to seamen who have made a long voy-
ge.

HOTTINGER, John Henry, one of the most learned and eminent of the Protestant divines of Swit-
zerland, was born at Zurich, in the year 1620. He discovered an invincible propensity to learning at a very early period, and acquired the knowledge of languages with astonishing facility. The trustees of the schools had their attention attracted towards Hottinger by his amaz-

HOTTINGER, Jacob, a celebrated engraver, whose great excellence consisted in the portrait line. His works are distinguished by an admirable softness and delicacy of execution, joined with good drawing and a fine taste. If his best performances have ever been surpassed, it is in the masterly determination of the features, which we find in the works of Nanteuil, Edelinck, and Drevet; this gives an animation to the countenance, more easily to be felt than described. His works are pretty numerous; and most of them being for English publications, they are sufficiently known in this country. In particular the greater and best part of the collection of portraits of illustrious men, published in London by I. and P. Knifton, were by his hand.

HOVEDON, Roger de, born of an illustrious family in Yorkshire, most probably at the town of that name, now called Howden, some time in the reign of Henry I. After he had received the first parts of education in his native country, he studied the civil and canon law, which were then most fashionable and lucrative branches of learning. He became domestic chaplain to Henry II. who employed him to transact several ecclesiastical affairs; in which he acquitted himself with honour. But his most meritorious work was his annals of England, from A.D. 731, when Bede's ecclesiastical history ends, to A.D. 1202. This work, which is one of the most voluminous of our ancient histories, is more valuable for the sincerity with which it is written, and the great variety of facts which it contains, than for the beauty of its style, or the regularity of its arrangement.

HOUGH, Ham, in the manege, the joint of the hind leg of a beast, which connects the thigh to the leg. See Ham.

To Hovor, or cut the Hought, is to ham-string, or to disable by cutting the sinews of the ham.

HOULIERES, Antoinette Des, a French lady, whose poetry is highly esteemed in France. Her works and those of her daughter have been collected and printed together in two volumes. Most of the idyls, particularly those on sheep and birds, surpass every thing of the kind in the French language: the thoughts and expressions are noble; and the style pure, flowing, and chaste. Mademoiselle des Houlières carried the poetic prize in the French academy against Fontenelle. Both of these ladies were members of the academy of Ricovrat; the mother was also a member of the academy of Arles. Those who desire to be more particularly acquainted with the history of Madame des Houlières, may consult her life prefixed to her works in the Paris edition of 1747, 2 vols 12mo.

HOULSWORTHY, a large town of Devonshire, seated between two branches of the river Tamar, having a good market for corn and provisions. It had 1206 inhabitants in 1811. W. Long, 2. 42. N. Lat. 50. 50.

Training of Hounds. Before we speak of the methods proper to be used for this purpose, it will be necessary to point out the qualities which sportsmen desire to meet with in these animals. It is generally understood, that hounds of the middle size are the most proper, it being remarked, that all animals of that description are stronger than either such as are very small or very large. The shape of the hound ought to be particularly attended to; for if he be not well proportioned, he can neither run fast nor do much work. His legs ought to be straight, his feet round, and not very large; his shoulders back; his breast rather wide than narrow; his chest deep, his back broad, his head small, his neck thin; his tail thick and bushy, and if he carry it well so much the better. None of those young bounds which are out at the elbows, or such as are weak from the knee to the foot, should ever be taken into the pack. That the pack may look well, it is proper that the hounds should be as much as possible of a size: and if the animals be handsome at the same time, the pack will then be perfect. It must not, however, be thought, that this contributes any thing to the goodness of a pack; for very unhandsome packs, consisting of hounds entirely different in size and colour, have been known to afford very good sport. It is only necessary that they should run well together; to which indeed an uniformity in size and shape would seem to contribute in some degree. The pack that can run 10 miles, or any other considerable space, in the shortest time, may be said to go fastest, though the hounds taken separately might be considerably inferior to others in swiftness. A pack of hounds, considered in a collective body, go fast in proportion to the excellence of their noses and the head they carry. Packs which are composed of hounds of various kinds seldom run well. When the packs are very large, the hounds are seldom sufficiently hunted to be good; 20 or 30 couple, therefore, or at most 40, will be abundantly sufficient for the keenest sportsman in this country, as thus he may be enabled to hunt three or even four times a day. The number of hounds to be kept must, however, in a considerable degree, depend on the strength of the pack, and the country in which you hunt. They should be left at home as seldom as possible; and too many old hounds should not be kept. None ought to be kept above five or six seasons, though this also is somewhat uncertain, as we have no rule for judging how long a hound will last.

In breeding of hounds, considerable attention ought to be paid to the dog from whom you breed. All such are to be rejected as have a tender nose, as are babblers or skitters. An old dog should never be put to an old bitch; nor should any attempts be made to cross the breed unless in a proper and judicious manner. Mr. Beckford informs us, that he has seen foxhounds bred out of a Newfoundland dog and foxhound bitch; the whelps were monstrously ugly, and had other bad qualities besides. The cross most likely to be of service to a fox-hound is the beagle. The reason of crossing the breeds sometimes is, that the imperfections of one may sometimes be remedied by another. The months of January, February, and March, are the best for breeding; late puppies seldom thrive. After the females begin to grow big with young, it will not be proper to let them hunt any more, or indeed to remain for a much longer time in the kennel. Sometimes these animals will have an extraordinary number of whelps. Mr. Beckford informs us, that he has known a bitch have 15 puppies at a litter; and he assures us, that a friend of his informed him, that a hound in his pack brought forth 16, all of them alive. In these cases it is proper to put some of the puppies to another bitch, if you want to keep them all; but if any are destroyed, the best coloured ought to be kept. The bitches should not only have plenty of flesh, but milk also; and the puppies should not be taken from them till they are able to take care of themselves; their mothers will be relieved when they learn to lap milk, which they will do in a short time. After the puppies are taken away from the mothers, the litter should have three purging balls given them, one every other morning, and plenty of whey the intermediate day. If a bitch bring only one or two puppies, and you have another that will take them, by putting the puppies to her the former will soon be fit to hunt again. She should, however, be first physicked, and it will also be of service to anoint her dogs with brandy and water.

Whelps are very liable to the distemper to which dogs in general are subject, and which frequently makes great havoc among them at their walks; and this is supposed by Mr. Beckford to be owing to the little care that is taken of them. "If the distemper (says he) once get among them, they must all have it: yet, notwithstanding that, as they will be constantly well fed, and will lie warm (in a kennel built on purpose), I am confident it would be the saving of many lives. If you should adopt this method, you must remember to use them early to go in couples: and when they become of a proper age, they must be walked out often; for should they remain confined, they would neither have the health, shape, or understanding, which they ought to have. When I kept hounds, I bred up some of the puppies at a distant kennel, but having no servants there to exercise them properly, I found them much inferior to such of their brethren as had the luck to survive the many difficulties and dangers they had undergone at their walks; these were afterwards equal to any thing, and afraid of nothing; whilst those that had been nursed with so much care, were weakly, timid, and had every disadvantage attending private education. I have often heard as an excuse for hounds not hunting a cold scent, that they were too high-bred. I confess I know not what that means: but this I know, that hounds are frequently too ill-bred to be of any service. It is judgment in the breeder, and patience afterwards in the huntsman, that makes them hunt."

When young hounds are first taken in, they should be kept separate from the pack; and as it will happen at a time of the year when there is little or no hunting, you may easily give them up one of the kennels and grass court adjoining. Their play frequently ends in a battle; it therefore is less dangerous where all are equally matched.—If you find that they take a dislike to any particular hound, the safest way will be to remove him, or it is probable they will kill him at last. When a feeder begins the hounds quarrel in the kennel, he balloos them to stop them; he then goes among them, and dogs every hound he can come near...
How much more reasonable, as well as efficacious, would it be, were he to see which were the combatants before he speaks to them. Punishment would then fall, as it ought, on the guilty only. In all packs there are some hounds more quarrelsome than the rest; and it is to them we owe all the mischief that is done. If you find chastisement cannot quiet them, it may be prudent to break their hollers; for since they are not necessary to them for the meat they have to eat, they are not likely to serve them in any good purpose. Young hounds should be fed twice a day, as they seldom take kindly to the kennel meat at first, and the distemper is most apt to seize them at this time. It is better not to round them till they are thoroughly settled; nor should it be put off till the hot weather, for then they will bleed too much. It may be better perhaps to round them at their quarters, when about six months old; should it be done sooner, it would make their ears tuck up. The tailing of them is usually done before they are put out; it might be better, perhaps, to leave it till they are taken in. Dogs must not be rounded at the time they have the distemper upon them, as the loss of blood would weaken them too much.

"If any of the dogs be thin over the back, or any more quarrelsome than the rest, it will be of use to cut them; I also say such bitches as I shall not want to breed from; they are more useful, are stouter, and are always in better order; besides it is absolutely necessary if you hunt late in the spring, or your pack will be very short for want of it. The latter operation, however, does not always succeed; it will be necessary therefore to employ a skillful person, and one on whom you can depend; for if it be ill done, though they cannot have puppies, they will go to heat notwithstanding. They should be kept low for several days before the operation is performed, and must be fed on thin meat for some time after."

It is impossible to determine how many young hounds ought to be bred in order to keep up the pack, as this depends altogether on contingencies. The deficiencies of one year must be supplied by the next; but it is probable, that from 30 to 35 couples of old hounds, and from eight to twelve couple of young ones, will answer the purpose where no more than 40 couple are to be kept. A considerable number, however, ought always to be bred; for it is undoubtedly and evidently true, that those who breed the greatest number of hounds must expect the best pack.

After the hounds have been rounded, become acquainted with the huntsman, and answer to their names, they ought to be coupled together, and walked out among sheep. Such as are particularly ill-natured ought to have their couples loose about their necks in the kennel till they become reconciled to them. The most stubborn ought to be coupled to old hounds rather than to young ones; and two dogs should not be coupled together when you can avoid it. As young hounds are awkward at first, a few ought only to be set out at a time with people to foot, and they will soon afterwards follow a horse. When they have been walked out often in this manner amongst the sheep, they should be uncoupled by a few a time, and those chastised who offer to run after the sheep; but it will be difficult to reclaim them after they have once been allowed to taste blood. Some are accustomed to couple the dogs with a ram in order to break them from sheep; but this is very dangerous for both parties. Mr. Beckford relates a story of a nobleman who put a large ram into his kennel in order to break his hounds from sheep; but when he came some time after to see how nobly the ram defended himself, he found him entirely eaten up, and the hounds gone to sleep after having filled their bellies.

When hounds are to be aired, it is best to take them out separately, the old ones one day, and the young another; though, if they are to be kept away from a distant dairy, both old and young may be taken out together, observing only to take the young hounds in couples, when the old ones are along with them. Young hounds are always apt to fall into mischief, and even old ones when idle will be apt to join them. Mr. Beckford mentions a whole pack running after a flock of sheep through the mere accident of a horse's falling, and then running away.

With regard to the first entering of hounds to a scent, our author gives such directions as have subjected him to a severe charge of inhumanity. We shall give them in his own words. "You had better enter them at their own game: it will save you much trouble afterwards. Many dogs, I believe, like that scent best which they were first bloodyed to: but be this as it may, it is most certainly reasonable to use them to that which it is intended they should hunt. It may not be amiss first when they begin to hunt to put light collars on them. Young hounds may easily get out of their knowledge; and shy ones, after they have been much beaten, may not choose to return home. Collars, in that case, may prevent their being lost.—You say you like to see your young hounds run a trail-scent.—I have no doubt that you would be glad to see them run over an open down, where you could so easily observe their action and their speed. I cannot think the doing of it once or twice could hurt your hounds; and yet as a sportsman I dare not recommend it to you. All that I can say is, that it would be less bad than entering them at here. A cat is as good a trail as any; but on no account should any trail be used after your hounds are stopped to a scent. I know an old sportsman who enters his young hounds first at a cat, which he drags along the ground for a mile or two, at the end of which he turns out a badger, first, taking care to break his teeth: he takes out about a couple of old hounds along with the young ones to hold them on. He never enters his young hounds but at vermin; for he says, 'Train up a child in the way he should go, and when he is old he will not depart from it.'"

Hounds ought to be entered as soon as possible, though the time must be uncertain, as it depends on the nature of country in which they are. In corn countries hunting may not be practicable till the corn is cut down; but you may begin sooner in grass countries, and at any time in woodlands. "If (says Mr. Beckford) you have plenty of foxes, and can afford to make a sacrifice of some of them for the sake of making your young hounds steady, take them first where you have least riot, putting some of the smallest of your old hounds among them. If in such a place you are fortunate enough to find a litter of foxes, you may assure yourself you will have but little trouble with your
Hound. your young hounds afterwards.—If, owing to a scarcity of foxes, you should stop your hounds at bare, let them by no means have the blood of her; nor, for, the sake of consistency, give them much encouragement. Hare-hunting has one advantage;—hounds are chiefly in open ground, where you can easily command them; but notwithstanding that, if foxes be in tolerable plenty, keep them to their own game.

Frequent ballooning is of use with young hounds; it keeps them forward, prevents them being lost, and binds them from hunting after the rest. The oftener therefore that a fox is seen and ballooned, the better. I by no means, however, approve of much ballooning to old hounds; though it is true that there is a time when ballooning is of use, a time when it does hurt, and a time when it is perfectly indifferent: but long practice and great attention to hunting can only teach the application.

"Hounds at their first entrance cannot be encouraged too much. When they are become handy, love a scent, and begin to know what is right, it will then be soon enough to chastise them for what is wrong; in which case one severe beating will save a great deal of trouble. When a hound is flogged, the whipper-in should make use of his voice as well as his whip. If any be very unsteady, it will not be amiss to send them out by themselves when the men go out to exercise their horses. If you have hares in plenty, let some be found sitting, and turned out before them; and you will find that the most riotous will not run after them. If you intend them to be steady from deer, they should often see deer, and then they will not regard them, and if after a proportion of this kind you turn out a cub before them, with some old hounds to lead them on, you may assure yourself they will not be unsteady long."

It is proper to put the young hounds into the pack when they stoop to a scent, become handy, know a rate, and stop easily. A few only are to be put to the pack at a time; and it is not advisable even to begin this till the pack have been out a few times by themselves, and are "got down well in blood." They should be low in flesh when you begin to hunt; the ground being generally hard at that time, so that they are liable to be shaken.—By hounds being handy, our author means their being ready to do whatever is required of them; and particularly, when cast, to turn easily which way the huntsman pleases.

Mr. Beckford begins to hunt with his young hounds in August. The huntsman, in the preceding months, keeps his old hounds healthy by giving them proper exercise, and gets his young hounds forward; and for this purpose nothing answers so well as taking them frequently out. The huntsman should go along with them, get frequently off his horse, and encourage them to come to him:—too much restraint will frequently incline the hounds to be riotous. Our author frequently walks out his hounds among sheep, hares, and deer. Sometimes he turns them down a cat before them, which they kill; or, when the time of hunting approaches, he turns out young foxes or badgers; taking out some of the most steady of his old hounds to lead on the young ones. Small covers and furze-breaks are drawn with them to use them to a hallow, and to teach them obedience. If they find improper game and hunt it, they are stopped and brought back; and as long as they will stop at a rate, they are not chastised. At such times as they are taken out to air, the huntsman leads them into the country in which they are designed to hunt; by which means they acquire a knowledge of the country, and cannot miss their way home at any time afterwards. When they begin to hunt, they are first brought into a large cover of his own, which has many ridings cut in it; and where young foxes are turned out every year on purpose for them. After they have been hunted for some days in this manner, they are sent to more distant covers, and more old hounds added to them. There they continue to hunt till they are taken into the pack, which is seldom later than the beginning of September; for by that time they will have learned what is required of them, and seldom give much trouble afterwards. In September he begins to hunt in earnest; and after the old hounds have killed a few foxes, the young ones are put into the pack, two or three at a time, till all have hunted. They are then divided; and as he seldom has occasion to take in more than nine or ten couple, one half are taken out one day, and the other the next, till they are steady.

To render fox-hunting complete, no young hounds should be taken into the pack the first season; a requisite too expensive for most sportsmen. The pack should consist of about 40 couple of hounds, that have hunted one, two, three, four or five seasons. The young pack should consist of about 20 couple of young hounds, and an equal number of old ones. They should have a separate establishment, and the two kennels should not be too near one another. When the season is over, the best of the young hounds should be taken into the pack, and the draught of old ones exchanged for them. Many must be bred to enable a sportsman to take in 20 couple of young hounds every season. It will always be easy to keep up the number of old hounds; for when your own draft is not sufficient, drafts from other packs may be obtained, and at a small expense. When young hounds are hunted together for the first season, and have not a sufficient number of old ones along with them, it does more harm than good.

Kennel of Hounds. See Kennel.

HOUNSLOW, a town of Middlesex, 10 miles from London. It is situated on a heath of the same name; and belongs to two parishes, the north side of the street to Heston, and the south side to Isleworth. Near it are powder-mills. It has fairs on Trinity-Monday, and Monday after September 29. Here is a charity-school and a chapel. In this place was formerly a convent of mendicant friars, who, by their institutions, were to beg alms for the ransom of captives taken by the infidels.—The heath is noted for robberies and horse-races. Population 2353 in 1811.

HOU-QUANG, a province of China, occupying nearly the centre of the empire: the river Yang-tse-kiang divides it from west to east; and is divided into two parts, the northern and southern. This province (the greater part of which is level, and watered by lakes, canals, and rivers) is celebrated for its fertility; the Chinese call it the store-house of the empire; and it is a common saying among them, that "the abundance
Houglang dance of Kiang-ai could furnish all China with a breakfast; but the province of Hou-guang alone could supply enough to maintain all its inhabitants." Some princes of the race of Hong-ven formerly resided in this province; but that family was entirely destroyed by the Tartars when they conquered China. The people here boast much of their cotton cloths, simples, gold-mines, wax, and paper made of the bamboo-reed. The northern part of the province contains eight fœs, or cities of the first class, and sixty of the second and third. The southern comprehends seven of the first class, and fifty-four of the second and third, exclusive of forts, towns, and villages, which are everywhere to be found.

HOUR, in Chronology, an aliquot part of a natural day, usually a 24th, but sometimes a 12th. The origin of the word Hour, or Æon, comes, according to some authors, from a surname of the sun, the father of hours, whom the Egyptians call Hora. Others derive it from the Greek ἡ ώρα, to terminate, distinguish, &c. Others from the word ὤρη, urine; holding, that Trismegistus was the first that divided the division of hours which he did from observation of an animal consecrated to Serapis, named cynocephalus, which makes water 12 times a day, and as often in the night, at equal intervals.

An hour, with us, is a measure or quantity of time, equal to a 24th part of the natural day, or nychthemeron or the duration of the 24th part of the earth's diurnal rotation. Fifteen degrees of the equator answer to an hour; though not precisely, but near enough for common use. It is divided into 60 minutes; the minute into 60 seconds, &c.

The division of the day into hours is very ancient; as is shown by Kircher, Oedip. Egyp. tom. ii. p. ii. class. vi. c. 8.; though the passages he quotes from Scripture do not prove it. The most ancient hour is that of the 12th part of the day. Herodotus, lib. ii. observes, that the Greeks learnt from the Egyptians, among other things, the method of dividing the day into twelve parts. — The astronomers of Calythes, &c. Bishop Beveridge observes, still retain this division. They call the hour chag; and to each chag give a peculiar name, taken from some animal: the first is called xæth, "mouse;" the second, chin, "bullock;" the third, sex, "leopard;" the fourth, man, "hare;" the fifth, chin, "crocodile," &c.

The division of the day into 24 hours was not known to the Romans before the first Punic war. Till that time they only regulated their days by the rising and setting of the sun. They divided the 24 hours of their day into four, viz. prime, which commenced at six o'clock; third, at nine; sixth, at twelve, and none, at three. They also divided the night into four watches, each containing three hours.

HOURS, Hour, in the ancient mythology, were certain goddesses, the daughters of Jupiter and Themis; at first only three in number, Eunomia, Dice, and Ixion, to which were afterwards added two more, Carpo and Thallote.

Homer makes them the doorkeepers of heaven. Odysseus equus Titan vehicibus imperat Hora.

And speaks of them as standing, at equal distances, about the throne of Sol:

et, posita spatiiis equalibus, Hora.

The poets represent them as dressed in fine coloured or embroidered robes, and gliding on with a quick and easy motion.

HOURS, Hour, in the Roman church, are certain prayers performed at stated times of the day; as matins, vespers, lauds, &c. The lesser hours are, prime, tierce, sext, &c. They are called hours or canonical hours, as being to be rehearsed at certain hours prescribed by the canons of that church, in commemoration of the mysteries accomplished at those hours. These hours were, in ancient times, also called course, cursum: F. Mahillon has a dissertation on them, entitled, De Cursum Gallicano.

The first constitution enjoining the observation of the canonical hours is of the ninth century, being found in a capitular of Hiéno bishop of Baci directed to his curates, importing that the priests shall never be absent at the canonical hours either by day or night.

Hour-Glass, a popular kind of chronometer or clepsydra, serving to measure the flux of time by the descent or running of sand out of one glass vessel into another. The best hour-glasses are those which, instead of sand, have egg-shells well dried in the oven, then beaten fine and sifted. — Hour-glasses are much used at sea for reckoning, &c.

HOURS, in modern history, is a name given by the Mahometans to those females that are designed for the faithful in Paradise. These are not the same with whom they have lived on earth, but formed for this purpose with singular beauty and unchanging charms.

HOUSE, a habitation, or place built with conveniences for dwelling in. See Architecture.

Houses, among the Jews, Greeks, and Romans, were not flat on the top, but were built upon, and had usually stairs on the outside, by which they might ascend and descend without coming into the house. Each house, in fact, was so laid out, that it enclosed a quadrangular area or court. This court was exposed to the weather, and being open to the sky, gave light to the house. This was the place where company was received, and for that purpose it was strewn with mats or carpets for their better accommodation. It was paved with marble or other materials, according to the owner's ability, and provided with an umbrella ofvellum to shelter them from the heat and inclemencies of the weather. This part of their houses, called by the Romans impluvium or casa adium, was provided with channels to carry off the water into the common sewers. The top of the house was level, and covered with a strong plaster by way of terrace. Hither, especially among the Jews, it was customary to retire for meditation, private converse, devotion, or the enjoyment of the evening breezes.

The Grecian houses were usually divided into two parts, in which the men and women had distinct mansions assigned. The part assigned to the men was towards the gate, and called andromus; the apartment of the women was the farthest part of the house, and called ipomanein. Jews, Greeks, and Romans, suppos
HOU [ 644 ] HOU

House are their houses to be polluted by dead bodies, and to stand in need of purification.

House is also used for one of the estates of the kingdom of Britain assembled in parliament. Thus we say, the house of lords, the house of commons, &c. See Peers, Commons, &c.

House is also used for a noble family, or a race of illustrious persons issued from the same stock. In this sense we say, the house or family of the Stautes, the Bourbons, the house of Hanover, of Austria, of Lorraine, of Savoy, &c.

Cheap, easy, and expeditious Method of constructing Houses, which have been found to be very useful hospitals for the recovery of the sick, and therefore may probably make very wholesome places of residence for the healthy.—The first thing to be done is to choose a dry and airy situation, on a gravelly or chalky soil if possible; upon this lay down the plan of your building, make one end of it face that quarter from whence the purest and healthiest winds may be expected to blow, of a breadth that can be conveniently roofed. Then, if boarding does not come so cheap, drive stakes, at about six feet distance from each other, into the ground, so as to stand about six feet above it; and, interlacing them with wattles, coat the wattles on the side next the weather with fresh straw; and make the roof in the same manner, but thicker, or of thatch in the usual way, with a hole at the very top of it, to open occasionally. Let the end of the building facing the wholesome quarter lie open some feet back, so as to form a porch, where the convalescents may take the air without danger of any injury from the weather. A large chimney and kitchen grate may be erected at the other end. If the soil happens to be chalky or gravelly, you may hollow it four or five feet deep, within a foot or eighteen inches of the walls; but let the steps into this hollow lie far enough within the porch, that no water may get into it, and, if of chalk, the steps may not grow slippery in wet weather. From time to time open the vent-hole at the roof; by means of which all the unwholesome infectious air, as being warmer, and consequently lighter, than that which is pure and wholesome, will be driven out by the rushing in of the fresh air; a purpose, which the little openings that may be left in the sides and roofs of such rude and hasty buildings, will, even of themselves, answer so well, as sufficiently to compensate any cold they may let in, even in the coldest months. Let the floor likewise be scraped three or four inches deep every five or six days, and what comes off removed to some distance. Halls of this kind, 50 feet long and 20 broad, cost but a trifle to build; yet, with these precautions (even without the addition of clean straw for every new patient to lie on, inclosed in clean washed sacks fit for the purpose, which come infinitely cheaper than the bare cleaning of flock or even feather-beds, supposing it possible to wash such beds), proved of infinitely more advantage in the recovery of sick soldiers, than the low-roofed rooms of the farm-houses of the Isle of Wight, or even the better accommodations of Carisbrooke castle in the same island, in which there perished four times the number of sick that there did in these temporary receptacles; which were first thought of by Doctor Brocklesby, on occasion of some terrible infections from confined animal effluvia.

Is it not surprising, that we have not availed ourselves more of the above discovery in natural history, being, perhaps, the most important the moderns can boast of, in the most useful science, viz. the superior lightness of unwholesome and infectious air! The upper sashes in most houses, even of those who pretend to some knowledge in these matters, are generally immovable, by means of which no part of the foul air above the level of the lowest rail of the other sash's greatest rise can escape by the window; and, if it escapes by the doors, it is generally, for want of a vent in the highest part of the roof, merely to accumulate in the upper story of the house, and add to the infection, which the great quantities of old furniture usually stored up there are of themselves but too apt to create, when care is not frequently taken to open the windows of it. Thus, the chief benefit to be expected from lofty rooms is in a great measure lost. Whereas, were the upper sashes contrived to come down, all the air might be easily changed, and that almost insensibly, by letting them down an inch or two. Nay, the upper sash might be often let entirely down with less danger or inconvenience from cold, than the lower thrown up the tenth part of an inch, though the doing of the former would be attended with infinitely more advantage to the health of the inhabitants than the latter. It is, perhaps, on this principle, that we are to account for the good health enjoyed by the poor who live crowded in damp cellars, and often with great numbers of rabbits, poultry, and even swine about them. These cellars are open to the street, with doors reaching from the floor to the very ceiling, but never so close at bottom or at top as to prevent a free circulation of air; in consequence of which, all vitifying fluid, as fast as it is spoiled by passing through the lungs of the inhabitants and their stock, or is infected by their insensible perspiration, excrements, &c. is driven out and replaced by the fresh air.

House, in Astrology, denotes the twelfth part of the heavens.

The division of the heavens into houses is founded upon the pretended influence of the stars, when meeting in them, on all sublunary bodies. These influences are supposed to be good or bad; and to each of these houses particular virtues are assigned, on which astrologers prepare and form a judgment of their horoscopes. The horizon and meridian are two circles of the celestial houses, which divide the heavens into four equal parts, each containing three houses; six of which are above the horizon, and six below it; and six of these are called eastern and six western houses.

A scheme or figure of the heavens is composed of 12 triangles, all called houses, by which are marked the stars, signs, and planets, so included by each of these circles. Every planet has likewise two particular houses, in which it is pretended that they exert their influence in the strongest manner; but the sun and moon have only one, the house of the former being Leo, and that of the latter Cancer.

The houses in astrology have also names given them according to their qualities. The first is the house of life:
life: this is the ascendant, which extends five degrees above the horizon, and the rest below it. The second is the house of riches; the third, the house of brothers; the fourth, in the lowest part of the heavens, is the house of relations, and the angle of the earth; the fifth, the house of children; the sixth, the house of health; the seventh, the house of marriage, and the angle of the west; the eighth, the house of death; the ninth, the house of piety; the tenth, the house of offices; the eleventh, the house of friends; and the twelfth, the house of enemies.

* See Villa. Country House, is the villa * of the ancient Romans, the quintess of the Spaniards and Portugese, the cloister and cassine of the French, and the vigino of the Italians.

It ought always to have wood and water near it, these being the principal beauties of a rural seat. The trees make a far better defence than hills, as they yield a cooling and healthy air, shade during the best of summer, and very much break the severities of the winter season.

It should not be situated too low, on account of the moisture of the air; and, on the other hand, those built on places exposed to the winds are expensive to keep in repair. Houses not above two stories high, and upon a good foundation, the length of two bricks, or 18 inches, for the heading course, will be sufficient for the ground-work of any common structure; and six or seven courses above the earth, to a water-table, where the thickness of the wall is 84 or 100 in. on either side the thickness of a brick, viz. two inches and a quarter. But for large and high houses of three, four, or five stories, with garrets, their walls ought to be three heading courses of bricks, or 28 inches at least, from the foundation to the first water-table; and at every story a water-table, or taking in, on the inside, for the summers, girders, and joists to rest upon, laid into the middle, or one quarter of the wall at least, for the better bond. But as for the partition-wall, a brick and half will be sufficiently thick; and for the upper stories a brick length or nine inch brick will suffice.

* See Rowe.

Hot-house. See Stove and Hypocaustum.

House-breaking, or Robbing, is the breaking into and robbing a house in the day-time; the same crime being termed burglary when done by night: both are felony without benefit of clergy.

House and Window Duty, a branch of the king's extraordinary revenue. As early as the Conquest, mention is made in Doomsday book of furniture or furniture, vulgarly called smoke-farthings; which were paid by custom to the king for every chimney in the house. And we read that Edward the Black Prince (soon after his successes in France), in imitation of the English custom, imposed a tax of a florin upon every hearth in his French dominions. But the first parliamentary establishment of it in England was by statute 12 and 14 Car. II. c. 10. whereby an hereditary revenue of 25s. for every hearth, in all houses paying to church and poor, was granted to the king for ever. And, by subsequent statutes, for the more regular assessment of this tax, the constable and two other substantial inhabitants of the parish, to be appointed yearly (or the surveyor appointed by the crown, together with such constable or other public officer), were, once in every year, em-powered to view the inside of every house in the parish. But, upon the Revolution, by stat. 1 W. and M. c. 10. hearth-money was declared to be "not only a great oppression to the poorer sort, but a badge of slavery upon the whole people, exposing every man's house to be entered into and searched at pleasure, by persons unknown to him; and therefore, to erect a lasting monument of their majesties goodness, in every house in the kingdom the duty of hearth-money was taken away and abolished." This monument of goodness remains among us to this day; but the prospect of it was somewhat darkened, when in six years afterwards, by statute 7 W. III. c. 18. a tax was laid upon all houses (except cottages) of 2s. now advanced to 3s. per house, and a tax also upon all windows, if they exceeded nine, in such house. These rates have been from time to time varied, being now extended to all windows exceeding six; and power is given to surveyors, appointed by the crown, to inspect the outside of houses, and also to pass through any houses, two days in the year, into any court or yard, to inspect the windows there.

Schemes of the different rates of duty upon houses and windows may be seen in the Almanacks, or in Kearsley's Tax-Tables published yearly.

House-leaf. See Sedum and Semperivium, Botany Index.

Household, the whole of a family considered collectively, including the mistress, children, and servants. But the household of a sovereign prince includes only the officers and domestics belonging to his palace.

The principal officers of his majesty's household are, the lord steward, lord chamberlain of the household, the groom of the stole, the master of the great wardrobe, and the master of the horse.

The civil government of the king's house is under the care of the lord steward of the king's household; who, being the chief officer, all his commands are observed and obeyed. His authority extends over all other officers and servants, except those of his majesty's chapel, chamber, and stable, and he is the judge of all crimes committed either within the court or the verge.

Under him are the treasurer of the household, the comptroller, cofferer, the master of the household, the clerks of the green-cloth, and the officers and servants belonging to the accounting-house, the marshallers, the verge, the king's kitchen, the household kitchen, the aterry, bake-house, pantry, buttery, cellar, pastry, &c. Next to the lord steward is the lord-chamberlain of the household, who has under him the vice-chamberlain, the treasurer, and comptroller of the chamber; 48 gentlemen of the privy chamber, 12 of whom wait quarterly, and two of them lies every night in the privy chamber; the pages of the presence-chamber; the mace-bearers, cup-bearers, couriers, musicians, &c. See Lord Chamberlain of the Household.

The groom of the stole has under him the 11 other lords of the bed-chamber, who wait weekly in the bed-chamber, and by turns lie there a-night on a pallet-bed; and also the grooves of the bed-chamber, the pages of the bed-chamber and back-stairs, &c. See Groom of the Stole.

The master or keeper of the great wardrobe has under
HOU [646]  

Household by him a deputy, comptroller, clerk of the robes, brusher, &c. and a number of tradesmen and artificers, who are all sworn servants to the king.

The master of the horse has under his command the esquireys, pages, footmen, grooms, coachmen, farriers, saddlers, and all the other officers and tradesmen employed in his majesty's stables.

Next to the civil list of the king's court, is the military, consisting of the band of gentlemen pensioners, the yeomen of the guards, and the troops of the household; of which the two first guard the king above stairs.

When the king dine in public, he is waited upon at table by his majesty's cup-bearers, carvers, and gentlemen sewers; the musicians playing all the time. The dinner is brought up by the yeomen of the guard, and the gentleman sewers set the dishes in order. The carvers cut for the king, and the cup-bearer serves him the drink with one knee on the ground, after he has first tasted it in the cover.

HOUSING, or House-Lime, in the sea-language, a small line, formed of three fine strands or twists of hemp, smaller than rope-yarn. It is chiefly used to seize blocks into their strops, to bind the corners of the sails, or to fasten the bottom of a sail to its bolt-ropes, &c. See Bolt-Rope.

HOUSING, or House, a cover laid over the saddle of a horse, in order to save it from the weather, dirt, &c. The word is formed of the French housse, which signifies the same thing; though it anciently denoted a kind of hood worn by country people.—The cavaliers appeared with their embroidered housings.

HOUSING, among bricklayers, a term used for a brick which is warped, or is cast crooked or hollow in burning; in such a case, they say it is housing.

HOUSSA, the metropolis of an empire in Africa, on the banks of the Niger, the population of which, according to the account of an Arab named Shabeni, which he delivered to the African Association, was only equalled by that of London and Cairo. The same person described the government as a limited monarchy, which administered justice in a severe manner, although in conformity to written laws. The rights of landed property are guarded by the institutions of particular hereditary officers, whose duties imply no ordinary degree of refinement and civilization. The merchants of Houssa have been celebrated for their probity, while the ladies are said not to be very remarkable for their conjugal fidelity. The art of writing is common, but their alphabet is entirely different from the Arabic and Hebrew. These observations appear to be confirmed by the testimony of Mr. Park; and to such an extent is disposed to doubt the possibility of so much refinement in the interior of a country deemed savage, it will be necessary to observe, that many of the Carthagians have retired to the southern parts of Africa, on the destruction of their own cities, and carried with them some portion of the arts, sciences, and commercial knowledge, for the knowledge of which we are assured that their ancestors were once so famous.

According to some maps of North Africa, particularly that of Major Rennel, the city of Houssa lies in Lat. 16° 20' N. and Long. 4° 30' E.

HOUSTONIA, a genus of plants belonging to the tetrandra class and in the natural method ranking under the 47th order, Stellateae. See Botany Index.

HOU-TCHEOU-FOU, a city of China, in the province of Tche-kiang. It is a city of the first class; and is situated on a lake, from which it takes its name. The quantity of silk manufactured here is almost incredible. To give some idea of it we shall only say, that the tribute paid by a city under its jurisdiction, named Te-tsin-hien, amounted to more than 500,000 ounces of silver. Its district contains seven cities, one of which is of the second, and six of the third class.

HOUZOUANAS, a wandering people, whose country, according to M. Vaillant, is situated between 16° and 29° E. Long., but in what latitude appears to be unknown, although it is extremely probable that it commences about the 23rd parallel, and stretches towards the north a considerable way. It is the opinion of the above-mentioned author, that the Houzouanas are the origin of all the eastern and western tribes of the Hottentots: and as to the Houzouanas themselves, they seem wholly ignorant of their own origin; for when they are interrogated upon this subject, their answer invariably is, that they live in the country which their ancestors inhabited, which in point of information is no answer at all. They have been often confounded by the planters with the Boshmen, who are not a distinct people, but a band of fugitives and freebooters. The Houzouanas have nothing in common with them, and only form alliances among themselves. So great are their courage and habits of plunder, that all surrounding nations are afraid of them, and even the very Hottentots, according to Vaillant, tremble to enter their territories. They are often guilty of shedding human blood, yet this does not appear to originate from an innate love of carnage, but merely for the purpose of making just reprisals.

They survey the adjacent countries from the summits of their mountains, and make incursions to carry off cattle or slaughter them upon the spot; but although they rob, they never kill, except in their own defence, or by way of retaliation; so that they are by no means the unrelenting cannibals which some have represented them. Like the Arabs, who are also plunderers, they adhere with unshaken fidelity to their engagements, and the traveller who puts himself under their protection by civilly purchasing their services, may rest assured of being defended to the last drop of their blood; which is more than can be said for the people of many countries professing to be civilized.

Amidst all this superiority to the other natives of Southern Africa, their stature is low, so that a person among them measuring five feet four inches in height, is considered as very tall;—a proof that intellectual excellence is not always to be met with in men of a gigantic stature. Their complexion is not so black as that of the Hottentots, but their heads are broader towards the chin. The heat of the climate renders clothing unnecessary, and the constant habit of going naked, makes them equally indifferent to the burning sands of the level country, or the frost and snow of the lofty mountains. They have no weapons but bows and arrows, in the use of which they discover remarkable dexterity. Their huts appear as cut vertically through the middle, so that it would require two of them exact-

HOW

Hougoum. ly to make one of the Hottentots. The Hougouanas
are remarkably nimble, considering the climbing of
mountains as nothing more than an amusement; and
they conducted M. Vaillant, that traveller informs us,
over such tremendous precipices as the Hottentots would
have deemed wholly impassable. The practice of mak-
ing signals by means of nocturnal fires, is known in all
savage countries; but the Hougouanas are said to dis-
play such uncommon sagacity and prudence in the
arrangement and variations of position from time to time,
as to render it impossible for the surrounding tribes to
penetrate their designs.

HOWARD, Henry, earl of Surrey, a soldier and
a poet, the son and grandson of two lord treasurers,
dukes of Norfolk, was born probably about the year
1520, and educated in Windsor castle, with young
Fitzroy earl of Richmond, natural son to King Hen-
ry VIII. Wood says, from tradition, that he was some-
time a student at Cardinal College, Oxford. In his
youth he became enamoured of the Fair Geraldine,
whom his sonnets have immortalized. In 1532, Howard
with his companion Richmond was at Paris, where
they continued some time. The latter died in 1536;
after which our young hero made a tour to Italy,
and at Florence, like a true enamorato, published a
challenge against all comers, whether Christians, Jews,
Saracens, Turks, or cannibals, in defence of the beau-
ty of his fair Geraldine; and was victorious in the
tournament instituted by the grand duke on the oc-
asion. The duke, we are told, was so charmed with
his gallant exploits, that he would gladly have retained
him at his court; but he rejected the invitation, be-
determined to maintain the superlative beauty of his
Geraldine in all the principal cities in Italy. This
romantic resolution was however frustrated by the
command of his sovereign, Henry VIII, to return to
England.

In 1540, he signalized himself in a tournament at
Westminster, against Sir John Dudley, Sir Thomas
Seymour and others. In 1542, he marched, under
the command of his father, against the Scots; and
in the same year was confined in Windsor castle for eat-
ing flesh in Lent, contrary to the king's proclamation.
In 1544, on the expedition to Boulogne in France, he
was appointed field-marshal of the English army; and
after the taking of that town, in 1546, made captain-
general of the king's forces in France. He was at this
time knight of the Garter. In the same year, attempt-
ing to intercept a convoy, he was defeated by the French,
and soon after superseded in his command by the
earl of Hertford.

Surrey, after his return to England, conscious of his
former services, and peevish under his disgrace, could
not help reflecting on the king and council. This was
his first step towards destruction. He had married
Frances, the daughter of John earl of Oxford; and,
after her death, is said to have made love to the prin-
cess Mary. For this the Seymours, rivals of the Nor-
folk family, and now in favour with the king, accused
him of aspiring to the crown, adding, that he already
presumed to quarter part of the royal arms with his
own: but, whatever might be the pretence, the cause
of his ruin was the jealousy and power of his enemies.
In short, the destruction of the Howards being deter-
mained, Surrey, and his father, the duke of Norfolk,
were committed to the Tower, in December 1546;
and on the 23rd of January following, Surrey was tried
at Guildhall by a common jury, and beheaded on
Tower-hill on the 19th day of the same month, nine
days before the death of the king; who thus, that the
measure of his crimes might be full, finished his life
with the murder of his best subject. The accusations
brought against this amiable and innocent young noble-
man on his trial, were so extremely ridiculous, that
one is astonished how it was possible, even in the most
despotic reign, to find a judge and jury so pusillani-
moreously villanous as to carry on the farce of justice on
the occasion. We boast of our excellent constitution,
and our trial by juries; but this example may teach
us, that our constitution and our juries are not incom-
patible with despotic monarchy. He was first in-
terred in the church of All-souls, Barkin, near Tower-
hill; and afterwards in the reign of King James I.
removed to Farmingham in Suffolk, by his son Henry
earl of Northampton.

As to the character of this unfortunate earl, all our
poets have sung his praise. Mr Walpole begins his
anecdotes of Surrey with these words: "We now
emerge from the twilight of learning to an almost clas-
ic author, that ornament of a boisterous, yet not un-
polished court, the earl of Surrey, celebrated by Dry-
ton, Dryden, Fenton, Pope, illustrated by his own
muse, and lamented for his unhappy death: a man (as
Sir Walter Raleigh says) no less valiant than learned,
and of excellent hopes." Leland calls him the con-
script enrolled heir of Sir Thomas Wyatt, the elder,
in his learning and other excellent qualities; and the
author of The Art of English Poetry says, that the earl
of Surrey and Sir Thomas Wyatt, may be justly call-
ed the <i>reformers of our poetry and style</i>. His poems
were published in 1557, 12mo; and in 1565, 1574,
1581, 1587, 8vo. Several of the sonnets are by Sir
Thomas Wyatt and others.

HOWARD, Charles, an able statesman and experi-
enced seaman, was the son of Lord William Howard,
baron of Effingham, and born in 1536. He served
under his father, who was lord high admiral of Eng-
land, till the accession of Queen Elizabeth. In January
1573, he succeeded his father in his title and estate;
after which he successively became chamberlain of
the household and knight of the Garter, and in 1585
was made lord high admiral, at that critical junc-
Howard expressed her sense of his merit in the most honourable terms; and granted him a pension for life. In 1596, he commanded in chief at sea, as Essex did by land, the forces sent against Spain, when his prudence and moderation were among the principal causes of the success the English met with in that great and glorious enterprise; so that, upon his return the next year he was advanced to the dignity of earl of Nottingham. The next eminent service in which his lordship was engaged was in 1597, when the Spaniards seemed to meditate a new invasion. Her majesty, who always placed her safety in being too quick for her enemies, drew together, in a fortnight's time, such a fleet, and such an army, as took away all appearance of success from her foreign and domestic enemies; and she gave the earl the sole and supreme command of both the fleet and army, with the title of lord lieutenant general of all England, an office unknown in succeeding times. When age and infirmity had unfitted him for action, he resigned his office, and spent the remaining part of his life in ease and retirement, till the time of his decease, which happened in 1624, in the 87th year of his age.

Howard, John, Esq., a man of singular and transcendent humanity, was the son of a reputable tradesman in St. Paul's church-yard. He was born about the year 1725 or 1726; and at a proper age was put apprentice to Mr. Nathaniel Newham, a wholesale grocer in Watling street. His father died, leaving only this son and a daughter, to both of whom he bequeathed handsome fortunes; and by his will directed that his son should not be considered of age till he was five and twenty. His constitution was thought very weak, and his health appeared to have been injured by the necessary duties of his apprenticeship; and therefore, at the expiration of it, he took an apartment in a lodging house in Church-street, Stoke Newington, Middlesex; but not meeting with the tenderest treatment there, he removed to another lodging-house in the same street, which was kept by a widow lady Mrs. Sarah Lardeau, a worthy sensible woman, but an invalid. Here he was nursed with so much care and attention, that he resolved to marry his landlady out of gratitude for her kindness. In vain she expostulated with him upon the extravagance of such a proceeding, he being about 20 and she about 31 years of age, and 20 years older in constitution: but nothing could alter his resolution, and they were privately married about the year 1752. She was possessed of a small fortune, which he presented to her sister. During his residence at Newington, the minister of the dissenting meeting-house there resigned his office, and a successor was elected; and Mr. Howard, who was bred a dissentor, and steadfastly adhered all his life to that profession, proposed to purchase the lease of a house near the meeting-house, and to appropriate it as a parsonage-house for the use of the minister for the time being, and contributed 50l. for that purpose. His wife died November 10, 1755, aged 34; and he was a sincere and affectionate mourner for her death. About this time it is believed, he was elected F. R. S. In the year 1756 he had the fortune to experience some of the evils which it afterwards became the business of his life to redress. He embarked that year in a Lisbon packet, the Hanover, in order to make the tour of Portugal; when the vessel was taken by a French privateer. "Be-fore we reached Brest (says he) I suffered the extreme of thirst, not having for above 40 hours one drop of water, nor hardly a morsel of food. In the castle of On Pe [1754, p. 11] at Brest I lay six nights upon straw; and observing how cruelly my countrymen were used there and at Morlaix, whither I was carried next, during the two months I was at Carhaix upon parole, I corresponded with the English prisoners at Brest, Morlaix, and Dinan; at the last of those towns were several of our ship's crew, and my servant. I had sufficient evidence of their being treated with such barbarity, that many hundreds had perished, and that 36 were buried in a hole at Dinnan in one day. When I came to England, still on parole, I made known to the commissioners of sick and wounded seamen the sundry particulars, which gained their attention and thanks. Remonstrance was made to the French court: our sailors had redress; and those that were in the three prisons mentioned above, were brought home in the first cartel ships.—Perhaps (adds Mr. Howard) what I suffered on this occasion increased my sympathy with the unhappy people whose case is the subject of this book." He afterwards, it is said, made the tour of Italy; and at his return settled at Brokenhurst, a retired and pleasant villa in the New Forest, near Lynington in Hampshire, having, April 25, 1758, married a daughter of Edward Leedes, Esq., of Croxton, Cambridgeshire, king's serjeant. This lady died in 1765 in childbed, of her only child, a son, who unfortunately became lunatic. After her death Mr. Howard left Lynington, and purchased an estate at Cardington, near Bedford.

"While he lived here in retirement (says Mr. Palmer), it was his meat and drink to make his neighbours happy. His neat but humble mansion was ever open a hospitable to a few select friends, but was never the scene of riot or luxurious banqueting. Though polite to all, he neither sought nor admitted the company of the profligate, however distinguished by rank or fortune.—His charity had no bounds, except those of prudence; and was not more commendable for the extent of it, than for the manner in which it was exercised. He gave not his bounty to countenance vice and idleness, but to encourage virtue and industry. He was singularly useful in furnishing employment for the labouring poor of both sexes, at those seasons when a scarcity of work rendered their situation most compassionate. And at other times, though never intentive to the tale of woe, he was not easily imposed upon by it, but made himself acquainted with the case. He had indeed a general acquaintance with the cases and characters of the poor around him, and made it his business to visit the abodes of affliction. In circumstances of bodily disorder, he often acted the part of a physician as well as a friend. But his kindness was not confined to the bodies of his fellow-creatures, it extended to their spiritual and immortal part. He carefully watched over the morals of his neighbourhood, and used his advice, his admonitions, and influence, to discountenance immorality of all kinds, and to promote the knowledge and practice of religion. As a most effectual means to this great end, he provided for the instruction of poor children, by erecting and supporting schools which he carefully superintended. In short, he was an universal blessing to the vil-
HOW

where he had found the most flagrant vices to prevail in such a degree, that they were become seminaries of wickedness and villany, and the most formidable nuisances to the community; in consequence of the promiscuous intercourse of prisoners of both sexes, and of all ages and descriptions; whereby the young and least experienced were initiated, by old and hardened sinners, into all the arts of villany and the mysteries of iniquity; so that, instead of being reformed by their confinement (which should be the chief end of punishment), those that were discharged became more injurious to society than before.

In order to the attainment of these great objects, Mr. Howard spared no pains nor expense, and cheerfully exposed himself to much inconvenience, and hazard; particularly from that malignant distemper, of which he saw many dying in the most loathsome dungeons, into which none, who were not obliged, besides himself, would venture. "I have been frequently (says Mr. Howard) asked what precautions I used to preserve myself from infections in the prisons and hospitals which I visited. I here answer, next to the free goodness and mercy of the Author of my being, temperance and cleanliness are my preservatives. Trusting in divine providence, and believing myself in the way of my duty, I visit the most noxious cells; and while thus employed, I fear no evil. I never enter an hospital or prison before breakfast; and in an offensive room, I seldom draw my breath deeply."

His laudable endeavours he had the pleasure to see, in some instances, crowned with success; particularly in regard to the healthiness of prisons, some of which were rebuilt under his inspection. Through his interposition also, better provision has been made for the instruction of prisoners, by the introduction of bibles and other pious books into their cells, and a more constant attendance of clergymen. The gaolers likewise have, by act of parliament, been rendered incapable of selling strong liquors, which had been the source of much drunkenness and disorder. But a minute detail of particulars is not to be expected here; for these the reader is referred to Mr. Howard's publications, which show that much is yet wanting.

But in order to a more general and happy regulation, and the reformation of criminals, he determined to visit other countries, to see the plans there adopted; in hope of collecting some information which might be useful in his own country. For this purpose he travelled into France, Flanders, Holland, Germany, and Switzerland. Afterwards through the Prussian and Austrian dominions. He visited also the capitals of Denmark, Sweden, Russia, and Poland, and some cities in Portugal and Spain. In all these expensive and hazardous journeys, he denied himself the usual gratifications of travellers, and declined the honours which were offered him by persons of the first distinction, applying himself solely to his one grand object. To him the inspection of a jail, or hospital, was more grateful than all the entertainments of a palace. With what astonishment and gratitude he was received by their miserable inhabitants may easily be imagined, since while he made observations on their situation, he mediated their relief; and many distressed prisoners abroad, as well as at home, partook of his bounty, and some were liberated by it; for he considered all of every na-
HOW

Howard, in his spartan of advice, or of reproof, as he saw occasion, to persons of rank and influence, whereby the miseries of their countrymen might be relieved. As he courted the favour of none, neither did he fear the frowns of any; but with a manly freedom and a Christian fortitude, spoke his mind to crowned heads (particularly the late emperor of Germany) in a manner to which they were accustomed; which, however, in a person of such disinterested views, procure him reverence and esteem, and in some instances proved effectual for relieving the miserable and oppressed. On his return, he published in 1777, "The State of the Prisons in England and Wales, with Preliminary Observations, and an Account of some foreign Prisons." 40. And in 1778 he took a third journey through the Prussian and Austrian dominions, and the free cities of Germany, and likewise extended his tour through Italy, and revisited some of the countries he had before seen. The observations he made in this tour were published in an appendix, 1780; containing also some remarks respecting the management of prisoners of war, and the hulks on the Thames. But wishing to acquire some further knowledge on the subject, he in 1781 again revisited Holland and some cities in Germany. He visited also the capitals of Denmark, Sweden, Russia, and Poland; and in 1783 some cities in Portugal and Spain, and returned through France, Flanders, and Holland. The substance of all these travels was afterwards thrown into one narrative, which was published in 1784. He also published a curious account of the Bastile, in 8vo.; that infamous French prison, happily now no more.

His travels and exertions, however, were not yet at an end. He conceived a further design, which was to visit the principal lazarettos in France and Italy, in order to obtain information concerning the best methods to prevent the spreading of the plague, with a view to apply them with respect to other infectious disorders. Not gaining all the satisfaction here which he wished for, he proceeded to Smyrna and Constantinople, where that most dreadful of human distempers actually prevailed, "pleasing himself (as he said) with the idea of not only learning, but of being able to communicate somewhat to the inhabitants of those distant regions." In the execution of this design, though he was so much exposed to danger, and actually caught the plague, "that merciful Providence (as he himself piously remarks) which had hitherto preserved him, was pleased to extend his protection to him in this journey also, and to bring him home once more in safety." In his return he revisited the chief prisons and hospitals in the countries through which he passed; and afterwards went again to Scotland, and then to Ireland, where he proposed a new and very important object; namely, to inspect the Protestant Charter Schools, in some of which he had before observed shameful abuses, which he had reported to a committee of the Irish House of Commons. In this more extensive tour, he took a particular account of what he observed amid the conduct of this noble charity, with a view to a reformation, and not without considerable success. In the course of these journeys, particular cities and communities were not unmindful to pay him proper respect. At Dublin, he was created by the university a Doctor of Laws; and the city of Glasgow and the town of Liverpool did honour to themselves by enrolling him among their members. Upon his return home, having again inspected the prisons in England, and the hulks on the Thames, to see what alterations had been made for the better (which he found to be very considerable, though yet imperfect), he published the result of his last laborious investigations, in "An Account of the Principal Lazarettos in Europe, with various Papers relative to the Plague, together with further Observations on some Foreign Prisons and Hospitals, and additional Remarks on the present State of those in Great Britain and Ireland," with a great number of curious plates. The work likewise contained Observations on Penitentiary Houses, which had been encouraged by act of parliament, for the correction and reformation of criminals, of which he and Dr Portegill had been nominated by the king to be superintendents. Beside these, he published the Grand Duke of Tuscany's "new Code of Criminal Law, with an English Translation." And of all his publications he gave away a vast number of copies among his acquaintance in the most liberal manner. His laying open the horrors of despotism in a neighbouring country had very nearly exposed him to the sufferings of them; and had it not been for the timely notice of our ambassador, he had ended his days in the Bastile.

Not satisfied, however, with what he had already done, he concludes his "Account of Lazarettos" with announcing his "intention again to quit his country, for the purpose of revisiting Russia, Turkey, and some other countries, and extending his tour in the east. I am not insensible (says he) of the dangers that must attend such a journey. Trusting, however, in the protection of that kind Providence which has hitherto preserved me, I calmly and cheerfully commit myself to the disposal of unerring wisdom. Should it please God to cut off my life in the prosecution of this design, let not my conduct be uncandidly imputed to rashness or enthusiasm, but to a serious deliberate conviction that I am pursuing the path of duty, and to a sincere desire of serving mankind as an instrument of more extensive usefulness to my fellow-creatures than could be expected in the narrower circle of a retired life." Accordingly, to the great concern of his friends, he set out in summer 1789 on this hazardous enterprise; the principal object of which was to administer a medicine in high repute at home, in malignant fevers, &c., under a strong persuasion that it would be equally efficacious in the plague. In this second tour in the east, "it did please God to cut off his life: for, having spent some time at Cherson, a new settlement of the emperor of Russia, on the mouth of the Dnieper or Borysthenes, toward the northern extremity of the Black sea, near Oczakov, he caught, in visiting the Russian hospital of that place, or as some say a young lady who was ill of the same complaint, a malignant fever, which carried him off on the 20th of January, after an illness of about twelve days: and after having been kept, according to his express directions to his servant, five days, he was buried, by his own desire, in the garden of a villa in the neighbourhood, belonging to a French gentleman from whom he had received...
received great civilities, by his faithful servant who had attended him on his former journeyings, and whom he expressly enjoined not to return home till five weeks from his death. While absent on his first tour to Turkey, &c. his character for active benevolence had so much attracted the public attention, that a subscription was set on foot to erect a statue to his honour, and in no long space above 3000L. was subscribed for that purpose. But some of those who knew Mr Howard best, never concurred in the scheme, being well assured that he would neither countenance nor accede to it; and in consequence of two letters from Mr Howard himself to the subscribers, the design was laid aside. It has, however, been resumed since his death: And surely, of all the statues or monuments ever erected by public gratitude to illustrious characters either in ancient or modern times, none was ever erected in honour of worth so genuine and admirable as his—who devoted his time, his strength, his fortune, and finally sacrificed his life, in the pursuits of humanity:—who (to adopt the expressive words of Mr Burke *) visited all Europe (and the east), not to survey the sumptuosities of palaces, or the stateliness of temples; not to make accurate measurements of the remains of ancient grandeur, nor to form a scale of the curiosity of modern art; not to collect medals, or to collate manuscripts: but to dive into the depth of dungeons; to plunge into the infection of hospitals; to survey the extremities of sorrow and of pain; to take the gauge and dimensions of misery, depression, and contempt; to remember the forgotten; to attend to the neglected; to visit the forsaken; and to compare and collate the distresses of all men in all countries. His plan is original; and it is as full of genius as it is of humanity. It is a voyage of discovery, a circumnavigation of charity; and already the benefit of his labour is felt more or less in every country.

HOWDEN, a town in the east riding of Yorkshire, 180 miles from London, stands on the north side of the Ouse, has a market on Saturdays, and four fairs in the year. Here was formerly a collegiate church of five prebendaries; adjacent to which the bishops of Durham, who possess many estates here with a temporal jurisdiction, have a palace. One of them built a very tall steeple to the church here, whither the inhabitants might retire in case of inundations; to which it is very liable from the great freshes that come down the Ouse sometimes at ebb. This part of the county is from hence called Howdeshire, and is watered by a confux of several large rivers that fall into the Humber. At Howdendike is a ferry over the Ouse. Population 1812, in 1811.

HOWE, RICHARD, EARL, an English naval commander of distinguished eminence, was born in the year 1725, being the second son of Lord Viscount Howe, by the daughter of Baron Kilmansegg. From his early attachment to the life of a mariner, he quitted the school of Eton at the age of 14, and went on board the Severn, the honourable Captain Legge being commander, destined for the South seas under Commodore Anson. Mr Howe next appeared in the Burford, Captain Lushington commander, who being killed in an expedition against the Caraccas, Commodore Knowles made Mr Howe an acting lieutenant. At the age of 20 he was promoted to the rank of commander in the Baltimore sloop of war, and he joined a squadron at that time cruising off the coast of Scotland, where he met with an opportunity of displaying his undaunted courage and intrepidity, by engaging and beating off two French frigates of 30 guns each, by the assistance of another armed ship, notwithstanding he was severely wounded in the head during the action. This service was immediately and very justly rewarded with the rank of post-captain. He was soon after appointed to the rank of captain on board Commodore Knowles's own ship of 80 guns, with which he returned to England in the year 1748. When hostilities again commenced, he commanded the Dunkirk of 60 guns, in North America; which ship constituted part of the squadron under Admiral Boscawen, and with which he captured a French man of war of superior metal off the coast of Newfoundland; viz. the Alcide of 64 guns. In order to annoy the coast of France, he received, in the year 1758, the command of a small squadron, with which he effected the destruction, at St Malo, of a number of magazines and ships. When he served on board the Essex, Prince Edward, afterwards duke of York, sailed with him, at which time he powerfully contributed to the reduction of the town of Cherbourg. In 1758 his elder brother fell in North America in the service of his king and country, on which event the young commodore succeeded to the family title and estate. In the following year he participated of the honourable victory gained by Sir Edward Hawke over the French fleet under Admiral Conflans. He afterwards served in the Channel, and was captain of the Amelia, the ship of admiral the duke of York. On the restoration of peace, he was nominated one of the lords of the admiralty, and some time afterwards, treasurer of the navy. He was in the year 1770, raised to the rank of rear-admiral of the blue; and chosen commander-in-chief on the Mediterranean station. In 1775, he rose to the station of rear-admiral of the blue; in consequence of which rapid promotions, Lord Hawke paid him the following compliment in the house of peers: "I advised his majesty to make the promotion. I have tried my Lord Howe on important occasions; he never asked me how he was to execute any service, but always went and performed it".

In the summer of 1776, Lord Howe appeared off Massachusetts, as commander-in-chief of his Britannic majesty's fleet acting in North America, and in the capacity of a commissioner for restoring the blessings of an amicable reconciliation. All the provincial governors were made acquainted with his arrival by means of circular letters, expressive also of the full extent of the authority invested in him and his fellow commissioners; but as congress did not deem the conditions which these letters contained to be at all satisfactory, they were ordered to be inserted in all the gazettes for the examination of the people. His powers being thus circumscribed at the very commencement, he could only act in the capacity of a naval commander, in which he aided the operations of the land forces with uncommon skill. It was not to be imagined, however, that much glory could redound to his lordship from such an unequal contest, till the junction of France with America placed the contending parties more upon a level. On the arrival of Admiral D'Estateign in the month of July 1778, off Sandy Hook, Lord Howe was certainly in a very
very critical situation; but by an exertion of uncommon skill and dexterity, the French commander thought it prudent to retire, when he was pursued by Lord Howe to Rhode island, after he obtained a reinforcement under Admiral Byron. The intentions of the enemy were completely counteracted, and the campaign was finally terminated with honour. Here he resigned his command, and came over to England; but in 1782 he was promoted to the rank of admiral of the blue, made a viscount of Great Britain, and chosen commander of the fleet which was sent for the relief of Gibraltar. The combined fleets of France and Spain were about a third superior to that under Lord Howe, who, with 34 sail of the line, appeared off Gibraltar in the month of October, being driven into the Mediterranean by contrary winds. Although he was pursued by the combined fleet, he found means to supply the fortress with provisions. He checked the enemy by a partial action, and notwithstanding he offered to give them battle, it was declined on their part; and he had the satisfaction to execute his commission prior to his return home, in spite of the numerous difficulties which he had to encounter.

He was succeeded first lord of the admiralty on the termination of the war, which he both resigned and resumed by different changes of administration. In the year 1787 he was chosen admiral of the white, and created an earl of Great Britain in the following year. When hostilities were renewed with France in 1793, his lordship accepted the command of the channel fleet, at the express desire of his Britannic majesty, but he had it not in his power to do anything decisive till the summer of 1794. On the ever memorable 1st of June, with a fleet consisting of 35 sail of the line, he gave battle to a French fleet of 26, gaining a most signal victory over the enemy, capturing seven of their ships, one of which was so shattered as to go to the bottom, and several others were, in the language of seamen, very much crippled. His lordship had the good fortune not to lose a ship, and comparatively but a few men, considering the prodigious loss in this respect sustained by the enemy. The gratitude of the nation was suitable to the importance of this naval victory, and it is more than probable that the first of June will never be forgotten. In 1795 he was made first general of marines; but the infirmities which seldom fail to be the concomitants of old age, induced him to resign his naval command in the year 1797, and on his final retreat he was presented with the honours of the Garter.

His great influence as a beloved officer, contributed greatly to stifle a spirit of mutiny and discontent which at this time exhibited alarming symptoms among the seamen of his majesty's fleets. He terminated his brilliant and honourable career on the 3rd of August 1799, in the 73rd year of his age, leaving none but female issue behind him. His lordship's valour, always cool and steady, was consequently of that nature which enables a commander to make the most of his situation; his judgment was sound and penetrating, which prevented him from being easily imposed upon by external appearances; and his seamanship was of the most consummate and masterly kind. It is with pleasure we close this concise account of his lordship's public life by observing, that his country was deeply sensible of the value and importance of his services, a truth fully avised by the honours and preferments which it heaped upon him.

**Howe Island**, a small island of the South sea, discovered by Captain Wallis, called by the inhabitants of the Society islands Mopeha; lies in S. Lat. 16° 45’ and W. Long. 154° 8’.

**Lord Howe's Island**, a small island in the neighbourhood of New South Wales, discovered on February 17th, 1788. S. Lat. 31° 56’ E. Long. 159° 42’. It is of an arched figure, lying from north-west to south-east, the two extremities including a space of about six miles, though, by reason of the curved figure of the island itself, it is near seven in length. It is deeply indented in the middle of the eastern part by a bay named Rosa's bay, and on the opposite and western part has another named Prince William Henry's bay; so that the whole has the appearance of two islands joined together by an isthmus, which in some places is not above half a mile broad. On the southern part of that division which lies most to the northward are two considerable bays, named Gallim's and Hunter's bay; and on the south-western part of the bay are two high mountains, the most southerly named Mount Gower, and the other Mount Lidgard. The convex part of the island lying towards the north-east, and the concave side towards the opposite quarter, is terminated by two points named Point King and Point Philip. No fresh water was found on the island; but it abounds with cabbage-palms, mangrove, and manchineel trees, even up to the summits of the mountains. There are plenty of goats, and a land fowl of a dusky brown colour, with a bill about four inches long, and feet like those of a chicken. These were found to be remarkably fine meat, and were very fat. There are many large pigeons, and the white birds found in Norfolk island were also met with in this place. The bill of this bird is red, and very strong, thick, and sharp pointed. Great numbers of the turtle frequent this island in summer, but go to the northward in winter. These, it was imagined, would prove of great service to the colony at Port Jackson; but, from some cause or other, it appears they have hitherto been disappointed. Plenty of fish were caught by a hook and line. At the distance of about four leagues from Lord Howe's island is a very remarkable and high rock, to which the name of Ball's Pyramid has been given. This island may be approached without danger; but about four miles from the south-west part of the pyramid there is a very dangerous rock, which shows itself above the surface of the water, and appears not to be larger than a boat. The southern part of the island is lined with a sandy beach, which is guarded against the sea by a reef of coral rocks, at the distance of half a mile from the beach, through which there are several small openings for boats; but there is nowhere a greater depth of water within the reef than four feet. By the account of Mr. Watts, who visited this island in his return from Port Jackson, the isthmus which joins the two parts has evidently been overflowed, and the island disjoined, as in the very centre the men saw large beds of coral rocks and great quantities of shells; and on the east, which seems in general to be the weather-side, the sea has thrown up a bank of sand from 25 to 30 feet high, which serves as a barrier against future inundations. The island also ap
pears to have suffered by volcanic eruptions, as great quantities of pomice-stones and other matters of that kind were found upon it. Mr Austin also found the whole reef which shelters the west bay a burn't-up mass. The time he visited the island was that of the incubation of the gamets, of which there were then prodigious numbers, their nests being only hollows made in the sand, there not being any quadrupeds on the island to disturb them. Besides the large pigeons already mentioned, they met with beautiful parrots and parroquets; a new species of the coote, as well as of the tit and magpie. They found likewise a very beautiful small bird of a brown colour with a yellow breast, and yellow on the wing, which seemed to be a species of humming bird. They found also a black bird like a sheepwater, having a hooked bill; and which burrows in the ground. The only insects met with here were the common earth-worm and ants: which last were in great plenty. Besides the trees already mentioned, they found several esculent vegetables, as currant-grass, celery, spinach, endive, and sapphire.

HOWITZ, a kind of mortar, mounted upon a field-carriage like a gun. The difference between a mortar and a howitz is, that the trunnions of the first are at the end, and at the middle in the last. The invention of howitzes is of much later date than mortars, for they really had their origin from them. The constructions of howitzes are as various and uncertain as those of mortars, excepting the chambers, which are all cylindric. They are distinguished by the diameter of the bore; for instance, a ten inch howitz is that of the diameter of which is 10 inches; and so of the smaller ones.

HOWTH, a promontory which forms the northern entrance of the bay of Dublin, having a small village about seven miles north-east from that city in the province of Leinster. It gives title of earl to the family of St Lawrence, who were so called from a victory obtained by them over the Irish on St Lawrence's day 1177, their former name being Tristram; and this place has continued in possession of the family above 650 years. N. Lat. 53. 21. W. Long. 6. 22. The shores off this hill are rocky and precipitous, affording, however, a few harbours for small craft. It was formerly called Ben-chedar, i. e. "the birds promontory;" and celebrated for having Dun Cromium, or the rath or royal palace of Cromium erected on it, he having been chief or king of that district, and memorable for making several successful descents on the coast of Britain against the Romans in the time of Agricola. Howth, though now strait of trees, was formerly covered with venerable oaks, and was a seat of the Druids; one of their altars still remains in a sequestered valley on the east side of the hill. The mansion-house is built in form of a castle, and was probably erected by Sir Armoricus Tristram. Near the house stands the family chapel, and on the western shore are the ruins of St Mary's church, with some ancient monuments of Lord Howth's ancestors. Due west of Howth house are the ruins of St Fenton's church.

HOY, a small vessel chiefly used in coasting, or carrying goods to or from a ship, in a road or bay, where the ordinary lighters cannot be managed with safety or convenience.

It would be very difficult to describe precisely the marks of distinction between this vessel and some others of the same size, which are also rigged in the same manner; because what is called a hoy in one place, would assume the name of a sloop or smack in another; and even the people who navigate these vessels, have, upon examination, very vague ideas of the marks by which they are distinguished from those above mentioned. In Holland the hoy has two masts; in England, it has but one, where the main-sail is sometimes extended by a boom, and sometimes without it. Upon the whole, it may be defined a small vessel, usually rigged as a sloop, and employed for carrying passengers and luggage from one place to another, particularly on the sea-coast.

HOY, one of the Orkney islands, which lie off the north coast of Scotland, is situated between the island of Pomona and the north coast of Caithness, and is separated from the small island of Grimsay by a sound of a mile broad. The whole island is nearly occupied by three large hills, of which that to the north-east rises from a broad base to the height of 1200 feet. Some veins of lead and iron have been discovered in this island. Birch trees of considerable size seem to have been produced on it in former times. But at present its vegetable productions, excepting what are fit for sheep pasture, are extremely limited. A few hardy alpine plants and stunted shrubs include the whole. The number of inhabitants does not exceed 540. The Dwarfie stone is the only monument of antiquity in the island. This is a large mass of sand-stone 32 feet long, 18 broad, and 7½ feet thick above the surface. It is hallowed within, and divided into three apartments, one of which, called the dwarf's bed, is five feet eight long, by two feet broad. It has probably been the retreated of a hermit. Tradition says that it was the habitation of a giant. Waas or Waes, which is often considered as a distinct island, makes part of Hoy. It is distinguished for the excellence of its harbours, particularly the Longhope, one of the finest and safest in Europe. Waes contains 725 inhabitants.

HOYE, a town of Germany in Westphalia, and capital of a county of the same name. It is seated on the river Weser, and is subject to the king of Hanover. E. Long. 9. 0. N. Lat. 53. 5.

HUAHEINE, one of the Society Islands, in the South sea, situated in S. Lat. 16. 43. W. Long. 150. 52. and is about seven or eight leagues in compass. Its surface is hilly and uneven, and it has a safe and convenient harbour. It was first discovered by Captain Cook in 1769. It is divided by a deep inlet into two peninsulas connected by an isthmus, which is entirely overflowed at high water. From the appearance of its hills it may be concluded, that the country has at some period or other been the seat of a volcano. The summit of one of them had much the appearance of a crater, and a blackish spongy earth was seen upon one of its sides, which seemed to be lava; and the rocks and clay every where had a burnt appearance. The island is plentifully supplied with water by many rivulets which descend from the mountains and broken rocks. The inhabitants are nearly as fair as Europeans; and their conduct is bolder than that of the inhabitants of the other Society islands. They are a stout large-made people, some of the tallest being six feet three inches in height: they are extremely indolent, and seem to have...
HUD [ 654 ] HUD

have as little curiosity as fear. The dogs are in great
favour with all their women, " who could not have ca-
sessed them (says Mr Forster) with a more ridiculous
affection if they had been European ladies of fashion."
Here was seen a middle-aged woman, whose breasts
were full of milk, offering them to a little puppy who
had been trained up to suck them. The sight disgusted
those who saw it so much, that they could not for-
bear expressing their dislike to it; but the woman smil-
ed, and told them that she allowed young pigs to do
the same. It appeared afterwards that this woman had
lost her child. Some of the gentlemen were present at
a dramatic entertainment on this island: the piece re-
presented a girl running away from her parents; and
seemed to be levelled at a female passenger who had
come in Captain Cook's ship from Otaheite, and who
happened to be present at the representation. It made
such an impression on the girl, that the gentlemen could
scarcely prevail upon her to see the piece out, or to re-
frain from tears while it was acting. It concluded
with the reception she was supposed to meet with from
her friends, which was made out not to be a very
agreeable one. — These people introduce extemporary
pieces upon occasion; and it is most probable that this
was meant as a satire upon the girl above mentioned,
and to discourage others from acting in the same man-
ner.

HUBERT, Sr, a town of the Netherlands, on the
confines of Liege, with a very fine abbey, where they
bring those that are bit by mad animals to be cured.
E. Long. 5. 25. N. Lat. 50. 1.

HUBNER, John, a learned geographer of
Germany, taught geography at Leipzig and Hamberg with
extraordinary reputation; and died at Hamburg in 1733,
aged 63. His principal work is A Geographical Tre-
atsie, printed at Basil in 1746, in 6 vols. 12mo.

Hudson, Jeffrey. See Dwarf.

Hudson, Henry. Of this eminent naval discov-
er we know nothing prior to the year 1607, when he
was employed by some London merchants in a small
vessel, for exploring a north-east passage to China and
Japan. He set sail on the 1st of May with only ten
men and a boy, and reached as high as 80° of N. Lat.
where being stopp'd by the ice, he returned to England
in the month of September following. In his next
voyage he landed at Nova Zembla, but could make no
farther east, and he returned in August next year.
The Dutch East India Company fitted him out in 1609,
with a crew of 20 men, English and Dutch, and after
in vain attempting to penetrate eastward, he steered for
the American coast, and went as far as Chesapeake bay.
His crew mutinying, he durst not attempt a westerly
passage through Davis's strait, and therefore returned
home.

His knowledge in consequence of these voyages in-
creased his ardour for discovery, and he again made an
offer of his services to the Dutch East India Company,
which were not accepted; and for his last voyage, Sir
Thomas Smith, Sir Dudley Digges, and some of his
friends, fitted him out. On the 17th of April he set
sail, and came in sight of Greenland on the 4th of June.
Sailing westward, he reached the mouth of the strait
which bears his name, through which he advanced
along the coast of Labrador, which he called Nova Brit-
tannia. Here he hoped he had discovered the long-
wished-for passage; but he found he was only in a bay,
in the southern part of which he determined to winter.
After this he fitted out his shallows for farther discov-
eries, but as he had no means of revictualling his ship,
he distributed his last remaining bread with tears in
his eyes, among his people, and returned home. His
mutinous crew entered his cabin by night, tied his
hands behind his back, and set him ashore at the west
end of the straits, with eight of the crew who were most
attached to him. They were never more heard of,
and it is probable they were swallowed up by the
waves. Such was the unfortunate end of this adventu-
rous mariner!

Hudson, William, a celebrated English botanist,
was born at Westmoreland about 1730. He was bound
apprentice to an apothecary in London, whose busi-
ness he took, and proved a friend to the widow and
daughters. It appears from the testimony of Dr Pulte-
ney, that he had a residence in the British museum, but we
are not informed in what capacity. He was also F.R.S.
and died of a paralytic distemper in May 1793. He
possessed a comprehensive knowledge of English plants,
which induced him to undertake an arrangement of
English botany according to the Linnean classification,
which had been previously attempted by Dr
Hill, but the execution was very imperfect. Hudson's
Flora Anglica appeared in 1762, in one volume 8vo,
the Latin preface to which was written by the ingenio-
us Mr Stillingsfield, and received with great applause,
and contributed greatly to the adoption in England of
the sexual system.

The merits of Mr Hudson are thus described by Dr
J. E. Smith. " His memory requires no studied eulo-
gium here, as every page of the present work is an in-
dex to his labours. May the writer of this leave no
more errors behind him as an author, or as a man."
Mr Hudson well understood the insects and shells of
Great Britain, and always meditated a Fauna Britan-
nica. His temper is said to have been gentle, rather
close, but kind to those who gained his esteem.

Hudson's Bay, a large bay of North America, ly-
ing between 51 and 60 degrees of latitude, discovered
in 1610, by Henry Hudson. This intrepid mariner,
in searching after a north-west passage to the South seas,
discovered three straits, through which he hoped to find
out a new way to Asia by America. He had made
two voyages before on the same adventure; the first
in 1607, and the second in 1608. In his third and last,
1610, he entered the straits that lead into this new
mediterranean, the bay known by his name; coasted
a great part of it; and penetrated to eighty degrees
d and a half into the heart of the frozen zone. His
ardour for the discovery now being abated by the diffi-
culties he struggled with in this empire of winter, and
world of frost and snow, he staid there until the ensu-
ing spring, and prepared in the beginning of 1611
to pursue his discoveries; but his crew, who suffered
equal hardships, without the same spirit to support
them, mutinied, seized upon him and seven of those
who were most faithful to him, and committed them
to the fury of the icy seas in an open boat. Hudson
and his companions were either swallowed up by the
waves, or gaining the inhospitable coast were destroyed
by the savages; but the ship and the rest of the men
returned home. Other attempts towards a discovery
were
Hud[655] Hudson's Bay.

were made in 1612 and 1667; and a patent for planting the country, with a charter for a company, was obtained in the year 1670. In 1746 Captain Ellis wintered as far north as 57 degrees and a half; and Captain Christopher attempted farther discoveries in 1753. But besides these and the late voyages, which satisfy us that we must not look for a passage on this side of the latitude 67 degrees north, we are indebted to the Hudson's Bay company for a journey by land; which throws much additional light on this matter, by affording what may be called demonstration, how much farther north, at least in some parts of their voyages, ships must go, before they can pass from one side of America to the other. The northern Indians, who come down to the company's factories to trade, had brought to the knowledge of our people a river, which, on account of much copper being found near it, had obtained the name of the Copper-mine river. The company being desirous of examining into this matter with precision, directed Mr. Hearne, a young gentleman in their service, and who having been brought up for the navy and served in it the war before last, was extremely well qualified for the purpose, to proceed over land under the convey of those Indians, for that river, which he had orders to survey if possible quite down to its exit into the sea; to make observations for fixing the latitudes and longitudes; and to bring home maps and drawings both of it and the countries through which he should pass. Accordingly Mr. Hearne set out from Prince of Wales's fort, on Churchill river, latitude 58° 47' north, and longitude 94° 31' west from Greenwich, on the 7th of December 1770. On the 13th of June he reached the Copper-mine river, and found it all the way, even to its exit into the sea, encumbered with shoals and falls, and emptying itself into it over a dry flat of the shore, the tide being then out, which seemed by the edges of the ice to rise about 12 or 14 feet. This rise, on account of the falls, will carry it but a very small way within the river's mouth, so that the water in it had not the least brackish taste. Mr. Hearne was nevertheless sure of the place it emptied itself into being the sea, or a branch of it, by the quantity of whale-bone and seal skins which the Esquimaux had at their tents, and also by the number of seals which he saw upon the ice. The sea at the river's mouth was full of islands and shoals as far as he could see by the assistance of a pocket telescope; and the ice was not yet (July 17th) broken up, but thawed away only for about three quarters of a mile from the shore, and for a little way round the islands and shoals which lay off the river's mouth. But he had the most extensive view of the sea when he was about eight miles up the river; from which station the extreme parts of it bore north-west by west and north-east. By the time Mr. Hearne had finished his survey of the river, which was about one o'clock in the morning on the 18th, there came on a very thick fog and drizzling rain; and as he had found the river and sea in every respect unlikely to be of any utility, he thought it unnecessary to wait for fair weather to determine the latitude more exactly by observation; but by the extraordinary care he took in observing the courses and distances, walking from Congecathwachanga, where he had two very good observations, he thinks the latitude may be depended on with 20' at the utmost. It appears from the map which Mr. Hearne constructed of this singular journey, that the mouth of the Copper-mine river lies in latitude 72° north, and longitude 23° west from Greenwich; that is, about 115° west of Greenwich. Mr. Hearne's journey back from the Copper-mine river to Churchill lasted till June 30th 1772; so that he was absent almost a year and seven months. The unparalleled hardships he suffered, and the essential service he performed, met with a suitable reward from his masters, and he was made governor of Prince of Wales's fort on Churchill river. The recent voyage of Captain Parry (1820) has shown that a sea does exist towards the parts where Hearne observed it, but whether this sea communicates directly with Hudson's bay remains to be discovered.

The country lying round Hudson's bay is called New Britain, or the country of the Esquimaux; comprehending Labrador, now North and South Wales. The entrance of the bay from the ocean, after leaving to the north Cape Farewell and Davis's straits, is between Resolution isles on the north, and Button's isles on the Labrador coast to the south, forming the eastern extremity of the straits distinguished by the name of its great discoverer. The coasts are very high, rocky, and rugged at top; in some places precipitous, but sometimes exhibit large beaches. The isles of Salisbury, Nottingham, and Digges, are also very lofty and naked. The depth of water in the middle of the bay is a hundred and forty fathoms. From Cape Churchill to the south end of the bay are regular soundings; near the shore shallow, with muddy or sandy bottom. To the north of Churchill the soundings are irregular, the bottom rocky, and in some parts the rocks appear above the surface at low water. From Moose river or the bottom of the bay to Cape Churchill the land is flat, marshy, and wooded with pines, birch, larch, and willows. From Cape Churchill to Wager's Water the coasts are all high and rocky to the very sea, and woodless, except the mouths of Pockerekeko and Seal rivers. The hills on their back are naked, nor are there any trees for a great distance inland.

The mouths of all the rivers are filled with shoals, except that of Churchill, in which the largest ships may lie; but ten miles higher, the channel is obstructed with land banks; and all these rivers, as far as has been navigated, are full of rapids and cataracts from ten to sixty feet perpendicular. Down these rivers the Indian traders find a quick passage; but their return is a labour of many months. As far inland as the company have settlements, which is six hundred miles to the west, at a place called Hudson House, lat. 53° long. 106. 27 from London, is a flat country: nor is it known how far to the eastward the great chain seen by our navigators from the Pacific ocean branches off.

The climate even about Haye's river, in only lat. 57°, is during winter excessively cold. The snows begin to fall in October, and continue falling by intervals the whole winter; and when the frost is most rigorous, in form of the finest sand. The ice on the rivers is eight feet thick. Port-wine freezes into a solid mass; brandy coagulates. The very breath fell on the blankets of the beds in the form of a hoar frost, and the bed-clothes often were found frozen to the wall.
The sun rises in the shortest day at five minutes past nine, and sets five minutes before three. In the longest day the sun rises at three, and sets about nine. The ice begins to disappear in May, and hot weather commences about the middle of June, which at times is so violent as to scourch the face of the hunters. Thunder is not frequent, but very violent. But there must be great difference of heat and cold in this vast extent, which reaches from lat. 50° 40' to lat. 63° north. During winter the firmament is not without its beauties. Mock suns and halos are not uncommon; they are very bright, and richly tinged with all the colours of the rainbow. The sun rises and sets with a large cone of yellowish light. The night is enlivened with the Aurora Borealis, which spreads a thousand different lights and colours over the whole concave of the sky, not to be defaced even by the splendour of the full moon; and the stars are of a fiery redness.

The eastern boundary of the bay is Terra di Labrador; the northern point has a straight coast facing the bay, guarded with a line of islands innumerable. A vast bay, called the Archiwinipy sea, lies within it, and opens into Hudson's bay by means of Gulf Hazard, through which the beluga whales dart in great numbers. Here the company had a settlement for the sake of the fishery, and for trading with the Esquimaux; but deserted it as unprofitable about the year 1758 or 1759. The eastern coast is barren past the efforts of cultivation. The surface is everywhere uneven, and covered with masses of stone of an amazing size. It is a country of fruitless valleys and frigant mountains, some of an astonishing height: the first watered by a chain of lakes, formed not from springs but rain and snow, so chilly as to be productive of only a few small trout. The mountains have here and there a blighted shrub, or a little moss. The valleys are full of crooked stunted trees, pines, fir, birch, and cedars, or rather a species of juniper. In lat. 60° on this coast, vegetation ceases. The whole shore, like that on the west, is faced with islands at some distance from land. The inhabitants among the mountains are Indians; along the coast, Esquimaux. The dogs of the former are very small; of the latter large, and headed like a fox. Notwithstanding they have reindeer, they never train them for the sledge; but apply the dogs to that use. Walruses visit a place called Nucluvink, in lat. 60° during winter; from thence the natives purchase the teeth with which they head their darts. Davis suspected that he had found a passage on this coast in 1586, to the Western ocean; but it proves no more than a deep bay.

The laudable zeal of the Moravian clergy induced them to send, in the year 1752, missionaries from Greenland to his country. They fixed on Nisbet's harbour for their settlement; but the first party was partly killed, partly driven away. In 1764, under the protection of our government, another attempt was made. The missionaries were well received by the Esquimaux, and the mission goes on with success.

The animals of these countries are, the moose, deer, stag, reindeer, bear, buffaloes, wolves, foxes, beavers, otters, lynxes, martins, squirrels, ermines, wild cats, and hares. The reindeer pass in vast herds towards the north in October, seeking the extreme cold. The male polar bears rove out at sea, on the floating ice, most of the winter, and till June: the females lie concealed in the woods, or beneath the banks of rivers till March, when they come abroad with their twin cubs, and bend their course to the sea in search of their consorts. Several are killed in their passage: and those which are wounded show vast fury, roar hideously, and bite and throw up into the air even their own progeny. The females and the young, when not interrupted, continue their way to sea. In June the males return to shore, and by August are joined by their consorts, with the cubs, by that time of a considerable size. The feathered kind are, gese, bustarde, ducks, partridges, and all manner of wild-fowls. Indeed multitudes of birds retire to this remote country, to Labrador and Newfoundland, from places most remotely south, perhaps from the Antilles; and some even of the most delicate little species. Most of them, with numbers of aquatic fowls, are seen returning southward with their young broods to more favourable climates. The seasons, in some respects, regulate their months by the appearance of birds; and have their goose month from the vernal appearance of gese from the south. All the gese kind, raven, cinereous crows, titmouse, and Lapland finch, brave the severest winter; and several of the falcons and owls seek shelter in the woods. Of fish, there are whales, morses, seals, cot-fish, and a white"fish preferable to herrings; and in their rivers and fresh waters, pike, perch, carp, and trout.

All the quadrupeds of these countries are clothed with a close, soft, warm fur. In summer there is here, as in other places, a variety in the colours of the several animals; when that season is over, which holds only for three months, they all assume the livery of winter, and every sort of beasts, and most of their fowls, are of the colour of the snow; every thing animate and inanimate is white. This is a surprising phenomenon. But what is yet more surprising, and what is indeed one of the most striking things, that draw the most inattentive to an admiration of the wisdom and goodness of Providence, is, that the dogs and cats from Britain that have been carried into Hudson's bay, on the approach of winter have entirely changed their appearance, and acquired a much longer, softer, and thicker coat of hair than they had originally.

Hudson's Bay Company. See Company.

Hudson's River, a large river of North America which rises on the coast of Lake Ontario, and running by Albany, and on the back of the south part of New England through part of New York, falls into the bay of the sea beyond the west end of Long-Island, and below the town of New York.

Hudsonia, a genus of plants belonging to the dodecandria class. See Botany Index.

Hue and Cry, in Law, the pursuit of a person who has committed felony on the highway.—Of this custom, which is of British origin, the following deduction is given by Mr Whitaker. "When it was requisite for the Britons to call out their warriors into the field, they used a method that was particularly marked by its expeditiousness and decisiveness, and remains partially amongst us to this moment. They raised a cry, which was immediately caught by others, and in an instant transmitted from mouth to mouth through all the region. And, as the notice passed along
but the new volcanic isle, twelve miles off the point of Reickenes, emitting fire and smoke, proves that the subterraneous fires and waters extend to that space: for those awful effects arise from the united fury of these two elements.

HUESCA, an ancient and considerable town of Spain, in the kingdom of Arragon, with a bishop’s see and a university. It is seated on the Issuela, in a soil producing excellent wine, in W. Long. 1. 2. N. Lat. 42. 18.

HUESCAR, or GUESCAR, a town of Spain, in the kingdom of Granada, seated on a plain, in W. Long. 2. 20. N. Lat. 37. 33.

HUESNE, or HUENA, a small island in the Baltic sea, in the Sound, where was the famous observatory of Tycho Brahé. F. Long. 12. 38. N. Lat. 55. 54.

HUET, PETER DANIEL, a very learned French writer, born at Caen in Normandy, on the 8th of February 1630. He discovered, from his infancy, a great inclination to the study of polite literature and the sciences; and at first applied himself to the law; but Des Cartes’s principles, and Bochart’s sacred geography, made him change his studies for those of philosophy, mathematics, the languages, and antiquities. His admiration for Bochart made him desirous of knowing him. He contracted a very strict friendship with him, and accompanied that learned man to Sweden. Here Christina would have engaged him in her service; but he, sensible of her inconstant temper, returned to France. All he brought with him was a copy of a MS. of Origen, which he transcribed at Stockholm. He refused several offers from Christina after she abdicated and went to Rome, and from Gustavus her successor.

In 1670, Mr Bossuet being appointed by the king preceptor to the dauphin, his majesty chose Mr Huet for his colleague, with the title of sub-preceptor to the prince. It was he that formed the plan of the commentaries in Usum Delphini, and directed the execution. His sentiments of piety determined him to enter into holy orders, which he did at the age of 46. Soon after this, he was presented by the king to the abbey of Annay; and in 1685 was nominated to the bishopric of Soissons, which he changed for the see of Avranches. After governing that diocese ten years, he resigned, and was made abbot of Fontenay near Caen. His love to his native place determined him to fix there. But lawsuits coming upon him, he retired to Paris, and lodged among the Jesuits in the Maison Professe, whom he had made heirs to his library. A severe distemper weakened his body extremely, but not the vivacity of his genius: he wrote his own life in a very elegant style: and died in 1721, aged 91. He was a man of very agreeable conversation; and of great probity, as well as immense erudition.—The following are the titles of his principal works. 1. De claris interpretibus, et de optimo genere interpretandi. 2. An edition of Origen’s Commentaries on the Holy Scriptures, in Greek and Latin. 3. A Treatise on the Origine of the Romans. 4. Demonstratio evangeltic. folio. 5. Questions, Admetana de concordantia et fals. 6. Of the Situation of the terrestrial Paradise, in French. 7. A History of the Commerce and Navigation of the Ancients, which has been translated into English. 8. Commentarius de rebus ad eum pertinentibus. 9. Huicotta. 10. Latin and Greek verses, &c.
HUGLY or Hoogly, a town of Asia, in the Kingdom of Bengal, seated on the most westerly branch of the river Ganges. It is now nearly in ruins, but was in the beginning of the 18th century a place of large extent, reaching about two miles along the riverside, and had a great trade in all the commodities of that country; affording rich cargoes for 50 or 60 ships annually, besides what was brought in carriages to the neighbouring towns. Salt petre was brought thither from Patna in vessels above 50 yards long and five broad. The inhabitants are chiefly Indians; but there are also Portuguese, English, and other Europeans. E. Long. 88. 28. N. Lat. 32. 30.

HUGO CAPET, chief of the third race of the kings of France, being count of Paris and Orleans; he was raised to the throne for his military valor and public virtues in 987. See FRANCE, No. 38.

HUGONIA, a genus of plants belonging to the monadelphia class; and in the natural method ranking with those of which the order is doubtful. See BOTANY INDEX.

HUGUENOTS, an appellation given by way of contempt to the reformed or Protestant Calvinists of France.

The name had its first rise in 1560; but authors are not agreed as to the origin and occasion thereof; but one of the two following seems to be the least forced derivation.

One of the gates of the city of Tours is called the gate Fourgon, by corruption from feu Hugon, i.e. the late Hugon. This Hugon was once count of Tours according to Egginhardus in his life of Charles the Great, and to some other historians. He was it seems a very wicked man, who by his fierce and cruel temper made himself dreadful; so that after his death he was supposed to walk about in the night-time, beating all those he met with; this tradition the judicious Thuanus has not scrupled to mention in his history. Davila and other historians pretend, that the nickname of Huguenots was first given to the French Protestants, because they used to meet in the night-time in subterraneous vaults near this gate of Hugon; and what seems to countenance this opinion is, that they were first called by the name of Huguenots at this city of Tours.

Others assign a more illustrous origin to that name; and say that the legeners gave it to the reformed, because they were for keeping the crown upon the head of the line descended from Hugh Capet; whereas they were for giving it to the house of Guise, as descended from Charles the Great.

Others again derive it from a French and faulty pronunciation of the German word edignossen, signifying confederates, and originally applied to that valiant part of the city of Geneva, which entered into an alliance with the Swiss cantons, in order to maintain their liberties against the tyrannical attempts of Charles III, Duke of Savoy.

These confederates were called Eignote, whence Huguenots.

The persecution which they underwent has scarce its parallel in the history of religion: though they obtained a peace from Henry III. in 1576, it was only of short continuance; and their sufferings, mitigated by the famous edict of Nantes, granted to them in 1598 by Henry IV. were again renewed, after the revocation Henry of that edict, by Louis XIV. in 1685.

HULK, an old ship of war, fitted with an apparatus to sink or take out the masts of his majesty's ships, as occasion requires.

The mast of this vessel is extremely high, and with proper strengthening by shrouds and stays, in order to secure what are called the sheers, which serve, as the arm of a crane, to hoist out or in the masts of any ship lying alongside. The sheers are composed of several long masts, whose heels rest upon the side of the hulk, and having their heads declining outward from the perpendicular so as to hang over the vessel whose masts are to be fixed or displaced. The tackle, which extend from the head of the mast to the sheer-heads, are intended to pull in the latter towards the masthead, particularly when they are charged with the weight of a mast after it is raised out of any ship, which is performed by strong tackles depending from the sheer-heads. The effort of these tackles is produced by two capstans, fixed on the deck for this purpose.

HULK is also a name bestowed on any old vessel laid by as unfit for further service. It is probably derived from the word, or vessels of burthen, of the ancient Greeks.

HULL, in the sea-language, is the main body of a ship, without either masts, yards, sails, or rigging. Thus to strike a hulk in a storm, is to take in her sails, and to lash the helm on the lee-side of the ship; and to hulk, or lie a-hull, is said of a ship whose sails are thus taken in, and helm lashed a-lee.

HULL, a river in Yorkshire, which falls into the Humber at Kingston upon Hull. See KINGSTON.

HUMAN, in general, is an appellation given to whatever relates to mankind: thus we say, the human soul, human body, human laws, &c.

HUMANITY, the peculiar nature of man, whereby he is distinguished from all other beings.

HUMANITIES, the plural, signify grammar, rhetoric, and poetry, known by the name of litterae humaniores; for teaching of which, there are professors in the universities of Scotland, called humanists.

HUMBER, a river formed by the Trent, Dee, Derwent, and several other streams. By means of inland navigation, it has a communication with the rivers Mersey, Dee, Ribble, Severn, Thames, Avon, &c., which navigation, including its windings, extends above 700 miles, in the counties of Lincoln, Nottingham, York, Lancaster, Westmoreland, Chester, Stafford, Warwick, Leicester, Oxford, Worcester. It divides Yorkshire from Lincolnshire, and falls into the German ocean near Holderness.

HUME, DAVID, Esq. a celebrated philosopher and historian, was born in the south part of Scotland on the 26th of April O.S. in the year 1711. Being the younger son of a country gentleman of good family, but no great fortune, his patrimony was of consequence insufficient to support him. For this reason he was destined for the bar, and passed through his academical courses in the university of Edinburgh; but being more inclined to studies of a different nature, he never put on the gown, nor even took the introductory steps for that purpose. The writings of Locke and Berkeley had directed the attention of the generality of learned men towards
which, however, he since disclaimed being the sole author. In 1756, the second volume of the History of the Stuarts was published, two years after the appearance of the first. This was better received, and helped to retrieve the character of the former volume. Three years after, his History of the House of Tudor made its appearance; which was almost as ill received as the History of the Stuarts had been, the reign of Elizabeth being particularly obnoxious. The author, however, had now learned to despise popular clamours; and continued to finish at his leisure the more early part of the English history, which was published in 1761, and was received with tolerable success.

Mr. Home being now turned of fifty, and having obtained by the sale of his books a competent and independent fortune, retired into his native country of Scotland, determined never more to set his foot out of it. From this resolution, however, he was diverted by the earl of Hertford, whom he attended as secretary on his embassy to Paris in 1753. In 1765, the earl being appointed lord-lieutenant of Ireland, Mr. Home was intrusted with the sole management of the business of the state till the arrival of the duke of Richmond towards the latter end of the year. In 1767, he returned to Edinburgh, with a much larger income, procured to him by the earl of Hertford, than he formerly had; and now formed the same design he had formerly entertained, namely, of burying himself in his philosophical retreat. In this, however, he was again disappointed, by receiving an invitation from General Conway to be under secretary; and this invitation he was prevented from declining, both by the character of the person, and his connexions with Lord Hertford. In 1769 he returned to Edinburgh, possessed of 1000l. a-year, healthy, and though somewhat stricken in years, yet having a prospect of long enjoying his ease, and of seeing the increase of his reputation. Of his last illness and character, he himself gives the following account. In spring 1775, I was struck with a disorder in my bowels; which at first gave me no alarm, but has since, as I apprehend it, become mortal and incurable. I now reekon upon a speedy dissolution. I have suffered very little pain from my disorder; and what is more strange, have notwithstanding the great decline of my person, never suffered a moment's abatement of my spirits; inno much, that were I to name the period of my life which I should most choose to pass over again, I might be tempted to point to this latter period. I possess the same ardour as ever in study, and the same anxiety to compare. I consider, besides, that a man of my age, five, by dying, cuts off only a few years of infirmities; and though I see many symptoms of my literary reputation breaking out at last with additional lustre, I know that I could have but few years to enjoy it. It is difficult to be more detached from life than I am at present.

"To conclude, historically, with my own character; I am, or rather was (for that is the style I must now use in speaking of myself, which emboldens me the more to speak my sentiments)—I was, I say, a man of mild dispositions, of command of temper, of an open, social, and cheerful humour, capable of attachment, but little susceptible of enmity, and of great moderation
Humiliation, in Ethics, is a virtue consisting in the moderate value which a person puts upon himself, and every thing relating to him. Or, more particularly, it consists in not attributing to ourselves any excellence or good which we have not; in not overrating any thing which we have or do; in not taking an immoderate delight in one's self; in not assuming more of the praise of a quality or action than belongs to us; and in a lowly sense and acknowledgment of our imperfections, errors, and sins. This virtue expresses itself in the modesty of our appearance, of our pursuits, and of our behaviour towards other men. It is distinguished from affectation, bashfulness, and meanness.

Humming-Bird. See Trochilus, Ornithology Index.

Humour, from the Latin humor, in its original signification, stands for moisture in general; from whence it has been restrained to signify the moisture of animal bodies, or those fluids which circulate through them.

It is distinguished from moisture in general in this, that humours properly express the fluids of the body; when in a vitiated state, it would not be improper to say, that the fluids of such a person's body were full of humours.

The only fluids of the body, which, in their natural and healthful state, are called humours, are those in the eye; we talk of the aconse humour, the crystalline humour, without meaning anything that is merid or diseased: yet when we say in general, that such a person has got a humour in his eye, we understand it in the usual sense of a vitiated fluid.

As the temper of the mind is supposed to depend upon the state of the fluids in the body, humour has come to be synonymous with temper and disposition. A person's humour, however, is different from his disposition, in this, that humour seems to be the disease of a disposition: it would be proper to say that persons of a serious temper or disposition of mind, were subject to lancinolus humours; that those of a delicate and tender disposition, were subject to peculiar humours.

Humour may be agreeable or disagreeable; but it is still humour; something that is whimsical, capricious, and not to be depended upon. An ill-natured man may have fits of good-humour, which seem to come upon him accidentally, without any regard to the common moral causes of happiness or misery.

A fit of cheerfulness constitutes the whole of good-humour; and a man who has many such fits, is a good-humoured man: yet he may not be good-natured; which is a character that supposes something more constant, equable, and uniform, than what is requisite to constitute good humour.

Humour is often made use of to express the quality of the imagination, which bears a considerable resemblance to wit.

Wit expresses something that is more designed, concerted, regular, and artificial; humour, something that is more wild, loose, extravagant, and fantastical; something which comes upon a man by fits, which he can neither command nor restrain, and which is not perfectly consistent with true politeness. Humour, it has been
HUMPHREY, DR LAWRENCE, a very learned English divine in the 16th century, who, during the persecution under Queen Mary, retired with other Protestant refugees to Zürich. He returned on the accession of Queen Elizabeth; and was made president of Magdalene college, Oxford, dean of Gloucester, and then dean of Winchester. He was a great and general scholar, an able linguist, and a deep divine; and published,
1. De religionibus conservatis et reformatione, deque primatus regnum. 2. De ratione interpretandi auctores. 3. Optimae; sive de nobilitate, ejusque origine. 4. Sermones, and other works. He died in 1590.

HUMULUS, the hop, a genus of plants belonging to the dioecia class; and in the natural method ranking under the 53rd order, Scabridae. For the culture and use of hops, see Hop.

HUNDRED, HUNDREDUM, or CENTURIA, a part or division of a county; which was anciently so called from its containing an hundred families, or from its furnishing an hundred able men for the king's wars. After King Alfred's dividing this kingdom into counties, and giving the government of each county to a sheriff, these counties were divided into hundreds, of which the constable was the chief officer. The grants of hundreds were at first made by the king to particular persons: but they are not now held by grant or prescription, their jurisdiction being devolved to the county-court; a few of them only excepted, that have been by privilege annexed to the crown, or granted to some great subjects, and still remain in the nature of a franchise.

Hundred Court. This is only a larger Court Baron, being held for all the inhabitants of a particular hundred instead of a manor. The free suitors are here also the judges, and the steward the register, as in the case of a court-baron. It is likewise no court of record; resembling the former in all points, except that in point of territory it is of a greater jurisdiction. This is said by Sir Edward Coke to have been derived out of the county-court for the ease of the people, that they might have justice done them at their own doors, without any charge or loss of time: but its constitution was probably coeval with that of hundreds themselves, which were formerly observed to have been introduced though not invented by Alfred, being derived from the policy of the ancient Germans. The centeni, we may remember, were the principal inhabitants of a district composed of different villages, originally in number an hundred, but afterwards only called by that name; and who probably gave the same denomination to the district out of which they were chosen. Caesar speaks positively of the judicial power exercised in their hundred-courts and courts-baron.

"Principes regionum, atque poporum," (which we may fairly construe, the lords of hundreds and manors) inter suas jus dicunt, controversiae minuant." And Tacitus, who had examined their constitution still more attentively, informs us not only of the authority of the lords, but of that of the centeni, the hundreders, or jury; who were taken out of the common freeholders, and had themselves a share in the determination. "Eliguntur in concilia et principes, qui jura per pagos virosque reddunt: centeni singulis, ex plebe comites, consilium simul et auctoritas, adsunt." This hundred-court was denominated hereda in the Gothic constitution. But this court, as causes are equally liable to removal from hence as from the common court-baron, and by the same writs, and may also be reviewed by writ of false judgment, is therefore fallen into equal disuse with regard to the trial of actions.

HUNGARY, a kingdom of Europe, the greatest part of which was anciently called Pannonia. It had the name of Hungary from the Hunns, a Scythian or Tartar nation, who subdued it in the ninth century. It lies between the 17th and 25th degrees of east long., and between the 44th and 49th degrees of north lat. being bounded to the north by the Carpathian mountains, which separate it from Poland; to the south by Servia, and the river Drave, which separates it from Sclavonia; to the west by Moravia, Austria, and Stiria; and to the east by Wallachia and Transylvania. It is about 380 miles in length, and 300 in breadth; and is divided into the Upper and Lower Hungary, the former being that part which lies towards the east, and the latter that which lies towards the west.

The northern parts of the kingdom are mountainous and barren, but healthy; the southern, on the contrary, are level, and exceeding fruitful, but not very healthy. The country along the Danube, from Presburg to Belgrade, for upwards of 200 miles, is one continued plain, and no soil can be more fertile; but the air, by reason of the many swamps and morasses, is not so wholesome as on the higher and drier grounds. Here are mines of gold, silver, copper, iron, lead, quicksilver, cinnabar, antimony, yellow orpiment, sulphur, vitriol, marcasite, salt native and fuchsites, salt-petre, magnesia, asbestos or stone-faces, marble of several colours, alabaster, with diamonds, and all sorts of precious stones. Corn is in such plenty, that it is sold for one-sixth of its price in England. Their grapes are large and luscious; and their wines preferred to any in Europe. They have vast numbers of cattle and horses, the latter mostly mouse-coloured, with buffaloes, deer, wild fowl, game, and fish, and many species of wild-beasts, particularly chamois goats, bears, and lynxes. Of vegetables, besides vines, and the common sorts, here are tobacco, saffron, buck-wheat, millet, melons, and chestnuts. Here also are excellent warm baths, and springs of various kinds and qualities. The chief mountains of Hungary are the Crapack or Carpathian, which is the general name for all those that separate this kingdom from Poland, Moravia, Silesia, and some part of Austria. The sides of most of them are covered with wood, and their tops with snow. The chief rivers are the Danube, the Drave, the Save, the Wag or Wang, the Gran, the Temes, the Raab, and the Thiess, all well stocked with fish. There are several lakes among the Carpathian mountains, and some also in the lowlands.
The inhabitants are a mixture of the descendants of the ancient Huns, Slavonians, Camani, Germans, Wallachians, Greeks, Jews, Turks, and a wandering people called Zigeuns, said to be of uncertain origin, but probably the same as those we call gypsies. The Hungarians are said to be of a sanguine choleric temper, and somewhat fierce, cruel, proud, and revengeful. They have been always reputed good soldiers, being much more inclined to arms, martial exercises, and hunting, than to arts, learning, trade, or agriculture. The nobility affect great pomp and magnificence, and are much addicted to feasting and carousing. The men in general are strong and well proportioned. They shave their beards, but leave whiskers on the upper lip; wearing fur caps on their heads, a close-bodied coat girt with a sash, with a short cloak or mantle over all, so contrived as to be buckled under the arm, and leave the right hand at liberty. Their horse is called Aussera, and their foot heyduck. The former wear a broadsword or scimitar, and carry a hatchet or battle-axe. Their horses are lean, but not so large as the German horses, and therefore they stand up on their short stirrups when they strike. The heydukes usually wear feathers in their caps, according to the number of the enemies they pretend to have killed. Both horse and foot are an excellent militia, very good at a pursuit, or ravaging and plundering a country, but not equal to regular troops in a pitched battle. The women, when they go abroad, wear short cloaks and a veil.

There are four languages spoken in this country, viz. the Hungarian, which, like the people, is of Scythian origin, and has little or no affinity with any European tongue; the German, Slavonian, Wallachian, and Latin. The last is spoken, not only by the better sort, but also by the common people, though very corruptly. The people called Zigeuns have also a particular jargon.—Christianity was planted in Hungary in the ninth and tenth centuries. In the sixteenth the reformation made a great progress in it; and at present the Roman Catholic religion is predominant, the Protestants enjoying only a bare toleration.

As to the traffic of this country, it is chiefly in the hands of the Greeks and Jews. The exports consist chiefly of wine, horses, cattle, metals, minerals, saffron, wool, and leather. Hungary, in particular, furnishes Austria, and other countries west of it, with vast droves of cattle; as well as a variety of excellent wines, of which those of Tokay are reckoned the best. The principal manufactures are those of copper, brass, iron, and other hard wares. Great quantities of brass and iron are exported, wrought and unwrought.

Hungary at first, like most other countries, was divided into many little principalities and states, which at length were united under one head, who had the title of duke. The last of these dukes was Georg; who, becoming a proselyte to Christianity, was baptised; after which he resigned the government to his son Stephen, who took the title of king, anno 1000. But as the throne was filled by election, though generally out of the same family, the disposal of the crown was disputed between the Turkish and German emperors for near two years: but after the year 1527, when Ferdinand, archduke of Austria, was advanced to the throne, the Austrians found means to influence the elections in such a manner, as to keep the crown in their family till 1687, when it was settled hereditarily on their heirs male; and now, in consequence of an act made by the diet at Pressburg in 1723, in case of the failure of heirs male, it is to descend to females. The states of the kingdom consist of the prelacies, the barons, the gentry, and the royal towns. To the first class belong two archbishops, about a dozen bishops, near as many abbots and provosts, with the Pauline and Premonstratensian Jesuits. To the second, the stadtholder or palatine, who represents the king; the court-judge; the ban or viceroy of Dalmatia, Croatia, and Slavonia; the stadtholder of Transylvania; the great treasurer, the great cup-bearer, the steward of the House of the, the lord chamberlain, the captain of the yeomen of the guard, and the grand marshal of the courts, who are styled the great barons. To the third class belong the gentry, some of whom have noble manners, and others only the privileges of nobles. To the fourth class belong the royal free cities, which are not subject to the courts, but hold immediately of the king. The gentry also, who hold of the archbishops and bishops, have the same privileges as the Hungarian nobility. The common people are vassals to the lords on whose lands they live, whether these lands belong to the crown, the clergy, nobility or gentry.

Hungary contained eight millions of inhabitants in 1805, including 13,728 males, and 102,495 clergy. Of these 4,647,832 were Catholics, 1,161,138 were of the Greek church, 1,002,490 were Calvinists or Reformed, and 624,776 were Lutherans. The Jews amounted to 72,128. The whole surface of the country amounts to 88,000 square miles, or 35,000,000 of jochs (each equal to 1/2 English acres). Of this soil only 23,000,000 acres are computed to be in cultivation or under wood. The total exports in 1802 amounted to 24,000,000 of florins, or about 2,400,000L sterling. The imports were about 1,800,000L. The revenue is reckoned to be about two millions sterling, of which only a very small portion from its way to Vienna. The military force of Hungary has long been the chief support of the Austrian monarchy. It consists of 13 complete regiments of infantry of 387 men each, and 13 complete hussar regiments of 1098 men each, making together 63,364 regulars. But in times of imminent danger this force is increased by a large body of irregulars. Pest, the principal town of Hungary, contained 41,882 inhabitants in 1817. See Hungary, Supplement.

Hungary-Water, a distilled water prepared from the tops of flowers of rosemary; so denominated from a queen of Hungary, for whose use it was first made. See Pharmacy.

Hunger, an uneasy sensation occasioned by long abstinence from food when the body is in a healthy state.—See Abstinence; Fasting, and Anatomy, No. 103.

The following useful observations upon hunger or famine are extracted from a paper by Dr Percival in the second volume of the Manchester Transactions.

In famine, life may be protracted (the doctor observes) with less pain and misery, by a moderate allowance of water. For the diminution and purgation of the humours are obviated by such dilution, the small vessels are kept permeable, and the lungs are furnished with that moisture which is essential
Hunger, central to the performance of their functions. Fontana, a writer of respectable authority in the estimation of Morgagni, relates the history of a woman who obstinately refused to take any sustenance, except twice, during the space of 50 days, at the end of which period she died. But he adds, that she used water by way of drink, though in small quantity. Redi, who made many experiments (cruel and unjustifiable in my opinion), to ascertain the effects of fasting on fowls, observed, that those were able to support life beyond the ninth day to whom drink was denied; whereas one indulged with water lived more than 20 days.

Hippocrates has observed, that children are more affected by abstinence than young persons; these, more than the middle-aged; and the middle-aged, more than old men. The power to endure famine, however, must depend less upon the state of health and strength than on the age of the sufferer. There are also particular constitutions which do not suffer much pain from the calls of hunger. Dr. Paracelsus was informed by a young physician from Geneva, that when he was a student at Montpelier, he fasted three nights and four days, with no other refreshment than a pint of water daily. His hunger was keen, but never painful, during the first and second days of his abstinence; and the two following days, he perceived only a faintness when he attempted either bodily or mental exertion: A sense of coldness was diffused over his whole frame, but more particularly affected the extremities: His mind was in a very unusual state of passionality; and he experienced a great tendency to tears whenever he recollected the circumstance which had been the occasion of his fasting. During the whole period, the alvine excrections were suppressed, but not those by the kidneys: and at the close of it, his skin became tinged with a shade of yellow. The first food he took was real broth; which had something of an intoxicating effect, producing a glow of warmth, and raising his spirits, so as to render him ashamed of his despondency. Perhaps in the case of Sextius Basulus, as recorded in the commentaries of Caesar, the extraordinary courage and prowess which he suddenly exerted, might be aided by the exhilarating effect of sustenance, which, under such circumstances, it is probable he would no longer decline. The fact, however, evinces, that neither his sickness nor the sensations of hunger had been so violent as much to impair his strength of body or vigour of mind. Pomponius Atticus, the celebrated friend of Cicero, who put a voluntary end to his life in the 77th year of his age by refusing all food, appears to have experienced ease from his disorder, rather than any acute sufferings by famine. "Sic cum biduo cibo se abstuinisset, subito febris decessit, leviore morbus esse except: tamen, propositum nihil secus perigit. Itaque die quinto, postquam id consilium inebrit, decessit." (Corn. Nepos in Vit. Pomp. Attic.) From the former circumstance it has been conjectured, that he did not wholly deny himself the use of water, or of some other diluent. But though a few examples of this kind may be adduced, we have the evidence of numerous melancholy facts to show, that the pressure of want is agonizing to the human frame. "I have talked (says an ingenious writer) with a captain of a ship, who was one of six that endured it in its extremity, and who was the only person that had not lost his senses when they received accidental relief. He assured me his pains at first were so great, as to be often tempted to eat a part of one of the men who died, and which the rest of his crew actually for some time lived upon. He said, that during the continuance of this paroxysm, he found his pains insupportable, and was desirous at one time of anticipating that death which he thought inevitable: But his pains, he said, gradually decreased after the sixth day (for they had water in the ship, which kept them alive so long), and then he was in a state rather of languor than desire; nor did he much wish for food, except when he saw others eating; and that for a while revived his appetite, though with diminished importunity. The latter part of the time, when his health was almost destroyed, a thousand strange images rose upon his mind; and every one of his senses began to bring him wrong information. The most fragrant perfumes appeared to him to have a fetid smell; and every thing he looked at took a greenish hue, and sometimes a yellow. When he was presented with food by the ship's company that took him and his men up, four of whom died shortly after, he could not help looking upon it with loathing instead of desire; and it was not till after four days that his stomach was brought to its natural tone; when the violence of his appetite returned with a sort of canine engerness."

To those who by their occupations are exposed to such dreadful calamities, it is of serious importance to be instructed in the means of alleviating them. The American Indians are said to use a composition of the juice of tobacco, and the shells of snails, cockles, and oysters cañímed, whenever they undertake a long journey, and are likely to be destitute of provisions. It is probable the shells are not burnt into quicklime, but only so as to destroy their tenacity, and to render them fit for levigation. The mass is dried, and formed into pills, of a proper size to be held between the gum and lip, which, being gradually dissolved and swallowed, abounds the sensations both of hunger and of thirst. Tobacco, by its narcotic quality, seems well adapted to counteract the uneasy impressions which the gastric juice makes on the nerves of the stomach when it is empty; and the combination of the cañímed powder with it may tend to correct the secretion that is supposed to be the chief agent in digestion, and which, if not acid, is always united with acidity. Certain at least it is, that their operation is both grateful and salutary; for we find the luxurious inhabitants of the East Indies mix them with the betel nut, to the chewing of which they are universally and immoderately addicted. Perhaps such absorbents may be usefully applied, both to divide the doses and to moderate the virulence of the tobacco. For, in the internal exhibition of this plant, much caution is required, as it produces sickness, vertigo, cold clammy sweats, and a train of other formidable symptoms, when taken in too large a quantity. During the time of war, the impressed sailors frequently bring on these maladies, that they may be admitted into the hospitals, and released from servitude. It would be an easy and safe experiment to ascertain the efficacy, and to adjust the ingredients, of the Indian composition mentioned. And there is reason to believe, that the trial would be in some degree successful; for it is known that smoking tobacco..."
HUN [ 664 ]

Hunger. — Tobacco gives relief to those habitual pains of the stomach which appear to arise from the irritation of the gastric secretion. The like effect is sometimes produced by increasing the flow of saliva, and swallowing what is thus discharged. And Dr Percival has related the case of a gentleman, who used to masticate, many hours daily, a piece of lead, which being neither hard, friable, nor offensive to the palate, suited his purpose, as he thought, better than any other substance. He continued the custom many years, deriving great ease from it, and suffering no sensible injury from the poisonous quality of the metal. On mentioning this fact to a navy surgeon, the doctor was told, that the sailors, when in hot climates, are wont to mitigate thirst by rolling a bullet in their mouths. A more innocent means, the doctor observes, might be devised; but the efficacy of this evince, that the salivary glands are for a while capable of furnishing a substitute for drink. When a scarcity of water occurs at sea, Dr Franklin has advised, that the mariners should bathe themselves in tubs of salt-water: For, in pursuing the amusement of swimming, he observed, that however thirsty he was before immersion, he never continued so afterwards; and that, though he soaked himself several hours in the day, and several days successively, in salt-water, he perceived not, in consequence of it, the least taste of saltiness in his mouth. He also further suggests, that the same good effect might perhaps be derived from dipping the sailor's apparel in the sea; and expresses a confidence that no danger of catching cold would ensue.

To prevent the calamity of famine, at sea, it has been proposed by Dr Lind, that the powder of saffron should constitute part of the provisions of every ship's company. This powder and portable soup, dissolved in boiling water, form a rich thick jelly; and an ounce of each of these articles furnishes one day's subsistence to a healthy full grown man. Indeed, from Dr Percival's experiments it appears, that saffron contains more nutritious matter, in proportion to its bulk, than any other vegetable production now used as food. It has the property also of concealing the nauseous taste of salt-water; and consequently may be of great advantage at sea, when the stock of fresh water is so far consumed, that the mariners are put upon short allowance. By the same mucilaginous quality, it covers the offensiveness, and even in some measure, corrects the acrimony, of salted and putrescent meats. But, as a preservative against hunger, saffron would be most efficacious combined with an equal weight of beef suet. By swallowing little balls of this lubricating compound at proper intervals, the coats of the stomach would be defended from irritation: and as oils and mucilages are highly nutritive, of slow digestion, and indisposed to pass off by perspiration, they are peculiarly well adapted to support life in small quantities. This composition is superior in simplicity, and perhaps equal in efficacy, to the following one, so much extolled by Avicenna the celebrated Arabian physician; to whom we are indebted for the introduction of rhubarb, cassia, tamarinds, and senna, into the materia medica. "Take sweet almonds and beef suet, of each one pound; of the oil of violets two ounces; and of the roots of marshmallows one ounce: Bray these ingredients together in a mortar, and form the mass into boluses, about the size of a common nut." Animal fat is singularly powerful in assuaging the most acute sensations of thirst, as appears from the narrative of the sufferings experienced by those who were confined in the black hole at Calcutta. A hundred and forty-six persons, exhausted by fatigue and military duty, were there thrust together into a chamber of 18 cubic feet, having only two windows, strongly barred with iron, from which, in a close sultry night, and in such a climate as that of Bengal, little or no circulation of fresh air could be enjoyed. In a few minutes, these wretched wretches fell into a profound a perspiration, that an idea can hardly be formed of it; and this was succeeded by a raging thirst, which increased in proportion as the body was drained of its moisture. Water! Water! became the universal cry; and an old soldier on the outside, through pity, furnished them with a few skinfuls of it. But these scanty supplies, like sprinklings on the fire, served only to feed and increase the flame. From this experience of its effects, Mr Holwell, their chief, determined to drink no more; and kept his mouth moist by sucking the perspiration out of his shirt sleeves, and catching the drops as they fell from his head and face.

"You cannot imagine (says he) how unhappy I was if any of them escaped me." He came into the prison without his coat, the season being too hot to bear it; and one of his miserable companions, observing the expedient he had hit upon of allaying his thirst, robbed him from time to time of a considerable part of his store. This plunderer, whom he found to be a young gentleman in the service of the East India Company, afterwards acknowledged, that he owed his life to the many comfortable draughts which he derived from him. Before Mr Holwell adopted this mode of relief, he had attempted, in an un governable fit of thirst, to drink his own urine: but it was so intensely bitter, that a second taste could not be endured; whereas, he assures us, no Bristol water could be more soft and pleasant than his perspiration. And this, we may presume, consisted chiefly of animal fat, melted by excessive heat, and exuding from the cellular membrane through the pores of the skin.

Persons who have been accustomed to animal food, are soon reduced when supplied only with the farinacea. Several years ago, to determine the comparative nutritive powers of different substances, an ingenious young physician, as Dr Percival informs us, made a variety of experiments on himself, to which he unfortunately fell a sacrifice. He lived a month upon bread and water; and under this regimen of diet he every day diminished much in his weight. But in 1784, a student of physic at Edinburgh confined himself for a longer space of time to a pint of milk and half a pound of white bread daily: And he assured our author, that he passed through the usual labors of study and exercise without feeling any decay of health or strength, and without any sensible loss of bulk. The cutaneous, urinary, and alvine excretions, were very scanty during the whole period; and the discharge of feces occurred only once in a week. In this case the oily and congealable parts of the milk probably furnished a larger proportion of aliment, and at the same time contributed to check the waste by perspiration and other discharges; for oleaginous substances are retained long in the body by their viscosity. Dr Russell,
Hunger.

Rassel, in his Natural History of Aleppo, relates, that in those seasons when oil abounds, the inhabitants, by indulgence in it, are disposed to fever, and affected with infarctions of the lungs; maladies which indicate both retention and obstruction. Milk has been suspected by some of producing similar effects, though in a slighther degree; and the free use of it has been on this account ascribed to the inhabitants of this country.

Gum arabic might be a good substitute for salep in the composition already recommended; and as it will give such firmness to the mass, as to require modification, the saliva, by this means separated and carried into the stomach, would further contribute to assuage the sensations both of hunger and of thirst. See Gum-Arabic. This gum, combined with sugar and the whites of eggs, has been lately extolled in France, under the name of patigeon, as a remedy for catarrhal deficient, by Dr Percival has seen cakes made of these ingredients, and thinks they might very well be applied to the purpose of obviating hunger. They are not perishable in the hottest climates, may be carried about the person with convenience, and though very tough are pleasant to the taste. In the formula by which they are made, the proportion of sugar is too large, and that of gum arabic too small, if the mass be intended to assuage the cravings of appetite. According to our author's information, the receipt is as follows. Take of fine sugar four ounces, and gum arabic one ounce. Levisal them well together; and add half an ounce of rose water, and of the white of eggs a sufficient quantity.

In our attempts to recover those who have suffered under the calamities of famine, great circumspection is required. Warmth, cordials, and food, are the means to be employed; and it is evident that these may prove too powerful in their operation, if not administered with caution and judgment. For the body, by long fasting, is reduced to a state of more than infantile debility; the minute vessels of the brain, and of the other organs, collapse for want of fluids to distend them; the stomach and intestines shrivel in their capacity; and the heart languidly vibrates, having scarcely sufficient energy to prop the scanty current of blood. Under such circumstances, a proper application of heat seems an essential measure, and may be effected by placing on each side a healthy man in contact with the patient. Pediluvia or fomentations may also be used with advantage. The temperature of these should be lower than that of the human body, and gradually increased, according to the effects of their stimulus. New milk, weak broth, or water gruel, ought to be employed both for the one and the other; as nutriment may be conveyed into the system this way, by passages probably the most pervious in a state of fasting, if not too long protracted. A lad at Newmarket, a few years ago, having been almost starved in order that he might be reduced to a proper weight for riding a match, was weighed at nine o'clock in the morning, and again at ten; and he was found to have gained near 30 ounces in weight in the course of an hour, though he had only drank half a glass of wine in the interval. The wine probably stimulated the action of the nervous system, and incited nature, exhausted by abstinence, to open the absorbent pores of the whole body, in order to suck in some nourishment from the air. But no such ab-

HUNGERFORD, a town of Berkshire in England, seated on the river Kennet, in a low and watery soil. It is a great thoroughfare in the Bath and Bristol road, sixty-five miles from London; and was formerly called Ingleford-Charmaston. The constable of this town, who is chosen annually, is lord of the manor, which he holds immediately of the crown. They have an annual fair here which holds only about a quarat, and appears by an inscription on it to have been given by John of Gaunt, together with a grant of the royal liberty, in part of the river which abounds with good trout and craw-fish. Here is a market on Wednesdays, and fair in August. Population 1537.

HUNNINGEN, a town of Alsace, subject to the French; seated on the Rhine, and fortified by Vauban. Its fortifications were demolished since 1816.

HUNNS, a fierce and savage nation, who formerly inhabited that part of Sarmatia bordering on the Palus Magistis and the Tanais, the ancient boundary between Europe and Asia. Their country, as described by Propopius, lay north of Mount Caucasus, which, extending from the Euxine to the Caspian seas, parts Asiatic Sarmatia from Colchis, Iberia, and Albania; lying on the isthmus between the two seas above mentioned. Here they resided unknown to other nations, and themselves ignorant of other countries, till the year 376. At this time, a band pursued by the hunters, or, according to some authors, an ox stung by a gad-fly, having passed the marsh, was followed by some Hunns to the other side, where they discovered a country much more agreeable than their own. On their return, having acquainted their countrymen with what they had seen, the whole nation passed the marsh, and falling upon the Alans, who dwelt on the banks of the Tanais, almost exterminated them. They next fell upon the Ostrogoths, whom they drove out of their country, and forced to retire to the plains between the Borysthenes and the Tanais, now known by the name of Podolit. Then attacking the Visigoths, they obliged them to shelter themselves in the most mountainous parts of their country; till at last the Gothic nations finding it impossible to withstand such an inundation of barbarians, obtained leave from the emperor Valens to settle in Thrace.
The Hunns then became masters of all the country between the Tissia and Danube in 376, where they continued quietly till the year 398, when great numbers of them were taken into the pay of Theodoric I. but, in the mean time, a party of them, called the Nephthelite or White Huns, who had continued in Asia, overran all Mesopotamia, and even laid siege to Edessa, where they were repulsed with great slaughter by the Romans. The European Huns frequently passed the Danube, committing the greatest ravages in the western empire; sometimes they fell upon the eastern provinces, where they put all to fire and sword. They were often defeated and repulsed by the Romans, but the empire was now too weak to subdue or confine them from making excursions; so that they continued to make daily encroachments, and became every day more formidable than before. In 411, the Huns, under Attila, threatened the western empire with total destruction. This monarch, having made himself master of all the northern countries from the confines of Persia to the banks of the Rhine, invaded Moesia, Thrace, and Illyricum; where he made such progress, that the emperor not thinking himself safe in Constantinople, withdrew into Asia. Attila then broke into Gaul; where he took and destroyed several cities, massacring the inhabitants with the greatest cruelty. At last he was driven out with great slaughter by Aetius, the Roman general, and Theoderic king of the Goths, and could never afterwards make any great progress.

About the year 452 or 453 Attila died, and his kingdom was immediately split into a number of small ones by his numerous children, who waged perpetual war with each other. The Huns then ceased to be formidable, and became daily less able to cope with the other barbarous nations whom Attila had kept in subjection. Still, however, their dominion was considerable; and in the time of Charles the Great they were masters of Transylvania, Wallachia, Servia, Carniola, Carinthia, and the greater part of Austria, together with Bosnia, Slavonia, and that part of Hungary which lies beyond the Danube. In the year 776, while Charles was in Saxony, two princes of the Huns, Caganus and Jugunnus, sent ambassadors to him, desiring his friendship and alliance. Charles received them with extraordinary marks of friendship, and readily complied with their request. However, they entered, not long after, into an alliance with Taffila duke of Bavaria, who had revolted from Charles, and raised great disturbances in Germany. Charles dismembered his resentment till he had entirely reduced Bavaria, when he resolved to revenge himself on the Huns for those succours they had underhand given to his enemy. Accordingly, he ordered levies to be made throughout his dominions; and having by that means assembled a very numerous army, he divided it into two bodies, one of which he commanded himself, and the other he committed to the care of his generals. The two armies entered the kingdom of the Huns at different places, ravaged their country far and near, burnt their villages, and took all their strong holds. This he continued for eight years, till the people were almost totally extirpated; nor did the Huns ever afterwards recover themselves, or appear as a distinct nation.

There were two different nations that went by the name of Huns; the Nephthelite or White Huns, and the Sarmatian or Scythian Huns. The former inhabited a rich country, bordering to the north on Persia, and at a great distance from the Sarmatian or Scythian Huns, with whom they had no intercourse, nor the least resemblance either in their persons or manners. They were a powerful nation, and often served against the Romans in the Persian armies; but in the reign of the emperor Zeno, being provoked by Perozes king of Persia laying claim to part of their country, they defeated the Persians in two pitched battles, slew their king, overran all Persia, and held it in subjection for the space of two years, obliging Cabades, the son and successor of Perozes, to pay them a yearly tribute. These Huns, called by the writers of those times the white Huns, did not wander, like the others, from place to place; but, contented with their own country, which supplied them with all necessaries, they lived under a regular government, subject to one prince, and seldom made inroads, unless provoked, either into the Persian or Roman territories. They lived according to their own laws, and dealt uprightly with one another, as well as with the neighbouring people. Each of their great men used to choose twenty or more companions to enjoy with him his wealth, and partake of all his diversions; but, upon his decease, they were all buried with him in the same grave. This custom savours of barbarity; but in every other respect, the Nephthelite were a far more civilized nation than the Scythian Huns, who, breaking into the empire, filled most of the provinces of Europe with blood and slaughter.

The latter were, according to Ammianus Marcellinus, a savage people, exceeding in cruelty the most barbarous nations. They began to practise their cruelty, says Jornandes, upon their own children the very first day they come into the world, cutting and mangling the cheeks of their males, to prevent the growth of hair which they must have looked upon, contrary to the sentiments of other nations, as unbecoming and unmanly. They had, perhaps, in this practice another view, which Jornandes seems to imitate elsewhere, viz. to strike terror into the enemy with their countenances, thus deformed and covered with scars. They had no other food but roots and raw meat, being quite unacquainted with the use of fire, and no houses at all, not even huts; but lived constantly exposed to the air in the woods, and on the mountains, where, from their infancy, they were inured to hunger, thirst, and all manner of hardships: nay, they had such an aversion to houses, which they called the sepulchres of the living, that, when they went into other countries, they could hardly be prevailed upon to come within the walls of any house, not thinking themselves safe when shut up and covered. They used even to eat and sleep on horseback, scarce ever dismounting; which, in all likelihood, induced Zosimus to write, that the Huns could not walk. They covered their nakedness with goatskins, or the skins of a sort of mice sewed together. Day and night were indifferent to them, as to buying, selling, eating, and drinking. They had no law, nor any kind of religion; but complied with their inclinations, whatever they prompted them to, without the least restraint, or distinction between good and evil. In war, they began the battle with great fury, and a hideous noise: but if they met with a vigorous opposition,
their fury began to abate after the first onset; and when once put into disorder, they never rallied, but fled in the utmost confusion. They were quite unacquainted with the art of besieging towns; and authors observe, that they never attacked the enemy's camp. They were a faithless nation, and thought themselves no longer bound by the most solemn treaties, than they found their advantage in observing them. Hence we often find them, upon the least prospect of obtaining more advantageous conditions, breaking into the Roman empire, in defiance of the most solemn oaths and engagements. Several corps of Huns, after their coming into Europe, served in the Roman armies against the Goths and other barbarous nations; and they, being hired, to fight against each other, being blind to every other regard and consideration.

HUNTER, a name given to a horse qualified to carry a person in the chase. The shape of the horse designed for this service, should be strong and well knit together, as the jockeys express it. Irregular or unequal shapes in these creatures are always a token of weakness. The inequalities in shape which show a horse improper for the chase, are the having a large head and a small neck, a large leg and a small foot, and the like. The head of the hunter should indeed always be large, but the neck should also be thick and strong to support it. The head should be lean, the nostrils wide, and the windpipe straight.

The hunter, in order to his behaving well in the field, ought to have great care and indulgence in the stable: he ought to have as much rest and quiet as may be, to be kept well supplied with good meat, clean litter, and fresh water by him; he should be often dressed, and suffered to sleep as much as he pleases. He should be so fed, that his dung may be rather soft than hard, and it must be of a bright and clean colour. All this may be easily managed by the continual observance and change of his food, as occasion requires. After his usual scourings he should have exercises and mashers of sweet malt, or bread and beans; or wheat and beans mixed together, are to be his best food, and beans and oats his worst.

Some very great sportsmen are for keeping their horses out at grass all the buck-hunting season, never taking them up into the stable at all, but allowing them in the field as much oats with their grass as they will eat. The horse may be thus rid three days in the week for the whole season, and never damaged by it, nor ever showing any marks of harm afterwards.

The whole shape of a horse intended for a hunter, should be this: The ears should be small, open, and pricked; or though they be somewhat long, yet if they stand up erect and well lined, it is a sign of toughness or hardiness. The forehead should be long and broad, not flat, or, as it is usually termed, more-faced, but rising in the middle like that of a hare; the feather should be placed above the eye, the contrary being thought by some to threaten blindness. The eyes should be full, large, and bright; the nostrils not only large, but looking red and fresh within; for an open and fresh nostril is always esteemed a sign of a good wind. The mouth should be large, deep in the wicks, and hairy. The windpipe should be large, and appear straight when he bridles his head; for if, on the contrary, it bends like a bow on his bridling, it is not formed for a free passage of the breath. This defect in a horse is expressed among the dealers by the phrase cock-throppled. The head should be so set on to the neck, that a space may be felt between the neck and the chine; when there is no such space, the horse is said to be bull-necked; and this is not only a blemish in the beauty of the horse, but it also occasions his wind not to be so good. The crest should be strong, firm, and well risen; the neck should be straight and firm, not loose andpliant; the breast should be strong and broad, the ribs rounded like a barrel, the fills large, the buttocks rather oval than broad, the legs clean, flat, and straight; and, finally, the mane and tail ought to be long and thin, not short and bushy, the last being counted a mark of dulness. When a hunter is thus chosen, and has been taught such obedience, that he will readily answer to the rider's signals both of the bridle and hand, the voice, the calf of the leg, and the spur; that he knows how to make his way forward, and has gained a true temper of mouth, and a right placing of his head, and has learned to stop and to turn readily, if his age be sufficiently advanced, he is ready for the field. It is a rule with all staunch sportsmen, that no horse should be used in hunting till he is full five years old; some will hunt them at four, but the horse at this time is not come up to his true strength and courage, and will not only fail at every tough trial, but will be subject to strains and accidents of that kind, much more than if he were to be kept another year first, when his strength would be more confirmed.

When the hunter is five years old, he may be put to grass from the middle of May till Bartholomew-tide; for the weather between these is so hot, that it will be very proper to spare him from work. At Bartholomew-tide, the strength of the grass beginning to be nipped by frosts and cold dew, so that it is apt to engender crudities in the horse, he should be taken up while his coat is yet smooth and sleek, and put into the stable. When he is first brought home, he should be put in some secure and spacious place, where he may evacuate his body by degrees, and be brought not all at once to the warm keeping; the next night he may be stabled up. It is a general rule with many not to clothe and stable up their horses till two or three days after they are taken from grass, and others who put them in the stable after the first night, yet will not dress and clothe them till three or four days afterward; but all this, except the keeping the horse one day in a large and cool place, is needless caution.

There is a general practice among the grooms, in many places, of giving their hunters wheat-straw as soon as they take them up from grass. They say they do this to take up their bellies; but there seems much reason to disapprove of this. The change is very violent, and the nature of the straw so heating and drying, that there seems great reason to fear that the astringent nature of it would be prejudicial, more than is at first perceived. It is always found that the dun is hard after this food, and is voided with pain and difficulty, which is in general very wrong for this sort of horse. It is better therefore to avoid this straw-feeding, and to depend upon moderate airing, warm clothing, and good old hay and old corn, than to have recourse to any thing of this kind.

When
When the horse has evacuated all his grass, and has been properly shod, and the shoes have had time to settle to his feet, he may be ridden abroad, and treated in this manner: the groom ought to visit him early in the morning, at five o'clock in the long days, and at six in the short ones; he must then clean out the stable, and feel the horse's neck, flank, and belly, to find the state of his health. If the flank feels soft and flabby, there is a necessity of good diet to harden it; otherwise any great exercise will occasion swellings and gonitnes in the heels. After this examination, a handful or two of good old oats, well sifted, should be given him: this will make him have more inclination to water, and will also make the water sit better on his stomach, than if he drank fasting. After this, he is to be tied up and dressed. If in the doing of this he opens his mouth, as if he would bite, or attempts to kick at the person, it is a proof that the teeth of the currycomb are too sharp, and must be filed blunter. If after this he continues the same tricks, it is through wantonness, and he should be corrected for it with the whip. The intent of currying being only to raise the dust, this is to be brushed off afterwards with a horse-tail nailed to a handle, or any other light brush. Then he is to be rubbed down with the brush, and dusted a second time; he should then be rubbed over with a wet hand, and all the loose hairs, and whatever fouleness there is, should be picked off. When this is done, and he is wiped dry as at first, a large saddle-cloth is to be put on, reaching down to the spurring place; then the saddle is to be put on, and a cloth thrown over it that he may not take cold: then rub down his legs, and pick his feet with an iron picket, and let the mane and tail be combed with a wet comb. Lastly, it is a custom to spurt some beer in his mouth just before the leading him out of the stable. He should then be mounted, and walked a mile at least to some running water, and there watered; but he must only be suffered to take about half his water at one drinking.

It is the custom of many to gallop the horse at a violent rate as soon as he comes out of the water; but this is extremely wrong for many reasons. It endangers the breaking a horse's wind more than any other practice, and often has been the occasion of bursting very good horses. It uses them also to a disagreeable trick we find in many horses, of running away as soon as ever they come out of the water: and with some it makes them averse to drinking, so that they will rather endure thirst, and hurt themselves greatly by it, than bring on the violent exercise which they remember always follows it. The better way is to walk him a little after he is out of the water, then put him to a gentle gallop for a little while, and after this to bring him to the water again. This should be done three or four times, till he will not drink any more. If there is a hilly place near the watering place, it is always well to ride up to it; if otherwise, any place is to be chosen where there is free air and sun. That the creature may enjoy the benefit of this, he is not to be galloped, but walked about in this place an hour, and then taken home to the stable. The pleasure the horse himself takes in these siring when well managed is very evident; for he will gaze, yawn, and shrug up his body: and in these, whenever he would stand still to stale, dung, or listen to any noise, he is not to be hindered from it, but encouraged in everything of this kind.

The advantages of these siring are very evident; they purify the blood, teach the creature how to make his breathing agree with the rest of the motions of his body, and give him an appetite to his food, which hunters and racers that are kept stalled up are otherwise very apt to lose. On returning from siring, the litter of the stable should be fresh, and by stirring this and whistling, he will be brought to stale. Then he is to be led to his stall, and tied up, and again carefully rubbed down; then he should be covered with a linen cloth next his body, and a canvas one over that, made to fit him, and reaching down to his legs. This, as the duke of Newcastle observes, is a custom which we learned of the Turks, who are of all people the most nice and careful of their horses. Over this covering there should be put a body-cloth of six or eight straps; this keeps his belly in shape, and does not hurt him. This clothing will be sufficient while the weather is not very sharp; but in severe seasons, when the hair begins to rise and start in the uncovered part, a woollen cloth is to be added, and this will always prove fully sufficient.

Different horses, and different seasons, make variety of the degree of clothing necessary; but there always is an obvious rule to point out the necessary changes, the roughness of the coat being a mark of the want of clothing, and the smoothness of it a proof that the clothing is sufficient. Therefore if at any time the hair is found to start, it is a notice that some further clothing is to be added.

If the horse sweat much in the night, it is a sign that he is over fed and wants exercise: this therefore is easily remedied. An hour or more after the horse is come in from his siring, the groom should give him a wisp of clean hay, making him eat it out of his hand; after this let the manger be well cleaned out, and a quarter of oats clean sifting be given him. If he eats up this with an appetite, he should have more given him; but if he is slow and indifferent about it, he must have more. The business is to give him enough, but not to cloy him with food.

If the horse gets flesh too fast on this home feeding, he is not to be stinted to prevent it, but only his exercise increased; this will take down his flesh, and at the same time give him strength and wind. After the feeding in the morning is over the stable is to be shot up, only leaving him a little hay on his litter. He need be no more looked at till one o'clock, and then only rubbed down, and left again to the time of his evening watering, which is four o'clock in the summer and three in the winter. When he has been watered, he must be kept out an hour or two, or more if necessary, and then taken home and rubbed as after the morning watering. Then he is to have a feed of corn at six o'clock, and another at nine at night; and being then cleaned, and his litter put in order, and hay enough left for the night, he is to be left till morning. This is the direction for one day, and in this manner he is to be treated every day for a fortnight; at the end of which time his flesh will be so hardened, his wind so improved, and his mouth so quickened, and his gallop brought to so good a stroke, that he will be fit to be put to moderate hunting. During the time that he is used

**Hunter.**

used to hunting, he must be ordered on his days of rest exactly as is directed for the fortnight when he is in preparation; but as his exercise is now greatly increased, he must be allowed a more strengthening food, mixing some old split beans at every feeding with his oats.

And if this is not found to be sufficient, the following bread must be given: let two pecks of old beans and one peck of wheat be ground together, and made into an indifferently fine meal; then knead it into dough with some warm water, and a good quantity of yeast; let it lie a time that it may rise and swell, which will make the bread the lighter; then make it into loaves of a peck each, and let it be baked in a slow oven, that it may be thoroughly done without being burnt; when it is taken out of the oven, it must be set bottom upwards to cool; when it is one day old the crust is to be chipped off, and the crumb given him for food. When this is ready, he should have some of it at least once in the day: but it is not to be made the only food, but some seeds are to be of oats alone, some of oats and this bread, and some of oats and beans mixed together. The making a variety in this manner being the best of all methods for keeping up the appetite, which is often apt to fail.

The day before the horse is to hunt, he must have no beans, because they are hard of digestion, but only some oats with this bread: or if he will be brought to eat the bread alone, that will be best of all. His evening feed should on this day be somewhat earlier than usual; and after this he is only to have a wisp of hay out of the groom's hand till he return from hunting.

**Hunter.** Dr William, a celebrated anatomist and physician, was born on the 23d of May 1718, at Kilbride in the county of Lanark in Scotland. He was the seventh of the children of John and Agnes Hunter, who resided on a small estate in that parish called Long Culderwood, which has been long in the possession of his family. His great grandfather by his father's side, was a younger son of Hunter of Hunterston, chief of the family of that name. At the age of fourteen his father sent him to the college of Glasgow. In this seminary he passed five years, and by his prudent behaviour and diligence acquired the esteem of the professors, and the reputation of being a good scholar. His father had designed him for the church: but the idea of subscribing to articles of faith was so repugnant to the liberal mode of thinking he had already adopted, that he felt an insuperable aversion to his theological pursuits. In this state of mind he happened to become acquainted with Dr Cullen, the late celebrated professor at Edinburgh, who was then just established in practice at Hamilton under the patronage of the Duke of Hamilton. Dr Cullen's conversation soon determined him to lay aside all thoughts of the church, and to devote himself to the profession of physic. His father's consent having been previously obtained, Mr Hunter in 1737 went to reside with Dr Cullen. In the family of this excellent friend and preceptor he passed nearly three years: and these, as he has been often heard to acknowledge, were the happiest years of his life. It was then agreed, that he should go and prosecute his medical studies at Edinburgh and London, and afterwards return to settle at Hamilton in partnership with Dr Cullen. He accordingly set out for Edinburgh in November 1740, and continued there till the following spring, attending the lectures of the medical professors, and amongst others those of the late Dr Alexander Monro, who many years afterwards, in allusion to this circumstance, styled himself his old master.

Mr Hunter arrived in London in the summer of 1741, and took up his residence at Mr, afterwards Dr, Savill's, who was at that time an apothecary in Pall Mall. He brought with him a letter of recommendation to his countryman Dr James Douglas, from Mr Foulis, printer in Glasgow, who had been useful to the doctor in collecting for him different editions of Horace. Dr Douglas was then intent on a great anatomical work on the bones, which he did not live to complete, and was looking out for a young man of abilities and industry whom he might employ as a dissector. This induced him to pay particular attention to Mr Hunter; and finding him acute and sensible, he desired him to make him another visit. A second conversation confirmed the doctor in the good opinion he had formed of Mr Hunter; and without any farther hesitation he invited him into his family to assist in his dissections and to superintend the education of his son.—Mr Hunter having accepted Dr Douglas's invitation, was by his friendly assistance enabled to enter himself as a surgeon's pupil at St George's Hospital under Mr James Wilkie, and as a dissecting pupil under Dr Frank Nichols, who at that time taught anatomy with considerable reputation. He likewise attended a course of lectures on experimental philosophy by Dr Desaguliers. Of these means of improvement he did not fail to make a proper use. He soon became expert in dissection, and Dr Douglas was at the expense of having several of his preparations engraved. But before many months had elapsed, he had the misfortune to lose this excellent friend.—The death of Dr Douglas, however, made no change in the situation of our author. He continued to reside with the doctor's family, and to pursue his studies with the same diligence as before.

In 1743 he communicated to the Royal Society an essay on the Structure and Diseases of articulating Cartilages. This ingenious paper, on a subject which till then had not been sufficiently investigated, affords a striking testimony of the rapid progress he had made in his anatomical inquiries. As he had it in contemplation to teach anatomy, his attention was directed principally to this object; and it deserves to be mentioned as an additional mark of his prudence, that he did not precipitately engage in the attempt, but passed several years in acquiring such a degree of knowledge and such a collection of preparations, as might insure him success. Dr Nichols, to whom he communicated his scheme, and who declined giving lectures about that time in favour of the late Dr Lawrence, did not give him much encouragement to prosecute it. But at length an opportunity presented itself for the display of his abilities as a teacher. A society of navy surgeons had an apartment in Covent Garden, where they engaged the late Mr Samuel Sharpe to deliver a course of lectures on the operations of surgery. Mr Sharpe continued to repeat this course, till finding that it interfered too much with his other engagements,
engagements, he declined the task in favour of Mr Hunter; who gave the society so much satisfaction, that they requested him to extend his plan to anatomy, and at first he had the use of their room for his lectures. This happened in the winter of 1746. He is said to have experienced much solicitude when he began to speak in public; but the applause he met with soon inspired him with courage; and by degrees he became so fond of teaching, that for many years before his death he was never happier than when employed in delivering a lecture. The profits of his two first courses were considerable; but by contributing to the wants of different friends, he found himself at the return of the next season obliged to defer his lectures for a fortnight, merely because he had not money enough to defray the necessary expense of advertisements.

In 1747 he was admitted a member of the corporation of surgeons; and in the spring of the following year, soon after the close of his lectures, he set out in company with his pupil, Mr James Douglas, on a tour through Holland and Paris. His lectures suffered no interruption by this journey, as he returned to England soon enough to prepare for his winter-course, which began about the usual time.

At first he practised both surgery and midwifery; but to the former of these he had always an aversion. His patron, Dr James Douglas, had acquired considerable reputation in midwifery, and this probably induced Mr Hunter to direct his views chiefly to the same line of practice. His being elected one of the surgeon-men-midwives, first to the Middlesex, and soon afterwards to the British Lying-in Hospital, assisted in bringing him forward in this branch of his profession, in which he was recommended by several of the most eminent surgeons of that time, who respected his anatomical talents and wished to encourage him. But these were not the only circumstances that contributed to his success. He owed much to his abilities, and much to his person and manner, which eminently qualified him for the practice of midwifery.

In 1750 he seems to have entirely relinquished his views in surgery; as in that year he obtained the degree of Doctor of Physic from the university of Glasgow, and began to practise as a physician. About this time he quitted the family of Mrs Douglas, and went to reside in Jermyn-street. In the summer of 1751 he revisited his native country, for which he always retained a cordial affection. His mother was still living at Long Calderwood, which was now become his property by the death of his brother James. Dr Cullen, for whom he always entertained a sincere regard, was then established at Glasgow, and had acquired considerable reputation both as a practitioner and teacher of physic; so that the two friends had the pleasure of being able to congratulate each other on their mutual prosperity. During this visit he showed his attachment to his little paternal inheritance by giving many instructions for repairing and improving it, and for purchasing any adjoining lands that might be offered for sale. After this journey to Scotland, to which he devoted only a few weeks, he was never absent from London, unless his professional engagements, as sometimes happened, required his attendance at a distance from the capital.

In 1755, on the resignation of Dr Layard, one of the physicians of the British lying-in hospital, we find the governors of that institution voting their thanks to Dr Hunter for the services he had done the hospital, and for his continuing in it as one of the physicians; so that he seems to have been established in this office without the usual form of an election. The year following he was admitted a licentiate of the Royal College of Physicians. Soon afterwards he was elected a member of the Medical Society; and to the Observations and Inquiries published by that society, he at different periods contributed several valuable papers.

In 1762, we find him warmly engaged in controversy, supposing his claim to different anatomical discoveries, in a work entitled Medical Commentaries, the style of which is correct and spirited. As an excuse for the tardiness with which he brought forth this work, he observes in his introduction, that it required a good deal of time, and he had little to spare; that the subject was unpleasant, and therefore he was very seldom in the humour to take it up. In this publication he confined himself chiefly to a dispute with the present learned professor of anatomy at Edinburgh, concerning injections of the testicle, the ducts of the lacrymal gland, the origin and use of the lymphatic vessels, and absorption by veins. He likewise defended himself against a reproach thrown upon him by Professor Monro senior, by giving a concise account of a controversy he was involved in with Mr Pott concerning the discovery of the Hernia Congenita. It was not long before Mr Pott took occasion to give the public his account of the dispute; and, in reply, Dr Hunter added a supplement to his commentaries. No man was ever more tenacious than Dr Hunter of what he conceived to be his anatomical rights. This was particularly evinced in the year 1780, when his brother communicated to the Royal Society a discovery he had made 25 years before, relative to the structure of the placenta, the communication between it and the uterus, and the vascularity of the spongy chorion. At the next meeting of the society, a letter was read, in which Dr Hunter put in his claim to the discovery in question. This letter was followed by a reply from Mr John Hunter, and here the dispute ended.

In 1762, when the queen became pregnant, Dr Hunter was consulted; and two years afterwards he had the honour to be appointed physician extraordinary to her majesty.

About this time his avocations were so numerous, that he became desirous of lessening his fatigue; and having noticed the ingenuity and assiduous application of the late Mr William Hawson, F. R. S. who was then one of his pupils, he engaged him first as an assistant, and afterwards as a partner in his lectures. This connection continued till the year 1770, when some dispute happened which terminated in a separation. Mr Hawson was succeeded in the partnership by Mr Cruikshank, whose anatomical abilities were deservedly respected.

In 1767, Dr Hunter was elected a fellow of the Royal Society; and in the year following communicated to that learned body observations on the bones, commonly supposed to be elephants bones, which have been found near the river Ohio in America. This was not the only subject of natural history on which...
our author employed his pen; for in a subsequent volume of the Philosophical Transactions, we had him offering his remarks on some bones found in the rock of Gibraltar, and which he proves to have belonged to some quadruped. In the same work, likewise, he published an account of the nyi-guan, an Indian animal not described before. In 1768, Dr. Hunter became a fellow of the Society of Antiquaries; and the same year, at the institution of a Royal Academy of Arts, he was appointed by his majesty to the office of professor of anatomy. This appointment opened a new field for his abilities; and he engaged in it, as he did in every other pursuit of his life, with unabating zeal. He now adapted his anatomical knowledge to the objects of painting and sculpture, and the novelty and justness of his observations proved at once the readiness and extent of his genius. In January 1781, he was unanimously elected to succeed the late Dr. John Forthingill as president of the Medical Society. As his name and talents were known and respected in every part of Europe, so the honours conferred on him were not limited to his own country. In 1780, the Royal Medical Society at Paris elected him one of their foreign associates; and in 1782, he received a similar mark of distinction from the Royal Academy of Sciences in that city.

The most splendid of Dr. Hunter’s medical publications was the Anatomy of the Human Gravid Uterus. The appearance of this work, which had been begun so early as the year 1751 (at which time 20 of the 34 plates it contains were completed), was retarded till the year 1775, only by the author’s desire of sending it into the world with fewer imperfections. This great work is dedicated to the king. In his preface to it, we find the author very candidly acknowledging, that in most of the dissections he had been assisted by his brother Mr. John Hunter, “whose accuracy (he adds) in anatomical researches is so well known, that to omit this opportunity of thanking him for that assistance would be in some measure to disregard the future reputation of the work itself.” He likewise confesses his obligations to the ingenious artists who made the drawings and engravings; “but particularly to Mr. Strange, not only for having by his hand secured a sort of immortality to two of the plates, but for having given his advice and assistance in every part with a steady and disinterested friendship.” An anatomical description of the gravid uterus was a work which Dr. Hunter had in contemplation to give the public. He had likewise long been employed in collecting and arranging materials for a history of the various concretions that are formed in the human body. Amongst Dr. Hunter’s papers have been found two introductory lectures, which are written out so fairly, and with such accuracy, that he probably intended no farther correction of them before they should be given to the world. In these lectures Dr. Hunter traces the history of anatomy from the earliest to the present times, along with the general progress of science and the arts. He considers the great utility of anatomy in the practice of physic and surgery; gives the ancient divisions of the different substances composing the human body, which for a long time prevailed in anatomy; points out the most advantageous mode of cultivating this branch of natural knowledge; and concludes with explaining the particular plan of his own lectures. Besides these manuscripts, he has also left behind him a considerable number of cases of dissection; mostly relating to pregnant women.

The same year in which the Tables of the Gravid Uterus made their appearance, Dr. Hunter communicated to the Royal Society an Essay on the Origin of the Venereal Disease. In this paper he attempted to prove, that this dreadful malady was not brought from America to Europe by the crew of Columbus, as had been commonly supposed, although it made its first appearance about that period. After this paper had been read to the Royal Society, Dr. Hunter, in a conversation with the late Dr. Mungrave, was convinced that the testimony on which he placed his chief dependence was of less weight than he had at first imagined, as many of Martyr’s letters afford the most convincing proofs of their having been written a considerable time after the period of their dates. He therefore very properly laid aside his intention of giving his essay to the public. In the year 1777 Dr. Hunter joined with Mr. Watson in presenting to the Royal Society a short account of the late Dr. Mary’s illness, and of the appearances on dissection; and the year following he published his Reflections on the Section of the Symphysis Pubis.

We must now go back a little in the order of time to describe the origin and progress of Dr. Hunter’s museum, without some account of which the history of his life would be very incomplete.

When he began to practise midwifery, he was desirous of acquiring a fortune sufficient to place him in easy and independent circumstances. Before many years had elapsed, he found himself in possession of a sum adequate to his wishes in this respect; and this he set apart as a resource of which he might avail himself whenever age or infirmities should oblige him to retire from business. After he had obtained this competency, as his wealth continued to accumulate, he formed a laudable design of engaging in some scheme of public utility, and at first had it in contemplation to found an anatomical school in this metropolis. For this purpose, about the year 1775, during the administration of Mr. Grenville, he presented a memorial to that minister, in which he requested the grant of a piece of ground in the Mews, for the site of an anatomical theatre. Dr. Hunter undertook to expend 7000l. on the building, and to endow a professorship of anatomy in perpetuity. This scheme did not meet with the reception it deserved.

In a conversation on this subject soon afterwards with the earl of Shelburne, his lordship expressed a wish that the plan might be carried into execution by subscription, and very generously requested to have his name set down for a thousand guineas. Dr. Hunter’s delicacy would not allow him to adopt this proposal. He chose rather to execute it at his own expense; and accordingly purchased a spot of ground in Great Windmill-street, where he erected a spacious house, to which he removed from Jermyn-street in 1770. In this building, besides a handsome amphitheatre and other convenient apartments for his lectures and dissections, there was one magnificent room, fitted up with great elegance and propriety as a museum. Of the magnitude and value of his anatomical collection some idea may be formed, when we consider the great length of years
years he employed in the making of anatomical prepa-
rations and in the dissection of morbid bodies, added
to the eagerness with which he procured additions
from the collections of Sandy, Hewson, Falconer,
Blackall, and others, that were at different times offer-
red for sale in this metropolis. His specimens of rare
diseases were likewise frequently increased by presents
from his medical friends and pupils; who, when any
thing of this sort occurred to them, very justly thought
they could dispose of it more properly than by
placing it in Dr Hunter's museum. Speaking of an
acquisition in this way in one of his publications, he
says, "I look upon every thing of this kind which is
given to me, as a present to the public; and consider
myself as thereby called upon to serve the public with
more diligence."

Before his removal to Windmill-street, he had con-

fined his collection chiefly to specimens of human and
comparative anatomy and of diseases; but now he ex-
tended his views to fossils, and likewise to the promo-
tion of polite literature and erudition. In a short space
of time he became possessed of "the most magnificent
treasure of Greek and Latin books that has been accu-
cumulated by any person now living since the days of
Mead." A cabinet of ancient medals contributed like-
wise much to the richness of his museum. A descrip-
tion of part of his coins in this collection, struck by
the Greek free cities, was afterwards published by the
Doctor's learned friend Mr Combe. In a classical de-
dication of this elegant volume to the queen, Dr Hunter
acknowledges his obligations to her majesty. In the
preface some account is given of the progress of the

collection, which has been brought together since the
year 1770, with singular taste, and at the expense of
upwards of 20,000l. In 1781, the museum received a

valuable addition of shells, corals, and other curious
subjects of natural history, which had been collected by
the late worthy Dr Fothergill, who gave directions by
his will, that his collection should be appraised after his
death, that Dr Hunter should have the refusal of it at
500l. under the valuation. This was accordingly done,
and Dr Hunter purchased it for the sum of 1000l. The
fame of this museum spread throughout Europe. Few
foreigners distinguished for their rank or learning vis-
ted this metropolis without requesting to see it. Men of
science of our own country always had easy access to
it.—Considered in a collective point of view, it is per-
haps without a rival.

Dr Hunter, at the head of his profession, honoured
with the esteem of his sovereign, and in possession of
every thing that his reputation and wealth could con-
fer, seemed now to have attained the summit of his
wishes. But these sources of gratification were embit-
tered by a disposition to the gout, which harassed him
frequently during the latter part of his life, with-
standing his very abstemious manner of living. On Sa-
turday the 15th of March 1783, after having for sev-

eral days experienced a return of a wandering gout, he
complained of great headache and nausea. In this state
he went to bed, and for several days felt more pain than
usual both in his stomach and limbs. On the Thurs-
day following he found himself so much recovered, that
he determined to give the introductory lecture to the
operations of surgery. It was to no purpose that his
friends urged to him the impropriety of such an at-
tempt. He was determined to make the experiment,
and accordingly delivered the lecture; but towards the

conclusion his strength was so exhausted that he fainted
away, and was obliged to be carried to bed by two ser-
vants. The following night and day his symptoms
were such as indicated danger; and on Saturday morn-
ing Mr Combe, who made him an early visit, was
alarmed on being told by Dr Hunter himself, that dur-
ing the night he had certainly had a paralytic stroke.

As neither his speech nor his pulse were affected,

and he was able to raise himself in bed, Mr Combe encou-

raged him to hope that he was mistaken. But the

event proved the doctor's idea of his complaint to be

but too well founded; for from that time till his death,

which happened on Sunday the 30th of March, he

avoided no urine without the assistance of the catheter,

which was occasionally introduced by his brother: and

purgative medicines were administered repeatedly

without procuring a passage by stool. These circum-
stances, and the absence of pain, seemed to show, that

the intestines and urinary bladder had lost their sensi-

bility and power of contraction; and it was reasonable
to presume that a partial palsy had affected the nerves
distributed to those parts.

By his will, the use of his museum, under the di-
rection of trustees, devolved to his nephew Dr Matthew
Bailie, and in case of his death to Mr Cruikshank for
the term of thirty years; at the end of which period
the whole collection is bequeathed to the university of
Glasgow, with eight thousand pounds sterling as a fund
for the support and augmentation of the collection,

which is now deposited at Glasgow.

Dr Hunter was regularly shaped, but of a slender
make, and rather below a middle stature. His man-
ner of living was extremely simple and frugal, and
the quantity of his food was small as well as plain. He
was an early riser; and when business was over, was
constantly engaged in his anatomical pursuits, or in
his museum. There was something very engaging in
his manner and address; and he had such an appearance
of attention to his patients, when he was making his
inquiries, as could hardly fail to conciliate their confi-
dence and esteem. In consultation with his medical
brethren, he delivered his opinions with diffidence and
candour. In familiar conversation he was cheerful and
unassuming. As a teacher of anatomy he has been
long and deservedly celebrated. He was a good or-
ator; and having a clear and accurate conception
of what he taught, he knew how to place in dis-

tinct and intelligible points of view the most abstruse
subjects of anatomy and physiology. Among other
methods of explaining and illustrating his doctrines,
he used frequently to introduce some appropriate story or

case that had occurred to him in his practice; and few
men had acquired a more interesting fund of anec-
dotes of this kind, or related them in a more agreeable
manner.

HUNTER, John, an eminent surgeon, was the young-
est child of John Hunter of Kilbride, in the county of
Lanark. He was born at Long Calderwood on the
31st of July 1728. His father died when he was about
ten years of age, from which circumstance his mother
was induced to grant him too much indulgence. In
consequence he made no progress at the grammar-school,
and was almost wholly illiterate at the age of 20, when he
he arrived in London. His brother Dr W. Hunter was at that time the most eminent teacher of anatomy, and John expressed a wish to attend him in his researches. The doctor, anxious to make trial of his talents, gave him an arm to dissect for the muscles, with proper instructions how it was to be performed; and the dexterity with which he managed his undertaking exceeded the expectations of his brother.

Having acquired some reputation from this first attempt, his brother employed him in a more difficult dissection, which was an arm wherein all the arteries were injected, and these and the muscles were to be preserved and exposed. In the execution of this task he also gave the highest satisfaction, and his brother predicted that he would become a good anatomist, and never want employment. Under the instructions of his brother, and Mr Symonds his assistant, he enjoyed every favourable opportunity of increasing his anatomical knowledge, since that school monopolized all the dissections then carried on in London.

He was admitted into partnership with his brother in the winter of 1755, and a certain department of the lectures was allotted to him, and he also lectured when the doctor was called away to attend his patients. The mind of Mr Hunter was peculiarly fitted for the study of anatomy, and the indefatigable ardour with which he prosecuted it is scarcely to be equalled. He applied to human anatomy for ten years, during which period he made himself master of every thing then known, and also made some considerable additions. He was the first who discovered the existence of the lymphatic vessels in birds.

With such eagerness did he apply himself to the study of comparative anatomy, that he even applied to the keeper of wild beasts in the Tower for the bodies of such as died there, and to all those who were in the habit of exhibiting wild beasts to the public. He made a purchase of every rare animal that came in his way, which, together with those presented to him by his friends, he gave to the showmen to keep till they died, the more effectually to prevail with them to assist him in his labours. So much was his health impaired by unwearied attention to his favourite pursuits, that in 1760 his friends advised him to go abroad, as he exhibited many symptoms of an incipient consumption. In October that year he was appointed a surgeon on the staff by the inspector-general of hospitals (Mr Adair), and in the spring of the ensuing year he went to Belleisle with the army.

He served during the continuance of the war, as senior surgeon on the staff, when he acquired his knowledge of gun-shot wounds. He settled in London on his return to England; but finding that his half pay and private practice could not support him, he taught practical anatomy and surgery for several winters. He built a house near Brompton, where he pursued the study of comparative anatomy with unabated ardour. He discovered the changes which animal and vegetable substances undergo in the stomach by the action of the gastric juice; the mode in which a bone retains its shape during its growth; and explained the process of exfoliation, by which a piece of dead bone is separated from the living.

On the 5th of February 1767, he was chosen F. R. S. In the year 1768 he became a member of the incorpora-

Vol. X. Part II.

ration of surgeons, and in the following year was elected one of the surgeons of St George's hospital, through the influence of his brother. He published his treatise on the natural history of the teeth in May 1771, and in July the same year he married Miss Home, daughter of Mr Home, surgeon to Burgoyne's regiment of light horse. His private practice and professional reputation advanced with rapidity after his marriage, and although his family increased, he devoted much of his time to the forming of his collection. He discovered the cause of failure in the cure of every case of hydrocele, and proposed a mode of operating in which that evil may certainly be avoided. He ascertained that simple exposure to the air can neither produce nor increase inflammation; and he considered the blood as alive in its fluid state. He also discovered that the stomach after death is sometimes acted on and dissolved by the gastric juice, respecting which he communicated a paper to the Royal Society.

Comparative anatomy occupied the greater part of his time and attention, and he suffered no opportunity to escape him. He dissected the torpedo in 1773, and laid an account of its electrical organs before the Royal Society. A young elephant which had been presented to the queen, having died, it was given to Dr Hunter, which afforded our author an opportunity of examining the structure of that monstrous animal, as did also two others which died in the queen's menagerie. In the year 1774, he published an account, in the Philosophical Transactions, of certain receptacles of air in birds, communicating with the lungs, and lodged in the muscular parts and hollow bones of these animals. Several animals belonging to the species of Gymnopus electricus of Surinam having been brought alive to Britain in 1775, their electrical properties excited a considerable share of the public attention, and Mr Hunter purchased many of them after they died, for the purpose of prosecuting his favourite experiments. He published an account of their electrical organs in the Philosophical Transactions for 1775; and in the same volume appeared his experiments on the power of animals and vegetables to produce heat.

Mr Hunter was appointed surgeon extraordinary to his majesty in 1775; in the autumn of which year he grew extremely ill, when both himself and his friends apprehended that his life was in danger, but he happily recovered so far as to be able to publish the second part of his treatise on the Teeth in 1778, which completed the subject; and in 1779 he published in the Philosophical Transactions his account of the Free Martin. He was chosen a fellow of the Royal Society of Sciences and Belles Lettres at Gottenburg, and in 1783 he became a member of the Royal College of Medicine and the Royal Academy of Surgery in Paris.

In the building which he formed for his valuable collection, there was a room 52 feet by 28, lighted from the top, with a gallery all round, for containing his preparations. At this time he had reached the height of his career as a surgeon, with his mind and body in full vigour; and his hands were capable of performing whatever was suggested by his capacious mind, and his judgement was fully ripened by long experience.

He removed a tumor from the head and neck of a patient in St George's hospital, as large as the head to which it was attached; and by bringing the cut edges...
HUNTER

edges of the skin into contact, the whole was almost healed by the first intention. He dissected or cut out a tumor on the neck, which one of the best surgeons in this country declared that none but a fool or a madman would ever attempt; yet the patient perfectly recovered. He discovered a new method of performing the operation for the popliteal aneurism, by taking up the femoral artery on the anterior part of the thigh, without doing any thing to the tumor or the ham. This, from many subsequent experiments which have been successfully performed, must be allowed to stand high among the modern improvements in surgery.

Mr Hunter was engaged in a very extensive private practice; he was surgeon to St George’s hospital; he gave a very long course of lectures during the winter season; he carried on his inquiries in comparative anatomy; he had a school of practical human anatomy in his own house, and was continually employed in some experiments respecting the animal economy. In 1786 he was chosen deputy-surgeon-general to the army, at which time he published his work on the venereal disease, the first edition of which met with a very rapid sale.

In the year 1787 he published a treatise on the effect of extirpating one ovariun on the number of young, which procured him the annual gold medal of Sir John Copley. His collection was now brought into a state of arrangement, which he owed to his friends and acquaintances twice a year, and in May to noblemen and gentlemen, who were only in town during the spring. When Mr Adair died, Mr Hunter was appointed inspector general of hospitals, and surgeon-general to the army. This event happened in 1792, at which time he was elected honorary member of the Chirurgical Physical Society of Edinburgh, and one of the vice-presidents of the Veterinary College of London, then first established. He published also three papers on the treatment of inflamed veins, on intravenous, and on the mode of conveying food into the stomach in cases of paralysis of the contiguous organs.

The production of comparative anatomy left by Mr Hunter remains an unequivocal testimony of his perseverance and abilities, and an honour to the country in which he was educated. In it is beheld the natural gradation from the lowest state in which life is found to exist, up to the most perfect and complex of the animal creation—man himself.

Mr Hunter enjoyed a good state of health, for the first 40 years of his life, during which he had no complaint of any consequence, except an inflammation of his lungs in 1759. The first attack of the gout which he ever experienced was occasioned by an affection of the mind, and every subsequent fit originated from the same source.

Mr Hunter was of a short stature, uncommonly strong and active, well formed, and capable of great bodily exertion. His countenance was open, animated, and deeply impressed with thoughtfulness towards the close of his life. Laverter seeing a print of him, is said to have exclaimed, "that man thinks for himself." For the last twenty years of his life he drank nothing stronger than water, and wine at no period agreed with his stomach. He was easily irritated, and not soon pacified when once provoked. He was an enemy to dissimilation, and free even to a fault. Few men required so little relaxation as Mr Hunter did, for he seldom slept above four hours in the night, but always an hour after dinner. In private practice he was scrupulously honest in declaring his opinion of the case before him, and ready on all occasions to confess his ignorance of what he did not understand. He sometimes spoke harshly of his cotemporaries; which did not originate from envy, but from a full conviction that surgery was as yet in its infancy, and he himself a novice in his own art.

On October the 16th 1793, when in his usual state of health, he went to St George’s hospital, and meeting with some things which irritated his mind, and not being perfectly master of the circumstances, he withheld his sentiments; in which state of restraint he went into the next room, and turning round to Dr Robertson, one of the physicians of the hospital, he gave a deep groan and dropped down dead, being then in his 65th year, the same age at which his brother Dr Hunter had died.

HUNTING, the exercise or diversion of pursuing four-footed beasts of game. See the article GAME.

Four-footed beasts are hunted in the fields, woods, and thickets, and that both with guns and hounds.

Birds, on the contrary, are either shot in the air, or taken with nets and other devices, which exercise is called Fowling; or they are pursued and taken by birds of prey, which is called Hawking. See the articles FOWLING, HAWKING, FALCONRY, SHOOTING, BIRD-Catching, and Decoy.

F. de Launay, professor of the French laws, has an express treatise of hunting. From those words of God to Adam, Gen. i. 26. and 28. and to Noah, Gen. ii. 2, 3. hunting was considered as a right devoted or made over to man; and the following ages appear to have been of the same sentiment. Accordingly we find, that among the most civilized nations it made one of their diversions; and as to the wilder and more barbarous it served them with food and necessaries. The Roman jurisprudence, on the contrary, was based on the manners of the first ages, made a law of it, and established it as a maxim, that as the natural right of things which have no master belongs to the first possessor, wild beasts, birds, and fishes, are the property of whosoever can take them first.

But the northern nations of barbarians who overran the Roman empire, bringing with them a stronger taste for the diversion, and the people being now possessed of other and more easy means of subsistence from the lands and possessions of those they had vanquished, their chiefs and leaders began to appropriate the right of hunting, and, instead of a natural right, to make it a royal one. Thus it continues to this day; the right of hunting, among us, belonging only to the king, and those who derive it from him.

The hunting used by the ancients was much like that now practised for the rein-deer; which is seldom hunted at force, or with hounds; but only drawn with a blood-hound, and forestalled with nets and engines. Thus did they with all beasts; whence a dog is never commanded by them for opening before he has discovered where the beast lies. Hence, they were not in any manner curious as to the music of their hounds, or the composition of their kennel or pack, either for
Hunting formed the greatest part of the employment of the ancient Germans, and probably of the Britons also, when they were not engaged in war. We are informed by some ancient historians, that this was the case even as late as the third century with the unconquered Britons who lived beyond Adrian's wall; nay, that their subsistence chiefly was in feeding they took in this way. The great attachment shown by all the Celtic nations to hunting, however, proceeded most probably from its being a kind of apprenticeship to war. Thus their youth acquired that courage, strength, swiftness, and dexterity in handling their arms, which made them so formidable in time of war to their enemies. Thus also they freed the country from many mischievous animals which abounded in the forests, furnishing themselves also with materials for those feasts which seem to have constituted their greatest pleasure. The young chieftains had thus likewise an opportunity of paying court to their mistresses, by displaying their bravery and agility, and making them presents of their game; nay, so strong and universal was the passion for hunting among the ancient Britons, that young ladies of the highest quality and greatest beauty spent much of their time in the chase. They employed much the same weapons in hunting that they did in war, viz. long spears, javelins, and bows and arrows; having also great numbers of dogs to assist them in finding and pursuing their game. These dogs, we are also told, were much admired among other nations, on account of their swiftness, strength, fierceness, and exquisite sense of smelling. They were of several different kinds, called by different names, and formed a considerable article of commerce. They were highly valued by all the Celtic nations, insomuch that some very comical penalties were inflicted upon those who were convicted of stealing them. From the poems of Ossian also it appears, that the Britons were not unacquainted with the art of catching birds with hawks trained for that purpose; but they seem to have been absolutely ignorant of the method of catching fish; for there is not a single allusion to this art in all the works of that venerable bard. Their ignorance of this art is both confirmed and accounted for by Dio NICEUS, who assures us, that the ancient Britons never tasted fish, though they had innumerable multitudes in their seas, rivers, and lakes. By the bye (says Dr. Henry), we may observe that this agreement between the poems of Ossian and the Greek historian, in a circumstance so singular, is at once a proof of the genuine antiquity of these poems, and that the Greek and Roman writers were not so ill informed about the affairs and manners of the ancient Britons as some have imagined.

The Mexicans, whatever imbecility may be imputed to them in other respects, were very dexterous in hunting. They used bows and arrows, darts, nets, snares, and a kind of tubes named carbotane, through which they shot by blowing out little balls at birds. Those which the kings and great men made use of were curiously carved and painted, and likewise adorned with gold and silver. Besides the exercise of the chase which private individuals took either for amusement or to provide food for themselves, there were general hunting-matches, sometimes appointed by the king; at others, undertaken with a view to provide plenty of victims for sacrifices. A large wood, generally that of Zacapaque, not far distant from the capital, was pitched upon as the scene of these grand hunting-matches. Here they chose the place best adapted for setting a great number of snares and nets. The wood was inclosed by some thousands of hunters, forming a circle of six, seven, or eight miles, according to the number of animals they intended to take. Fire was then set to the grass in a great number of places, and a terrible noise made with drums, horns, shouting, and whistling. The hunters gradually contracted their circle, continuing the noise till the game were inclosed in a very small space. They were then killed or taken in snares, or with the hands of the hunters. The number of animals taken or destroyed on these occasions was so great, that the first Spanish viceroy of Mexico would not believe it without making the experiment himself. The place chosen for his hunting-match was a great plain in the country of

(A) Si quis canem vel truvaum vel petrunclus, presumerit involare, jubemus ut convictus, coram omni populo, posteriora ipsius oculos oculatur.
the Otomies, lying between the villages of Xilotepec and S. Giovani del Rio; the Indians being ordered to proceed according to their usual customs in the times of their paganism. The viceroy, attended by a vast retinue of Spaniards, repaired to the place appointed, where accommodations were prepared for them in houses of wood erected for the purpose. A circle of more than 15 miles was formed by 11,000 Otomies, who started such a quantity of game on the plain, that the viceroy was quite astonished, and commanded the greater part of them to be set at liberty, which was accordingly done. The number retained, however, was still incredibly great, were it not attested by a witness of the highest credit. On this occasion upwards of 600 deer and wild goats, 100 cajotes, with a surprising number of hares, rabbits, and other smaller animals. The plain still retains the Spanish name Cuzadera, which signifies the "place of the chase."

The Mexicans, besides the usual methods of the chase, had particular contrivances for catching certain animals. Thus, to catch young asses, they made a small fire in the woods, putting among the burning coals a particular kind of stone named cacatl, "raven or black stone," which bursts with a loud noise when heated. The fire was covered with earth, and a little maize laid around it. The asses quickly gathered about their young, in order to feed upon the maize; but while they were thus employed, the stone burst, and scared away the old ones by the explosion, while the young ones, unable to fly, were carried off by the hunters. Serpents were taken even by the hands, seizing them intrepidly by the neck with one hand, and sewing up their mouths with the other. This method is still practised. They showed the greatest dexterity in tracing the steps of wild beasts, even when an European could not have discerned the smallest print of their feet. The Indian method, however, was by observing sometimes the herbs or leaves broken down by their feet; sometimes the drops of blood which fell from them when wounded. It is said that some of the American Indians show still greater dexterity in discovering the tracks of their enemies, which to an European would be altogether imperceptible.

Hunting was a favourite diversion of the great and bloody conqueror Jenghiz Khan, if indeed we can apply the word diversion to a monster whose mind was set upon the destruction of his own species, and who only endeavoured to make the murder of brutes subservient to that of men, by keeping his soldiers in a kind of warfare with the beasts when they had no human enemies to contend with. His expeditions were conducted on a plan similar to that of the Mexicans already mentioned; and were no doubt attended with still greater success, as his numerous army could enclose a much greater space than all the Indians whom the Spanish viceroy could muster. The East Indian princes still show the same inclination to the chase; and Mr. Biane, who attended the hunting excursions of Asoph Ul Dowlah visir of the Mogul empire and nabob of Oude in 1785 and 1786, gives the following account of the method practised on this occasion.

The time chosen for the hunting party is about the beginning of December; and the diversion is continued till the heat, which commences about the beginning of March, oblige them to stop. During this time a circuit of between 400 and 600 miles is generally made; the hunters bending their course towards the skirts of the northern mountains, where the country is wild and uncultivated. The visit takes along with him not only his court and seraglio, but a great part of the inhabitants of his capital. His immediate attendants may amount to about 2000; but besides these he is also followed by 600 or 800 horse, and several battalions of regular sepoyos with their field-pieces. Four or five hundred elephants are also carried along with him: of which some are used for riding, others for fighting, and some for clearing the jungles and forests of the game. About as many sumpter horses of the beautiful Persian and Arabian breeds are carried along with him. A great many wheel carriages drawn by bullocks likewise attend, which are used chiefly for the convenience of the women; sometimes also he has an English chaise or two, and sometimes a chariot; but all these as well as the horses are merely for show, the visir himself never using any other conveyance than an elephant, or sometimes when fatigued or indisposed a palanquin. The animals used in the sport are principally greyhounds, of which there may be about 200; he has also about 200 hawks, and a few trained leopards for hunting deer. There are a great number of marksmen, whose profession it is to shoot deer; with many fowlers, who provide game: as none of the natives of India know how to shoot game with small shot, or to hunt with slow hounds. A vast number of matchlocks are carried along with the company, with many English pieces of various kinds, 40 or 50 pairs of pistols, bows and arrows, besides swords, daggers, and sabres without number. There are also nets of various kinds, some for quail, and others very large, for fishing, which are carried along with him upon elephants, attended by fishermen, so as always be ready for throwing into any river or lake that may be met with. Every article that can contribute to luxury or pleasure is likewise carried along with the army. A great many carts are loaded with the Ganges water, and even ice is transported for cooling the drink. The fruits of the season and fresh vegetables are daily sent to him from his gardens by bearers stationed at the distance of every ten miles; which means each article is conveyed day or night at the rate of four miles an hour. Besides the animals already mentioned, there are also fighting antelopes, buffaloes, and rams in great numbers; also several hundred pigeons, some fighting cocks, with a vast variety of parrots, nightingales, &c.

To complete the magnificence or extravagance of this expedition, there is always a large bazar, or moving town, which attends the camp; consisting of shop-keepers and artificers of all kinds, money-changers, dancing-women; so that, on the most moderate calculation, the whole number of people in his camp cannot be computed at fewer than 20,000. The nabob himself, and all the gentlemen of his camp, are provided with double sets of tents and equipage, which are always sent on the day before to the place to which he intends to go; and this is generally eight or ten miles in whatever direction most game is expected; so that by the time he has finished his sport in the morning, he finds his whole camp ready pitched for his reception.
The nabob, with the attending gentlemen, proceeded in a regular moving court or durbar, and thus they keep conversing together and looking out for game. A great many foxes, hares, jackals, and sometimes deer, are picked up by the dogs as they pass along; the hawks are carried immediately before the elephants, and let fly at whatever game is sprung for them, which is generally partridges, bustards, quails, and different kinds of herons; these last affording excellent sport with the falcons or sharp-winged hawks. Wild boars are sometimes started, and either shot or run down by the dogs and horsemen. Hunting the tyger, however, is looked upon as the principal diversion, and the discovery of one of these animals is accounted a matter of great joy. The cover in which the tyger is found is commonly long grass, or reeds of such a height as frequently to reach above the elephants; and it is difficult to find him in such a place, as he commonly endeavours either to steal off, or lies so close to the ground that he cannot be roused till the elephants are almost upon him. He then roars and skullis away, but is shot at as soon as he can be seen; it being generally contrived that the nabob shall have the compliment of firing first. If he be not disabled, the tyger continues to skulk along, followed by the line of elephants; the nabob and others shooting at him as often as he can be seen till he falls. The elephants themselves are very much afraid of this terrible animal, and discover their apprehensions by shriking and roaring as soon as they begin to smell him or hear him growl; generally attempting to turn away from the place where he is. When the tyger can be traced to a particular spot, the elephants are disposed of in a circle round him; in which case he will at last make a desperate attack, springing upon the elephant that is nearest, and attempting to tear him with his teeth or claws. Some, but very few, of the elephants, can be brought to attack the tyger; and this they do by curling up their trunks under their mouths, and then attempting to toss, or otherwise destroy him with their tusks, or to crush him with their feet or knees. It is considered as good sport to kill one tyger in a day; though sometimes, when a female is met with her young ones, two or three will be killed.

The other objects of pursuit in these excursions are wild elephants, buffaloes, and rhinoceroses. Our author was present at the hunting of a wild elephant of vast size and strength. An attempt was first made to take him alive by surrounding him with tame elephants, while he was kept at bay by crackers and other fire-works; but he constantly eluded every effort of this kind. Sometimes the drivers of the tame elephants got so near him, that they threw strong ropes over his head, and endeavoured to detain him by fastening them around trees; but he constantly snapped the ropes like pack-threads, and pursued his way to the forest. Some of the strongest and most furious of the fighting elephants were then brought up to engage him; but he attacked them with such fury that they were all obliged to desist. In his struggle with one of them he broke one of his tusks, and the broken piece, which was upwards of two inches in diameter, of solid ivory, flew up into the air several yards above their heads. Orders were now given to kill him, as it appeared impossible to take him alive; but even this was not accomplished without the greatest difficulty. He twice turned and attacked the party who pursued him; and in one of these attacks struck the elephant obliquely on which the prince rode, threw him upon his side, but then passed on without offering further injury. At last he fell dead, after having received as was supposed upwards of 1000 balls into his body.

Notwithstanding the general passion among most nations for hunting, however, it has by many been deemed an exercise inconsistent with the principles of humanity. The late king of Prussia expressed himself on this subject in the following manner. "The chase is one of the most sensual of pleasures, by which the powers of the body are strongly exerted, but those of the mind remain unemployed. It is an exercise which makes the limbs strong, active, and pliable: but leaves the head without improvement. It consists in a violent desire in the pursuit, and the indulgence of a cruel pleasure in the death, of the game. I am convinced that man is more cruel and savage than any beast of prey: We exercise the dominion given us over these our fellow-creatures in the most tyrannical manner. If we pretend to any superiority over the beasts, it ought certainly to consist in reason; but we commonly find that the most passionate love of the chase reconciles this privilege, and converse only with their dogs, horses, and other irrational animals. This renders them wild and unfeeling; and it is probable that they cannot be very merciful to the human species. For a man who can in cold blood torture a poor innocent animal, cannot feel much compassion for the distresses of his own species. And, besides, can the chase be a proper employment for a thinking mind?"

The arguments used by his majesty against hunting seem indeed to be much confirmed by considering the various nations who have most addicted themselves to it. There, as must be seen from what has already been said, were all barbarous; and it is remarkable, that Nimrod, the first great hunter of whom we have any account, was likewise the first who oppressed and enslaved his own species. As nations advanced in civilization, it always became necessary to restrain by law the inclination of the people for hunting. This was done by the wise legislator Solon, last the Athenians should neglect the mechanic arts on its account. The Lacedemonians, on the contrary, indulged themselves in this diversion without control; but they were barbarians, and most cruelly oppressed those whom they had in their power, as is evident from their treatment of the Helots. The like may be said of the Egyptians, Persians, and Scythians; all of whom delighted in war, and oppressed their own species. The Romans, on the other hand, who were somewhat more civilized, were less addicted to hunting. Even they, however, were exceedingly barbarous, and found it necessary to make death and slaughter familiar to their citizens from their infancy. Hence their diversions of the amphitheatre and circus, where the hunting of wild beasts was shown in the most magnificent and cruel manner; not to mention their still more cruel sport of gladiators, &c.

In two cases only does it seem possible to reconcile the practice of hunting with humanity; viz. either when
when an uncultivated country is overrun with noxious animals; or when it is necessary to kill wild animals for food. In the former case, the noxious animals are killed because they themselves would do so if they were allowed to live; but if we kill even a lion or a tyger merely for the pleasure of killing him, we are undoubtedly chargeable with cruelty. In like manner, our modern foxhunters expressly kill foxes, not in order to destroy the breed of these noxious animals, but for the pleasure of seeing them exert all their power and cunning to save their lives, and then beholding them torn in pieces after being half dead with fatigue. This refinement in cruelty, it seems, is their favourite diversion; and it is accounted a crime for any person to destroy these animals in self-defence, as appears from the following passage in Mr. Beckford's treatise on hunting: "Besides the digging of foxes, by which method many young ones are taken and old ones destroyed, traps, &c. are too often fatal to the. Farmers for their lamb, (which by the bye, few foxes ever kill) gentlemen for their game, and old women for their poultry, are their invertebrate enemies. In the country where I live, most of the gentlemen are sportsmen; and even those who are not, show every kind of attention to those who are. I am sorry it is otherwise with you; and that your old gouty neighbour should destroy your foxes, I must own concerns me. I know some gentlemen, who, when a neighbour had destroyed all their foxes, and thereby prevented them from pursuing a favourite amusement, loaded a cart with spaniels, and went all together and destroyed his pheasants. I think they might have called this very properly les tabions: and it had the desired effect; for so the gentleman did not think it prudent to fight them all, he took the wiser method, he made peace with them. He gave an order that no more foxes should be destroyed, and they never afterwards killed any of his pheasants."

In the first volume of the Manchester Transactions we have a dissertation upon the diversions of hunting, shooting, &c., as separable from the principle of humanity. One argument used by the author is, that death is no positive evil to brutes. "It would perhaps (says he) be too hasty an assertion to affirm, that death to brutes is no evil. We are not competent to determine whether their existence, like our own, may not extend to some future mode of being, or whether the present limited sphere is all in which they are interested. On so speculative a question little can be advanced with precision; nor is it necessary for the investigation of the subject before us. If we may be allowed to reason from what we know, it may be safely conjectured, that death to brutes is no positive evil: we have no reason to believe they are endowed with foresight; and therefore, even admitting that with them the pleasures of life exceed its pains and cares, in terminating their existence, they only suffer a privation of pleasure."

On this extraordinary piece of reasoning we may observe, that it would hold much more against the human species than against the brutes. There are few amongst us willing to allow that the pleasures we enjoy are equivalent to our pains and cares: death therefore must be to us a relief from pain and misery, while to the brutes it is a privation of pleasure. Hence, if it be no positive evil for a brute to suffer death, to a man it must be a positive good: add to which, that a man lives in hope of an endless and glorious life, while a brute has no such hope; so that, if to kill a brute, on our author's principles, be no cruelty, to kill a man must be an act of tenderness and mercy!

Another argument, no less inconclusive, is our author's supposing that death from disease is much more to be dreaded in a brute than a violent death. Were brutes naturally in as helpless a state as man, no doubt their want of support from society in cases where they are attacked by sickness would be very deplorable; but it must be considered that the parallel between the two species is in this respect by no means fair. A brute has everywhere its food at hand, and is naturally capable of resisting the inclemencies of the weather; but man has not only a natural inability to procure for himself in the way that the brutes do, but is, besides, very tender and incapable of resisting the inclemencies of the air. Hence, a man unassisted by society must very soon perish; and, no doubt, it would be much more merciful for people to kill one another at once, than to deprive them of the benefits of society, as is too frequently done in various ways needless to be mentioned at present. A brute, however, has nothing to fear. As long as its stomach can receive food, nature offers an abundant supply. One that feeds upon grass has it always within reach; and a carnivorous one will content itself with worms or insects, which, as long as it is able to crawl, it can still make a shift to provide; but so totally helpless is man when left in a state of weakness, that many barbarous nations have looked upon the killing of their old and infirm people to be an act of mercy.

Equally unhappy is our author in his other arguments, that the quick transition from a state of perfect health to death mitigates the severity. The transition is not quick. The sportsmen estimate their diversion by the length of the chase; and during all that time the creature must be under the strongest agonies of terror and pain. The principle of humanity is there who must not feel for an animal in this situation? All this is assented to by our author, who says, "Hard is the heart who does not commiserate the sufferer." Is not this an acknowledgment on his part, that before a person can become a thorough sportman he must harden his heart, and stifle those amiable sensations of compassion, which on all occasions ought to be encouraged towards every creature, unless in cases of necessity. But in the present case no necessity is or can be pretended. If a gentleman chooses to regulate himself with venison of any kind, he may breed the animals for the purpose. We call Domitian cruel, because he took pleasure in catching flies, and stabbing them with a bodkin. A butcher is excluded from sitting on a jury on account of his being accustomed to sights which are deemed inhuman; but whether it is more inhuman to knock down an ox at once with an axe, or to tear him in pieces with dogs, (for they would accomplish the purpose if properly trained), must be left to the sportsmen to determine.

Lastly, the great argument in favour of hunting, that it contributes to the health of the body and exhilaration of the spirits, seems equally fallacious with the rest. It cannot be proved that hunters are more healthy or long-lived.
HUNTING lived than other people. That exercise will contribute to the preservation of health, as well as to the exhilaration of the mind, is undoubted; but many other kinds of exercise will do this as well as hunting. A man may ride from morning to night, and amuse himself with viewing and making remarks on the country through which he passes; and surely there is no person will say that this exercise will tend to impair his health or sink his spirits. A man may amuse and exercise himself not only with pleasure, but profit also, in many different ways, and yet not accustom himself to behold the death of animals with indifference. It is this that constitutes the cruelty of hunting; because we thus wilfully extinguish in part that principle naturally implanted in our nature, which if totally eradicated would set us not only on a level with the most ferocious wild beasts, but perhaps considerably below them; and it must always be remembered, that whatever pleasure terminates in death is cruel, let us use as many palliatives as we please to hide that cruelty from the eyes of others, or even from our own.

The gentlemen and masters of the sport have invented a set of terms which may be called the hunting-language. The principal are those which follow:
1. For beasts as they are in company—They say, a herd of harts, and all manner of deer. A bay of roes. A sounder of swine. A rout of wolves. A richness of martens. A brace or leash of bucks, foxes, or hares. A couple of rabbits or conies.
4. For their copulation.—A hart or buck goes to rut. A roe goes to tour. A boar goes to brum. A hare or coney goes to buck. A fox goes to climaciting. A wolf goes to match or make. An otter hunteth for his kind.
5. For the footing and treading.—Of a hart, we say the stat. Of a buck, and all fallow-deer, the view. Of all deer, if on the grass and scarce visible, the foiling. Of a fox, the print; and of other the like vermin, the footing. Of an otter, the marks. Of a boar, the track. The hare when in open field, is said to sore; when she winds about to deceive the hounds, she doubles; when she beats on the hard highway, and her footing comes to be perceived, she pricketh: in snow, it is called the trace of the hare.
6. The tail of a hart, buck, or other deer, is called the single. That of a boar, the sweathe. Of a fox, the brush or drag; and the tip at the end, the chape. Of a wolf, the stern. Of a hare and coney, the scut.
7. The ordure or excrement of a hart and all deer, is called fresmenets or festernishing. Of a hare, corbiles or corbling. Of a boar, lesser. Of a fox, the bittling; and of other the like vermin, the snotte. Of an otter, the sponcipe.
8. As to the attire of deer, or parts thereof, those of a stag, if perfect, are the bur, the pears, the little knowes on it, the beam, the gutter, the antler, the surantler, royal, sur-royal, and all at top the croches. Of the buck, the bur, beam, brow-antler, black-antler, advanced, palm, and spellers. If the croches grow in the form of a man's hand, it is called a palmèd head. Heads bearing not above three or four, and the croches placed aloft, all of one height, are called crownèd heads. Heads having double croches, are called forkèd heads, because the croches are planted on the top of the beam like forks.
9. They say, a litter of cubs, a nest of rabbits, a squirrel's-drey.
10. The terms used in respect of the dogs, &c. are as follow.—Of grehounds, two make a brace; of hounds a couple. Of grehounds, three make a leash; of hounds, a couple and half. They say, let slip a grehound; and, cast off a hound. The string wherein a grehound is led, is called a leash; and that of a hound, a ympne. The grehound has his collar, and the hound his ympnes. We say a kennel of hounds, and a pack of beagles.

HUNTING, as practised among us, is chiefly performed with dogs; of which we have various kinds, accommodated to the various kinds of game, as, hounds, grehounds, bloodhounds, terriers, &c. See Canis, hound, &c.

In the kennels or packs they generally rank them under the heads of enterors, drivers, flyers, tyers, &c.

On some occasions, nets, spears, and instruments for digging the ground, are also required: nor is the hunting horn to be omitted.

The usual chases among us are, the hart, buck, roe, hare, fox, badger, and otter. We shall here give something of what relates to each thereof: first premising an explanation of some general terms and phrases, more immediately used in the progress of the sport itself; what belongs to the several sorts of game in particular being reserved for the respective articles.

When the hounds, then, being cast off, and finding the scent of some game, begin to open and cry; they are said to challenge. When they are too busy are the scent be good, they are said to bubble. When too busy where the scent is good, to bellow. When they run it endewise orderly, holding in together merrily, and making it good, they are said to be in full cry. When they run along without opening at all, it is called running mute.

When spaniels open in the string, or a grehound in the course, they are said to lapae.

When beagles bark and cry at their prey, they are said to yawn.

When the dogs hit the scent the contrary way, they are said to draw amiss.

When they take fresh scent, and quit the farmer chase for a new one, it is called hunting change.

When they hunt the game by the heel or track, they are said to hunt counter.
Hunting. When the chase goes off, and returns again, traversing the same ground, it is called hunting the field.

When the dogs run at a whole herd of deer, instead of a single one, it is called running riot.

Dogs set in readiness where the game is expected to come by, and cast off after the other hounds are passed, are called a relay. If they be cast off ere the other dogs be out, it is called evanting.

When, finding where the chase has been, they make a progress to enter, but return, it is called a semisirch.

A lesson on the horn to encourage the hounds, is named a call, or a rocchet. That blown at the death of a deer, is called the mors. The part belonging to the dogs of any chase they have killed, is the reward. They say, take off a deer’s skin; strip or case a hare, fox, and all sorts of vermin; which is done by beginning at the snout, and turning the skin over the ears down to the tail.

Hunting is practised in a different manner, and with different apparatus, according to the nature of the beasts which are hunted, a description of which may be found under their respective articles, infra.

With regard to the seasons, that for hart and buck-hunting begins a fortnight after midsummer, and lasts till Holy-rood day; that for the hind and doe, begins on Holy-rood day, and lasts till Candlemas; that for fox-hunting begins at Christmas, and holds till Lady-day; that for roe-hunting begins at Michaelmas, and ends at Christmas, hare-hunting commences at Michaelmas, and lasts till the end of February; and from where the wolf and boar are hunted, the season for each begins at Christmas, the first ending at Lady-day, and the latter at the Purification.

When the sportsmen have provided themselves with nets, spears, and a hunting horn to call the dogs together, and likewise with instruments for digging the ground, the following directions will be of use to them in the pursuit of each sort of game.

Badger-Hunting. In doing this, you must seek the earths and burrows where he lies, and in a clear moonshine night go and stop all the burrows, except one or two, and therein place some sacks, fastened with drawing strings, which may shut him in as soon as he strainteth the bag. Some use no more than to set a hoop in the mouth of the sack, and so put it into the hole; and as soon as the badger is in the sack and strainteth it, the sack slippereth off the hoop, and follows him to the earth, so he lies tumbling therein till he is taken. These sacks or bags being thus set, cast off the hounds, beating about all the woods, coppices, hedges, and tufts, round about, for the compass of a mile or two; and what badgers are abroad, being alarmed by the hounds, will soon betake themselves to their burrows; and observe, that he who is placed to watch the sacks, must stand close and upon a clear wind: otherwise the badger will discover him, and will immediately fly some other way into his burrow. But if the hounds can encounter him before he can take his sanctuary, he will then stand at a bay like a boar, and make good sport, grievously biting and clawing the dogs; for the manner of their fighting is lying on their backs, using both teeth and nails; and by blowing up their skins, defend themselves against all bites of the dogs, and blows of the men upon their noses. And for the better preservation of your dogs, it is good to put broad collars about their necks made of gray hair skins.

When the badger perceives the terriers to begin to yearn him in his burrow, he will stop the hole between him and the terriers, and if they still continue baying, he will remove his couch into another chamber or part of the burrow, and so from one into another, barricading the way before them, as they retreat, until they can go no further. If you intend to dig the badger out of his burrow, you must be provided with the same tools as for digging out a fox; and besides, you should have a pail of water to refresh the terriers, when they come out of the earth to take breath and cool themselves. It will also be necessary to put collars of bells about the necks of your terriers, which making a noise may cause the badger to bolt out. The tools used for digging out of the badger, being troublesome to be carried on men’s backs, may be brought in a cart. In digging, you must consider the situation of the ground, by which you may judge where the chief angles are; for else, instead of advancing the work, you will hinder it. In this order you may besiege them in their folds, or castles; and may break their platforms, parapets, casemates, and work to them with mines and countermines until you have overcome them.

Having taken a live and lusty badger, if you would make sport, carry him home in a sack and turn him out in your court-yard, or some other enclosed place, and there let him be hunted and worried to death by your hounds.

There are the following profits and advantages which accrue, by killing this animal. Their flesh, blood, and grease, though they are not good food, yet are very useful for physicians and apothecaries for ointments, salves, and powders for shortness of breath, the cough of the lungs, for the stone, sprained sinews, colt-achet, &c.; and the skin being well dressed, is very warm and good for old people who are troubled with paralytic distempers.

Boar-Hunting. See Boar.

Buck-Hunting. Here the same bounds and methods are used as in running the stag; and, indeed, he that can hunt a hart or stag well, will not hunt a buck ill.

In order to facilitate the chase, the game-keeper commonly selects a fat buck out of the herd, which he shoots in order to main him, and then he is run down by the hounds.

As to the method of hunting the buck. The company generally go out very early for the benefit of the morning. Sometimes they have a deer ready lodged, if not, the covert is drawn till one is roused; or sometimes in a park a deer is pitched upon, and forced from the herd, then more bounds are laid on to run the chase. If you come to be at a fault, the old staunch bounds are only to be relied upon till you recover him again: if he be sunk, and the hounds thrust him up, it is called an imprist, and the company all sound a rocchet; when he is run down, every one strives to get in to prevent his being torn by the hounds, follow deer seldom or never standing at bay.

He that first gets in, cries hoo-up, to give notice that he is down, and blows a death. When the company all come in, they paunch him, and reward the hounds, and generally the chief person of quality amongst them takes say, that is, cuts his belly open, to see how fat he
do not get forward enough to take advantage of this eagerness and impetuosity, and direct it properly, seldom know enough of hunting to be of much use to them afterwards. Though a huntsman cannot be too fond of hunting, a whipper-in easily may. His business will seldom allow him to be forward enough with the hounds to see much of the sport. His only thought therefore should be to keep the hounds together, and to contribute as much as he can to the killing of the fox: keeping the hounds together is the surest means to make them steady. When left to themselves they seldom refuse any blood they can get; they become conceived; learn to tie upon the scent; and besides this they frequently get a trick of hunting by themselves, and are seldom good for much afterwards.

"Every country is soon known; and nine foxes out of ten, with the wind in the same quarter, will follow the same track. It is therefore easy for the whipper-in to cut short, and catch the hounds again. With a high scent you cannot push on hounds too much. Screams keep the fox forward, at the same time that they keep the hounds together, or let in the tail-hounds: they also enliven the sport; and, if discreetly used, are always of service; but in cover they should be given with the greatest caution. Halloos seldom do any hurt when you are running up the wind, for then none but the tail hounds can hear you: when you are running down the wind, you should hallow no more than may be necessary to bring the tail hounds forwards; for a hound that knows his business seldom wants encouragement when he is upon a scent.—Most fox-hunters wish to see their hounds run in a good style. I confess I myself am one of those; I hate to see a string of them; nor can I bear to see them creep where they can leap. A pack of harriers, if they have time, may kill a fox, but I defy them to kill him in the style in which he ought to be killed; they must hunt him down. If you intend to tire him out, you must expect to be tired also yourself; I never wish a chase to be less than one hour, or to exceed two: It is sufficiently long if properly followed: it will seldom be longer unless there be a fault somewhere either in the day, the huntsman, or the hounds.

"Changing from the hunted fox to a fresh one is as bad an accident as can happen to a pack of fox-hounds, and requires all the ingenuity and observation that man is capable of to guard against it. A fox-hound distinguishes a hunted fox as the deer-hound does the deer that is blown, fox-hunting would then be perfect. A huntsman should always listen to his hounds while they are running in cover; he should be particularly attentive to the headmost hounds, and he should be constantly on his guard against a skirter: for if there be two scents, he must be wrong. Generally speaking, the best scent is least likely to be that of the hunted fox: and as a fox seldom suffers bounds to run up to him as long as he is able to prevent it; so, nine times out of ten, when foxes are hallowed early in the day, they are all fresh foxes. The hounds most likely to be right are the hard-running line-hunting ones; or such as the huntsman knows had the lead before there arose any doubt of changing. With regard to the fox, if he break over an open country, it is no sign that he is hard run; for they seldom at any time will do that unless they are a great way before the hounds. Also if he runs up
When the hounds divide, and are in two parts, the
whipper-in, in stopping, must attend to the hunt-
sman and wait for his halloo, before he attempts to stop ei-
ther: for want of proper management in this respect, I
have known the hounds stopped at both places, and
both foxes lost. If they have many scents, and it is
quite uncertain which is the hunted fox, let him stop
those that are farthest down the wind; as they can hear
the others, and will reach them sooner: in such a case
there will be little use in stopping those that are up
the wind. When hounds are at a check, let every one be
silent and stand still. Whippers-in are frequently at
this time coming on with the tail hounds. They should
never halloo to them when the hounds are at fault;
the least thing does them harm at such a time, but a hal-
loo more than any other. The huntsman, at a check,
had better let his hounds alone; or content himself
with holding them forward, without taking them off
their noses.—Should they be at a fault, after having
made their own cast (which the huntsman should always
first encourage them to do), it is then his business to
assist them further; but except in some particular in-
stances, I never approve of their being cast as long as
they are inclined to hunt. The first cast I bid my
huntsman make it generally a regular one, not choosing
to rely entirely on his judgment: if that should not suc-
ced, he is then at liberty to follow his own opinion,
and proceed as observation or genius may direct. When
such a cast is made, I like to see some mark of good
sense and meaning in it; whether down the wind, or
through some likely cover or strong earth. However,
as it is at best uncertain, I always wish to see a regular
cast before I see a knowing one: which, as a last res-
source, should not be called forth till it be wanted.
The letting hounds alone is but a negative goodness
in a huntsman; whereas it is true this last shows real
genius; and to be perfect it must be born with him.
There is a fault, however, which a knowing huntsman
is too apt to commit: he will find a fox, and then
claim the merit of having recovered the hunted one.
It is always dangerous to throw hounds into a cover to
retrieve a lost scent; and unless they hit him in, is not
to be depended on.

Gentlemen, when hounds are at fault, are too apt
to themselves to prolong it. They should always stop
their horses some distance behind the hounds; and if
it be possible to remain silent, this is the time to be so.
They should be careful not to ride before the hounds
or over the scent; nor should they ever meet a hound
in the face, unless with a design to stop him. Should
you at any time be before the hounds, turn your horse’s
head the way they are going, get out of their track,
and let them pass by you. In dry weather, and par-
specially in heathy countries, foxes will run the roads.
If gentlemen at such times will ride close upon the
hounds, they may drive them miles without any scent.
—High-metted fox-hounds are seldom inclined to stop
while horses are close at their heels. No one should
ever ride in a direction which if persisted in would
carry him amongst the hounds, unless be be at a great
distance behind them.

The first moment that hounds are at fault is a crit-
ical one for the sport people, who should then be very
attentive. Those who look forward may perhaps see
the fox; or the running of sheep, or the pursuit of
crows, may give them some tidings of him. Those
who listen may sometimes get a hint which may be
not gone from the chattering of a magpie; or perhaps
be at a certainty from a distant halloo: nothing that
can give any intelligence at such a time ought to be
neglected. Gentlemen are too apt to ride all to-
gether: were they to spread more, they might sometimes
be of service; particularly those who, from a know-
ledge of the sport, keep down the wind: it would
then be difficult for either hounds or fox to escape their
observation.—You should, however, be cautious how
you go to a halloo. The halloo itself must in a great
measure direct you; and though it afford no certain
rule, yet you may frequently guess whether it can be
 depended upon or not. At the sowing time, when
boys are keeping off the birds, you will sometimes be
deceived by their halloos; so that it is best, when you
are in doubt, to send a whipper-in to know the cer-
tainty of the matter.”

Hounds ought not to be cast as long as they are able
to hunt. It is a common, though not very just idea,
that a hunted fox never stops; but our author informs
us that he has known them stop even in wheel-ruts in
the middle of a down, and get up in the middle of the
hounds. The greatest danger of losing a fox is at the
first finding him, and when he is sinking; at both which
times he frequently will run short, and the eagerness
of the hounds will frequently carry them beyond the scent.
When a fox is first found, every one ought to keep be-
hind the hounds till they are well settled on the scent;
and when the hounds are catching him, our author
wishes them to be as ultrat as possible; and likewise
to eat him eagerly after he is caught. In some places
they have a method of freeing him; that is, throwing
him across the branch of a tree, and suffering the
hounds to lay at him for some minutes before he is
thrown among them; the intention of which is to make
them more eager, and to let in the tail hounds; doing
this interval also they recover their wind, and are apt
to eat him more readily. Our author, however, ad-
vises not to keep him too long, as he supposes that the
hounds have not any appetite to eat him longer than
while they are angry with him.

2. Under-ground. In case a fox does not escape
as to earth, countrymen must be got together with shov-
els, spades, mattocks, pick-axes, &c. to dig him out,
if they think the earth not too great. They make
their earths as near as they can in ground that is hard
to dig, as in clay, stone ground, or amongst the roots of
trees; and their earths have commonly but one hole,
and that is a straight long way in before you come at
their couch. Sometimes craftily they take possession of
a badger’s old burrow, which hath a variety of cham-
bers, holies, and angles.

Now to facilitate this way of hunting the fox, the
huntsman must be provided with one or two terriers to
put into the earth after him, that is, to fix him into an
angle; for the earth often consists of many angles: the
**Hunting**. The use of the terrier is to know where he lies; as soon as he finds him, he continues baying or barking, so that which way the noise is heard that way dig to him. Your terriers must be garnished with bells hung on collars, to make the fox bolt the sooner; besides, the collars will be some small defence to the terriers.

The instruments to dig withal are these, a sharp-pointed spade, which serves to begin the trench where the ground is hardest and broader tools will not so well enter; the round hollowed spade, which is useful to dig among roots, having very sharp edges; the broad flat spade to dig withal, when the trench has been pretty well opened, and the ground softer; mattocks and pick-axes to dig in hard ground, where a spade will do but little service; the coal-rake to clean the hole, and to keep it from stopping up; clamps, wherewith you may take either fox or badger out alive to make sport with afterwards. And it would be very convenient to have a pail of water to refresh your terriers with, after they are come out of the earth to take breath.

**Hare-Hunting.** As, of all chases, the hare makes the greatest pastime, so it gives no little pleasure to see the craft of this small animal for her self-preservation. If it be rainy, the hare usually takes to the high-ways; and if she comes to the side of a young grove, or spring, she seldom enters, but ска Hun down till the hounds have overtaken her; and then she will return the very way she came, for fear of the wet and dew that hang on the bushes. In this case, the huntsman ought to stay a hundred paces before he comes to the wood-side, by which means he will perceive whether she return as foreseen; which if she do, be must halloo in his hounds; and call them back; and that presently, that the hounds may not think it the counter she came first.

The next thing that is to be observed, is the place where the hare sits, and upon what wind she makes her form, either upon the north or south wind: she will not willingly run into the wind, but run upon a side, or down the wind; but if she form in the water, it is a sign she is foul and measured: if you hunt such a one, have a special regard all the day to the brook-sides; for there, and near plashes, she will make all her crossings, doubling, &c.

Some hares have been so crafty, that as soon as they have heard the sound of a horn, they would instantly start out of their form, though it was at the distance of a quarter of a mile, and go and swim in some pool, and rest upon some rush bed in the midst of it; and would not stir from there till they have heard the sound of the horn again, and then have started out again, swimming to land, and have stood up before the hounds four hours before they could kill them, swimming and using all subtilities and crossings in the water. Nay, such is the natural craft and subtility of a hare, that sometimes after she has been hunted three hours, she will start a fresh hare, and squat in the same form. Others having been hunted a considerable time, will creep under the door of a sheep cot, and hide themselves among the sheep; or, when they have been hard hunted, will run in among a flock of sheep, and will by no means be gotten out from among them till the hounds are coupled up, and the sheep driven into their pens. Some of them (and that seems somewhat strange will take the ground like a soney, and that is called going to the result. Some hares will go up one side of the hedge, and come down the other, the thickness of the bough being the only distance between the courses.

A hare that has been sorely hunted, has got upon a quicker hedge, and run a good way upon the top thereof, and then leapt off upon the ground. And they will frequently betake themselves to forge bushes, and will leap from one to the other, whereby the hounds are frequently in default.

Having found where a hare hath relieved in some pasture or corn-field, you must then consider the season of the year, and what weather it is: for if it be in the spring-time, or summer, a hare will not then set in bushes, because they are frequently infested with pis-mires, snakes, and adders; but will set in corn-fields, and open places. In the winter-time, they set near towns and villages, in tufts of thorns and brambles, especially when the wind is northerly or sotherly. According to the season and nature of the place where the hare is accustomed to sit, there beat with your hounds, and start her; which is much better sport than trailing of her from her relief to her form.

After the hare has been started and is on foot, then step in where you saw her pass, and hallow in your hounds, until they have all undertaken it and go on with it in full cry; then recheat to them with your horn, following fair and softly at first, making not too much noise either with horn or voice; for at the first, hounds are apt to overshoot the chace through too much heat. But when they have run the space of an hour, and you see the hounds are well in with it, and stick well upon it, then you may come nearer with the hounds, because by that time their heat will be cooled, and they will hunt more soberly. But above all things, mark the first doubling, which must be your direction for the whole day; for all the doublings that she shall make afterwards will be like the former; and according to the policies that you shall see her use, and the place where you hunt, you must make your compasses great or little, long or short, to help the defaults, always seeking the moistest and most commodious places for the hounds to scent in.

To conclude: Those who delight in hunting the hare must rise early, lest they be deprived of the scent of her footsteps.

**Hunt or Stag Hunting.** Gesner, speaking of hart-hunting, observes, that this wild, deceitful, and subtle beast, frequently deceives its hunter by windings and turnings. Wherefore the prudent hunter must train his dogs with words of art, that he may be able to set them on, and take them off again at pleasure.

First of all, he should encompass the beast in her own layer, and so unharbour her in the view of the dogs, that so they may never lose her slot or footing. Neither must he set upon every one, either of the herd or those that wander solitary alone, or a little one; but partly by sight, and partly by their footing and fumes, make a judgment of the game, and also observe the largeness of his layer.

The huntsman, having made these discoveries in order to the chase, takes off the couplings of the dogs; and some on horseback, others on foot, follow the cry, with the greatest art, observation, and speed; remembering and intercepting him in his subtle turnings and headings;
HUNTING. [ 684 ]

Hunting, headings; with all agility leaping hedges, gates, pales, ditches; neither fearing thorns, down-hills, nor woods, but mounting a fresh horse if the first tire. Follow the largest head of the whole herd, which must be singled out of the chase; which the dogs perceiving, must follow; not following any other. The dogs are animated to the sport by the winding of horns, and the voices of the huntsmen. But sometimes the crafty beast sends forth his little squire to be sacrificed to the dogs and hunters, instead of himself, lying close the mean time. In this case, the huntsman must sound a retreat, break off the dogs, and take them in, that is, leam them again, until they be brought to the fairer game; which riseth with fear, yet still striveth by flight, until he be wearied and breathless. The nobles call the beast a noise hurt, who, to avoid all his enemies, runneith into the greatest herds, and so brings a cloud of error on the dogs, to obstruct their further pursuit; sometimes also bearing some of the herd into his footings, that so he may the more easily escape by amoung the dogs. Afterwards he betakes himself to his heels again, still running with the wind, not only for the sake of refreshment, but also because by that means he can the more easily hear the voice of his pursuers whether they be far from him or near to him.

At last being again discovered by the hunters and sagacious scent of the dogs, he flies into the herds of cattle, as cows, sheep, &c. leaping on a cow or ox, laying the fore parts of his body thereon, that so touching the earth only with his hinder feet, he may leave a very small or no scent at all behind for the hounds to discern. But their usual manner is; when they see themselves hard beset and every way intercepted, to make force at their enemy with their horns, who first comes upon him, unless they be prevented by spear or sword. When the beast is slain, the huntsman with his horn windeth the fall of the beast; and then the whole company comes up, blowing their horns in triumph for such a conquest; among whom, the skillest opens the beast, and rewards the hounds with what properly belongs to them, for their future encouragement; for which purpose the huntsmen dip bread in the skin and blood of the beast to give to the hounds.

It is very dangerous to go in to a hart at bay; of which there are two sorts, one on land and the other in water. Now, if the hart be in a deep water, where you cannot well come at him, then couple up your dogs; for should they continue long in the water, it would endanger their surturing or foundering. In this case, get a boat, and swim to him, with dagger drawn, or else with rope that has a noose, and throw it over his horns: for if the water be so deep that the hart swims, there is no danger in approaching him; otherwise you must be very cautious.

As to the land-bay, if a hart be burnishered, then you must consider the place; for if it be in a plain and open place, where there is no wood nor covert, it is dangerous and difficult to come in to him; but if he be on a hedge-side, or in a thicket, then, while the hart is starring on the hounds, you may come softly and covertly behind him, and cut his throat. If you miss your aim, and the hart turn head upon you, then take refuge at some tree; and when the hart is at bay, couple up your hounds; and when you see the hart turn head to fly, gallop in roundly to him, and kill him with your sword.

Directions at the Death of a Hart or Buck. The first ceremony, when the huntsman comes in to the death of a deer, is to cry "were haunch," that the bounds may not break into the deer; which being done, the next is the cutting his throat, and there blooding the youngest hounds, that they may the better love a deer, and learn to leap at his throat: then the mort having been blown, and all the company come in, the best person who hath not taken any before, is to take up the knife that the keeper or huntsman is to lay across the belly of the deer, some holding by the fore legs, and the keeper or huntsman drawing down the pizzle, the person who takes says, is to draw the edge of the knife leisurely along the middle of the belly, beginning near the brisket, and drawing a little upon it, enough in the length and depth to discover how fat the deer is; then he that is to break up the deer, first slits the skin from the cutting of the throat downward, making the leisure, that so the ordure may not break forth, and then be paunches him, rewarding the bounds with it.

In the next place, he is to present the same person who took say, with a drawn hanger, to cut off the head of the deer. Which being done, and the bounds rewarded, the concluding ceremony is, if it be a stag, to blow a triple mort; and if a buck, a double one; and then all who have horns, blow a reechet in concert, and immediately a general whoop, whoop.

Otter-Hunting is performed with dogs, and also with a sort of instruments called otter-spears; with which when they find themselves wounded, they make to land, and fight with the dogs, and that most furiously, as if they were sensible that cold water would annoy their green wounds.

There is indeed craft to be used in hunting them, but they may be caught in snares under water, and by river-sides; but great care must be taken, for they bite sorely and venomously; and if they happen to remain long in the snare, they will not fail to get themselves free by their teeth.

In hunting them, one man must be on one side of the river, and another on the other, both beating the banks with dogs; and the beast not being able to endure the water long, you will soon discover if there be an otter or not in that quarter; for he must come out to make his spraints, and in the night sometimes to feed on grass and herbs.

If any of the hounds finds out an otter, then view the soft grounds and moist places, to find out which way he bent his head; if you cannot discover this by the marks, you may partly perceive it by the spraints; and then follow the hounds, and lodge him as a hart or deer. But if you do not find him quickly, you may imagine he is gone to couche somewhere farther off from the river; for sometimes they will go to feed a considerable way from the place of their rest, choosing rather to go up the river than down it. The persons that go a-hunting otters, must carry their spears, to watch his vents, that being the chief advantage; and if they perceive him swimming under water, they must endeavour to strike him with their spears, and if they miss, must pursue him with the hounds, which, if they be good and perfectly entered, will go chast
Hunting and travelling along by the river-side, and will beat every root of a tree, and osier-lead, and tuft of bushes; nay, they will sometimes take water, and bait the beast, like a spaniel, by which means he will hardly escape.

Roe-buck Hunting is performed divers ways, and very easily in the woods.

When chased, they usually run against the wind, because the coolness of the air refreshes them in their course; therefore the huntsmen place their dogs with the wind: they usually, when hunted, first take a large ring, and afterwards hunt the hounds. They are also often taken by counterfeiting their voice, which a skilful huntsman knows how to do by means of a leaf in his mouth. When they are hunted, they turn much and often, and come back upon the dogs directly; and when they can no longer endure, they take foil, as the hart does, and will hang by a bough in such a manner, that nothing of them shall appear above the water but their snout, and they will suffer the dogs to come just upon them before they will stir.

The venison of a roe-buck is never out of season, being never fat, and therefore they are hunted at any time; only that some favour ought to be shown the doe while she is big with fawn, and afterwards till her fawn is able to shift for himself; but some roe does have been killed with five fawns in their bellies.

He is not called, by the skilful in the art of hunting, a great roe-buck, but a fair roe-buck; the herd of him is called a bevy: and if he hath not bevy-grease upon his tail, when he is broken up, he is more fit to be dog's meat than man's meat. The hounds must be rewarded with the bowels, the blood, and feet slit saunder, and boiled altogether; this is more properly called a dose or a reward.

Hunting-Match. The first thing that is to be considered by one who designs to match his horse for his own advantage, and his horse's credit, is not to flatter himself with the opinion of his horse, by fancying that he is a swift, when he is but a slow galloper; and that he is a whole-running-horse, that is, that he will run four miles without a sob at the height of his speed, when he is not able to run two or three. Very probably some gentlemen are led into this error, by their being mistaken in the speed of their hounds, who for want of trying them against other dogs that have been really fleet, have supposed their own to be so, when in reality they are but of a middling speed; and because their horse, when trained, was able to follow them all day, and upon any hour, to command them upon deep as well as light earths, have therefore made a false conclusion, that their horse is as swift as the best; but, upon trial against a horse that has been rightly trained after hounds that were truly fleet, have bought their experience perhaps full dear. Therefore it is advisable for all lovers of hunting to procure two or three couple of tried hounds, and once or twice a-week to follow after them at train-scent; and when he is able to top them on all sorts of earth, and to endure heat and colds stoutly, then he may better rely on his speed and toughness.

That horse which is able to perform a bare-chase of five or six miles briskly and courageously, till his body be as it were bathed in sweat; and then, after the hare has been killed, in a nipping frosty morning, can endure to stand till the sweat be frozen on his back, so that he can endure to be pierced with the cold as well as the heat; and then, even in that extremity of cold, to ride another chase as briskly, and with as much courage as he did the former; that horse which can thus endure heats and colds is most valued by sportsmen. Therefore in order to make a judgment of the goodness of a horse, observe him after the death of the first hare, if the chase has been any thing brisk: if, when he is cold, he shrinks up his body, and draws his legs up together, it is an infallible sign of want of vigour and courage: the like may be done by the slackening of his girths after the first chase, and from the dulness of his teeth, and the dulness of his countenance, all which are true tokens of fastness and being tired; and such a horse is not to be relied on in case of a wager.

Here it will not be improper to take notice of the way of making matches in former times, and the modern way of deciding wagers. The old way of trial was, by running so many trains of hounds, as was agreed upon between the parties concerned, and a bell-course, this being found not so uncertain, but more durable than bare-hunting; and the advantage consisted in having the trains led on earth most suitable to the qualifications of the horses. But now others choose to hunt the hare till such an hour, and then to run this wild-goose chase; a method of racing that takes its name from the manner of the flight of wild geese, which is generally one after another; so the two horses after running of twelvescore yards, had liberty, which horse soever could get the leading, to ride what ground he pleased, the hindmost horse being bound to follow him, within a certain distance agreed on by articles, or else to be whipped up by the triers or judges which rode by; and whichever horse could distance the other won the match.

But this chase, in itself very inhuman, was soon found to be very destructive to good horses, especially when two good horses were matched; for neither being able to distance the other till both were ready to sink under their riders through weakness, it sometimes the match was fain to be drawn and left undecided, though both the horses were quite spoiled.

This brought up the custom of train-scents, which afterwards was changed to three heats and a straight course; and that the lovers of horses might be encouraged to keep good ones, plates have been erected in many places in Britain. The fewer of these before you come to the course, if your horse be fiery and mettled, the better; and the shorter the distance, the better. Also, above all things, be sure to make your bargain to have the leading of the first train; and then make choice of such grounds where your horse may best show his speed, and the fleetest dogs you can procure: give your hounds as much law before you as your triers will allow, and then making a loose, try to win the match with a wind; but if you fail in this attempt, then bear your horse, and save him for the course; but if your horse be slow, but well-wind-ed, and a true spurred nag, then the more train-scents you run before you come to the straight-course, the better. But here you ought to observe to gain the leading of the first train, which in this case you must lead.
Huntingdon, the county-town of Huntingdonshire in England, seated upon an easy ascent, on the north side of the river Ouse. It was made a free borough by King John, consisting of a mayor, 12 aldermen, burgesses, &c. by whom the two members of parliament are chosen. It had anciently 15 parish churches, and has now but two; in one of which, called St John’s, Oliver Cromwell was born, in 1599. Here was formerly a castle, built by William the Conqueror, which afterwards belonged to David, a prince of Scotland, with the title of earl; but Henry VIII. gave it to George Hastings, with the earldom annexed, in whose family it still continues. It stands on the great north road; and has a bridge built of free-stone over the Ouse, which is made navigable for small vessels as high as Bedford. It is the place where the assizes are kept, and where the county-jail stands. It has a good marketplace, and several convenient inns, besides a grammar-school, and contained 2907 inhabitants in 1811. W. Long. 0. 11. N. Lat. 52. 17.

Huntingdonshire, a county of England, bounded on the south by Bedfordshire; on the west by Northamptonshire, as also on the north; and by Cambridgeshire on the east; extending 26 miles in length from north to south, 20 in breadth from east to west, and nearly 67 in circumference. This county, which is in the diocese of Lincoln, is divided into four hundreds, and contains 6 market-towns, 29 vicarages, 78 parishes, 256 villages, about 6841 houses, and in 1811, 42,208 inhabitants; but sends only four members to parliament, namely, two knights of the shire, and two members for Huntingdon. It is a good corn country; and abounds in pastures, especially on the eastern side, which is fenny. The rest is diversified by rising hills and shady groves, and the river Ouse waters the southern part.

The air of this county is in most parts pleasant and wholesome, except among the fens and meres, though they are not so bad as the hundreds of Kent and Essex. The soil is fruitful, and produces great crops of corn, and the billy pastures afford a fit pasture for sheep. They have great numbers of cattle; and plenty of water-fowl, fowl, and turf for firing; which last is of great service to the inhabitants, there being but little wood, though the whole county was a forest in the time of Henry II. The only river besides the Ouse is the Nene, which runs through Whittlesey mere.

H-U-Quang, a province of the kingdom of Chins, in Asia, which has a great river called Yang, and Tsie-chiang, which runs across it from east to west. It is divided into north and south parts, the former of which contains eight cities of the first rank, and 60 of the second and third; and the latter, seven of the first rank, and five of the second and third. It is a flat, open country, watered everywhere with brooks, lakes, and rivers, in which there are great numbers of fish. Here is plenty of wild-fowl; the fields nourish cattle without number, and the soil produces corn, and various kinds of fruit. There is gold found in the sands of the rivers; and in the mines they have iron, mica, &c. In short, there is such a variety of all sorts of commodities, that it is called the magazine of the empire.

Hura, in Botany, a genus of plants belonging to the monocotyledon class, and in the natural method ranking under the 38th order, Tricoccas. See Botany Index.

Hurdle, is the name of a sledge used to draw traitors to the place of execution.

Hurdles, in Fortification, are made of twigs of willows, or osiers interwoven close together, sustained by long stakes. They are made in the figure of a long square, the length being five or six feet, and the breadth three and a half. The closer they are walled together, the better. They serve to render the batteries firm, or to consolidate the passage over muddy ditches; or to cover traverses and lodgments for the defence of the workmen against fire-works or stones thrown against them.

The Romans had a kind of military execution for mutineers, called putting to death under the hurdles. The manner of it was this: The criminal was laid at his length in a shallow water, under an hurdle, upon which was heaped stones, and so pressed down till he was drowned.

Hurdles, in Husbandry, certain frames made either of split timber, or of hazel-rods wattled together, to serve for gates in inclosures, or to make sheepfolds, &c.

Hurds, or Hords, of flax or hemp; the coarser parts separated in the dressings from the tear, or fine stuff. See FLAX.

Hurl-bone, in a horse, a bone near the middle of the buttock, very apt to go out of its sockets with a hurt or strain.

Hurlers, a number of large stones, set in a kind of square figure near St Clare in Cornwall, so called from an old opinion held by the common people, that they are so many men petrified, or changed into stones, for profaning the sabbath-day by hurling the ball, an exercise for which the people of that country have been always famous.

The hurlers are oblong, rude, and unhewn. Many authors suppose them to have been trophies erected in memory of some battle; others take them for boundaries to distinguish lands. Lastly, others, with more probability, hold them to have been sepulchral monuments.

Hurly-burly, in vulgar language, denotes confusion or tumult, and is said to owe its origin to two neighbouring families, Hurleigh and Burleigh, which filled their part of the kingdom with contest and violence.

Huron, a vast lake of North America, situated between 80° and 84° W. Long. and between 43° and 46° of N. Lat. from whence the country contiguous to it is called the country of the Hurons, whose language is spoken over a great extent in the southern parts of America.

Hurricane, a general name for any violent storm of wind; but which is commonly applied to those storms which happen in the warmer climates, and which greatly exceed the most violent storms known in this country. The ruin and desolation accompanying
HUSBANDRY, as defined by some, includes not only agriculture, but several other branches connected with it, such as the rearing of cattle, the management of the dairy, making butter and cheese, raising flax, timber, &c. See AGRICULTURE.

Virginian Husbandry, a term used by authors to express that sort of husbandry, the precepts of which are so beautifully delivered in Virgil's Georgics. The husbandry in England is Virgilian in general, as is seen by the method of paring and burning the surface, of raftering or cross-ploughing, and of the care in destroying weeds, upon the same principle, and by much the same means. In those parts of England along the southern coast, where the Romans principally inhabited, not only the practice, but the expressions, are in many respects the same with those of the ancient Romans, many of the terms used by the ploughmen being of Latin origin, and the same with those used by those people on like occasions. And on a strict observation, more of Virgil's husbandry is at this time practised in England than in Italy itself. This change in the Italian husbandry is, however, much more to the credit of that people, than the retaining the Virgilian scheme is to ours.

Tull, who has established a new method of husbandry, observes, that it is upon the whole so contradictory to this old plan, that it may be called the anti-Virgilian husbandry; and adds that no practice can be worse than the Virgilian.

HUSK, the same with what botanists call the calyx or cup of a flower. See CALYX, BOTANY INDEX.

HUSO. See ACCIPENSER, Ichthyology Index.

HUS, JOHN. See HUSITES.

HUS SARS, are the national cavalry of Hungary and Croatia. Their regimentals consist in a rough furled cap, adorned with a cock's feather (the officers either an eagle's or a heron's); a doublet, with a pair of breeches to which the stockings are fastened, and yellow or red boots: besides, they occasionally wear a short upper waistcoat edged with fur, and five rows of round metal buttons; and in bad weather a cloak. Their arms are a sabre, carbine, and pistole. They are irregular troops: hence, before beginning an attack, they lay themselves so flat on the necks of their horses, that it is hardly possible to discern their force; but being come within pistol-shot of the enemy, they raise themselves with such surprising quickness, and begin the fight with such vivacity on every side, that, unless the enemy is accustomed to their method of engaging, it is very difficult for troops to preserve their order. When a retreat is necessary, their horses have so much fire, and are so indefatigable, their equippage so light, and themselves such excellent horsemen, that no other cavalry can pretend to follow them. They leap over ditches, and swim over rivers, with surprising facility. They never encamp, and consequently are not burdened with any camp-equipage, saving a kettle and a hatchet to every six men. They always lie in the woods, out-houses, or villages, in the front of the army. The emperor, queen of Hungary, and king of Prussia, have the greatest number of troops under this name in their service.

HUSITES, in ecclesiastical history, a party of reformers, the followers of John Huss.

John Huss, from whom the Hussites take their name.
Huss, name, was born in a little village in Bohemia, called
Husovice, and lived at Prague in the highest reputation,
both on account of the sanctity of his manners and the
purity of his doctrine. He was distinguished by his
uncommon erudition and eloquence, and performed
at the same time the functions of professor of divinity in
the university, and of ordinary pastor in the church
of that city. He adopted the sentiments of Wickliffe,
and the Waldenses; and in the year 1407 began openly
to oppose and preach against divers errors in doctrine,
as well as corruptions in point of discipline, then reigning
in the church. Huss likewise endeavoured to the
 utmost of his power to withdraw the university of
Prague from the jurisdiction of Gregory XII., whom
the kingdom of Bohemia had hitherto acknowledged
as the true and lawful head of the church. This occasioned
a violent quarrel between the incensed archbishop of Prague and the zealous reformer, which the
latter inflamed and augmented from day to day, by his
pathetic exclamations against the court of Rome, and
the corruptions that prevailed among the sacerdotal order.

There were other circumstances that contributed to
inflame the resentment of the clergy against him. He
adopted the philosophical opinions of the realists, and
vehemently opposed and even persecuted the nominalists,
whose number and influence were considerable in
the university of Prague. He also multiplied the number
of his enemies in the year 1408, by procuring through h is great credit, a sentence in favour of the
Bohemians, who disputed with the Germans concerning
the number of suffrages which their respective nations
were entitled to in all matters that were carried
by election in the university. In consequence of a
decree obtained in favour of the former, which restored
them to their constitutional right of three suffrages,
 usurped by the latter, the Germans withdrew from
Prague, and, in the year 1409, founded a new academy
at Leipsick. This event no sooner happened,
than Huss began to inveigh with greater freedom than
he had done before against the vices and corruptions of
the clergy, and to recommend, in a public manner, the
writings and opinions of Wickliffe, as far as they
related to the papal hierarchy, the despotism of the court of
Rome, and the corruption of the clergy. Hence
an accusation was brought against him, in the year
1410, before the tribunal of John XXIII., by whom
he was solemnly expelled from the communion of the
church. Notwithstanding this sentence of excommunication, he proceeded to expose the Romish church
with a fortitude and zeal that were almost universally
applauded.

This eminent man, whose piety was equally sincere
and fervent, though his zeal was perhaps too violent,
and his prudence not always circumstantial, was sum-
moned to appear before the council of Constance.
Secured, as he apprehended, from the rage of his ene-
emies by the safe conduct granted him by the emperor
Sigismund, for his journey to Constance, his residence
in that place, and his return to his own country, John
Huss obeyed the order of the council, and appeared
before it to demonstrate his innocence, and to prove
that the charge of his having deserted the church of
Rome was entirely groundless. However, his enemies
so far prevailed, that by the most scandalous breach of
public faith, he was cast into prison, declared a her-
etic because he refused to plead guilty against the dict-
tates of his conscience, in obedience to the council, and
burnt alive in 1415; a punishment which he endured
with unparalleled magnanimity and resignation.

The same unhappy fate was borne by Jerome of
Prague, his intimate companion, who attended the council, in order to support his persecuted friend.
Jerome, indeed, was terrified into temporary submission; but he afterwards resumed his fortitude, and
maintained his opinions, which he had for a while desert-
ed through fear, in the flames in which he expired in
1416.

The disciples of Huss adhered to their master's doctrine after his death with a zeal which broke out into
an open war, that was carried on with the most savage and unparalleled barbarity. John Ziska, a Bohemian
knight, in 1420, put himself at the head of the Hussites, who were now become a very considerable
party, and threw off the despotism yoke of Sigismund,
who had treated their brethren in the most barbarous
manner. Ziska was succeeded by Procopius, in the
year 1424. The acts of barbarity that were committed
on both sides were shocking and horrible beyond
expression; for notwithstanding the irreconcilable
opposition between the religious sentiments of the con-
tending parties, they both agreed in this one horrible
principle, that it was innocent and lawful to persecute
and extirpate with fire and sword the enemies of the
true religion; and such they reciprocally appeared to
each other. Those commotions in a great measure subsided, by the interference of the council of Basile,
in the year 1433.

The Hussites, who were divided into two parties, the
Calixtines and Taborites, spread over all Bohemia
and Hungary, and even Silesia and Poland; and there
are some remains of them still subsisting in all those
parts.

HUSTINGS (from the Saxon word hustings, i.e.
concilium, or curia), a court held in Guildhall before
the lord-mayor and aldermen of London, and reckoned
the supreme court of the city. Here deeds may be
inrolled, outlawries sued out, and repelvis and writs
of error determined. In this court also is the election
of aldermen, of the four members of parliament for
the city, &c. This court is very ancient, as appears
by the laws of Edward the Confessor. Some other ci-
ties have likewise had a court bearing the same name,
as Winchester, York, &c.

HUSUM, a town of Denmark, in the duchy of
Sleswick, and capital of a bailiwick of the same name,
with a strong citadel and a very handsone church. It
is seated near the river Ow, on the German sea; and
is subject to the duke of Holstein-Gottorp. E. Long.
9°. 41'. N. Lat. 54°. 5.

HUTCHESON, DR FRANCIS, a very elegant wri-
ter and excellent philosopher, was the son of a dispens-
ing minister in the north of Ireland, and was born on
the 8th of August 1694. He early discovered a su-
perior capacity; and having gone through a school-
education, began his course of philosophy at an aca-
demy, whence he removed to the university of Glas-
gow, where he applied himself to all the parts of li-
terature, in which his progress was suitable to his un-
common abilities.
Hutchison. He then returned to Ireland: and entering into the ministry, was just about to be settled in a small congregation of dissenters in the north of Ireland, when some gentlemen about Dublin, who knew his great abilities and virtues, invited him to take up a private academy there. He complied with the invitation, and met with much success. He had been fixed but a short time in Dublin, when his singular merits and accomplishments made him generally known; and his acquaintance was sought by men of all ranks, who had any taste for literature, or any regard for learned men. Lord Viscount Molesworth is said to have taken great pleasure in his conversation, and to have assisted him with his criticisms and observations upon his "Inquiry into the Ideas of Beauty and Virtue," before it came abroad. He received the same favour from Dr Synge, lord bishop of Elphin, with whom he also lived in great friendship. The first edition of this performance came abroad without the author's name, but the merit of it would not suffer him to be long concealed. Such was the reputation of the work, and the ideas it had raised of the author, that Lord Granville, who was then lord lieutenant of Ireland, sent his private secretary to inquire at the bookseller's for the author; and when he could not learn his name, he left a letter to be conveyed to him: in consequence of which he soon became acquainted with his Excellency, and was treated by him, all the time he continued in his government, with distinguished marks of familiarity and esteem.

From this time his acquaintance began to be still more courted by men of distinction either for station or literature in Ireland. Archbishop King, the author of the celebrated book De origine mali, held him in great esteem; and the friendship of that prelate was of great use to him in screening him from two different attempts made to prosecute him for daring to take upon him the education of youth, without having qualified himself by subscribing the ecclesiastical canons, and obtaining a license from the bishops. He had also a large share in the esteem of the primate Bolter, who through his influence made a donation to the university of Glasgow of a yearly fund for an exhibition to be bared to any of the learned professions. A few years after his Inquiry into the Ideas of Beauty and Virtue, his Treatise on the Passions was published: both these works have been often reprinted; and always admired, both for the sentiment and language, even by those who have not assented to the philosophy of them, nor allowed it to have any foundation in nature. About this time he wrote some philosophical papers accounting for laughter, in a different way from Hobbes, and more honourable to human nature: which papers were published in the collection called Hibernicus's Letters.

After he had taught in a private academy at Dublin for seven or eight years with great reputation and success, he was called in the year 1729, to Scotland, to be a professor of philosophy in the university of Glasgow. Several young gentlemen came along with him from the academy, and his high reputation drew many more thither both from England and Ireland. Here he spent the remainder of his life in a manner highly honourable to himself and ornamental to the university of which he was a member. His whole time was divided between his studies and the duties of his office; except what he allotted to friendship and society. A firm constitution and a pretty uniform state of good health, except some few slight attacks of the gout, seemed to promise a longer life; yet he did not exceed the 53rd year of his age. He was married, soon after his settlement in Dublin, to Mrs Mary Wilson, a gentleman's daughter in the county of Longford; by whom he left behind him one son, Francis Hutchison, doctor of medicine. By this gentleman was published, from the original manuscript of his father, "A system of Moral Philosophy, in three books, by Francis Hutchison, LL. D. at Glasgow, 1755," in two volumes, 4to.

HUTCHINSON, JOHN, a philosophical writer, whose notions have made no inconsiderable noise in the world, was born in 1674. He served the duke of Somerset in the capacity of steward; and in the course of his travels from place to place employed himself in collecting fossils: we are told that the large and noble collection bequeathed by Dr Woodward to the university of Cambridge was actually made by him, and even unfairly obtained from him. When he left the duke's service to indulge his studies with more freedom, the duke, then master of the horse to George I. made him his riding surveyor, a kind of sinecure place of 200l. a year with a good house in the Meuse. In 1724 he published the first part of Moses's Principia, in which he ridiculed Dr Woodward's Natural History of the Earth, and exploded the doctrine of gravitation established in Newton's Principia: in 1727, he published a second part of Moses's Principia, containing the principles of the Scripture Philosophy. From this time to his death, he published a volume every year or two, which, with the MSS. he left behind, were published in 1748, in 12 vols 8vo. On the Monday before his death, Dr Mead urged him to be bled; saying pleasantly, "I will soon send you to Moses," meaning to his studies: but Mr Hutchinson taking it in the literal sense, answered in a muttering tone, "I believe, Doctor, you will," and was so displeased, that he dismissed him for another physician; but died in a few days after, August 28. 1737. Singular as his notions are, they are not without some defenders, who have obtained the appellation of Hutchinsonians. The reader may find a distinct and comprehensive account of the Hutchinsonian system in a book intitled, Thoughts concerning Religion, &c. printed at Edinburgh 1743; and in a letter to a bishop, annexed to it, first printed in 1732.

HUTTON, Dr James, physician and naturalist, was the son of Mr William Hutton, a respectable merchant in Edinburgh. He was born on the 3d of June 1726, and lost his father while he was very young, the charge of his education devolving on his mother, who determined that it should be very liberal. Having finished his grammar-school education at the high school of Edinburgh, he entered the university at the age of 14 in the year 1740. He always considered himself as greatly indebted to Professor Stevenson's lectures on logic, not because they made him a logician, but because they accidentally gave him a predilection for chemistry which he retained and cherished to the close of life. As an illustration of some particular doctrine, the professor observed, that while the acids can singly dissolve
the bater metals, they must unite their strength before they can have any influence upon gold; that metal is only to be dissolved by nitro-muriatic acid, formerly denominated aqua regia. From this remark he found his thirst for chemical knowledge daily increase, and sought for information from every quarter.

He always evinced talents sufficient to encourage the prosecution of his studies; but it was the wish of his friends that he should turn his attention to business, with which he complied though contrary to his own inclinations. In 1743 he was put an apprentice to Mr. George Chalmers, writer to the signet, where he soon discovered the ruling propensity of his mind; for when he should have been transcribing law papers, he was amusing his fellow apprentices with experiments in chemistry. Mr. Chalmers perceiving this, generously freed him from his obligations to serve him, desiring him to turn his attention to some other employment more congenial to his views. He fixed his choice on the study of medicine as nearly related to his favourite pursuits, and after spending about three years at Edinburgh, he studied two years at Paris, and returning home by the Low Countries, took his degree of doctor of medicine at Leyden, in September 1749. The subject of his thesis was De Spongine et Circulatione in Microcosmo.

When he arrived in London, about the end of 1749, he conceived the design of settling in the world. He justly conjectured that Edinburgh did not hold out for him any flattering prospects in the capacity of a physician, as the principal practice was in the hands of a few eminent physicians who had been long established. He accordingly wrote to his friends in Edinburgh with much anxiety, as to the subject of his future prospects in life. To Mr. James Davie, a young man nearly of his own age, with whom he contracted a friendship which death only could extinguish, he also communicated the perplexed state of his mind. Their mutual knowledge of the nature of sal ammoniac led them to establish this manufacture, which afterwards became a most lucrative concern to both. The sentiments of Mr. Davie were communicated to Dr. Hutton while yet in London, which probably was the chief reason why he resolved to abandon entirely the practice of physic.

On his return to Edinburgh, in the year 1750, he resolved to devote all his attention to agriculture, which might probably be occasioned by his having succeeded to a small property in Berwickshire on the death of his father. Mr. Playfair of the university of Edinburgh has ascribed it, and we apprehend with great propriety, to the native simplicity of his character, and the moderation of his views, which were always free from ambition. His attachment to the life of a farmer was increased by his acquaintance with Sir John Hall of Dun- glass, a gentleman who was very ingenious, a friend and lover of science, and one who well understood agriculture. Determined to make himself master of rural economy, Dr. Hutton went into the county of Norfolk, where he continued for some time in the house of a farmer, who was at once his preceptor and his host. The farmer's name was John Dybould, whose practical knowledge of agriculture Dr. Hutton always mentioned in terms of the highest respect.

During his residence in this county, which was to him a paradise, he made frequent excursions into different parts of England; and although information respecting rural economy was the great and primary object of his pursuits, yet it was here that he first commenced the study of mineralogy, to serve him as an amusement on the road. He acquainted his friend Sir John Hall, that he was become remarkably fond of studying the surface of the earth, and was narrowly examining every pit, or ditch, or bed of a river that fell in his way. The agricultural knowledge he acquired in Norfolk increased his desire to pay a visit to Flanders, the only place in Europe where husbandry can boast of the greatest antiquity. He set out accordingly in the spring of 1754, and returned to England during the summer of the same year. Soon after his arrival in London, he observed in a letter to Sir John Hall; "had I doubted of it before I set out, I should have returned fully convinced that they are good husbandmen in Norfolk."

About this time he returned to his native country, and was for some time at a loss what place to fix upon for the purpose of carrying into effect his agricultural improvements. His own farm at length became his choice, and a ploughman whom he had brought with him from Norfolk gave the first specimen of excellent tillage ever exhibited in that part of Scotland. To Dr. Hutton the country is indebted for the introduction of the new husbandry into a county where it may be said to have made more astonishing progress than in almost any other part of the British empire. In the year 1764, he made an excursion into the north of Scotland, in company with Commissioner Clerk, who was afterwards Sir George Clerk, a man of singular worth and abilities. They went by Crieff, Dalwhinnie, Fort Augustus, and Inverness, and returned along the coast by Aberdeen to Edinburgh. To increase his knowledge of geology was Dr. Hutton's chief aim in this tour, so that he was now determined to pay the most unremitting attention. About the year 1768 he devoted his whole time to scientific pursuits, and having met with a favourable opportunity of letting his farm on advantage, he took up his constant residence in Edinburgh. He now turned his attention very much to the study of chemistry, and we believe he was the first who discovered that mineral sulphur is contained in zeolite. The same fact has since been confirmed by the experiments of that celebrated mineralogist M. Klaproth, as well as by those of Dr. Kennedy, which have led to others of a similar nature.

Dr. Hutton gave the world his first publication in 1777, which was a small pamphlet of 57 pages, entitled, "Considerations on the nature, quality, and distinction of Coal and Cumb. It was designed to answer a question which began to be much-agitated, whether the small coal of Scotland is the same with the coal of England? and whether it ought to be carried coastwise free of all duty? This created a keen contest between the proprietors and revenue officers, the one insisting that it should, and the other that it should not pay any duty. It was discussed before the board of customs in Scotland, and even occupied the attention of the privy council. The small coal of Scotland was finally exempted from the payment of duty, to which the pamphlet of Dr. Hutton greatly contributed.

During a period of 30 years the attention of the doctor was turned towards geological studies, to qualify him
him for writing on his favourite topic, a new theory of the earth. Long before that theory made its appearance in the world, he had completed the great outline of it, which was only shown to a few confidential friends. He was first induced to publish it by communicating an abridgment of it to the Royal Society of Edinburgh. Of the merits or defects of this theory (for an account of which, see GEOLOGY), our readers must judge for themselves. It has found a very able advocate in Professor Playfair of the university of Edinburgh, whose illustrations of it have received a very candid and ingenious reply from an anonymous writer, who entitles his book, A comparative view of the Huttonian and Neptunian systems of geology. Dr Hutton's theory did not meet with that reception from the public which the doctor's admirers expected, and which it is probable he looked for himself. Professor Playfair thinks it was in a great measure owing to the obscurity with which he wrote, so repugnant to the perspicuity of his conversation; but as the world had received so many unsatisfactory theories before, it is not improbable that men were become disgusted with every thing of the kind, and almost determined to refuse a hearing to every subsequent attempt.

A theory of rain from the same author appeared in the first volume of the Edinburgh Transactions. He had made meteorology his study for a considerable time; and his theory has been pronounced one of the few to be met with in that department of knowledge which is deserving of the name. Soon after this publication, Dr Hutton gave the world, in three volumes quarto, An investigation of the principles of knowledge, and of the progress of reason from sense to science and philosophy. His elements of agriculture, the result of much study and long experience, was the last work which he seemed anxious to publish, but it was left in manuscript at his death, which took place in 1796-7. On the 26th of March he was seized with a shivering, which induced him to send for his friend Mr Russell, who attended him as surgeon; but before it was possible for that gentleman to arrive, all medical aid was absolutely vain. Having with some difficulty stretched out his hand to Mr Russell, he instantly expired.

To the name of a philosopher Dr Hutton was most justly entitled, by virtue of his natural talents, acquisitions, and temper. The direction of his studies was rather uncommon and irregular; but for that very reason it was peculiarly fitted to develop his quick penetration and originality of thought, by which his intellectual character was strikingly marked. The vast acquisitions of wealth and fortune never excited more lively sensations of pleasure in the minds of men, than those which arose in the mind of Dr Hutton on hearing of a new invention, or the being made acquainted with a new truth. This pleasure, which appeared almost ridiculous to those who could not enter into his views, was not confined to any one branch of science; for in the language of Professor Playfair, "he would rejoice over Watt's improvements on the steam engine, or Cook's discoveries in the South sea, with all the warmth of a man who was to share in the honour or the profit about to accrue from them." Dr Hutton was not exclusively attached to the company of men of letters, whose conversation was entirely directed to subjects of literature; for he could occasionally unbend himself, and enjoy the innocent hilarity of promiscuous company, when he freely indulged in the gratification of his native pleasantry.

Dr Hutton was never married, but kept house with his three sisters, who were ornaments to their sex, and had the sole management of his domestic concerns. One of them, Miss Isabella, survived her worthy brother, and lived to lament a death which was certainly a loss to the literary world, as a very large share of his knowledge unavoidably perished with himself. He left no particular directions behind him as to the disposal of his collection of fossils, which was accordingly presented to Dr Black, who gave it to the Royal Society of Edinburgh, on condition that it should be completely arranged, and always kept separate, for the purpose of illustrating the Huttonian Theory of the Earth.

HUXING of pike, among fishermen, a particular method of catching that fish.

For this purpose, they take 30 or 40 as large bladders as can be got; blow them up, and tie them close and strong; and at the mouth of each tie a line, longer or shorter according to the depth of the water. At the end of the line is fastened an armed hook, artfully baited: and thus they are put into the water with the advantage of the wind, that they may gently move up and down the pond. When a master pike has struck himself, it affords great entertainment to see him bounce about in the water with a bladder fastened to him; at last, when they perceive him almost spent, they take him up.

HUY, a town of the Netherlands, in the bishopric of Liege, and capital of Condrass. It is advantageously seated on the river Maase, over which there is a bridge.

E. Long. 5. 15. N. Lat. 52. 32.

HUYGENS, CHRISTIAN, one of the greatest mathematicians and astronomers of the 17th century, was the son of Constantine Huygens, lord of Zuylicheem, who had served three successive princes of Orange in the quality of secretary; and was born at the Hague, in 1629. He discovered from his infancy an extraordinary fondness for the mathematics; in a little time made a great progress in them; and perfected himself in those studies under the famous professor Schooten, at Leyden. In 1649, he went to Holstein and Denmark, in the retinue of Henry count of Nassau; and was extremely desirous of going to Sweden, in order to see Des Cartes, but the count's short stay in Denmark, would not permit him. He travelled into France and England; was, in 1663, made a member of the Royal Society; and, upon his return into France, M. Colbert, being informed of his merit, settled a considerable pension upon him to engage him to fix at Paris; to which Mr Huygens consented, and stayed there from the year 1666 to 1681, where he was admitted a member of the Academy of Sciences. He lived a quiet and studious manner of life, and frequently retired into the country to avoid interruption, but did not contract that moroseness which is so frequently the effect of solitude and retirement. He was the first who discovered Saturn's ring, and a third planet belonging to that planet, which had hitherto escaped the eye of astronomers. He discovered the means of rendering clocks exact, by applying the pendulum, and rendering all its vibrations equal by the cycloid. He brought telescopes to perfection, made many other useful discoveries, and died at the Hague in 1695. He...
was the author of several excellent works. The principal of these are contained in two collections; the first of which was printed at Leyden in 1682, in quarto, under the title of Opera varia; and the second at Amsterdam in 1728, in two volumes quarto, entitled Opera reliqui.

HUYSUM, the name of several Dutch painters; the most celebrated of whom was John, whose subjects were flowers, fruit, and landscapes. According to Mr. Pilkington, this illustrious painter had surpassed all who have ever painted in that style; and his works excite as much surprise by their finishing as they excite admiration by their truth. He was born at Amsterdam in 1682, and was a disciple of Justus van Huysum his father. He set out in his profession with a most commendable principle, not so much to paint for the acquisition of money as of fame; and therefore he did not aim at expedition, but at delicacy, and, if possible, to arrive at perfection in his art. Having attentively studied the pictures of Magnon, and all other artists of distinction who had painted in his own style, he tried which manner would soonest lead him to imitate the lightness and singular beauties of each flower, fruit, or plant, and then fixed on a manner peculiar to himself, which seems almost inimitable. His pictures are finished with inconceivable truth; for he painted every thing after nature; and was so singularly exact, as to watch even the hour of the day in which his model appeared in its greatest perfection. By the judicious he was accounted to paint with greater freedom than Magnon or Breughel; with more tenderness and moisture than Mario da Fiori, Michael Angelo di Campidoglio, or Segers; with more mellowness than De Heem, and greater force of colouring than Baptist. His reputation rose to such a height at last, that he fixed immoderate prices on his works; so that none but princes, or those of princely fortunes, could pretend to become purchasers. Six of his paintings were sold at a public sale in Holland for prices that were almost incredible. One of them, a flower-piece, for fourteen hundred and fifty guilders; a fruit-piece for a thousand and five guilders; and the smaller pictures for nine hundred. The vast sums which Van Huysum received for his works, caused him to redouble his endeavours to excel; no person was admitted into his room while he was painting, not even his brothers; and his method of mixing the tints, and preserving the lustre of his colours, was an impenetrable secret, which he never would disclose. Yet this conduct is certainly not to his honour, but rather an argument of a low mind, fearful of being equalled or surpassed. From the same principle, he would never take any disciples, except one lady, named Haverman; and he grew envious and jealous even of her merit. By several domestic discourses, his temper became changed; he grew morose, fretful, and apt to withdraw himself from society. He had many enviers of his fame, which has ever been the severe lot of the most deserving in all professions; but he continued to work, and his reputation never diminished. It is universally agreed that he has excelled all who have painted fruit and flowers before him, by the confessed superiority of his touch, by the delicacy of his pencil, and by an amazing manner of finishing; nor does it appear probable that any future artist will become his competitor. The care which he took to purify his oils and prepare his colours, and the various experiments he made to discover the most lustrous and durable, are instances of extraordinary care and industry as well as capacity. From having observed some of his works that were perfectly finished, some only half finished, and others only begun, the principles by which he conducted himself may perhaps be discovered. His cloths were prepared with the greatest care, and primed with white, with all possible purity, to prevent his colours from being obscured, as he laid them on very lightly. He glazed all other colours except the clear and transparent, not omitting even the white ones, till he found the exact tone of the colour; and over that he finished the forms, the lights, the shadows and the reflections, which are all executed with precision and warmth, without dryness or negligence. The greatest truth, united with the greatest brilliancy, and a velvet softness on the surface of his objects, are visible in every part of his compositions; and as to his touch, it looks like the pencil of nature. Whenever he represented flowers placed in vases, he always painted those vases after some elegant model, and the base of the flowers is as exquisitely finished as any of the other parts. Through the whole he shows a delicate composition, a fine harmony, and a most happy effect of light and shadow. Those pictures which he painted on a clear ground are preferred to others of his hand, as having greatest lustre, and as they demanded more care and exactness in the finishing; yet there are some on a darkish ground, in which appears rather more force and harmony. It is observed of him, that in the grouping of his flowers, he generally designed those which were brightest in the centre, and gradually decreased the force of his colour from the centre to the extremities. The birds nests and their eggs, the feathers, insects, and drops of dew, are expressed with the utmost truth, so as even to deceive the spectator. And yet, after all this merit and just praise, it cannot but be confessed, that sometimes his fruits appear like wax or ivory, without that peculiar softness and warmth which is constantly observable in nature. Beside his merit as a flower painter, he also painted landscapes with great applause. They are well composed; and although he had never seen Rome, he adorned his scenes with the noble remains of ancient magnificence which are in that city. His pictures in that style are well coloured, and every tree is distinguished by a touch that is proper for the leafing. The grounds are well broken, and disposed with taste and judgment; the figures are designed in the manner of Lairesse, highly finished, and touched with a great deal of spirit; and through the whole composition the scene represents Italy, in the trees, the clouds, and the skies. He died in 1749, aged 67.

HUZZOOR, a Hindostan word, signifying The presence; applied, by way of cantineuse, to the Mogul's court. According to polite usage, it is now applied to the presence of every nabob or great man.

HUZZOOR NEVES; the secretary who resides at court, and keeps copies of all the firmaments, records, or letters.

HYACINTH, in Natural History, a species of the zircon genus. See Zircon, Mineralogy Index.

HYACINTHUM, HYACINTH, a genus of plants, belonging
HYB

Hyacinthus belonging to the hexandria class; and in the natural method ranking under the 10th order, Coronaria. See Botany Index.

HYacinthia, in antiquity, feasts held at Sparta, in honour of Apollo, and in commemoration of his favourite Hyacinth.

This Hyacinth was the son of Amyclas king of Sparta, and was beloved both by Apollo and Zephyrus. The youth showing most inclination to the former, his rival grew jealous; and, to be revenged, one day as Apollo was playing at the discus, i.e. quoits, with Hyacinth, Zephyrus turned the direction of a quoit which Apollo had pitched full upon the head of the unhappy Hyacinth, who fell down dead. Apollo then transformed him into a flower of the same name; and as a farther token of respect, they say, commanded this feast. The Hyacinthia lasted three days; the first and third whereof were employed in bewailing the death of Hyacinth, and the second in feasting and rejoicing.

HYADES, in Astronomy, are seven stars in the bull's head, famous among the poets for the bringing of rain. Whence their name Κόρες, from the Greek Κώρε, to rain. The principal of them is in the left eye, by the Arabs called Aldebaran.

The poets feign them the daughters of Atlas and Pleione. Their brother Hyas being torn to pieces by a lioness, they devout his death with such vehemence, that the gods, in compassion to them, translated them into heaven, and placed them in the bull's forehead, where they continue to weep; this constellation being supposed to presage rain. Others represent the Hyades as Bacchus' nurses; and the same with the Dodonides, who fearing the resentment of Juno, and flying from the cruelty of King Lycurgus, were translated by Jupiter into heaven.

HYÆNA. See Canis, Mammalia Index.

HYÆNIUS LAPIS, in Natural History, the name of a stone said to be found in the eyes of the hyæna. Pliny tells us, that those creatures were in old times hunted and destroyed for the sake of those stones, and that it was supposed they gave a man the gift of prophecy by being put under his tongue.

HYBERNACULUM, in Botany, Winter-quarters; defined by Linnaeus to be that part of the plant which defends the embryo herb from injuries during the severities of the winter. See Bulb and Gemma.

HYBLA, in Ancient Geography, or Megara; which last name it took from the Megareans, who led thither a colony; called also Hybla Porana and Galcotta. In Strabo's time Megara was extinct; but the name Hybla remained on account of its excellent honey named from it. It was situated on the east coast of Sicily, between Syracuse and the Leonintes. Galcota and Megarenses, the names of the people, who were of a prophetic spirit, being the descendants of Galus the son of Apollo. Hybleus the epithet. — The Hybleus colles, small eminences at the springs of the Albus near this place, were famous from their variety of flowers, especially thyme; the honey gathered from which was by the ancients reckoned the best in the world, excepting that of Hymenta in Attica. By the moderns it was called Mel Passi, for the same reason, namely, on account of its excellent honey, and extraordinary fertility, till it was overwhelmed by the lava of Etna; and having then become totally barren, its name was changed to Mel Passi. In a second eruption, by a shower of ashes from the mountain, it soon reassumed its ancient beauty and fertility, and for many years was called Bel Passi: and, last of all, in the year 1669, it was again laid under an ocean of fire, and reduced to the most wretched sterility; since which time it is again known by the appellation of Mel Passi. However, the lava, in its course over this beautiful country, has left several little islands or hillocks, just sufficient to show what it formerly was. These make a singular appearance in all the bloom of the most luxuriant vegetation, surrounded and rendered almost inaccessible by large fields of black and rugged lava.

HYBLA Major, in Ancient Geography, was situated in the tract lying between Mount Etna and the river Symethus. In Pausanius's time desolate.

HYBLA Major, or Herae, in Ancient Geography, an inland town of Sicily, situated between the rivers Oanua and Hermiumnis. Now Ragusa.

HYBRIDA PLANTA, a monstrous production of two different species of plants, analogous to a mule among animals. The seeds of hybrid plants will not propagate.

HYBRISTICA, (of sponde, injury), in antiquity, a solemn feast held among the Greeks, with sacrifices and other ceremonies, at which the men attended in the apparel of women, and the women in that of men, to do honour to Venus in quality either of a god or a goddess, or both. Or, according to the account given by others, the hybristica was a feast celebrated at Argos, wherein the women being dressed like men, insulted their husbands, and treated them with all marks of superiority, in memory of the Argian dames having ancienly defended their country with singular courage against Cleomenes and Demaratus.

Plutarch speaks of this feast in his treatise of the great actions of women. The name, he observes, signifies injuriam; which is well accommodated to the occasion, wherein the women straited about in men's clothes, while the men were obliged to dangle in petticoats.

HYDATIDES, in Medicine, little transparent vessels or bladders full of water, sometimes found solitary, and sometimes in clusters, upon the liver and various other parts, especially in hydroptic cases.

HYDATOSCOPIA, called also HYDROMANCY, a kind of divination or method of foretelling future events by water.

HYDE, Edward, earl of Clarendon, and lord high-chancellor of England, was a very eminent statesman and historian, son of Henry Hyde, a private gentleman, resident at Dinton in Wiltshire, where his lordship was born, in the month of February 1608. The first rudiments of his education he received in his father's house, the vicar of the parish being his preceptor, under whose tuition he made such rapid progress, that he was sent to Oxford at the age of 13, where he studied only for one year in Magdalen-hall, as his father entered him in the Middle Temple, that he might be trained up to the profession of the law. He repaired to London at the age of 17, being countenanced and protected by his uncle, who was afterwards chief justice of the court of king's bench. On the death of his uncle he was still a student, yet such a
heavy misfortune did not deter him from the prosecution of his designs. As a licentiousness of manners was at that time extremely prevalent, the well-disposed part of the community considered early marriage as a commendable preservative against irregularity of conduct; and therefore in compliance with an opinion so respectable, Mr. Hyde united himself in wedlock with a beautiful young lady, when he was only in the 21st year of his age, whom he had the misfortune to lose in six months after the celebration of their nuptials, she having fallen a victim to that loathsome malady the small-pox. After a widowhood of three years continuance, he married the daughter of Sir Thomas Aylesbury, with whom he lived 36 years in conjugal felicity. He considered it as a fortunate circumstance that he was made acquainted at an early period with a number of very distinguished characters, among whom we find the names of Lord Falkland, Selden, Kenelm Digby, Carew, Shelton, May, Waller, Hales of Eton, Morley, Chillingworth, and others; of whom he has made respectable mention in memoirs written by himself; and to their instructive conversation he nobly subscribes the principal part of his literary acquisitions. His diffidence is very amiably expressed in these words: “that he never was so proud, or thought himself so good a man, as when he was the worst man in the company.”

Being concerned in a cause in behalf of the merchants of London, he was thus introduced to the notice of Archbishop Laud, commissioner of the treasury, by whom he was treated with much respect, and had his advancement in the profession of the law greatly promoted. His easy circumstances and respectable connections powerfully contributed to bring him forward and increase his business as a barrister. But in the multiplicity of causes which he was employed to bring before different courts, he never lost sight of polite literature, on the study of which he bestowed indefatigable attention, and in his general deportment he exhibited more of the polished gentleman than of the mere lawyer. So great was the reputation which by this time he had acquired, that in 1640 he was chosen burgess for Wotton-Basset and Shaftesbury, in the parliament summoned by Charles I. on account of the Scotch rebellion. As public grievances first attracted the attention of this new parliament, Hyde brought forward a statement of the illegal oppressions and malpractices of the earl marshal’s court; but as it was soon dissolved, a radical investigation of the conduct of that court was for a time prevented. The borough of Saltash made choice of him for the new parliament, in which he pleaded so effectually against the earl marshal’s court as to procure its suppression. He now totally abandoned the profession of a barrister, and wholly confined himself to the discussion of public business; and as he was generally supposed to be attached to no particular party, he was frequently appointed chairman of committees in the transaction of the most important affairs.

Hyde was represented to his majesty in such a favourable light, that the king requested a private interview with him, in the course of which he expressed his great obligations to him for his meritorious services, and was much pleased with his zealous attachment to the church. After this interview he may be considered as devoted to the royal cause; and in order to make a proper estimate of his subsequent conduct, it will be necessary for our readers to attend to his own declaration.

He informs us that he had “a very particular passion and devotion for the person of the king; and a most zealous esteem and reverence for the constitution of government, which he believed to be so equally poised, that if the least branch of the prerogative was torn off, the subject suffered by it; and he was as much troubled when the crown exceeded its just limits.” He believed the church of England to be most admirably calculated for the promotion of literature, piety, and peace, perhaps of any other in the whole world, and deemed the application of any part of its revenue to civil purposes to be the most abominable sacrilege and unpardonable robbery. He also considered the removal of bishops from the house of peers as a violation of the principles of justice, which made him an enemy to every innovation in the church from conscientious motives.

When the commons published their remonstrance on the state of the nation, Hyde drew up a reply to it, merely to gratify his own personal inclination, according to his own confession, without the smallest intention of making it public, although it is more than probable that Lord Digby was made acquainted with its contents. He was, however, at length prevailed upon to allow it to appear as the king’s answer with the advice of his council. This procured him an offer of the office of solicitor-general, which he thought proper to decline, although he undertook the management of the king’s affairs in parliament, in conjunction with Lord Digby and Sir John Colepepper. He opposed the king’s assent to the bill for depriving the bishops of their seats in the house of peers, in which the sovereign acted in direct opposition to the sentiments of his professed friend, by giving his assent. In the year 1642 his majesty sent for Hyde to York, where he contributed his assistance in drawing up various papers in the case of the falling monarch. He was recalled by parliament, but he refused to obey the summons without the royal permission, which excluded him from pardon by a vote of the house.

Soon after the breaking out of hostilities between the king and parliament, when the court of the former was held at Oxford, Hyde was appointed chancellor of the exchequer, sworn a member of the privy council, and created a knight. He continued with his majesty till the month of March 1644, when he was appointed to accompany Prince Charles to the west, and afterwards to the island of Jersey, where Sir Edward Hyde continued during two years after the departure of the prince, prosecuting his studies with indefatigable industry, and composing a history of those memorable transactions in which he himself had borne a distinguished part. He likewise published a reply to the parliamentary declaration of February 1647, in which it was declared improper to send any more addresses to the king. In 1648 he received orders to attend the prince at Paris, who having in the mean time set out for Holland, Sir Edward took shipping for Dunkirk. The prince was at the Hague when he received the melancholy intelligence of his royal father’s fate. Upon the the council of the young king determined to send ambassadors to Spain, and for this purpose made choice of Sir Edward Hyde and Lord Collington, who arrived at Madrid in 1649; and when their residence in the metropolis
Euphrasia was no longer necessary, Sir Edward returned to Paris. The king's court at the Hague was torn by dissension, which made Sir Edward apply for, and obtain leave to retire to Antwerp, the residence of his wife and children, as he clearly perceived that his personal attendance was not likely to be productive of any substantial good. This retreat afforded him literary and domestic happiness, and was better suited to the reduced state of his finances. The princess of Orange, eldest daughter of the unfortunate Charles I, having assigned Sir Edward a house at Breda free of rent, out of gratitude for his warm attachment to her father, he was prevailed upon to remove to that city.

In the year 1657 he was appointed lord high-chancellor of England; a nomination which to our readers may probably seem ridiculous, as coming from a king who was not possessed of a kingdom; but it should be remembered that the young sovereign was of an easy and too pliable a disposition, incapable of denying any request; and therefore as applications were continually made to him for contingent grants and revenues, he justly considered it as a prudent step to raise a man to that high rank, who had sufficient firmness to reject all improper requisitions.

It is but doing justice to the memory of Sir Edward Hyde to say that he was the most confidential and faithful minister of Charles II. at the time of the restoration; and by the consent of all parties, the many public and private difficulties which this event occasioned, were settled by him with much wisdom, integrity and honour. Notwithstanding he was a warm advocate for the royal prerogative, it says much for the wisdom of his head and the goodness of his heart, that he was an enemy to the extension of it beyond the limits prescribed by the constitution; for when it was proposed to raise a great standing revenue, which would have made the king independent of parliament, it met from Sir Edward the warmest opposition, and he restrained the zeal of the royalists, and their desire of revenge. His zeal for episcopacy was, however, carried to an extravagant height, as it led him to wish for the annihilation of every vestige of presbyterianism. He was chosen chancellor of the university of Oxford in 1692, and at the same time created a peer; being in the year following made Viscount Cornbury and earl of Clarendon. But as his new dignity was far superior to his fortune, the crown made several grants to him to enable him to support it. This sudden elevation, and the strictness of his moral deportment, which bordered on austerity, did not fail to create a number of enemies in such a licentious coast as that of Charles II.

It would perhaps be improper to omit a remarkable circumstance respecting his daughter, who was a maid of honour to the princess of Orange, as it had every appearance of affecting his future fortune in a very material degree. The duke of York was so captivated with the charms of his lordship's daughter, that he was delighted with her into a private contract of marriage, when he found it impracticable to triumph over her virtue, or procure her for a mistress. Finding herself pregnant, she boldly insisted that the duke would make an open avowal of their marriage, which rendered it necessary to make the king acquainted with it; but when it reached the ears of her father, he behaved on the occasion in such a manner, as greatly to tarnish a character so illustrious. He said he would rather see his daughter the duke's mistress than his consort; advised to confine her in the Tower, and even asserted that she ought to lose her head. He was afraid of the king's indignation, from a supposition that he was privy to the marriage, which there is no good reason for believing, yet such an apprehension might bring such expressions from him as were wholly incompatible with the feelings of a parent. His extravagant notions of royalty might also have their own weight in producing such an unnatural conduct, since he would conceive the blood of majesty to be contaminated by such an alliance. To the honour of Charles he behaved on the occasion in a very commendable manner; and notwithstanding the rage of the queen-mother, the base conduct of the duke in denying his marriage, and attempting by calumny to impeach the chastity of his consort, she was at length acknowledged as the duchess of York, and became the mother of two English queens.

Earl Clarendon's influence with the crown was naturally increased by this marriage, while it as naturally procured him the envy of his fellow courtiers, and paved the way to his subsequent degradation. The sale of Dunkirk to the French was viewed as dishonourable by the nation at large, although perhaps on the score of economy and sound policy it was capable of vindication. To this we may add the unpopular measure of opposing the bill for granting liberty of conscience, as it brought him the displeasure both of the king and of all religious sectaries. Even the unfortunate war with the Dutch was charged to his account, although he was known to be its enemy from its very commencement. Rigidity virtuous himself, the rigorous course of life pursued by his master could not fail to give him offence, and he certainly displeased the king by the freedom of his reports. In defiance, therefore, of all his former services, he was basely abandoned to the indignation of the people, and driven from every office of public trust in the month of August 1667. He was charged with the crime of high treason by the house of commons, but the peers refused to convict him upon their charge; but while the dispute between the two houses was yet undetermined, Clarendon received his majesty's orders to quit the kingdom. His apology to the peers was burnt by the common executioner, and a bill of banishment was issued against him for flying from justice. While he proceeded from Calais to Rouen, the court of France sent an order to him to quit that kingdom, which bodily distress at that time rendered impracticable, upon which the cruel order was reversed. The savage rage of some Englishmen nearly deprived him of his life as he passed from Rouen to Avignon after his recovery; but the court of France punished the perpetrators of the deed. At Montpellier he met with very respectful treatment during a residence of four years, which time he devoted to the vindication of his conduct. Having spent some time at Moulin, he fixed his residence at Rouen, where he terminated his career in December 1674, in the 68th year of his age. His remains were brought to England, and interred in the abbey of Westminster.

Lord Clarendon was the author of Contemplations and Reflections on the Psalms; Animadversions on a book of Mr Cressy's in the Roman Catholic Controver.
HYD, in Astronomy, a southern constellation, consisting of a number of stars, imagined to represent a water serpent. The stars in Hydra, in Ptolemy's catalogue, are twenty-seven; in Tycho's, nineteen; in Hevelius's, thirty-one.

HYDRA, in Zoology, a genus of the order of zoophyta, belonging to the class of vermes. See Helminthology Index.

HYDROGOGUES, among physicians, remedies which evacuate a large quantity of water in dropsies. The word is formed of ὕδης, water, and γογγύς, to draw or lead; but the application of the term proceeds upon a mistaken supposition, that every purgative had some particular humour which it would evacuate, and which could not be evacuated by any other. It is now, however, discovered, that all strong purgatives will prove hydrogogues, if given in large quantity, or in weak constitutions. The principal medicines recommended as hydrogogues, are the juice of elder, the root of iris, soldanella, mechoasan, jalap, &c.

HYDRANGEA, a genus of plants belonging to the decandria class, and in the natural method ranking under the 13th order, Succulenta. See Botany Index.

HYDRASTIS, a genus of plants, belonging to the polyandria class, and in the natural method ranking with those of which the order is doubtful. See Botany Index.

HYDARGYRUM, a name given to mercury, or quicksilver. The word is formed of ὕδης, aqua, "water," and ἀργυρός, argentum, "silver." q. d. water of silver, on account of its resembling liquid or melted silver.

HYDRAULICS, the science of the motion of fluids and the construction of all kinds of machines relating thereto. See Hydrodynamics in this work, and Hydraulics, Supplement.

HYDRENEROCELE, in Surgery, a species of hernia, wherein the intestines descend into the scrotum, together with a quantity of water.

HYDROCEPHALUS, a preternatural distension of the head to an uncommon size by a stagnation and extravasation of the lymph; which, when collected in the inside of the cranium, is then termed internal; as that collected on the outside is termed external. See Medicine Index.

HYDROCHARIS, the Little Water-Lily, a genus of plants belonging to the diccia class, and in the natural method ranking under the first order, Palmae. See Botany Index.

HYDROCOTYLE, WATER-NAVELWORT, a genus of plants belonging to the pentandria class, and in the natural method ranking under the 45th order, Umbellatae. See Botany Index.

HYDRODYNAMICS.
HYDRODYNAMICS.

1. HYDRODYNAMICS, from the Greek, "water," and ἀέρας, "power," is properly that science which treats of the power of water, whether it acts by pressure or by impulse. In its more enlarged acceptation, however, it treats of the pressure, equilibrium, cohesion, and motion of fluids, and of the machines by which water is raised, or in which that fluid is employed as the first mover. Hydrodynamics is divided into two branches, Hydrostatics and Hydraulics. Hydrostatics comprehends the pressure, equilibrium, and cohesion of fluids, and Hydraulics their motion, together with the machines in which they are chiefly concerned.

HISTORY.

2. The science of hydrodynamics was cultivated with less success among the ancients than any other branch of mechanical philosophy. When the human mind had made considerable progress in the other departments of physical science, the doctrine of fluids had not begun to occupy the attention of philosophers; and, if we except a few propositions on the pressure and equilibrium of water, hydrodynamics must be regarded as a modern science, which owes its existence and improvement to those great men who adorned the 17th and 18th centuries.

3. Those general principles of hydrostatics which are to this day employed as the foundation of that part of the science, were first given by Archimedes in his work De Insidentibus Humido, about 250 years before the birth of Christ, and were afterwards applied to experiments by Marinus Ghetaldus in his Archimedes Promotus. Archimedes maintained that each particle of a fluid mass, when in equilibrio, is equally pressed in every direction; and he inquired into the conditions, according to which a solid body floating in a fluid should assume and preserve a position of equilibrium. We are also indebted to the philosopher of Syracuse for that ingenious hydrostatical process by which the purity of the precious metals can be ascertained, and for the screw engine which goes by his name, the theory of which has lately exercised the ingenuity of some of our greatest mathematicians.

4. In the Greek school at Alexandria which flourished under the auspices of the Ptolemies, the first attempts were made at the construction of hydraulic machinery. About 120 years after the birth of Christ, the fountain of compression, the syphon, and the forcing pump, were invented by Ctesibius and Hero; and though these machines operated by the elasticity and weight of the air, yet their inventors had no distinct notions of these preliminary branches of mathematical science. The syphon is a simple instrument which is employed to empty vessels full of water or spiritsuous liquors, and is of great utility in the arts. The forcing pump, on the contrary, is a complicated and abstruse invention, which could scarcely have been expected in the infancy of hydraulics. It was probably suggested to Ctesibius by the Egyptian wheel or Noria, which was common at that time, and which was a kind of chain pump, consisting of a number of earthen pots carried round by a wheel. In some of these machines the pots have a valve in their bottom which enables them to descend without much resistance, and diminishes greatly the load upon the wheel; and if we suppose that this valve was introduced so early as the time of Ctesibius, it is not difficult to perceive how such a machine might have led this philosopher to the invention of the forcing pump.

5. Notwithstanding these inventions of the Alexandrian school, its attention does not seem to have been directed to the motion of fluids. The first attempt to investigate this subject was made by Sextus Julius Frontinus, inspector of the public fountains at Rome in the reigns of Nerva and Trajan; and we may justly suppose that his work entitled De Aqueductibus urbium Romae Commentarii contains all the hydraulic knowledge of the ancients. After describing the Roman aqueducts, and mentioning the date of their construction, he considers the methods which were at that time employed for ascertaining the quantity of water discharged from intakes and the mode of distributing the waters of an aqueduct or a fountain. He justly remarks that the expense of water from an orifice, depended not only on the magnitude of the orifice itself, but also on the height of the water in the reservoir; and that a pipe employed to carry off a portion of water from an aqueduct, should, as circumstances required, have a position more or less inclined to the original direction of the current. But as he was unacquainted with the true law of the velocities of running water as depending upon the depth of the orifice, we can scarcely be surprised at the want of precision which appears in his results.

6. The labours of the ancients in the science of hydrodynamics terminated with the life of Frontinus. The sciences had already begun to decline, and that night of ignorance and barbarism was advancing across, which for more than a thousand years brooded over the nations of Europe. During this lengthened period of mental degeneracy, when less abstruse studies ceased to attract the notice, and rouse the energies of men, the human mind could not be supposed capable of that vigorous exertion, and patient industry, which are so indispensable in physical researches. Poetry and the fine arts, labour of which accordingly had made considerable progress under the patronage of the family of Medici, before Galileo began to extend the boundaries of science. This great man, who deserves to be called the father and restorer of physics, does not appear to have directed his attention to the doctrine of fluids: but his discovery of the uniform acceleration of gravity, laid the foundation of its future progress, and contributed in no small degree to aid the exertions of genius in several branches of science.

7. Castelli and Torricelli, two of the disciples of Galileo, applied the discoveries of their master to the science of hydrodynamics. In 1638 Castelli published...
HYDRODYNAMICS.

History. a small work, in which he gave a very satisfactory explanation of several phenomena in the motion of fluids. But he committed a great paradoxism in supposing the velocity of the water proportional to the depth of the orifice below the surface of the vessel. Torricelli observing that in a jet d'eau where the water rushed through a small adjutage, it rose to nearly the same height with the reservoir from which it was supplied, imagined that it ought to move with the same velocity as if it had fallen through that height by the force of gravity. And hence he deduced this beautiful and important proposition, that the velocities of fluids are as the square roots of the pressures, abstracting from the resistance of the air and the friction of the orifice. This theorem was published in 1643, in his treatise De Motu Gravitati naturaliter accelerato. It was afterwards confirmed by the experiments of Raphaei Magiotti, on the expence of water discharged from different adjutages under different pressure; and though it is true only in small orifices, it gave a new turn to the science of hydraulics.

Of Torricelli. The science relates to the motion of rivers seems to have originated from Italy. This fertile country receives from the Alps, besides a great number of torrents, which traverse several of the principalities before they mingle their waters with those of the Po, into which the greater part of them fall. To defend themselves from the inundations with which they were threatened, it became necessary for the inhabitants to change the course of their rivers; and while they thus drove them from their own territories, they let them loose on those of their neighbours. Hence arose the continual quarrels which once raged between the Bolognese, and the inhabitants of Modena and Ferrara. The attention of the Italian engineers was necessarily directed to this branch of science; and hence a greater number of works were written on the subject in Italy than in all the rest of Europe.

Of Pascal. Guglielmini was the first who attended to the motion of water in rivers and open canals. Embracing the theorem of Torricelli, which had been confirmed by repeated experiments, Guglielmini concluded that each particle in the perpendicular section of a current has a tendency to move with the same velocity as if it issued from an orifice at the same depth from the surface. The consequences deducible from this theory of running waters are in every respect repugnant to experience, and it is really surprising that it should have been so hastily adopted by succeeding writers. Guglielmini himself was sufficiently sensible that his paradoxical theory was contradictory to fact, and endeavoured to reconcile them by supposing the motion of rivers to be obstructed by transverse currents arising from irregularities in their bed. The solution of this difficulty was given by Mariotte, who was more satisfactory, and was afterwards adopted by Guglielmini, who maintained that the viscosity of water had a considerable share in retarding its motion.

Of Mariotte. The effects of friction and viscosity in diminishing the velocity of running water were noticed in the Principia of Sir Isaac Newton, who has thrown much light upon several branches of hydrodynamics. At a time when the Cartesian system of vortices universally prevailed, this great man found it necessary to investigate that absurd hypothesis, and in the course of his investigation he has shown that the velocity of any stratum of the vortex is an arithmetical mean between the velocities of the strata which enclosed it; and from this it evidently follows, that the velocity of a filament of water moving in a pipe is an arithmetical mean between the velocities of the filaments which surround it. Taking advantage of these results, it was afterwards shown by M. Flot that the retardations arising from friction are inversely as the diameters of the pipes in which the fluid moves. The attention of Newton was also directed to the discharge of water from orifices in the bottom of vessels. He supposed a cylindrical vessel full of water to be perforated in its bottom with a number of holes by which the water escaped, and thought the vessel to be supplied with water in such a manner that it always remained full at the same height. He then supposed this cylindrical column of water to be divided into two parts; the first being
HYDRODYNAMICS.

The oscillation of waves is one of the most difficult in the science of hydrodynamics, was first investigated by Sir Isaac Newton. By the 44th proposition of the 2d book of his Principia, he has furnished us with a method of ascertaining the velocity of the waves of the sea, by observing the time in which they rise and fall. If the two vertical branches of the syphon, which communicate by means of a horizontal branch be filled with a fluid of known density, the two liquid columns when, in a state of rest, will be in equilibrium and their surfaces horizontal. But if the one column is raised above the level of the other, and left to itself, it will descend below that level, and raise the other column above it; and after a few oscillations, they will return to a state of repose. Newton occupied himself in determining the duration of these oscillations, or the length of a pendulum isochronous to their duration; and he found, by a simple process of reasoning, that, abstracting from the effects of friction, the length of a synchronous pendulum is equal to one-half of the length of the syphon, that is, of the two vertical branches and the horizontal one, and hence he deduced the isochronism of these oscillations. From this Newton concluded, that the velocity of waves formed on the surface of water either by the wind or by means of a stone, was in the subduplicate ratio of their size. When their velocity therefore is measured, which can be easily done, the size of the waves will be determined by taking a pendulum which oscillates in the time that a wave takes to rise and fall.

14. In the year 1718 the Marquis Poleni published at Padua his work De Castelli per quae derivatur Fluviorum aquarum, &c. He found from a great number of experiments, that if A be the aperture of the orifice, and D its depth below the surface of the reservoir, the quantity of water discharged in a given time will be as

\[
2 \pi \times 2.571 \times 1000
\]

while it ought to be as 2 \pi AD, if the velocity of the issuing fluid was equal to that acquired by falling through D. By adapting to a circular orifice through which the water escaped, a cylindrical tube of the same diameter, the marquis found that the quantity discharged in a determinate time was considered greater than when it issued from the circular orifice itself; and this happened whether the water descended perpendicularly or issued in a horizontal direction.

15. Such was the state of hydrodynamics in 1738, when Daniel Bernouilli published his Hydrodynamica, a theory of seu de viribus et motibus Fluidorum Commentarius. His theory of the motion of fluids was founded on two suppositions, which appeared to him conformable to experience. He supposed that the surface of a fluid, contained in a vessel which was emptying itself by an orifice, remains always horizontal; and if the fluid mass is conceived to be divided into an infinite number of horizontal strata of the same bulk, that these strata remain contiguous to each other, and that all their points descend vertically, with velocities inversely proportional to their breadth, or to the horizontal sections of the reservoir. In order to determine the motion of each stratum, he employed the principle of the conservatio virium vivorum, and obtained very elegant solutions. In the opinion of the abbé Bosuti, his work was one of the finest productions of mathematical genius.

16. The uncertainty of the principle employed by Daniel Bernouilli, which has never been demonstrated in a general manner, deprived his results of that confidence which they would otherwise have deserved; and it became desirable to have a theory more certain, and depending solely on the fundamental laws of mechanics. Maclaurin and John Bernouilli, who were of this opinion, resolved the problem by more direct methods, the one in his Fluxions, published in 1742, and the other in his Hydrodynamica nempe primum detecta, et directe demonstrata ex principiis puri mechanicae, which forms the fourth volume of his works. The method employed by Maclaurin has been thought not sufficiently rigorous; and that of John Bernouilli is, in the opinion of La Grange, defective in perspicuity and precision.

17. The theory of Daniel Bernouilli was opposed by D'Alembert also by the celebrated D'Alembert. When generalising James Bernouilli's Theory of Pendulums, he discovered a principle of dynamics so simple and general, applied to the motion of pendulums, that it reduced the laws of the motion of bodies to that of fluids. He applied this principle to the motion of fluids, and gave a specimen of its application at the end of his Dynamics in 1743. It was more fully developed in his Traité des Fluides, which was published in 1744, where he has resolved, in the most simple and elegant manner, all the problems which resi...
HYDRODYNAMICS.

late to the equilibrium and motion of fluids. He makes use of the very same suppositions as Daniel Bernoulli, though his calculus is established in a very different manner. He considers, at every instant, the actual motion of a stratum, as composed of a motion which it had in the preceding instant, and of a motion which it has lost. The laws of equilibrium between the motions lost, furnish him with equations which represent the motion of the fluid. Although the science of hydrodynamics had then made considerable progress, yet it was chiefly founded on hypothesis. It remained a desideratum to express by equations the motion of a particle of the fluid in any assigned direction. These equations were found by D’Alembert, from two principles, that a rectangular canal, taken in a mass of fluid in equilibrium, is itself in equilibrium; and that a portion of the fluid, in passing from one place to another, preserves the same volume when the fluid is incompressible, or dilates itself according to a given law when the fluid is elastic. His very ingenious method was published in 1752, in his Essai sur la resistance des fluides. It was brought to perfection in his Opuscules Mathematiques, and has been adopted by the celebrated Euler.

Before the time of D’Alembert, it was the great object of philosophers to submit the motion of fluids to general formulæ, independent of all hypothesis. Their attempts, however, were altogether fruitless; for the method of fluxions, which produced such important changes in the physical sciences, was but a feeble auxiliary in the science of hydraulics. For the resolution of the questions concerning the motion of fluids, we are indebted to the method of partial differences, a new calculus, with which Euler enriched the sciences. This great discovery was first applied to the motion of water by the celebrated D’Alembert, and enabled both him and Euler to represent the theory of fluids in formulæ restrained by no particular hypothesis.

18. An immense number of experiments on the motion of water in pipes and canals was made by Professor Michelotti of Turin, at the expense of the sovereign. In these experiments the water issued from holes of different sizes, under pressures of from five to twenty-eight feet, from a tower constructed of the finest masonry. Basins built of masonry, and lined with stucco, received the effluent water, which was conveyed in canals of brickwork lined with stucco, of various forms and declivities. The whole of Michelotti’s experiments were conducted with the utmost accuracy; and his results are, in every respect, entitled to our confidence.

19. The experiments of the Abbé Bossut, whose labours in this department of science have been very assiduous and successful, have, in as far as they coincide, afforded the same results as those of Michelotti. Though performed on a smaller scale, they are equally entitled to our confidence, and have the merit of being made in cases which are most likely to occur in practice. In order to determine what were the motions of the fluid particles in the interior of a vessel emptying itself by an orifice, M. Bossut employed a glass cylinder, to the bottom of which different appendages were attached; and he found that all the particles descend at first suddenly, but that at a certain distance from the orifice they turn from their first direction towards the aperture. In consequence of these oblique motions, the fluid vein forms a kind of truncated conoid, whose greatest base is the orifice itself, having its altitude equal to the radius of the orifice, and its bases in the ratio of 3 to 2. It appears also, from the experiments of Bossut, that when water issues through an orifice made in a thin plate, the expence of water, as deduced from theory, is to the real expence as 16 to 10, or as 8 to 5; and, when the fluid issues through an additional tube, two or three inches long, and follows the sides of the tube, as 16 to 12. In analyzing the effects of friction, he found, 1. That small orifices gave less water in proportion than great ones, on account of friction; and, 2. That when the height of the reservoir was augmented, the contraction of the fluid vein was also increased, and the expence of water diminished; and by means of these two laws he was enabled to determine the quantity of water discharged, with all the precision he could wish. In his experiments on the motion of water in canals and tubes, he found that there was a sensible difference between the motion of water in the former and the latter. Under the same height of reservoir, the same quantity of water always flows in a canal, whatever be its length and declivity; whereas, in a tube, a difference in length and declivity has a very considerable influence on the quantity of water discharged. According to the theory of the resistance of fluids, the impulse upon a plane surface, is as the product of its area multiplied by the square of the fluid’s velocity, and the square of the sine of the angle of incidence. The experiments of Bossut, made in conjunction with D’Alembert and Condorcet, prove, that this is sensibly true when the impulse is perpendicular; but that the aberrations from theory increase with the angle of impulsion. They found, that when the angle of impulsion was between $60^\circ$ and $90^\circ$, the ordinary theory may be employed, that the resistances thus found will be a little less than they ought to be, and the more so as the angles recede from $90^\circ$.

The attention of Bossut was directed to a variety of other interesting points, which we cannot stop to notice, but for which, most refer the reader to the works of that ingenious author.

20. The oscillation of waves, which was first discussed by Sir Isaac Newton, and afterwards by D’Alembert, in the article Ondes in the French Encyclopaedia, was now revived by M. Flaugergues, who attempted to overthrow the opinions of these philosophers. He maintained, that a wave is not the effect of a motion in the particles of water, by which they rise and fall alternately, in a serpentine line, when moving from the centre where they commenced; but that it is a kind of intumescence, formed by a depression at the place where the impulse is first made, which propagates itself in a circular manner when removing from the point of impulse. A portion of the water, thus elevated, he imagines, flows from all sides into the hollow formed at the centre of impulse, so that the water being, as it were, hooped up, produces another intumescence, which propagates itself as formerly. From this theory, M. Flaugergues concludes, and he has confirmed the conclusion by experiment, that all waves, whether great or small, have the same velocity. This difficult subject has also been discussed by M. de la Grange, in his Mechanique Analytique. He de la Grange, found, that the velocity of waves, in a canal, is equal to the height of the water
PART II.

HYDRODYNAMICS.

24. The science of hydrodynamics has of late years been cultivated by M. Eytelev in Berlin, whose practical conclusions coincide nearly with those of Bossut;—Eytelev by Dr. Matthew Young, late bishop of Clonfert, who has explained the cause of the increased velocity of efflux through additional tubes, and by Mr. Vince, Dr. T. Young, Coulomb, and Don George Jean; but the limits of this work will not permit us to give any further account of their labours at present. We must now proceed to initiate the reader into the science itself, beginning with that branch of it which relates to the pressure, equilibrium, and cohesion of non-elastic fluids.

PART I. HYDROSTATICS.

Definition of Hydrostatics.

HYDROSTATICS is that branch of the science of hydrodynamics which comprehends the pressure and equilibrium of non-elastic fluids, as water, oil, mercury, &c.; the method of determining the specific gravities of substances, the equilibrium of floating bodies (A), and the phenomena of capillary attraction.

Definition of a fluid.

Perfect fluids.

26. A fluid is a collection of very minute particles,cohering so little among themselves, that they yield to the smallest force, and are easily moved among one another.

27. Fluids have been divided into perfect and imperfect. In perfect fluids the constituent particles are supposed to be endowed with no cohesive force, and if they were to be united one among another by a pressure infinitely small. But, in imperfect or viscous fluids, the mutual cohesion of their particles is very sensible, as in oil, varnish, fluids, melted glass, &c.; and this tenacity prevents them from yielding to the smallest pressure. Although water, mercury, alcohol, &c. have been classed among perfect fluids, yet it is evident that neither these nor any other liquid is possessed of perfect fluidity. When a glass vessel is filled with water above the brim, it assumes a convex surface; and when a quantity of it is thrown
HYDRODYNAMICS.

thrown on the floor, it is dispersed into a variety of little globules, which can scarcely be separated from one another. Even mercury, the most perfect of all the fluids, is endowed with such a cohesive force among its particles, that if a glass tube, with a small bore, is immersed in a vessel full of this fluid, the mercury will be lower in the tube than the surface of the surrounding fluid;—if a small quantity of it be put in a glass vessel, with a gentle rising in the middle of its bottom, the mercury will desert the middle, and form itself into a ring, considerably rounded at the edges; or if several drops of mercury be placed upon a piece of flat glass, they will assume a spherical form; and if brought within certain limits, they will conglobulate and form a single drop. Now, all these phenomena concur to prove, that the particles of water have a mutual attraction for each other; that the particles of mercury have a greater attraction for one another, than for the particles of glass; and, consequently, that these substances are not entitled to the appellation of perfect fluids.

28. It was universally believed, till within the last 45 years, that water, mercury, and other fluids of a similar kind, could not be made to occupy a smaller space, by the application of any external force. This opinion was founded on an experiment made by Lord Bacon, who inclosed a quantity of water in a leaden globe, and by applying a great force attempted to compress the water into less space than it occupied at first. The water, however, made its way through the pores of the metal, and stood on its surface like dew. The same experiment was afterwards repeated at Florence by the academy del Cimento, who filled a silver globe with water, and hammered it with such force as to alter its form, and drive the water through the pores of the metal. Though these experiments were generally reckoned decisive proofs of incompressibility, yet Bacon himself seems to have drawn from his experiment a very different conclusion; for after giving an account of it, he immediately adds, that he computed into how much less space the water was driven by this violent pressure (B). This passage from Lord Bacon does not seem to have been noticed by any writer on hydrostatics, and appears a complete proof that the compressibility of water was fairly deducible from the issue of his experiment. In consequence of the reliance which was universally placed on the result of the Florentine experiment, fluids have generally been divided into compressible and incompressible, or elastic and non-elastic fluids: water, oil, alcohol, and mercury, being regarded as incompressible and non-elastic; and air, steam, and other aëriiform fluids, as compressible or elastic.

29. About the year 1761, the ingenious Mr. Canton began to consider this subject with attention, and drawing the result obtained by the academy del Cimento, resolved to bring the question to a decisive issue (C). Having procured a small glass tube, about two feet long, with a ball at one end, an inch and a quarter in diameter, he filled the ball and part of the tube with mercury, and brought it to the temperature of 50° of Fahrenheit. The mercury then stood six inches and a half above the ball; but after it had been raised to the top of the tube by heat, and the tube sealed hermetically, then, upon bringing the mercury to its former temperature of 50°, it stood 1 foot 1 inch higher in the tube than it did before. By repeating the same experiment with water exhausted of air, instead of mercury, the water stood 1/31th of an inch higher in the tube than it did at first. Hence it is evident, that when the weight of the atmosphere was removed, the water and mercury expanded, and that the water expanded 1/31th of an inch more than the mercury. By placing the apparatus in the receiver of a condensing engine, and condensing the air in the receiver, he increased the pressure upon the water, and found that it descended in the tube. Having thus ascertained the fact, that water and mercury are compressible, he subjected other fluids to similar experiments, and obtained the results in the following table.

<table>
<thead>
<tr>
<th>Millimoth Parts</th>
<th>Specific Gravity</th>

<tr>
<td>spirit of wine,</td>
<td>66</td>
</tr>
</tbody>
</table>

Lest it should be imagined that this small degree of compressibility arose from air imprisoned in the water, Mr. Canton made the experiment on some water which had imbibed a considerable quantity of air, and found that its compressibility was not in the least augmented. By inspecting the preceding table, it will be seen that the compressibility of the different fluids is nearly in the inverse ratio of their specific gravities.

30. The experiments of Mr. Canton have been lately and correctly confirmed by Professor Zimmerman. He found that when water was compressed 1/41th part of its bulk when inclosed in the cavity of a strong iron cylinder, and under the influence of a force equal to a column of sea-water 1000 feet high. From those facts, it is obvious that fluids are susceptible of contraction and dilatation, and that there is no foundation in nature for their being divided into compressible and incompressible. If fluids are compressible, they will also be elastic; for when the compressing force is removed, they will recover their former magnitude; and hence their division into elastic and non-elastic is equally improper.

31. The doctrines of hydrostatics have been deduced by different philosophers from different properties of fluids. Euler has founded his analysis on the following property, "that when fluids are subjected to any pressure, that pressure is so diffused throughout the mass, that when it remains in equilibrium all its parts are equally pressed in every direction (D)," D'Alembert at first (E) deduced the principles of hydrostatics from the property which fluids have of rising to the same altitude in any number of communicating vessels; but he afterwards

HYDRODYNAMICS.

PROPOSITION I.

32. When a mass of fluid, supposed without weight, is subjected to any pressure, that pressure is so diffused throughout the whole, that when it remains in equilibrio all its parts are equally pressed in every direction.

As it is the distinguishing property of fluids that their particles yield to the smallest pressure, and are easily moved among themselves (16), it necessarily follows, that if any particle is more pressed towards one side than towards another, it will move to that side where the pressure is least; and the equilibrio of the fluid mass will be instantly destroyed. But by the hypothesis the fluid is in equilibrio, consequently the particle cannot move towards one side, and must therefore be equally pressed in every direction.

In order to illustrate this general law, let EF (fig. 1.) be a vessel full of any liquid, and let \( mn, op \) be two orifices at equal depths below its surface; then, in order to prevent the water from escaping, it will be necessary to apply two pistons, A and B, to the orifices \( mn, op \) with the same force, whether the orifice be horizontal or vertical, or in any degree inclined to the horizon; so that the pressure to which the fluid mass is subject, which in this case is its own gravity, must be distributed in every direction. But if the fluid has no weight, then the pressure exerted against the fluid at the orifice \( op \), by means of the piston \( B \), will propagate itself through every part of the circular vessel \( EF \), so that if the orifices \( mn, tu \) are shut, and \( rs \) open, the fluid would rush through this aperture in the same manner as it would rush through \( ms \) or \( tw \), were all the other orifices shut. This proposition, however, is true only in the case of perfect fluids; for when there is a sensible cohesion between the particles, as in water, an equilibrium may exist even when a particle is less pressed in one direction than in another; but this inequality of pressure is so exceedingly trilling, that the proposition may be considered as true, even in cases of imperfect fluidity.

PROPOSITION II.

33. If to the equal orifices \( mn, tu, op, rs \) of a vessel, containing a fluid destitute of weight, be applied equal powers \( A, B, C, D \) in a perpendicular direction, or if the orifices \( mn, bc \) be unequal, and the powers \( A, B, c \) which are respectively applied to them be proportional to the orifices, these powers will be in equilibrio.

It is evident from the last proposition, that the pressure exerted by the power \( B \) is transmitted equally to the orifices \( mn, rs, tu \), that the pressure of the power \( C \) is transmitted equally to the orifices \( mn, op, tu \), and so on with all the other powers. Every orifice then is influenced with the same pressure, and, consequently, none of the powers \( A, B, C, D \) can yield to the action of the rest. The fluid mass, therefore, will neither change its form nor its situation, and the powers \( A, B, C, D \) will be in equilibrio. If the powers \( A, B, C, D \) are not equal to one another, nor the orifices \( mn, op, rs, tu \); but if \( A = B = mn \), \( op \), and so on with the rest, the fluid will still be in equilibrio. Let \( A \) be greater than \( B \), then \( mn \) will be greater than \( op \); and whatever number of times \( B \) is contained in \( A \), so many times will \( op \) be contained in \( mn \). If \( A = 2B \), then \( mn = 2op \), and since the orifice \( mn \) is double of \( op \), the pressure upon it must also be double; and, in order to resist that pressure, the power \( A \) must also be double of \( B \); but, by hypothesis, \( A = 2B \), consequently the pressures upon the orifices, or the powers \( A, B, \) will be in equilibrio. If the power \( A \) is any other multiple of \( B \), it may be shown in the same way that the fluid will be in equilibrio.

PROP. III.

34. The surface of a fluid influenced by the force of gravity and in equilibrio in any vessel, is horizontal, or at right angles to the direction of gravity.

Let the surface of the fluid be supposed to assume the surface waving form \( ABE \). Any particle \( P \) in the surface of the fluid be horizontal, or at right angles to the direction of gravity.

Of the fluid is influenced by the force of gravity, which may be represented by \( PS \), and which may be decomposed into two forces \( PM, PN \) in the direction of the two elementary portions of the surface \( PM, PN \) (see Dynamics, 148). But since the particle \( P \) is in a state of equilibrio, the force of gravity acting in the direction \( PM, PN \) must be destroyed by equal and opposite forces, exerted by the neighbouring particles against \( P \) in the direction \( MP, NP \); therefore the forces \( PM, PN \) are equal to the forces \( MP, NP \). Now the particle \( P \) being in equilibrio, must be equally pressed in every direction (32). Wherefore the forces \( PM, PN \) are equal, and by the doctrine of the composition of forces (see Dynamics, 133. D), the angle \( \angle MPN \) formed by the two elementary portions \( PM, PN \) of the surface of the fluid, must be bisected by \( PS \), the line which represents the direction of gravity. The same may be proved of every other point of the surface of the fluid; and therefore this surface must be horizontal or perpendicular to the direction of gravity.

35. This proposition may be otherwise demonstrated. From the principles of mechanics, it is obvious, that when the centre of gravity of any body is at rest, the body itself is at rest; and that when this centre is not supported, the body itself will descend, till it is prevented by some obstacle from getting farther. In the same manner the centre of gravity of a liquid mass will descend to the lowest point possible; and it can be shown that this centre will be in its lowest position when the surface of the fluid mass is horizontal. For let \( FGH \) (fig. 2.) be any surface, whether solid or fluid, and C its centre of gravity, the point C is nearer the line HI when FG is parallel to HI and rectilineal, than when it has any other form or position. When the surface \( FGH \) is suspended by the point C, or balanced upon it, it will be in equilibrio; but if the line FI is made to assume any other form as FRSG, by removing the portion Gop of the surface to rs, the equilibrio...
HYDRODYNAMICS.

Pressure, &c. of Fluids.

equilibrium will be destroyed, and the side FG will preponderate. In order, therefore, to restore the equilibrium, the surface must be balanced on a point C farther from HI; that is, the centre of gravity of the surface FSTOHI is C. In the same way it may be shown that whatever be the form of the bounding line FG, the quantity of surface remaining the same, its centre of gravity will be nearest HI, when FG is rectilinear and parallel to it. On the truth contained in this proposition depends the art of levelling, and the construction of the spirit level, for an account of which see LEVELLING.

36. As the direction of gravity is in lines which meet near the centre of the earth; and as it appears from this proposition, that the surface of fluids is perpendicular to that direction, their surface will be a portion of a spheroid similar to the earth. When the surface has no great extent, it may be safely considered as a plane; but when it is pretty large, the curvature of the earth must be taken into the account.

PROP. IV.

37. The surface of a fluid influenced by the force of gravity, and contained in any number of communicating vessels, however different in form and position, will be horizontal.

The surface of a fluid in any number of communicating vessels is horizontal.

Fig. 3.

Let ABCDEF be a system of communicating vessels into which a quantity of fluid is conveyed: It will rise to the same height in each vessel, and have a horizontal surface ABCDE. Suppose AGFE, a large vessel full of water. By the last proposition, its surface ABCDE will be horizontal. Now, if any body be plunged into this vessel, the cylinder C for instance, the surface of the fluid will still be horizontal; for no reason could be assigned for the water’s rising on one side of this body any more than on another. Let us now take out the cylinder C, and immerse into the fluid, successively, the solid bodies A a, B b, C c, D d, then after each immersion the surface will still be horizontal; and when all these solids are immerged, the large vessel AF will be converted into the system of communicating vessels represented in fig. 4; in which the surface of the fluid will, of consequence, be horizontal.

38. This proposition may be also demonstrated by supposing the parts A a, B b, C c, D d, converted into ice without changing their former magnitude. When this happens, the equilibrium will not be disturbed; and the fluid mass AF, whose surface was proved to be horizontal by the last proposition, will continue in the same state after the congelation of some of its parts. That is, the surface of the fluid in the communicating vessels A, B, C, D, E will be horizontal.

This proposition is not true, when the communicating vessels are capillary tubes.

39. When the communicating vessels are so small that they may be regarded as capillary tubes, the surface of the fluid will not be horizontal. From the attraction which all fluids have for glass, they rise to a greater height in smaller tubes than in larger ones, and the quantity of elevation is in the inverse ratio of the diameters of the bores. In the case of mercury, and probably of melted metals, the fluid substance is depressed in capillary tubes, and the depression is subject to the same law. The subject of capillary attraction will be treated at length in a subsequent part of this article.

40. This proposition explains the reason why the surface of small pools in the vicinity of rivers is always on a level with the surface of the rivers themselves, when there is any subterraneous communication between the river and the pool. The river and the pool may be considered as communicating vessels.

PROP. V.

41. If a mass of fluid contained in a vessel be in equilibrio, any particle whatever is equally pressed in every direction, with a force equal to the weight of a column of particles whose height is equal to the depth of the particle pressed below the surface of the fluid.

Immerse the small glass tube mp, into the vessel AB Fig. 5; if the tube is not of the capillary kind, the fluid will rise to n on the same level with the surface AB of the fluid in the vessel. Now it is evident, that the particle p at the bottom of the tube mp is pressed downwards by the superincumbent column of particles np, which is equal to the depth of the particle p below the surface of the fluid. But since the mass of fluid is in equilibrio, the particle p is pressed equally in every direction: Therefore, the particle p is pressed equally in every direction by a force equal to the superincumbent column np.

PROP. VI.

42. A very small portion of a vessel of any form, filled with a fluid, is pressed with a force which is in the compound ratio of the number of particles contained in that surface, its depth below the surface of the fluid, and the specific gravity of the fluid.

Let Dp EB be the vessel, and rs a very small portion of its surface, the pressure upon rs is in the compound ratio of the number of particles in rs, and np its depth below the horizontal surface DB. Suppose the glass tube mp to be inserted in the infinitely small aperture p, then, abstracting from the influence of capillary attraction, the fluid in the glass tube will ascend to m on a level with DB, the surface of the fluid in the vessel, and the particle p will be pressed with a column of particles, whose height is np. In the same way it may be shewn, that every other particle contained between rs and p is pressed with a similar column. Then, since pxnp will represent the pressure of the column np on the particle p; if N be the number of particles in the space rs, Nxpnp will be the force of the column supported by the space rs. And as the weight of this column must increase with the specific gravity of the fluid, SxpNxpnp will represent its pressure, S being the specific gravity of the fluid.

PROP. VII.

43. The pressure upon a given portion of the bottom of a vessel, whether plane or curved, filled with any...
any fluid, is in the compound ratio of the area of that portion, and the mean altitude of the fluid, that is, the perpendicular distance of the centre of gravity of the given portion from the surface of the fluid; or, in other words, the pressure is equal to the weight of a column of fluid whose base is equal to the area of the given portion, and whose altitude is the mean altitude of the fluid.

Let AEGB be the vessel, and AFB the surface of the fluid which it contains. Let GH be a given portion of its bottom, and C the centre of gravity of that portion: Then shall CH be the mean altitude of the fluid.—Conceive the portion GH to be divided into an infinite number of small elements $H_i$, $G_i$, &c. then (42.) the pressure sustained by the elements $H_i$, $G_i$, will be respectively $S \times H_i \times H_i$, $S \times G_i \times G_i$, &c. the specific gravity of the fluid being called S. But it follows from the nature of the centre of gravity, that the sum of all these products is equal to the product of the whole portion GH into CH, of the distance of its centre of gravity from the horizontal surface of the fluid (9). Therefore, the pressure upon the portion GH is in the compound ratio of its surface converted into a plane, and the mean altitude of the fluid.

44. From this proposition we may deduce what is generally called the Hydrostatic paradox, viz. that the pressure upon the bottoms of vessels filled with fluid does not depend upon the quantity of fluid which they contain, but upon its altitude; or, in other words, that any quantity of fluid, however small, may be made to balance any quantity or any weight, however great. Let ACQRPDB be a vessel filled with water, the bottom QR will sustain the same pressure as if it supported a quantity of water equal to MQRN. It is evident (43.) that the part EF is pressed with the column of fluid ABEF, and that the part DG equal to CD is pushed upwards with the weight of a column equal to ABCD. Now, as section and reaction are equal and contrary, the part DG reacts upon FH with a force equal to the weight of the column ABEF, and FH evidently sustains the smaller column DGFH; therefore FH sustains a pressure equal to the weight of the two columns $ABCD$ and $DGFH$, that is, of the column BIHF. In the same way it might be shown, that any equal part of the bottom QR sustains a similar pressure; and therefore it follows, that the pressure upon the bottom QR is as great as if it supported the whole column MNQR.

45. The same truth may be deduced from Prop. IV.

For since the fluid in the two communicating vessels $AB$, $CD$ will rise to the same level, whatever be their size, the fluid in $AB$ evidently balances the fluid in $CD$; and any surface $mn$ is pressed with the same force in the direction $Bm$ by the small column $AB$, as it is pressed in the direction $Dm$ by the larger column $CD$.

46. Cor. 1. From this proposition it follows that Corollaries.

the whole pressure on the sides of a vessel which are perpendicular to its base, is equal to the weight of a rectangular prism of the fluid, whose altitude is that of the fluid, and whose base is a parallelogram, one side of which is equal to the altitude of the fluid, and the other to half the perimeter of the vessel.

Cor. 2. The pressure on the surface of a hemispherical vessel full of fluid, is equal to the product of its surface multiplied by its radius.

Cor. 3. In a cubical vessel the pressure against one side is equal to half the pressure against the bottom; and the pressure against the sides and bottom together, is to that against the bottom alone as three to one. Hence, as the pressure against the bottom is equal to the weight of the fluid in the vessel, the pressure against both the sides and bottom will be equal to three times that weight.

Cor. 4. The pressure sustained by different parts of the side of a vessel are as the squares of their depths below the surface; and if these depths are made the abscissae of a parabola, its ordinate will indicate the corresponding pressures.

47. The centre of pressure is that point of a surface exposed to the pressure of a fluid, to which if the total pressure were applied, the effect upon the plane would be the same as when the pressure was distributed over the whole surface: Or, it is that point to which if a force equal to the total pressure were applied in a contrary direction, the one would exactly balance the other, or, in other words, the force applied and the total pressure would be in equilibrium.

Prop. VIII.

48. The centre of pressure coincides with the centre of percussion.

Let $AB$ be a vessel full of water, and $CE$ the section of a plane whose centre of pressure is required, centre of percussion. Prolong $CE$ till it cuts the surface of the water in $M$. Let $AB$ be a vessel full of water, and $CE$ the section of a plane whose centre of pressure is required, centre of percussion. Take any point $D$, and draw $DO$, $EP$, $CN$ perpendicular to the surface $MP$. Then if $M$ be made the axis of suspension of the plane $CE$, the centre of percussion of

(y) This will be evident from the following proposition. If every indefinitely small part of a surface be multiplied by its perpendicular distance from a given plane, the sum of the products will be equal to the product of the whole surface, multiplied by the perpendicular distance of its centre of gravity from the same plane. In Plate CCLXIIL, fig. 7, let $a$, $c$ represent two weights suspended at their centre of gravity by the lines $aA$, $cC$ attached to the constant horizontal plane of which $ABC$ is a section, and let $b$ be the common centre of gravity of these weights and $bB$ the distance of this centre from the given plane, then $a \times a + c \times c = a + c \times c \times b B$. —Draw $a n$, $c m$ at right angles to $b B$. Then since $b$ is the common centre of gravity of the weights $a$, $c$, we shall have by the similar triangles $a n b$, $c m b$ $(Eucl. VI. 4.)$ $n b = m b = (b a + b c) : b c = c : a$ (See Mechanics, Centre of Gravity). Hence $a \times a = b c \times b c$, or $a \times a = b B \times b B = a \times a \times b B = c \times c \times a B$; but $b B = a A$, $b b = c c$, therefore, by substitution $a \times a + c \times c = a + c \times b B$. By supposing the two weights $a$ and $c$ united in their common centre of gravity, the same demonstration may be extended to any number of weights.
HYDRODYNAMICS.

Sect. II. Instruments and Experiments for illustrating the Pressure of Fluids.

Machine for illustrating the hydrostatic paradox.

Pl. CCLXIV. fig. 1.

49. We have already shown in art. 41. that the pressure upon the bottoms of vessels filled with fluids does not depend upon the quantity of fluid which they contain, but upon its particular altitude. This proposition has been called the Hydrostatical Paradox, and is excellently illustrated by the following machine. In fig. 1, $AB$ is a box which contains about a pound of water, and $a$ $b$ $c$ $d$ a glass tube fixed to the board $C$ of the beam of the balance, and the other end to a moveable bottom which supports the water in the box, the bottom and wire being of an equal weight with an empty scale hanged at the other end of the balance. If one pound weight be put into the empty scale, it will make the bottom rise a little, and the water will appear at the bottom of the tube $a$, consequently it will press with a force of one pound upon the bottom. If another pound be put into the scale, the water will rise to $b$, twice as high as the point $a$, above the bottom of the vessel. If a third, a fourth, and a fifth pound be successively put into the scale, the water will rise at each time to $c$, $d$, and $e$, the divisions $ab$, $bc$, $cd$, $de$ being all equal. This will be the case, however small may be the bore of the glass tube; and since when the water is at $b$, $c$, $d$, $e$, the pressures upon the bottom are successively twice, thrice, four times, and five times as great as when the water was contained within the box, we are entitled to conclude that the pressure upon the bottom of the vessel depends altogether on the altitude of the water in the glass tube, and not upon the quantity it contains. If a long narrow tube full of water, therefore, be fixed in the top of a cask likewise full of water, then though the tube be so small as not to hold a pound of water, the pressure of the water in the tube will be so great on the bottom of the cask as to be in danger of bursting it; for the pressure is the same as if the cask was continued up in its full size to the height of the tube, and filled with water. Upon this principle it has been confirmed that a certain quantity of water, however small, may be rendered capable of exerting a force equal to any assignable one, by increasing the height of the column, and diminishing the base on which it presses. This, however, has its limits; for when the tube becomes so small as to belong to the capillary kind, the attraction of the glass will support a considerable quantity of the water it contains, and therefore diminish the pressure upon its base.

50. The preceding machine must be so constructed, that the moveable bottom may have no friction against the inside of the box, and that no water may get between it and the box. The method of effecting this will be manifest from fig. 2, where $ABCD$ is a section of the box, and $a$ $b$ $c$ $d$ its lid, which is made very light. The moveable bottom $E$, with a groove round its edges, is put into a bladder $fg$, which is tied close around it in the groove, by a strong waxed thread. The upper part of the bladder is put over the top of the box at $a$ and $d$ all around, and is kept firm by the lid $a$ $b$ $c$ $d$, so that if water be poured into the box through the aperture $ll$ in its lid, it will be contained in the space $f$ $E$ $g$ $h$, and the bottom may be raised by pulling the wire $f$ fixed to it at $E$.

51. The upward pressure of fluids is excellently illustrated by the hydrostatical bellows. The form given was proposed to this machine by the ingenious Mr. Ferguson (Lectures on the Mechanism of the World, vol. ii. p. 111.) is represented in fig. 3, where $ABCD$ is an oblong square box, into one of whose sides is fixed the upright glass tube $a$, which is bent back into a right angle at the lower end as at $i$, fig. 4; and to this bent extremity is tied the neck of a large bladder $K$, which lies in the bottom of the box. Over this bladder is placed the moveable board $L$, fig. 3, and 4, in which the upright wire $M$ is fixed. Lead weights $NN$, with holes in their centre, to the amount of 16 pounds, are put upon this wire, and press with all their weight upon the board $L$. The cross bar $p$ is then put on, in order to keep the glass tube in an upright position; and afterwards the piece $EFG$ for keeping the weights $NN$ horizontal, and the wire $M$ vertical. Four upright pins, about an inch long, are placed in the corners of the box, for the purpose of supporting the board $L$, and preventing it from pressing together the sides of the bladder. When the machine is thus fitted up, pour water into the tube $I$ till the bladder is filled up to the board $L$. Continue pouring in more water, and the upward pressure which it will excite in the bladder will raise the board with all the weights $NN$, even though the base of the tube should be so small as to contain no more than an ounce of water.

52. That the pressure of fluids arises from their gravity, and is propagated in every direction, may be proved by the following experiment. Insert into an empty vessel, a number of glass tubes bent into various angles, into their lower orifices introduce a quantity of mercury, which will rest in the longer legs on a level with those in the orifices. Let the vessel be afterwards filled with water; and it will be seen, while the vessel is filling, that the mercury is gradually pressed from the lower orifices towards the higher, where the water is prevented from entering. Now, in consequence of the various angles into which the glass tubes are bent, the lower orifices point to almost every direction; and therefore it follows, that the pressure of the superincumbent water is propagated in every direction. When a straight tube is employed to shew the upward pressure of fluids, the mercury which is introduced into its lower extremity must be kept in by the finger till the height of the water above the orifice is equal to fourteen times the length of the column of quicksilver: When the finger is removed the mercury will ascend in the tube.

53. The pressure of the superior strata of fluids upon the interior strata may be shown in the following manner. Immerse two tubes of different bores, but of the capillary kind, in a vessel of mercury. The mercury will rise in the tube on a level with its surface.
in the vessel. Let water then be poured upon the mercury so as not to enter the upper orifices of the tubes, the pressure of the water upon the inferior fluid will cause the mercury to ascend in the tubes above the level of that in the vessel, but to the same height in both tubes. The columns of quicksilver in the two tubes are evidently supported by the pressure of the water on the inferior fluid. The same experiment may be made with oil and tinged water, the latter being made the inferior fluid.

54. The syphon is an instrument which shows the gravitation of fluids, and is frequently employed for decanting liquors. It is nothing more than a bent tube EABC, having one of its legs longer than the other. The shorter leg BCF is immersed in the fluid contained in the vessel D, and if, by applying the mouth to the orifice E, the air be sucked out of the tube, the water in the vessels will flow off till it be completely emptied. Now it is obvious that the atmosphere has a tendency to raise the water in the shorter leg EB by its pressure on the surface of the water at C, has the same tendency to prevent the water from falling from the orifice E by its pressure there, and therefore if the syphon had equal legs as AB, BC, no water could possibly issue from the orifice E. But when the leg EB is longer than BC, the column of fluid which it contains being likewise longer, will by its superior weight cause the water to flow from the orifice E, and the velocity of the issuing fluid will increase as the difference between the two legs of the syphon is made greater.

55. In order to show that the effect of the syphon depends upon the gravitations of fluids, M. Pascal devised the following experiment. In the large glass vessel AB, fasten by means of bees wax two cylindrical cups a, b, containing tinged water, whose surface is about an inch higher in the one than in the other. Into the tined water insert the legs of a glass syphon e d, having an open tube c fixed into the middle of it, and put a wooden cover on the vessel with a hole in its centre to receive the tube and keep it in a vertical position. Then through the funnel f, fixed in another part of the cover, pour oil of turpentine into the larger vessel till it flow into the cup b, and rise upon the arch of the syphon. The pressure of the oil upon the tined water in the cups will cause the water to pass through the syphon from the higher cup to the lower, till the surfaces of the water in both the cups be reduced to a level. In order to explain this, suppose a horizontal plane c b to pass through the legs of the syphon, and the tined water in the cups, the parts of this plane within the legs when the syphon is full, will be equally pressed by the columns of tined water e d, b c within the syphon; but the equal parts of this plane between the circumference of each leg of the syphon, and the circumference of each cylindrical cup, their diameters being equal, will sustain unequal pressures from their superincumbent columns, through the altitudes of these columns be equal. For since the pressure upon c is exerted by a column of oil a e, and a column of water a e, whereas the pressure upon b is exerted by a column of oil b c, and a column of water a e, the column a e which contains the greatest quantity of water, will evidently exert the greatest force, and by its pressure will drive the tined water from the cup a, through the syphon a c d into the cup b, until a perfect equilibrium is obtained by an equality between the columns of water a e and b c.

SECTION III. Application of the Principles of Hydrostatics to the Construction of Dykes, &c. for resisting the pressure of water.

Definition.

A dyke is an obstacle either natural or artificial, which opposes itself to the constant effort of water to spread itself in every direction.

56. In discussing this important branch of hydraulic architecture, we must inquire into the thickness and forms in which must be given to the dyke in order to resist the pressure of the water. In this inquiry the dyke yield to the may be considered as a solid body which the water pressure of water tends to overthrow by turning it round upon its posterior angle C; or it may be regarded as a solid, whose foundation is immovable, but which does not resist the pressure of the water through the whole of its height, and which may be separated into horizontal sections by the efforts of the fluid. A dyke may be considered also as a solid body which can be neither broken nor overturned, but which may be pushed horizontally from its base, and can preserve its stability only by the friction of its base on the ground which supports it. On these conditions are founded the calculations in the following propositions which contain the most useful information that theory can suggest upon the construction of dykes.

Property I.

57. To find the dimensions of a dyke which the water tends to overthrow by turning it round upon its posterior angle.

Let ABCD be the section of the dyke, considered as a continuous solid, or a piece of firm masonry, round its HK the level of the water which tends to overthrow it posteriorly by turning it round its posterior angle C, supposed to be fixed, and let AC, BD, be right lines or known curves. It is required to determine CD the thickness which must be given to its base to prevent it from being overturned.

To the surface of the water HK draw the ordinates PM, p m infinitely near each other, and let fall from the points H and M the perpendiculars, HT, MX. Draw the horizontal line ML and raise the perpendicular CL, and suppose

\[
\begin{align*}
&HP = S \\
&PM = Y \\
&Pp \text{ or } MV \text{ the fluxion of } x \\
&Mv \text{ the fluxion of } y \\
&HT = a \\
&DT = b \\
&CD = c \\
&\text{The moment of the area ABCD, or the force with which it resists being turned round the fulcrum C} = z \\
&\text{The specific gravity of water} = \frac{S}{x} \\
&\text{The specific gravity of the dyke} = \frac{1}{\gamma}
\end{align*}
\]

58. It is obvious from art. 41, that every element sustains a perpendicular pressure proportional to the height PM. Let BM perpendicular to MM represent the

\[
4 U 2
\]
HYDRODYNAMICS.

Pressures &c. of Fluids.

force exerted by the column of water $MmpF$, and let it be decomposed into two other forces, one of which $RQ$ is horizontal, and has a tendency to turn the dyke round the point $C$, and the other $RY$ is vertical and tends to press the dyke upon its base. The force $RQ$ is evidently $= sxym = \frac{VM}{rM}$, and therefore the horizontal part of it will be only $sxym = \frac{V}{rM}$. But the triangles $RQ$, $RQ$, $VM$ are evidently similar, consequently $RQ = VM : MM$; hence

$\frac{RQ}{RM} = \frac{VM}{MM}$.

Therefore by substitution we have the force $RQ = \frac{sy}{{x}}m = \frac{VM}{rM}$, and dividing by $MM$, we have $RQ = \frac{sy}{x}m$. The force $RQ$, therefore, will always be the same as the force against $VM$, whatever be the nature of the curve $BD$. Now the momentum of this force with relation to the fulcrum $C$, or its power to move the dyke, revolve round $C$, is measured by the perpendicular $CL$, that is, from the centre of motion to the direction in which the force is exerted (See Mechanics), consequently this momentum will be $m = \frac{sy}{x}CL = \frac{sy}{x}a-y$ (since $CL = HT - PM = a-y$) $= \frac{sy}{x}y$, whose fluent is $rac{sy}{x}y$, which by supposing $a-y$ becomes $\frac{1}{2}sa^2$, for the total momentum of the horizontal force of the water to turn the dyke round $C$. The vertical force $RY$ or $Qm$, which presses the dyke upon its base, is evidently $syym = \frac{MQ}{rM}$, but

on account of the similar triangles $\frac{MQ}{rM} = \frac{x}{y}$, consequently by substitution we shall have the force $RY = \frac{sy}{x}y = \frac{s}{x}y$, after division by $MM$. The momentum, therefore, of the vertical force $RY$ with relation to $C$, or its power to prevent the dyke from moving round the fulcrum $C$, will be $sya = CX$, $CX$ being the arm of the lever by which it acts, or the perpendicular let fall from the fulcrum upon the direction of the force. Now $CX = CD - DT + TX$ or $HF$, that is $CX = a - b + x$, therefore the momentum of the force $RY = sya = a - b + x$, and the sum of the similar moments from $F$ to $H$ will be the fluent $\int (a - b + x) dy$, the combined momentum of all the vertical forces which resist the efforts of the horizontal forces to turn the dyke round $C$. But the efforts of the horizontal forces are also resisted by the weight of the dyke whose momentum we have called $Z$, therefore $+ Z$, $Z$ being the specific gravity of the dyke, will be the momentum of the dyke. We have now three forces acting at once, viz. the horizontal force of the water striving to overturn the dyke, and the vertical force of the water combined with the momentum of the dyke, striving to resist its overthrow, therefore we shall have an equilibrium between these three forces, when the momentum of the horizontal forces is made equal to the momentum of the vertical forces, added to that of the dyke itself, consequently

$\frac{1}{2}sa^2 = \int \frac{dy}{a - b + x} + \frac{1}{2}sa^2$.

59. As it is necessary, however, to give more stability to the dyke than what is just requisite to preserve its equilibrium, we must make its dimensions such as to resist a force greater than the horizontal forces, a force, for example, $n$ times the momentum of the horizontal forces $c$. The equation will therefore become

$\int \frac{dy}{a - b + x} = \frac{1}{2}sa^2$, which comprehends every possible case of stability; for if we wish the stability of the dyke to have double the stability of equilibrium, we have only to make $n = 2$. The preceding general equation is susceptible of a variety of applications according to the nature of the curves which form the sides of the dyke. It is at present worthy of remark that since the momentum of the horizontal forces is always the same whatever be the curvature of the sides $AC, BD$, and since the momentum of the vertical forces increases as the angle $CDH$ diminishes, it follows that it will always be advantageous to diminish the angle $CDH$ and give as much slope as possible to the sides of the dyke.

60. Let us now consider the conditions that may be necessary to prevent the dyke $ABCD$ from sliding on its base $CD$. Since the base of the dyke is supposed to be horizontal, the force which the dyke opposes to the horizontal efforts of the water arises solely from the adhesion of the dyke to its base, and from the resistance of friction. These two forces, therefore, combined with the weight of the dyke, form the force which resists the horizontal efforts of the water; an equilibrium will consequently obtain when the three forces are made equal to the last. But the force of adhesion, and the resistance of friction, being unknown, may be made equal to the weight of the dyke multiplied by the constant quantity $m$, which must be determined by experience. Now calling $A$ the area of the section $ABCD$, we shall have $\frac{1}{2}sa$ for its weight, and $m$ $\frac{1}{2}sa$ for the resistance which is opposed to the horizontal efforts of the water. But we have already seen that the horizontal forces of the water upon $M$ are equal to $sy$, whose fluent $\frac{1}{2}sa^2$ (when $a = y$) is the sum of all the horizontal forces, consequently when an equilibrium takes place between these opposing forces we shall have

$\int \frac{dy}{a - b + x} = \frac{1}{2}sa^2$, or $MA = \frac{1}{2}sa^2$.

We might have added to the weight of the dyke the vertical pressure of the water, but it has been neglected for the purpose of having the dyke sufficiently strong to resist an additional force.

61. We

(c) The dimensions of the dyke would be sufficiently strong to resist any additional force by neglecting the term $+ Z$, which represents the vertical pressure of the water tending to keep the dyke upon its base.
61. We shall now proceed to inquire into the form which the general equation assumes when the sides of the dyke are rectilinear. Let AC, BD, fig. 9, be two lines inclined to the horizon under given angles ACD, BDC, and let AB, CD be two horizontal lines. Retaining the construction and symbols in art. 57, let fall AQ, BZ perpendicular to CD, and make AQC = BZ = d, CQ = r, and DZ = r'. On account of the similar triangles HPM, FTH we shall have\( h = \frac{a}{2}\), instead of \( x \) in the general equation, art. 34. We have\( \int (\alpha - b + x) \, y \, a = \int b \, (\alpha - b) \, \frac{\alpha}{a} \), (making\( x \omega = \frac{b}{a} \)\( b^2 \omega = \frac{\alpha}{a} \)\( \frac{b^3}{a} \)\( \frac{\omega}{a} \))\( y = \omega = \frac{b^2}{a} \), now the moment of the dyke ABCD with respect to C, is equal to the whole area of the dyke ABCD collected in its centre of gravity, and placed at the end of a lever whose length is the horizontal distance of that centre of gravity from the fulcrum C. The area of ABQZ = QZ × ZB = \( \int \frac{dr}{2} \), the area of the triangle ACQ = \( \frac{dr}{2} \), and the area of the triangle BZD = \( \frac{dr}{2} \). Now the lever by which the area ABQZ, collected in its centre of gravity F, acts upon the fulcrum, is evidently \( d = \frac{d}{r} \), and therefore the terms in which \( \omega \) dyke is vertical.

63. When the angles ACQ and BDZ are both right, the dyke becomes rectangular, with its sides perpendicular to its base. In this case both \( r \) and \( r' \) become \( \omega \). In the case of a dyke \( = 0 \), the last term of the preceding equation in which \( r \) appears will vanish, consequently the equation will now become

\[
\text{Resulting equation when the posterior side of the dyke is vertical.}
\]

64. In order to show the application of the preceding formulae, and at the same time the advantages of inclining the sides of the dyke, let us suppose the depth of the water and also the height of the dyke to be 18 feet, so that B will coincide with H. Let us also suppose, what is generally the case in practice, that the declivity of the sides is \( \frac{a}{3} \) of their altitude, that is \( DZ = \frac{1}{3} BZ \). Let the specific gravity of the dyke be to that of water as 12 to 7; and suppose it is wished to make the stability of the dyke twice as great as the stability of equilibrium, that is, to make it capable of resisting a force twice as great as that which it really sustains. Then, upon these conditions, we shall have BZ = HT or \( \omega = \frac{1}{3} \); CQ = DZ = DT, or \( r = \frac{1}{3} r' \); \( s = 7 \); \( s = 12 \); \( a = 2 \). By substituting these numerical values in the general equation, No III. it becomes

\[
\omega = \frac{45}{36} \times \frac{4999}{39} \text{ feet;}
\]

\( \omega \) being a quadratic equation which after reduction will give \( \omega = 12 \) feet nearly. When \( s = 12 \), the area of the dyke ABCD will be 162 square feet. 65. Let us now suppose the sides of the dyke to be vertical, the equation No V. will give us \( s = 18 \) feet, 18 inches of 2 inches, which makes the area of the dyke more than the dyke 201 square feet. The area of the dyke with inclined sides
HYDRODYNAMICS.

PROP. II.

To find the dimensions of a dyke which can neither slide upon its base, nor turn round its posterior angle; but which is composed of horizontal sections which may be separated from each other.

In solving this proposition we must find the curvature of the side exposed to the pressure of the water, which will make all the different sections or horizontal laminae equally capable of resisting the different forces which tend to separate them. If the lamina NM does not resist the column PM, which partly presses it in the direction MN as powerfully as the lamina nm, the lamina NM is in danger of being separated from the lamina nm. But if the lamina NM, nm resist with equal force the horizontal effects of the water, and if the dyke cannot be made to slide upon its base nor turn round its posterior angle T; it cannot possibly yield to the pressure of the water; for it is impossible to separate one lamina from another, unless the one opposes a less resistance than the other. To simplify the investigation as much as possible, let us suppose the posterior side of the dyke to be vertical, and the depth of the water to be equal to the height of the dyke.

67. Let ABC be the section of the dyke, AK the surface of the water, AC the curvature required, AB its posterior side; MN nm a horizontal lamina infinitely small, in the direction of which the dyke has a tendency to break in consequence of the efforts of the water upon AM.

If the dyke should break in the direction MN, the superior part AMN will detach itself from the inferior part MBNC, by moving from M towards N; and at the moment when the impulse takes place it will have a small motion of rotation round the point N. We must therefore determine the forces which act upon the lamina MN nm, and form an equation expressing their equilibrium round the point N. The forces alluded to are evidently, 1. The horizontal efforts of the water; 2. The vertical efforts of the water; 3. The weight of the part AMN; and 4. The adhesion of the two surfaces MN, nm. Of these four forces the first is the only one which has a tendency to overthrow the portion AMN of the dyke; and its efforts are resisted by the three other forces. In order to find the momenta of these forces with regard to the point N let us suppose

\[ AP = NM = m \]
\[ PM = y \]
\[ \text{The specific gravity of water} \quad = s \]
\[ \text{The specific gravity of the dyke} \quad = r \]

Then we shall have,

1. The momentum of the horizontal forces of the water will be \( \frac{1}{2} sy^2 \), by the same reasoning that was employed in art. 57.

By taking the fluxion we have

\[ \frac{1}{2} sy^2 \frac{dy}{dx} = \frac{1}{2} s x \frac{dx}{dy} \times s \frac{dy}{dx}, \text{ which by reduction becomes} \]

\[ y = \sqrt{x} x \]

The line AMC therefore is rectilinear, and the base BC is to the altitude BC as \( \sqrt{s} : \sqrt{s} \); that is, as the square root of the specific gravity of the water is to the square root of the specific gravity of the dyke.

68. In order to simplify the calculus, and at the same time increase the stability of the dyke, we shall neglect the vertical force of the water, and the adhesion of the two surfaces MN, nm. The only force therefore which we have to consider, are the horizontal efforts of the water acting against the momentum of the superior part AMN. By making an adhesion between these forces we shall have the following equation

\[ \frac{1}{2} sy^2 = s y x y \times \frac{1}{2} s x y \frac{dy}{dx} = \frac{1}{2} s x \frac{dy}{dx} \]

By taking the fluxion we have

\[ \frac{1}{2} sy^2 \frac{dy}{dx} = \frac{1}{2} s x \frac{dx}{dy} \times s \frac{dy}{dx}, \text{ which by reduction becomes} \]

\[ y = \sqrt{x} x \]

Hence the base BC of the dyke is to its altitude BA as the specific gravity of water is to a multiple of the specific gravity of the dyke, \( s \) being a constant quantity which experiments alone can determine.

In a work by the Abbé Bosset and M. Viallet, entitled \textit{Recherches sur la Construction la plus adoucissante des Digue}, the reader will find a general solution of the preceding problem, in which the vertical efforts of the water and the adhesion of the surfaces are considered. This able work, which we have followed in the preceding investigation, contains much practical information on the construction of dykes of every kind; and may be considered as a continuation of the second part of Belidor's \textit{Architecture Hydraulique}.

CHAP.
HYDRODYNAMICS.

Let $mH$ be the section of a body immersed in a fluid. Any portion $m$ of its Gravities. upper surface is pressed downwards by the column of fluid $CmD$ (43); but the similar portion $EF$ of its lower surface is pressed upwards with a column of fluid a parallel to CEFD, therefore the part $EF$ is pressed downwards with the difference of these forces, that is, with a force equivalent to the column of fluid $mEHs$, for Fig. 2.

CEFD—$CmD=mEFn$. In the same way it may be shown, that the remaining part $EH$ is pressed upwards with a force equal to the weight of a column $nFH$; and therefore it follows, that the rectangle $mEHs$ is pressed upwards with a force equivalent to a column $mEHn$ that is, to the quantity of fluid displaced.

74. If the body floats in the fluid like CH in the vessel AB (fig. 3), the same consequence will follow; for the body CH is evidently pressed upwards with a force equal to the column $mEH$, that is, to the part immersed or the quantity of fluid displaced. Now as the same may be demonstrated of every other section of a solid parallelepiped, we may conclude, that the proportion is true with respect to every solid whose section is rectangular.

75. When the solid has any other form as CD, how-When the ever irregular, we may conceive its section to be divided into a number of very small rectangles $no$: then any other (41) the small portion of the solid at $o$ is pressed downwards by a column of particles $mno$, and the small portion at $o$ is pressed upwards by a column of particles equal to $no$; therefore the differences of these forces, viz, the column $n$, is the force with which the portion $o$ is pressed upward. In the same manner it can be shown, that every other similar portion of the lower surface of the solid CD is pressed upwards with a force equal to a column of particles whose height is equal to the vertical breadth of the solid; but all these columns of particles must occupy the same space as the solid itself, therefore any solid body immersed in a fluid, or floating on its surface, is pressed upwards with a force equal to the weight of the quantity of fluid displaced.

76. COR. 1. When a body floats in a fluid, the weight of the quantity of fluid displaced is equal to the weight of the floating solid. For since the solid is in equilibrium with the fluid, the force which causes it to descend must be equal to the force which presses it upwards; but the force which keeps a part of the solidity of fluid im-merged in the fluid is the weight of the solid, and the force which presses the solid upward, and prevents it from sinking, is equivalent to the weight of the quantity of fluid displaced (73); therefore these forces and the weights to which they are equivalent must be equal.

77. COR. 2. A solid weighed in a fluid loses as much of its weight as is equal to the weight of the quantity of fluid displaced; for since the body is pressed upwards with a force equal to the weight of the fluid displaced (3), this pressure acts in direct opposition to the natural gravity or absolute weight of the solid, and therefore diminishes its absolute weight by a quantity equal to the weight of the fluid displaced. The part of the weight thus lost is not destroyed: It is only sustained by a force acting in a contrary direction.

78. COR. 3. A solid immersed in a fluid will sink, if its specific gravity exceed that of the fluid: It will
HYDRODYNAMICS

Chap. I

79. Cor. 4. The specific gravities of two or more fluids are to one another as the losses of weight sustained by the same solid body, and specifically heavier than the fluid, when weighed in each fluid respectively. The solid in this case displaced equal quantities of each fluid; but the losses of weight are respectively as the absolute weights of the quantities displaced (Cor. 2), therefore the specific gravities, which are as the absolute weights of equal quantities of any body (70), must be as the losses of weight sustained by the immersed solid.

80. Cor. 5. The specific gravity of a solid is to that of a fluid as the absolute weight of the solid is to the loss of weight which it sustains when weighed in the fluid. For since the loss of weight sustained by the solid is equal to the absolute weight of the quantity of fluid displaced, or of a quantity of fluid of the same bulk as the solid, the specific gravities, which (70) are in the ratio of the absolute weights of equal volumes, must be as the absolute weight of the solid to the less weight which it sustains.

81. Cor. 6. The specific gravity of a solid floating in a fluid, is to the specific gravity of the fluid itself, as the bulk of the part immersed is to the total bulk of the solid.

82. Cor. 7. Bodies which sustain equal losses of weight are of the same bulk. For, since the losses of weight are as the weights of the quantities of fluid displaced, and as the quantities displaced are as the bulks of the solids which displace them, the bulks must be equal when the losses of weight are equal.

83. The preceding corollaries may be expressed algebraically, and may be deduced from a general equation in the following manner. Let B be the total bulk of a floating body, and C the part of it which is immersed; let S be the specific gravity of the solid, and s that of the fluid. Then it is obvious, that the absolute weight of the solid will be expressed by B × S, and the absolute weight of the fluid displaced by C × s; for the fluid displaced has the same bulk as the part of the solid which is immersed. In order that an equilibrium may obtain between the solid and fluid, we must have B × S = C × s. Now, when s < 1, we have B < C, so that the solid will float, which is the second case of Cor. 3. When s = 1 we have B = C, which is the third case of Cor. 3. When s > 1 we have C > B, that is, the body will sink below the surface; and it will descend to the bottom, for it cannot be suspended in the fluid without some power to support it; and if such a power were necessary, we should have B × S > C × s, which is contrary to the equation of equilibrium.

84. From the equation B × S = C × s we have (Euclid VI. 16.) S = B : C, which is Cor. 6. When the body is completely immersed we have B = C, in which case the equation becomes B × S = B × s, and when the solid is specifically heavier than the fluid, it will require a counterweight to keep the solid suspended in the fluid. Let W be the counterweight necessary for keeping the solid suspended in the fluid, then in the case of an equilibrium the equation will be B × s + W = B × S, or B × S = B × s + W, or B × S = W × B, or S × B = W × S, or B × W = S × B, or (Euclid VI. 16.) S : B = B : S, or B : W = S : B, which is Cor. 5.

85. If the same solid body is plunged in a second fluid of a different specific gravity from the first let e be the specific gravity of the second fluid, and w the counterweight necessary to keep the solid suspended in it. Then the equation for the fluid was B × s + W = B × S (84), and the equation for the second fluid will be B × e + W = B × S; therefore we shall have, by the first equation S × B = W × e × B, and by the second S × B = W × e × B, and consequently s × B = e × B, and consequently S × B = W × S × B = W × e, or (Euclid VI. 16.) e : s = S × B : W × S, for the losses of weight in each fluid are evidently represented by S × B : W × S.

86. If B and b express the bulks of two solids, B and b; and s their specific gravities, s the specific gravity of the fluid, and w the counterweights which keep them in equilibrium with the fluid, then with the solid S the equation will be B × s + W = S × B (84); and with the solid s the equation will be s × b + w = s × B. Therefore, if the two solids sustain equal losses of weight, we shall have S × B = s × b + w, since each side of the equation represents the loss of weight sustained by each solid respectively. Consequently, × B = s × b, and dividing by b, we have B = B, which is corollary 7.

87. From the preceding proposition and its corollaries, we may deduce a method of detecting adulteration in the precious metals, and of resolving the problem proposed to Archimedes, by Hiero king of Syracuse. Take a real golden and a counterfeit one made of copper and gold. If the latter be lighter than the former, when weighed in a pair of scales, the impostion is instantly detected; but if both their weights be the same, let the two coins be weighed in water, and let the loss of weight sustained by each be carefully observed, it will then be found that the counterfeit will lose more of its weight than the unadulterated coin. For, since the specific gravity of copper exceeds that of gold, and since the absolute weights of the coins were equal, the counterfeit gold must be greater in bulk than the real one, and will therefore displace a greater quantity of water, that is (77.), it will lose a greater part of its weight.

88. Hiero, king of Syracuse, having employed a famous goldsmith to make him a crown of gold, suspected that part of the metal had been adulterated, and inquired of Archimedes if his suspicions could be verified or disproved without injuring the crown. The particular method by which Archimedes detected the fraud of the goldsmith is not certainly known; but it is probable that he did it in the following manner. A quantity of gold, of the same absolute weight as the crown, would evidently have the same bulk also, if the crown were pure gold, and would have a greater bulk if the crown was made...
HYDRODYNAMICS.

89. If two immiscible fluids, of different specific gravities, and a solid of an intermediate specific gravity, be put into a vessel, the part of the solid in the lighter fluid will be to the whole solid, as the difference between the specific gravities of the solid and the heavier fluid, is to the difference between the specific gravities of the two fluids.

Let AB (fig. 5) be the vessel which contains the two fluids, suppose mercury and water, and the solid CD. The mercury being heavier than water will sink to the bottom and have m n for its surface, and the water will occupy the space AB m n. The solid having a greater specific gravity than water, will sink in the water (78), but having a less specific gravity than mercury, it will float in the mercury. It will, therefore, be suspended in the fluids, having one portion C in the water, and the other portion D in the mercury. Now let S be the specific gravity of the mercury, s the specific gravity of the water, σ that of the solid, C the part of the solid in the water, and D the part of the mercury. Then the bulk of the solid is C + D, and its weight $\sigma \times (C + D)$. The quantity of water displaced by the part C, or the loss of weight sustained by the part C, will be $C \times s$; and the quantity of mercury displaced, or the loss of weight sustained by part D, will be $D \times s$. But as the solid is suspended in the fluids, and therefore in equilibrium with them, the whole of its weight is lost. Consequently, the part of its weight which is lost in the water, added to the part lost in the mercury, must be equal to its whole weight, that is, $C \times s + D \times s = \sigma \times (C + D)$, or $C + SD = \sigma + \sigma \times (C + D)$. Transposing $C$ and $SD$, we have $\sigma \times C = SD \times \sigma$, or $C \times \sigma = D \times s - \sigma$, and (Euclid VI. 16.) $C : D = \sigma : s$. Then, by inversion and composition (Euclid V. Propositions B and 18.) $C : \sigma + D = D = \frac{s}{\sigma} : \frac{s}{\sigma}$. Q. E. D.

90. Cor. 1. From the analogy $C : D = \sigma : s$, we learn that the part of the solid in the heavier fluid, is to the part in the lighter fluid, as the difference between the specific gravities of the solid and the lighter fluid, is to the difference between the specific gravities of the solid and the heavier fluid.

91. Cor. 2. When $s$ is very small compared with $\sigma$, we may use the analogy $C + D = \sigma : s$, though in cases where great accuracy is necessary this ought not to be done. When the specific gravity of a body, lighter than water, is determined by comparing the part immersed with the whole body, there is evidently a small error in the result; for the body is suspended partly in water and partly in air. It is in fact a solid of an intermediate specific gravity floating in two immiscible fluids, and therefore its specific gravity should be ascertained by the present proposition.

Prop. IV.

92. If two bodies, whether solid or fluid, be mixed together so as to form a compound substance, the bulk of the heavier is to the bulk of the lighter ingredient, as the difference between the specific gravities of the compound, and the lighter ingredient, is to the difference between the specific gravities of the compound and the heavier ingredient.

Let $S$ and $s$ be the specific gravities of the two ingredients, $\sigma$ the specific gravity of the compound, and $b$ the bulk of the ingredients; then the bulk of the compound will be $S + b$, and its weight $\sigma \times (S + b)$. The weight of the ingredient $B$ will be $S \times S$, and that of the other ingredient $b \times s$; and as the weight of the compound must be equal to the weight of its ingredients, we have the following equation. $\sigma \times S + \sigma \times b = S \times S + b \times s$; therefore (Euclid VI. 16.) $\sigma : S = b \times s : S$. Q. E. D.

93. In the preceding proposition, it has been taken as granted that the magnitude of the compound is bound up, in some manner, with the magnitude of the two other solid ingredients. This, however, does not obtain universally. For example, combined with a cubic inch of water, will form a compound which will measure less than two cubic inches; and a cubic inch of tin, when incorporated in a fluid state with a cubical inch of lead, will form a compound, whose bulk will exceed two cubical inches. The preceding proposition, however, is, even in these cases, of great use in ascertaining the increase or decrease of bulk sustained by the compound, by comparing the computed with the observed bulk. See Specific Gravity.

Prop. V. Problem.

94. How to determine the specific gravities of bodies whether solid or fluid.

The simplest and most natural way of finding the specific gravities of bodies would be to take the absolute weights of a cubic inch, or any other determinate quantity, of each substance; and the number thus found would be their specific gravities. But as it is difficult to form two bodies of the very same size, and often impossible, as in the case of precious stones, to give a determinate form to the substance under examination, we are obliged to weigh them in a fluid, and deduce their specific gravities from the losses of weight which they severally sustain. Water is a fluid which is always employed for this purpose, not only because it can be had without difficulty, but because it can be procured at the same temperature, and of the same density, in every part of the world. The specific gravity of water is always called 1.000, and with this, as a standard, the specific gravity of every other substance is compared. Thus, if.

\[ a \text{ is the specific gravity of some other substance.} \]
HYDRODYNAMICS.

Part I.

A certain quantity of water weighed four pounds, and a similar quantity of mercury weighed 56 pounds. The specific gravity of the mercury would be called 14, because 14 : 56 :: 4 : 14. In order, therefore, to determine the specific gravities of bodies, we have occasion for no other instrument than a common balance with a hook fixed beneath one of its scales. When fitted up in this way, it has been called the hydrostatic balance, which has already been described under the article Balance, Hydrostatical.

95. When the substance is heavier than its bulk of water.—suspend the solid by means of a fine silver wire to the hook beneath the scale, and find its weight in air. Fill a jar with pure distilled water, of the temperature of 62° of Fahrenheit's thermometer, and find the weight of the solid when immersed in this fluid. The difference of these weights is the loss of weight sustained by the solid. Then, (80.) as the loss of weight is to the weight of the solid in air, so is 1,000 the specific gravity of water to a fourth proportional, which will be the specific gravity of the solid. But as the third term of the preceding analogy is always 1,000, the fourth proportional, or density of the solid, will always be had by dividing the weight of the solid in air by its loss of weight in water. If the solid substance consists of grains of platinum or metallic filings, place it in a small glass bucket. Find the weight of the bucket in air, when empty, and also its weight when it contains the substance. The difference of these weights will be the weight of the substance in air. Do the same in water, and its weight in water will be had. Its specific gravity will then be found as formerly.—If the body is soluble in water, or so porous as to absorb it, it should be covered with varnish or some opaque substance. When it is weighed in water, it should never touch the sides of the glass jar, and it must be carefully freed from any bubbles of air that happen to adhere to it.

96. When the substance is lighter than its bulk of water.—fasten to it another solid heavier than water, so that they may sink together. Find the weight of the denser body, and also of the compound body, both in air and in water; and by subtracting their weight in water from their weight in air, find how much weight they have severally lost. Then say as the difference between their losses of weight is to the weight of the light body in air, so is 1,000 to the specific gravity of the body.

To find the specific gravity of a solid lighter than water.

97. When the substance is a powder which absorbs water, or is soluble in it.—place a glass phial in one scale, and counterpoise it by weights in the other. Fill this phial with the powder to be examined; and having screwed it as close as possible to the very top, find the weight of the powder. Remove the powder from the phial, and fill it with distilled water, and find its weight. The weight of the powder, divided by the weight of the water, will be the specific gravity of the former.

To find the specific gravity of powders.

98. When the substance is a fluid, its specific gravity may be determined very accurately by the method in the preceding article, or by the following method deduced from article 79.—Take any solid specifically heavier than water, and the given fluid. Find the loss of weight which it sustains in water, and also in the given fluid. Then, since the specific gravities are as the losses of weight sustained by the same solid, the specific gravity of the fluid required will be found by dividing the loss of weight sustained by the solid in the given gravity fluid, by the loss of weight which it sustains in water.

Sect. II. On the Hydrometer.

99. In order to determine, with expedition, the strength of spirituous liquors, which are inversely proportional to their specific gravities, an instrument more simple, yet less accurate, than the hydrostatic balance, has been generally employed. This instrument is called a hydrometer, sometimes an arcometer and gravimeter, and very erroneously a hydrometer by some foreign authors. It seems to have been invented by Hypatia, the daughter of Theon Alexandrinus, who flourished about the end of the fourth century; though there is some foundation for the opinion that the invention is due to Archimedes.

100. The hydrometer of Fahrenheit, which is one of the simplest that has been constructed, is represented in the first figure. AB is a cylindrical stem, and C, D two hollow balls appended to it. Into the lower ball D is introduced a quantity of mercury, sufficient to make the ball C sink to E, a little below the surface of distilled water. If this apparatus be plunged into a fluid lighter than water, the ball C will sink farther below the surface; and if it be immersed in a heavier fluid, it will rise nearer the surface. In this way we can tell whether one fluid is more or less dense than another. But in order to determine the real specific gravities of the fluids, the hydrometer must either be loaded with different weights, or have a scale AB engraved on its stem. The former of these methods was employed by Fahrenheit. Having placed some small weights on the top A, he marked any point E, to which the instrument sunk in distilled water. By weighing the instrument thus loaded, he found the weight of a quantity of water equal to the part immersed (76.). When the hydrometer was placed in a fluid denser than water, he loaded it with additional weights till it sunk to the same point E. The hydrometer being again found, gave him with the weight of a quantity of the denser fluid equal to the part immersed; but as the part immersed was the same in both cases, the weights of the hydrometer were equal to the absolute weights of equal quantities of the two fluids; and consequently the specific gravities of the water and other fluid were in the ratio of these weights. When the fluid, whose density is required, has less specific gravity than water, some of the weights are to be removed from the top A till the instrument sinks to E; and the density of the fluid to be determined as before.—Instead of making the weight of the hydrometer variable, it is more simple, though less accurate, to have a scale of equal parts upon the stem AB. In order to graduate this scale, immerse the hydrometer in distilled water, at the temperature of 60° Fahrenheit, so that it may sink to B near the bottom of the stem, which may be easily effected, by diminishing or increasing the quantity of mercury in the ball D. At B place the number 1,000, which shows that every fluid, in which the hydrometer sinks to B, has its specific gravity 1,000, or that of distilled water. The hydrometer is then to be plunged in another fluid less dense than water, suppose oil, whose specific gravity
HYDRODYNAMICS.

Temperature produces a change in the specific gravity of solids, the spirits, Mr. Jones found it necessary to attach a thermometer to the instrument, and thus make a proper allowance for every variation of temperature. Almost all bodies expand with heat and contract with cold; and as their volume becomes different at different temperatures, their specific gravities must also be variable, and will diminish with an increase of temperature. M. Honberg, and M. Eisenmehm found that the absolute weight of a cubic inch of brandy was four drams 42 grains in winter, and only four drams 38 grains in summer, and that the difference in spirits of nitre was still greater. It has been found, indeed, upon an average, that 32 gallons of spirits in winter will expand to 33 gallons in summer. As the strength of spirituous liquors is inversely as their specific gravities, they will appear much stronger in summer than in winter. This change in their strength had been formerly estimated in a rough way; but by the application of the thermometer, and by adjusting its divisions experimentally, Mr. Jones has reduced it to pretty accurate computation. It has already been stated (93) that where two substances are composed of the same compound body and sometimes greater and sometimes less than the sum of the magnitudes of the two ingredients, and that this mutual penetration particularly happened in the mixture of alcohol and water. In strong spirits, this concentration is sometimes so great, as to produce a diminution of four gallons in the 100; for if to 100 gallons of spirit of wine found by the hydrometer to be 66 gallons in the 100 over proof, you add 66 gallons of water to reduce it to proof, the mixture will consist only of 162 gallons instead of 166 of proof spirits. This mutual penetration of the particles of alcohol and water has also been considered in Mr. Jones' hydrometer, which we shall now describe with greater minuteness.

104. In fig. 7, the whole instrument is represented with the thermometer attached to it. Its length AB is about 9½ inches: the ball C is made of hard brass, and nearly oval, having its conjugate diameter about 1½ inches. The stem AD is a parallelopiped, on the four sides of which the different strengths of spirits are engraved: the three sides which do not appear in fig. 7 are represented in fig. 8 with the three weights numbers 1, 2, 3, corresponding with the sides similarly marked at the top. If the instrument when placed in the spirits sinks to the divisions on the stem without a weight, their strength will be shown on the side AD marked o at the top, and any degree of strength from 74 gallons in the 100 to 47 in the 100 above proof, will thus be indicated. If the hydrometer does not sink to the divisions without a weight, it must be loaded with any of the weights 1, 2, 3, till the ball C is completely immersed. If the weight N° 1 is necessary, the side marked 1 will show the strength of the spirits, from 46 to 13 gallons in the 100 above proof. If the weight N° 2 is employed, the corresponding side will indicate the remainder of over proof, marked P in the instrument, and likewise every gallon in 100 under proof, down to 29. When the weight N° 3 is used, the side similarly marked will show any strength from 50 gallons in the 100 under proof, down to water; which is marked W in the scale. The small figures at 46, 37 at 61, 23 at 48 (fig. 7.) indicate the diminution of
HYDRODYNAMICS.

Of Specific of bulk which takes place when water is mixed with spirits of wine in order to reduce it to proof: thus, if the spirit be 61 gallons in the 100 over proof, and if 61 gallons of water are added in order to render it proof, the magnitude of the mixture will be 31 gallons less than the sum of the magnitudes of the ingredients, that is, instead of being 161 it will be only 157.5 gallons. The thermometer F connected with the hydrometer, has four columns engraved upon it, two on one side as seen in the figure, and two on the other side. When any of the scales upon the hydrometer, marked 0, 1, 2, 3, are employed, the column of the thermometer similarly marked must be used, and the number at which the mercury stands carefully observed. The divisions commence at the middle of each column which is marked 0, and is equivalent to a temperature of 60 degrees of Fahrenheit; then, whatever number of divisions the mercury stands above the zero of the scale, the same number of gallons in the 100 must the spirit be reckoned weaker than the hydrometer indicates, and whatever number of divisions the mercury stands below the zero, so many gallons in the 185 must the spirit be reckoned stronger.

105. The patent hydrometer invented by Mr. Dicas of Liverpool, possesses all the advantages of that which has now been described, but is superior to it in regard to the accuracy with which it estimates the aberration arising from a change of temperature. It is constructed in the common form, with 36 different weights, which are valued from 0 to 370, including the divisions on the stem; but the chief improvement consists in an ivory sliding rule which accompanies the instrument. In order to understand the construction of this sliding rule the reader must have recourse to the instrument itself.

Quin's universal hydrometer.

Plate CCLXV. fig. 9.

106. Quin's universal hydrometer is constructed in such a manner, as to ascertain, with the greatest expedition, the strength of any spirit from alcohol to water, and also the concentration and specific gravity of each different strength. With the assistance of four weights, it discovers likewise the gravity of worts, and is therefore of more universal use than any other hydrometer. The instrument is represented in fig. 9, with the four sides of its stem graduated and marked at the top so as to correspond with the weights below. The side of the stem marked A, B, C, D, &c. to Z, shows the strength of any spirit from alcohol to water, and the three other sides numbered 1, 2, 3, are adapted for worts. The variation of density arising from the contraction and dilatation of the fluid is determined by means of a sliding rule, differing very little from that of Mr. Dicas. In order to use this instrument, place any of the weights, if necessary, on the stem at C; find the temperature of the spirit by a thermometer, and bring the star on the sliding rule to the degree of heat on the thermometer's scale: then opposite to the number of the weight and the letter on the stem, you have the strength of the spirit pointed out on the sliding rule, which is lettered and numbered in the same way as the instrument and weights. In ascertaining the strength of worts, the weight No. 4 is always to continue on the hydrometer, and the weights, No. 1, 2, 3, are adapted to the sides No. 1, 2, 3, of the square stem, which point out the exact gravity of the worts.

107. A considerable improvement on the hydrometer has lately been made by Mr. Nicholson, who has rendered it capable of ascertaining the specific gravities both of solids and fluids. In fig. 10, F is a hollow ball of copper attached to the dish AA by a stem B, made of hardened steel. To the lower extremity of the ball is affixed a kind of iron stirrup FF, carrying another dish G of such a weight as to keep the stem vertical when the instrument is used. The parts of the hydrometer are so adjusted, that when the lower dish G is empty, and the upper dish AA contains 1000 grains, it will sink in distilled water at the temperature of 60° of Fahrenheit, so that the surface of the fluid may cut the stem DB at the point D. In order to measure the specific gravities of fluids, let the weight of the instrument, when loaded, be accurately ascertained. Then, this weight is equal to that of a quantity of distilled water at the temperature of 60°, having the same volume as that part of the instrument which is below the point D of the stem. If the hydrometer, therefore, is immersed to the point D in any other fluid of the same temperature, which may be done by increasing or diminishing the weights in the dish AA, the difference between this last weight and 1000 grains will express the difference between equal bulks of water and the other fluid. Now as the weight of the mass of water is equal to the weight of the instrument, which may be called W, the above-mentioned difference or D must be either added to or subtracted from W, (according as the weight in the dish AA was increased or diminished) in order to have the weight of an equal bulk of the fluid; then W±D will be W as the specific gravity of the given fluid is to that of water. This ratio will be expressed with considerable accuracy, as the cylindrical stem of the instrument being no more than ⅛th of an inch in diameter, will be elevated or depressed nearly an inch by the subtraction or addition of 75 of a grain, and will, therefore, easily point out any changes of weight, not less than 75 of a grain, or 360000 of the whole, which will give the specific gravities to five places of figures. The solid bodies whose specific gravities are to be determined by this hydrometer, must not exceed 1000 grains in weight. For this purpose, immerse the instrument in distilled water, and load the upper dish till the surface of the water is on a level with the point D of the stem. Then, if the weight required to produce this equilibrium be exactly 1000 grains, the temperature of the water will be 60° of Fahrenheit; but if they be greater or less than 1000 grains, the water will be colder or warmer. After noting down the weight necessary for producing an equilibrium, unload the upper dish, and place on it the body whose specific gravity is required. Increase the weight in the upper dish, till the instrument sinks to the point D, and the difference between this new weight and the weight formerly noted down will be the weight of the body in air. Place the body in the lower dish G, and add weights in the upper dish till the hydrometer again sinks to D. This weight will be the difference between 1000 grains and the weight of the body in water; and since the weight of the body in air, and its weight in water, are ascertained, its loss of weight will be known, and consequently its specific gravity (80.).

108. The areometer or hydrometer of M. de Parcieux consists of a small glass phial EG, about two inches in diameter...

Fluids do not rise to the same level in a system of communicating vessels when their diameters are very minute.

### CHAP. III. On Capillary Attraction, and the Cohesion of Fluids.

We have already seen, when discussing the equilibrium of fluids, that when water or any other fluid is poured into a vessel, of any number of communicating vessels, its surface will be horizontal, or it will rise to the same height in each vessel, whatever be its form or position. This proposition, however, only holds true when the diameter of these vessels or tubes exceeds the fifteenth of an inch; for if a system of communicating vessels be composed of tubes of various diameters, the fluid will rise to a level surface in all the tubes which exceed one-fifteenth of an inch in diameter; but in the tubes of a smaller bore, it will rise above that level to heights inversely proportional to the diameters of the tubes. The power by which the fluid is raised above its natural level is called capillary attraction, and the glass tubes which are employed to exhibit its phenomena are named capillary tubes. These appellations derive their origin from the Latin word capillus, signifying a hair, either
either because the bores of these tubes have the fineness of a hair, or because that substance is itself supposed to be of a tubular structure.

112. When we bring a piece of clean glass in contact with water or any other fluid, except mercury and fused metals, and withdraw it gently from its surface, a portion of the fluid will not only adhere to the glass, but a small force is necessary to detach this glass from the fluid mass, which seems to resist any separation of its parts. Hence it is obvious that there is an attraction of cohesion between glass and water, and that the constituent particles of water have also an attraction for each other. The suspension of a drop of water from the lower side of a plate of glass is a more palpable illustration of the first of these truths; and the following experiment will completely verify the second. Place two large drops of water on a smooth metallic surface, their distance being about the tenth of an inch. With the point of a pin unite these drops by two parallel canals, and the drops will instantly rush to each other through these canals, and fill the dry space that intervenes. This experiment is exhibited in fig. 2, where AB is the metallic plate, C, D the drops of water, and m, n the two canals.

113. Upon these principles many attempts have been made to account for the elevation of water in capillary tubes; but all the explanations which have hitherto been offered, are founded upon hypothesis, and are very far from being satisfactory. Without presuming to substitute a better explanation in the room of those which have been already given, and so frequently repeated, we shall endeavour to illustrate that explanation of a phenomenon of capillary attraction which seems liable to the fewest objections. For this purpose let E be a droop of water laid upon a clean glass surface AB. Every particle of the glass immediately below the drop E, exerts an attractive force upon the particles of water. This force will produce the same effect upon the drop as a pressure in the opposite direction, the pressure of a column of air, for instance, on the upper surface of the drop. The effect of the attractive force, therefore, tending to press the drop to the glass will be an enlargement of its size, and the water will occupy the space FG; this increase of its dimensions will take place when the surface AB is held downwards; and that it does not arise from atmospheric pressure may be shown by performing the experiment in vacuo. Now let AB (fig. 2.) be a section of the plate of glass AB (fig. 3.) held vertically, part of the water will descend by its gravity, and form a droop B, while a small film of the fluid will be supported at m by the attraction of the glass. Bring a similar plate of glass CD into a position parallel to AB, and make them approach nearer and nearer each other. When the drops B and D come into contact, they will rush together from their mutual attraction, and will fill the space OP. The gravity of the drops B and D being thus diminished, the film of water at m and n which was prevented from rising by their gravity will move upwards. As the plates of glass continue to approximate, the space between them will fill with water, and the films at m and n being no longer prevented from yielding to the action of the glass immediately below them (by the gravity of the water at OP), which is diminished by the mutual action of the fluid particles) will rise higher in proportion to the approach of the plate. Hence it may be easily understood how the water rises in capillary tubes, and how its altitude is inversely as their internal diameters. For the altitude A, a = the altitudes of the fluid in two tubes of tubes of different diameters D, d; and let C, c be the two cylin- 

114. Having thus attempted to explain the causes of capillary attraction, we shall now proceed to consider some of its most interesting phenomena. In fig. 4, MN is a vessel of water in which tubes of various forms are immersed. The water will rise in the tubes A, B, C to different altitudes m, n, o, inversely proportional to their diameters. If the tube B is broken at a, the water will not rise to the very top of it at a, but will stand at b, a little below the top, whatever be the length of the tube or the diameter of its bore. If the tube be taken from the fluid and laid in a horizontal position, the water will recede from the end that was immersed. These Jurin's hypothesis seems to counterpoise the opinion of Dr. Jurin and other philosophers, that the water is elevated in the tube by the attraction of the annulus, or ring of water, immediately above the cylinder of water. This hypothesis is sufficiently plausible; but supposing it to be true, the ring of glass immediately below the surface of the cylinder of fluid should produce an equal and opposite effect, and therefore the water instead of rising should be stationary, being influenced by two forces of an equal and opposite kind.

115. If a tube D composed of two cylindrical tubes of different bores be immersed in water with the widest part downwards, the water will rise to the altitude p, and if another tube E of the same size and form be plunged in the fluid with the smaller end downwards, the water will rise to the same height q as it did in the tube D. This experiment seems to be a complete re-

116. When a vessel of water is plunged in water, and the lower part of it filled by suction until the fluid enters the part F, the water will rise to the same height as it does in the capillary tube C, whose bore is equal to the bore of the part F. In this experiment the portions of water tux and uwx on each side of the column Fw are supported by the pressure of the atmosphere on the surface of the water in the vessel MM; for if this vessel be placed in the exhausted receiver of an air-pump, these portions of water will not be sustained. Dr. Jurin, indeed, maintains that these portions will retain their position in vacuo, but in his time the exhausting power of the air-pump was not sufficiently great to determine a point of so great nicety. The column tux, which is not sustained by atmospheric pressure, is kept in its position by the attraction of the water immediately around and above it, and the column Fw is supported by the attraction of the glass surface with which it is in contact. According to Dr. Jurin's hypothesis, the column tux is supported by the ring of glass immediately above r, which is a very unlikely supposition.

117. The preceding experiment completely overturns the hypothesis of Dr. Hamilton and Dr. Matthew Young. These philosophers maintained that the fluid was sustained in the tube by the lower ring of glass contiguous to the bottom of the tube, that this ring raises the portion of water immediately below it, and then other portions successively till the portion of water thus raised be in equilibrium with the attraction of the annulus in question. But if the elevation of the fluid were produced in this way, the quantity supported would be regulated by the form and magnitude of the orifice at the bottom of the tube; whereas it is evident from every experiment, that the cylinder of fluid sustained in capillary tubes has no reference whatever to the form of the lower annulus, but depends solely upon the diameter of the tube immediately above the elevated column of water.

118. If the experiments which we have now explained be performed in the exhausted receiver of an air-pump, the water will rise to the same height as when they are performed in air. We may therefore conclude, that the amount of the water is not occasioned, as some have imagined, by the pressure of the atmosphere acting more freely upon the surface of the water in the vessel than upon the column of fluid in the capillary tube.

119. It appears from the following table constructed by Mr. B. Martin, that different fluids rise to very different heights in capillary tubes, and that spirituous liquors, whose specific gravity is less than that of water, are not raised to the same altitude. Mr. Martin's experiments were made with a tube about 1/10 of an inch in diameter. He found that when capillary tubes charged with different fluids were suspended in the sun for months together, the enclosed fluid was not in the least degree diminished by evaporation.

120. To the preceding table as given by Mr. Martin we have added the constant number for each fluid, or the product of the altitude of the liquid, and the diameter of the tube (art. 115.). By this number, therefore, we can find the altitude to which any of the preceding fluids will rise in a tube of a given bore, or the diameter of the bore when the altitude of the fluid is known; for since the constant number $C = \frac{DA}{L}$ (art. 113.), we shall have $D = \frac{C}{L} \times x$, and $A = \frac{C}{D}$. Since the constant number, however, as deduced from the experiments of Martin, may not be perfectly correct, it would be improper to derive from it the diameter of the capillary bore when great accuracy is necessary. The following method, therefore, may be adopted as the most correct that can be given. Put into the capillary tube a quantity of mercury, whose weight in troy grains is $W$, and let the length $L$ of the tube which it occupies be accurately ascertained; then if the mercury be pure and at the temperature of 60° of Fahrenheit, the diameter of the capillary tube $D = \sqrt{\frac{W}{L \times 0.019241}}$, the specific gravity of mercury being 13.580. The weight of a cubic inch of mercury being 3438 grains, and the solid content of the mercurial column being $D^2 L \times 0.784$: we shall have $1 : 3438 = \frac{D^2 L \times 0.784}{W}$. Hence (Geometry, Sect. IV. Theor. VIII.) $D^2 L \times 0.784 \times \frac{1}{W}$ $= 3438$, and dividing we have $D^2 = \frac{W}{L \times 0.784 \times 3438} \times 0.019241$. If the whole tube be filled with mercury, and if $W$ be the difference in troy grains between its weight when empty,
Capillary Attraction.

Should the temperature of the mercury happen to be 32° of Fahrenheit, its specific gravity will be 13.619, which will alter a very little the constant multiplier 0.01924.

The motion of water in capillary tubes accelerated by electricity and by heat.

When water is made to pass through a capillary tube of such a bore that the fluid is discharged only by successive drops; the tube, when electrified, will furnish a constant and accelerated stream, and the acceleration is proportional to the smallness of the bore. A similar effect may be produced by employing warm water. Mr. Leslie found that a jet of warm water rose to a much greater height than a jet of cold water, though the water in both cases moved through the same aperture, and was influenced by the same pressure. A syphon also which discharged cold water only by drops, yielded warm water in an invariable stream.

The ascent of fluids between two inclined plates of glass.

On the ascent of fluids between two inclined plates of glass.

Plate CCF.XVI. Fig. 5.

The common hyperbola. As the plates are infinitely near, each other at the apex E, the water will evidently rise to that point, whatever be the height of the plates.

123. The phenomena which we have been endeavoring to explain, are all referable to one simple fact, that the particles of glass have a stronger attraction for the particles of water than the particles of water have for each other. This is the case with almost all other fluids except mercury, the particles of which have a stronger descent in a vessel full of mercury. Fig. 7. Plunge into the fluid the capillary tube CD, and the mercury, instead of rising in the tube, will remain stationary at E, its depression below the level surface AB being inversely proportional to the diameter of the bore. This was formerly ascribed to a repulsive force supposed to exist between mercury and glass, but we shall presently see that it is owing to a very different cause.

124. That the particles of mercury have a very strong attraction for each other, appears from the globular form of mercury in a vessel full of water, the fluid will rise in such a manner between the glass plates as to form the curve D q o m E, which represents the surface of the elevated water. By measuring the ordinates m, n, o, p, &c. of this curve, and also its abscissae F, m, F, p, &c. Mr. Hawkins found it to be the common Apollonian hyperbola, having for its asymptotes the surface DF of the fluid, and EF the common intersection of the two planes. To the very same conclusion we are led by the principles already laid down; for as the distance between the plates diminishes at every point of the curve D q o m E from D towards E, the water ought to rise higher at o than at q, still higher at m than at n, and highest of all at E, where the distance between the plates is a minimum. To illustrate this more clearly, let ABEF and CDEF be the same plates of glass, (inclined at a greater angle for the sake of distinctness) and let E m n D, and E o s B be the curves which bound the surface of the elevated fluid. Then, since the altitudes of the water in capillary tubes are inversely as their diameters or the distances of their opposite sides, the altitudes of the water between two glass plates, should at any given point be inversely as the distances of the plates at that point. Now, the distance of the plates at the point m is obviously m o, or its equal n p, and the distance at q is q r or r s; and since m n is the altitude of the water at m, and q r its altitude at q, we have m n :: q r :: n p :: r s; but (Geometry, Sect. IV. Theor. XVII.) F n :: F r :: n p :: r s; therefore m n : q r = F n : F r, that is, the altitudes of the fluid at the points m, q, which are equal to the abscissae F n, F r (fig. 5.) are proportional to the ordinates q r, m n, equal to F n, F r, in fig. 5. But in the Apollonian hyperbola the ordinates are inversely proportional to their respective abscissae, therefore the curve D q o m E is the
HYDRODYNAMICS.

will sink between the plates, and its descent will continue as the pieces of glass approach. Hence the depression of the mercury in capillary tubes becomes very intelligible. If two glass planes form a small angle, as in fig. 5, be immersed in a vessel of mercury, the fluid will sink below the surface of the mercury in the vessel, and form an Apollonian hyperbola like $\triangle D O E$, having for its asymptotes the common intersection of the planes and the surface of mercury in the vessel.

The depression of mercury in capillary tubes is evidently owing to the greater attraction that subsists between the particles of mercury, than between the particles of mercury and those of glass. The difference between these two attractions, however, arises from an imperfect contact between the mercury and the capillary tube, occasioned by the interposition of a thin coating of water which generally lines the interior surface of the tube, and weakens the mutual action of the glass and mercury; for this action always increases as the thickness of the interposed film is diminished by boiling.

In the experiments which were made by Laplace and Lavoisier on barometers, by boiling the mercury in them for a long time, the convexity of the interior surface of the mercury was often made to disappear. They even succeeded in rendering it concave, but could always restore the convexity by introducing a drop of water into the tube. When the ebullition of the mercury is sufficiently strong to expel all foreign particles, it often rises to the level of the surrounding fluid, and the depression is even converted into an elevation.

Newton, Clairaut, and other geometers, have maintained, that the action of the capillary tube is sensible at a small distance, and that it is extended to the particles of fluid in the axis of the tube. Laplace and other philosophers who have lately attended to this subject, suppose capillary attraction to be like the refractive force, and all the chemical affinities, which are not sensible except at imperceptible distances; and it must be allowed that this opinion is consistent with many of the phenomena. It has been often observed that water rises to the same height in glass tubes, of the same bore, whether they be very thin or very thick. The zones of the glass tube therefore, which are at a small distance from the interior surface, do not contribute to the ascent of the water, though in each of these zones, taken separately, the water would rise above its level. When the interior surface of a capillary tube is lined with a very thin coating of an unctuous substance, the water will no longer ascend. Now if the attraction of the glass tube were similar to the attraction of gravity, of electricity, or magnetism, it ought to act through bodies of all kinds, and, notwithstanding the thin coating of grease, should elevate the fluid in which it is immersed. But as the intervention of an attenuated film of grease destroys capillary action, there is reason to conclude, that it does not extend to sensible distances. The same conclusion is deductible from the fact in the preceding paragraph.

Opinion of Laplace.

127. From these facts Laplace concludes, that the attraction of capillary tubes has not any influence on the elevation or depression of the fluids which they contain, except by determining the inclination of the first planes of the surface of the interior fluid, which are extremely near the sides of the tube. He supposes that when the attraction of the tube upon the fluid exceeds the attraction of the fluid upon itself, the fluid will in that case attach itself to the tube, and form an anterior tube, which alone will raise the fluid.

128. It is interesting, says Laplace, to ascertain the radius of curvature of the surface of water included in capillary tubes of glass. This may be known by a curious experiment, which shows at the same time the effects of the concavity and convexity of surfaces. It consists in plunging in water, to a known depth, a capillary tube of which the diameter is likewise known. The lower extremity of the tube is then to be closed with the finger, and the tube being taken out of the water, its external surface must be gently wiped. Upon withdrawing the finger in this last situation, the water is seen to subside in the tube and form a drop at its lower base; but the height of the column is always greater than the elevation of the water in the tube above the level in the common experiment of plunging it in water. This excess in the height is owing to the action of the drop upon the column on account of its convexity; and it is observable that the increase in the elevation of the water is more considerable, the smaller the diameter of the drop beneath. The length of the fluid column which came out by subscindence to form the drop, determines its mass; and as its surface is spherical as well as that of the interior fluid, if we know the height of the fluid above the summit of the drop, and the distance of this summit from the plane of the interior base of the tube, it will be easy to deduce the radius of these two surfaces. Some experiments lead me to conclude that the surface of the interior fluid approaches very nearly to the figure of an hemisphere.

129. 'The theory which I have adopted, observes the same philosopher, likewise gives the explanation and has a measure of a singular phenomenon presented by experiment. Whether the fluid be elevated or depressed between two vertical planes, parallel to each other, and plunged in the fluid at their lower extremities, the planes tend to come together. Analysis shows us, that if the plane fluid be raised between them, each plane will undergo from without inwards a pressure equal to that of a column of the same fluid, of which the height would be half the sum of the elevations above the level of the points of contact of the interior and exterior surfaces of the fluids with the plane, and of which the base should be the parts of the plane comprised between the two horizontal lines drawn through those points. If the fluid be depressed between the planes, each of them will in like manner undergo from without inwards, a pressure equal to that of a column of the same fluid, of which the height would be half the sum of the depressions below the level of the points of contact of the interior and exterior surfaces of the fluid with the plane, and of which the base should be the part of the plane comprised between the two horizontal lines drawn through those points.'

130. As most philosophers seem to agree in thinking that all the capillary phenomena are referable to the cohesive attraction of the superficial particles of the fluid, a variety of experiments has been made in order to determine the force required to raise a horizontal solid surface from the surface of a fluid. Mr. Archard found that a disc of glass, 15 French inches in diameter, required a weight of 91 French grains to raise it
HYDRODYNAMICS.

Chap. III.

Capillary Attraction, &c.

it from the surface of the water at 62° of Fahrenheit, which is only 37 English grains for each square inch. At 44° of Fahrenheit the force was \( \frac{1}{2} \) greater, or 39.7 grains, the difference being \( \frac{2}{7} \) for each degree of Fahrenheit. From these experiments Dr Young concludes that the height of ascent in a tube of a given bore, which varies in the duplicate ratio of the height of adhesion, is diminished about \( \frac{2}{7} \) for every degree of Fahrenheit that the temperature is raised above 50°; and he conjectures that there must have been some considerable source of error in Achard's experiments, as he never found this diminution to exceed \( \frac{2}{7} \). According to the experiments of Dutour, the force necessary to elevate the solid, or the quantity of water raised, is equal to 44.1 grains for every square inch.

331. According to the experiments of Morveau, the force necessary to elevate a circular inch of gold from the surface of mercury is 446 grains; a circular inch of silver, 429 grains; a circular inch of tin, 418 grains; a circular inch of lead, 397 grains; a circular inch of bismuth, 317 grains; a circular inch of zinc, 204 grains; a circular inch of copper, 142 grains; a circular inch of metallic antimony, 126; a circular inch of iron, 115 grains; and a similar surface of cobalt required 8 grains. The order in which these metals are arranged is the very order in which they are most easily amalgamated with mercury.

332. The approach of two floating bodies has been ascribed by some to their mutual attraction, and by others to the attraction of the portions of fluid that are raised round each by the attraction of cohesion. Dr Young, however, observes that the approach of the two floating bodies is produced by the excess of the atmospheric pressure on the remote sides of the solids, above its pressure on their neighbouring sides; or, if the experiments are performed in a vacuum, by the equivalent hydrostatic pressure or suction derived from the weight and immediate cohesion of the intervening fluid. This force varies alternately in the inverse ratio of the square of the distance; for when the two bodies approach each other, the altitude of the fluid between them is increased in the simple inverse ratio of the distance; and the mean action, or the negative pressure of the fluid on each particle of the surface, is also increased in the same ratio. When the floating bodies are surrounded by a depression, the same law prevails, and its demonstration is still more simple and obvious.

333. A number of experiments on the adhesion of fluids have been lately made by Count Rumford, which authorise him to conclude, that on account of the mutual adhesion of the particles of fluid, a pellicle or film is formed at the superior and inferior surfaces of water, and that the force of the film to resist the descent of bodies specifically heavier than the fluid increases with the viscosity of the water. He poured a stratum of sulphuric ether upon a quantity of water, and introduced a variety of bodies specifically heavier than water into this compound fluid. A sewing needle, granulated tin, and small globules of mercury, descended through the ether, but floated upon the surface of the water. When the eye was placed below the level of the aqueous surface, the floating body, which was a sphereule of mercury, seemed suspended in a kind of bag a little below the surface. When a larger sphereule of mercury was employed, about the 40th or 50th of an inch in diameter, it broke the pellicle and descended to the bottom. The same results were obtained by using essential oil of turpentine or oil of olives instead of ether. When a stratum of alcohol was incumbent upon the water, a quantity of very fine powder of tin thrown upon its surface, descended to the very bottom, without seeming to have met with any resistance from the film at the surface of the water. This unexpected result Count Rumford endeavours to explain by supposing that the aqueous film was destroyed by the chemical action of the alcohol. In order to ascertain with greater accuracy the existence of a pellicle at the surface of the water, Count Rumford employed a cylindrical glass vessel 10 inches high and 15 inches in diameter, and filled it with water and ether as before. A number of small bodies thrown into the vessel descended through the ether and floated on the surface of the water. When the whole was perfectly tranquil, he turned the cylinder three or four times round with considerable rapidity in a vertical position. The floating bodies turned round along with the glass, and stopped when it was stopped; but the liquid water below the surface did not at first begin to turn along with the glass; and its motion of rotation did not cease with the motion of the vessel. From this Count Rumford concludes that there was a real pellicle at the surface of the water, and that this pellicle was strongly attached to the sides of the glass, so as to move along with it. When this pellicle was touched by the point of a needle, all the small bodies upon its surface trembled at the same time. The apparatus was allowed to stand till the ether had entirely evaporated, and when the pellicle was examined with a magnifier, it was in the same state as formerly; and the floating bodies had the same relative positions.

334. In order to shew that a pellicle was formed at the inferior surface of water, Count Rumford poured water upon mercury, and upon that a stratum of ether. He threw into a vessel a sphereule of mercury about one-third of a line in diameter, which being too heavy to be supported by the pellicle at the superior surface of the water, broke it, and descending through that fluid, was stopped at its inferior surface. When this sphereule was moved, and even compressed with a feather, it still preserved its spherical form, and refused to mix with the mass of mercury. When the viscosity of the water was increased by the infusion of gum-arabic, much larger sphereules were supported by the pellicle. From the very rapid evaporation of ether, and its inability to support the lightest particles of a solid upon its surface, Count Rumford very justly concludes, that the mutual adhesion of its particles is very small.

335. Those who wish to extend their inquiries concerning the cohesion of fluids, may consult an ingenious work on Capillary Action by Professor Leslie, in the Specula Phil. Mag. for 1802; Dr Thomas Young's Essay on the Cohesion of Fluids, in the Phil. Trans. 1805; an Abstract of a Memoir of Laplace, in Nicholson's Journal, No. 57; and an Account of Rumford's Experiments in the same Journal, No. 60, 61, and 62.

PART II. HYDRAULICS.

136. HYDRAULICS is that branch of the science of hydrodynamics which relates to fluids in motion. It comprehends the theory of running water, whether issuing from orifices in reservoirs by the pressure of the superincumbent mass, or rising perpendicularly in jets d’eaux from the pressure of the atmosphere; whether moving in pipes and canals, or rolling in the beds of rivers. It comprehends also the resistance or the percussion of fluids, and the oscillation of waves.

CHAP. I. Theory of Fluids issuing from Orifices in Reservoirs, either in a Lateral or a Vertical direction.

137. If water issues from an orifice either in the bottom or side of a reservoir, the surface of the fluid in the reservoir is always horizontal till it reaches within a little of the bottom. When a vessel therefore is emptying itself, the particles of the fluid descend in vertical lines, as is represented in fig. 1; but when they have reached within three or four inches of the orifice mn, the particles which are not immediately above it change the direction of their motion, and make for the orifice in directions of different degrees of obliquity. The velocities of these particles may be decomposed into two others, one in a horizontal direction, by which they move parallel to the orifice, and the other in a vertical direction by which they approach that orifice. Now, as the particles about C and D move with greater obliquity than those nearer E, their horizontal velocities must also be greater, and their vertical velocities less. But the particles near E move with so little obliquity that their vertical are much greater than their horizontal velocities, and very little less than their absolute ones. The different particles of the fluid, therefore, will rush through the orifice mn with very different velocities, and in various directions, and will arrive at a certain distance from the orifice in different times. On account of the mutual adhesion of the fluid particles, however, those which have the greatest velocity will be the first to go through the orifice, and the former move through the centre of the orifice, the breadth of the issuing column of fluid will be less at or p than the width of the orifice mn.

138. That the preceding phenomena really exist when a vessel of water is discharging its contents through an aperture, experience sufficiently testifies. If some small substances specifically heavier than water be thrown into the fluid when the vessel is emptying itself, they will at first descend vertically, and when they come within a few inches of the bottom they will deviate from this direction, and describe oblique curves similar to those in the figure. The contraction of the vein or column of fluid at or p is also manifest from observation. It was first discovered by Sir Isaac Newton, and denominated the venae contractae. The greatest contraction takes place at a point whose distance from the orifice is equal to half its diameter, so that

\[ \frac{mn}{2} \]

and the breadth of the vein or column of fluid at or is to the width of the orifice as 5 to 8 according to Bosent, or as 5.197 to 8 according to the experiments of Mecchiotti, the orifice being perforated in a thin plate. But when the water is made to issue through a short cylindrical tube, the same contraction, though not obvious to the eye, is so considerable, that the diameter of the contracted vein is to that of the orifice as 6.5 to 8. If A therefore be the real size of the orifice in a thin plate, its corrected size, or the breadth of the contracted vein, will be

\[ \frac{5.197 \times A}{8} \]

and when a cylindrical tube is employed it will be

\[ \frac{13 \times A}{16} \]

In the first case the height of the water in the reservoir must be reckoned from the surface of the fluid to the point where the vein ceases to contract; and when a cylindrical tube is employed, it must be reckoned from the same surface to the exterior aperture of the tube.

139. Suppose the fluid ABCD divided into an infinite number of equal strata or laminae by the horizontal surfaces MN, gh infinitely near each other; let the orifice mnop be a small column of fluid which issues from the orifice in the same time that the surface MN descends to gh. The column mnop is evidently equal to the lamina MN gh, for the quantity of fluid which is discharged during the time that MN descends to gh is evidently MN gh; and to the quantity discharged in that time, the column mnop was equal by hypothesis. Let A be the area of the base MN, and B the area of the base mn; let x be the height of a column equal to MN gh, and having A for its base, and let y be the height of the column mnop. Then, since the column mnop is equal to the lamina MN gh, we shall have

\[ A = \frac{B}{x} \]

and (Geometry, Sect. IV, Theor. IX) that

\[ x = \frac{A}{B} \]

but as the surface MN descends to gh in the same time that mn descends to op, x will represent the mean velocity of the lamina MN gh, and y the mean velocity of the column mnop. The preceding analogy, therefore, informs us, that the mean velocity of any lamina is to the velocity of the fluid issuing from the orifice reciprocally as the area of the orifice is to the area of the base of the lamina. Hence it follows, that, if the area of the orifice is infinitely small, with regard to the area of the base of the lamina into which the fluid is supposed to be divided, the mean velocity of the fluid at the orifice will be infinitely greater than that of the lamina; that is, while the velocity at the orifice is finite, that of the lamina will be infinitely small.

140. Before applying these principles to the theory of hydraulics, it may be proper to observe, that several distinguished philosophers have founded the science upon the same general law from which we have deduced the principles of hydrostatics (32). In this way they have represented the motion of fluids in general formulas; but these formulas are so complicated from the
Chapter II. HYDRODYNAMICS.

The nature of the theory, and the calculations are so intricate, and sometimes impracticable from their length, that they can afford no assistance to the practical engineer.

DEFINITION.

141. If the water issues at \( m n \) with the same velocity \( V \) that a heavy body would acquire by falling freely through a given height \( H \), this velocity is said to be due to the height \( H \), and inversely the height \( H \) is said to be due to the velocity \( V \).

PROP. I.

142. The velocity of a fluid issuing from an infinitely small orifice in the bottom or side of a vessel, is equal to that which is due to the height of the surface of the fluid above that orifice, the vessel being supposed constantly full.

Let \( AB \) be the vessel containing the fluid, its velocity when issuing from the aperture \( m n \) will be that which is due to the height \( Dm \), or equal to that which a heavy body would acquire by falling through that height. Because the orifice \( m n \) is infinitely small, the velocity of the laminae into which the fluid may be supposed to be divided, will also be infinitely small (art. 138). But since all the fluid particles, by virtue of their gravity, have a tendency to descend with the same velocity; and since the different laminae of the fluid lose this velocity, the column \( mnst \) must be pressed by the superincumbent column \( Dm \); and calling \( S \) the specific gravity of the fluid, the moving force which pushes out the column \( mnst \) will be \( S \times Dm \times mn \) (art. 42).

Now let us suppose, that, when this moving force is pushing out the column \( mnst \), the absolute weight of the column \( mnp \), which may be represented by \( S \times mn \times np \), causes itself to fall through the height \( np \). Thus, if \( V \), \( U \) be the velocities impressed upon the columns \( mnst \) and \( mnp \), by the moving forces \( S \times Dm \times mn \) and \( S \times mn \times np \); these moving forces must be proportional to their effects, or to the quantities of motion which they produce, that is, to \( V \times mnst \) and \( U \times mnp \).

But since the volumes \( mnst \) and \( mnp \) are to one another as their heights \( m, n, o \), and as their heights are run through in equal times, and consequently represent the velocity of their motion, \( mnst \) may be represented by \( V \times mn \) and \( mnp \) by \( U \times mn \); therefore we shall have \( S \times Dm \times mn \times np = V \times mn \times np = U \times mn \times np \), and dividing by \( mn \), \( S \times Dm = np \times V = np \times U \), and by permutation \( Dm = np \times V = np \times U \), by substitution \( (\text{Euclid V. 15}) \) \( Dm = V \times np = np \), therefore by 

143. Cor. 1. If the vessel \( AB \) empties itself by the small orifice \( m n \), so that the surface of the fluid takes successively the positions \( DP, QR, ST \), the velocities with which the water will issue when the surfaces have these positions will be those due to the heights \( E_n, F_n, G_n \).

144. Cor. 2. Since the velocities of the issuing fluid when its surface is at \( E, F, G \), are those due to the heights \( E_n, F_n, G_n \), it follows from the properties of falling bodies (see Mechanics), that if these velocities were continued uniformly, the fluid would run through spaces equal to \( 2 E_n, 2 F_n, 2 G_n \) respectively, in the same time that a heavy body would fall through \( E_n, F_n, G_n \), respectively.

145. Cor. 3. As fluids press equally in all directions, the preceding proposition will hold true, when the orifices are at the sides of vessels, and when they are formed to throw the fluid upwards, either in a vertical or an inclined direction, provided that the orifices are in these several cases at an equal distance from the upper surface of the fluid. This corollary holds also in the case mentioned in Cor. 1.

146. Cor. 4. When the fluid issues vertically, it will rise to a height equal to the perpendicular distance of the orifice from the surface of the fluid; for (see Mechanics), this is true of falling bodies in general, and must therefore be true in the case of water, owing to the resistance of the air, however, and the friction of the issuing fluid upon the sides of the orifice, jets of water do not exactly rise to this height.

147. Cor. 5. As the velocities of falling bodies are as the square roots of the heights through which they fall (see Mechanics), the velocity \( V \) of the effluent water when the surface is at \( E \), will be to its velocity \( v \) when the surface is at \( G_m \) as \( \sqrt{E_n} : \sqrt{G_n} \) (Cor. 1.) that is, the velocities of fluids issuing from a very small orifice are as the square roots of the altitude of the water above these orifices. As the quantities of fluids discharged are as the velocities, they will also be as the square roots of the altitude of the fluid. This corollary holds true of fluids of different specific gravities, notwithstanding Belidor (Architect. Hydraul. tom. i. p. 187.) has maintained the contrary; for though a column of mercury \( Dm \) presses with \( 1.4 \) times the force of a similar column of water, yet the column \( mnp \) of mercury which is pushed out is also \( 1.4 \) times as heavy as a similar column of water; and as the resistance bears the same proportion to the moving force, the velocities must be equal.

148. Cor. 6. When a vessel is emptying itself, if the area of the laminae into which we may suppose it divided, be everywhere the same, the velocity with which the surface of the fluid descends, and also the velocity of efflux, will be uniformly retarded. For (art. 150) as the velocity \( V \) with which the surface descends is to the velocity \( v \) at the orifice, as the area \( A \) of the orifice to the area \( A \) of the surface, then \( V : v = A : A \), but the ratio of \( A : A \) is constant, therefore \( V \) varies as \( v \), that is, \( V = v \); but, (Cor. 1.) \( v = \sqrt{h} \); \( \sqrt{h} \), being the height of the surface above the orifice, therefore \( V = \sqrt{h} \); \( \sqrt{h} \). But this is the property of a body projected vertically from the earth's surface, and as the retarding force is uniform in the one case (see Mechanics), it must also be uniform in the other.

149. Cor. 7. If a cylindrical vessel be kept constantly full, twice the quantity contained in the vessel will run out during the time in which the vessel would have emptied.
HYDRODYNAMICS.

PROP. II.

151. To find the quantity of water discharged from a very small orifice in the side or bottom of a reservoir, the time of discharge, and the altitude of the fluid, the vessel being kept constantly full, and any two of these quantities being given.

Let \( A \) be the area of the orifice \( mn \); \( W \) the quantity of water discharged in the time \( T \); \( H \) the constant height \( Dm \) of the water in the vessel, and let \( 16.087 \) feet be the height through which a heavy body descends in a second of time. Now, as the times of description are proportional to the square roots of the heights described, the time in which a heavy body will fall through the height \( H \) will be found from the following analogy, \( \sqrt[4]{16.087} : \sqrt[4]{H} = 1 : \sqrt[4]{16.087} \) the time required.\n
But as the velocity at the orifice is uniform, a column of fluid whose base is \( mn \) and altitude \( 2H \) (Prop. I. Cor. 2.) will issue in the time \( 16.087 \sqrt[4]{H} \), or since \( A \) is the area of the orifice \( mn \), \( A \times 2H \) or \( 2HA \) will represent the column of fluid discharged in that time. Now since the quantities of fluid discharged in different times must be as the times of discharge, the velocity at the orifice being always the same, we shall have \( \sqrt[4]{H} : T = 2HA : W \), and (GEOMETRY, Sect. IV. Theor. VIII.) \( W = \frac{2HAT}{16.087} \) or \( W = \frac{2HAT \times 16.087}{\sqrt[4]{H}} \), and since \( \sqrt[4]{H} = \sqrt[4]{H} \) we shall have \( W = 2AT \sqrt[4]{H} \times 16.087 \), an equation from which we deduce the following formule, which determine the quantity of water discharged, the time of discharge, the altitude of the fluid, and the area of the orifice, any three of these four quantities being given:

\[
W = 2AT \sqrt[4]{H} \times 16.087 \quad A = \frac{W}{2T \sqrt[4]{H} \times 16.087} \\
H = \frac{4AT^2 \times 16.087}{W} \\
T = \frac{W}{2A \sqrt[4]{H} \times 16.087}
\]

152. It is supposed in the preceding proposition that the orifice in the side of the vessel is so small that every part of it is equally distant from the surface of the fluid. But when the orifice is large like \( M \) (63. 3.), the depths of different parts of the orifice below the surface of the fluid are very different, and consequently the preceding formule will not give very accurate results.

(8) When a fluid runs through a conical tube kept continually full, the velocities of the fluid in different sections will be inversely as the area of the sections. For as the same quantity of fluid runs through every section in the same time, it is evident that the velocity must be greater in a smaller section, and as much greater as the section is smaller, otherwise the same quantity of water would not pass through each section in the same time. Now the area of the \( vena contracta \) is to the area of the orifice, as \( 1 : \sqrt{2} \); therefore the velocity at the \( vena contracta \) must be to the velocity at the orifice as \( \sqrt{2} : 1 \).
HYDRODYNAMICS.

the whole orifice GL will be found by multiplying the constant quantity \( T \sqrt{16.687 x \frac{MO}{P}} \). Now the area FHED is equal to the difference between the areas CDE and CFH. But (CONIC SECTIONS, Part I. Prop. X.) the area CDE = \( 4CD \times DE \); and since \( P = 4CD \), and (CONIC SECTIONS, Part I. Prop. X.) \( DE = CD \times P \) we have \( DE = CD \times 4CD = 4CD^2 \). The area CFH = \( 4CF \times FH \), consequently the area FHED = \( 4CD^2 - 4CF \times FH \), which multiplied by the constant quantity, gives for the quantity of water discharged, \( 4P \), being substituted instead of its equal \( 4CD^2 \).

\[
W = T \sqrt{16.687 x MO \times \frac{P}{P}} - 4CF \times \sqrt{CF \times P} \frac{P}{P}
\]

and dividing by \( \frac{P}{P} \) gives us

\[
W = T \sqrt{16.687 x MO \times \frac{P}{P}} - 4CF \times \sqrt{CF \times P}
\]

hence

\[
T = \sqrt{16.687 x MO \times \frac{P}{P}} - 4CF \times \sqrt{CF \times P}
\]

\[
MO = \frac{9W}{4T \sqrt{16.687} + 3CF \sqrt{CF}}
\]

and since \( P = 4CD \)

\[
CD = \frac{9W}{16T \sqrt{16.687} + 12CF \sqrt{CF}}
\]

\[
CF = \frac{9W}{16T \sqrt{16.687} + 4P \sqrt{P}}
\]

In these formulae \( W \) represents the quantity of water discharged, \( T \) the time of discharge, \( MO \) the horizontal width of the rectangular orifice, \( P \) the parameter of the parabola \( = 4CD \), \( CD \) the depth of the water in the vessel or the altitude of the water above the bottom of the orifice, and \( CF \) the altitude of the water above the top of the orifice. The vertical breadth of the orifice is equal to \( CD - CF \).

154. Let \( x \) be the mean height of the fluid above the orifice, or the height due to a velocity, which, if communicated to all the particles of the issuing fluid, would make the same quantity of water issue in the time \( T \) as if all the particles moved with the different velocities due to their different depths below the surface, then by Prop. II. the quantity discharged or \( W = 2T \times MO \times CD - CF \times \sqrt{2 \times 16.687}, \) the area of the orifice being \( MO \times \frac{P}{P} \).
HYDRODYNAMICS.

of the area of the surface at DE divided by the ordinate HF. Now (Conic Sections, Part I. Prop. X.) that

\[ \frac{HF}{\sqrt{\frac{DE}{m}}} = \frac{DE}{HF} \]  

or \( HF \) is equal to \( \frac{DE}{\sqrt{m}} \). But by the construction of the curve MN, we have

\[ \frac{DE}{HF} = \frac{DE}{\sqrt{m}} \]

the elementary time therefore, expressed by

\[ \frac{DE \times o b}{\sqrt{16.087 \times 2A \times \sqrt{o m}}} \]

will, by the different substitutions now mentioned, be \( \frac{H r \times o b}{\sqrt{2A \times \sqrt{16.087}}} \) or \( \frac{2A \times \sqrt{16.087}}{2A \times \sqrt{16.087}} \times H r \times o b \). But the factor \( \frac{2A \times \sqrt{16.087}}{2A \times \sqrt{16.087}} \), consisting of constant quantities is itself constant, and the other factor \( H r \times o b \) represents the variable curvilinear area \( H r \times o b \). Now as the same may be shown of every other element of the time \( T \), compared with the corresponding elements of the area \( G U \times M \), it follows that the time \( T \) required, will be found by multiplying the constant quantity

\[ \frac{\sqrt{\frac{P}{\sqrt{16.087}}} \times G P \times N M}{\sqrt{16.087 \times 2A}} \]

Cor. The quantity of fluid discharged in the given time \( T \) may be found by measuring the contents of the vessel \( AB \) between the planes \( AB \), and the time in which the surface descends to \( m \), or in which the vessel empties itself, will be equal to

\[ \frac{\sqrt{\frac{P}{\sqrt{16.087}}}}{\sqrt{16.087 \times 2A}} \]

PROP. V.

156. To find the time in which a quantity of fluid equal to \( ABRT \) will issue out of a small orifice in the side or bottom of the vessel \( AB \), that is, the time in which the surface \( AB \) will descend to \( RT \).

Let us suppose that a body ascends through the height \( m \) \( C \) with a velocity increasing in the same manner as if the vessel \( AB \) were inverted, and the body-fell from \( m \) to \( C \). The velocity of the ascending body at different points of its path being proportional to the square roots of the heights described, will be expressed by the ordinates of the parabola \( PVQ \). The line \( DE \) being infinitely near to \( d e \), as soon as the body arrives at \( b \) it will describe the small space \( b o \) or \( H \) in a portion of time infinitely small, with a velocity represented by the ordinate \( HF \). Now the time in which the body will ascend through the space \( m \) \( C \) or its equal \( PG \) will be

\[ \frac{\sqrt{\frac{P}{\sqrt{16.087}}}}{\sqrt{16.087}} \]  

(See Mechanics); and if the velocity

impressed...
HYDRODYNAMICS.

Motion of impressed upon the body when at C were continued uniformly, it would run through a space equal to 2GP or GQ in the time \( \frac{\sqrt{PG}}{\sqrt{16.087}} \). But (Dynamics, 22.) the times of description are as the spaces described directly, and the velocities inversely, and therefore the time of describing the space 2GP or GQ uniformly, viz. the time \( \frac{\sqrt{PG}}{\sqrt{16.087}} \) will be to the time of describing the space \( HH \) uniformly, as \( \frac{GQ}{\sqrt{16.087}} = \frac{GQ}{\sqrt{16.087}} \).

That is, as \( \frac{GQ}{\sqrt{16.087}} \) or 1 : \( \frac{\sqrt{PG}}{\sqrt{16.087}} = \frac{HA}{HA} \). Substituting this value of \( \sqrt{PG} \) in the last formula, we shall have the expression of the time of describing \( HA \) uniformly \( \frac{\sqrt{PG}}{\sqrt{16.087}} \times \frac{HA}{HA} \).

But by Prop. IV. the time in which the surface DH descends into the position \( dh \), that is, in which it describes \( HA \), is represented by \( \frac{\sqrt{PG}}{\sqrt{16.087}} \times \frac{Hr \times bc}{2A} \). Therefore the time in which the ascending body moves through \( HH \), is to the time in which the descending surface moves through \( HA \) as \( \frac{\sqrt{PG}}{\sqrt{16.087}} \) : \( \frac{Hr \times HA}{2A} \), which expressions after being multiplied by 2 and after substituting in the latter \( DE \) instead of \( Hr \), which is equal to it by construction, will become \( \frac{\sqrt{PG}}{\sqrt{16.087}} \times \frac{HA}{A \times \sqrt{16.087}} \times \frac{DE \times HA}{A \times \sqrt{16.087}} \), \( DE \) representing, in this and in the following proposition, the area of the surface of the fluid at D. Now, if we multiply the first of these expressions by \( DE \), and the second by \( A \), we shall find the two products equal; consequently (Euclid VI. 16.) the first expression is to the second, or the time of the body's ascent through \( HH \) is to the time of the surface's descent through \( HA \), as the area \( A \) of the orifice is to the area \( DE \) of the base of the cylindrical vessel; and as the same may be demonstrated of every elementary time in which the ascending body and the descending surface describe equal spaces, it follows that the whole time in which the ascending body will describe the height \( mC \) or \( PG \), is to the whole time in which the surface \( AB \) will descend to \( mn \), or in which the vessel will empty itself, as the area \( A \) of the orifice is to the area of the surface \( DE \), that is \( A : DE = \frac{\sqrt{PG}}{\sqrt{16.087}} \).

\[ a : \frac{\sqrt{PG}}{\sqrt{16.087}} = \frac{DE}{A} \] is the time in which the vessel \( AB \) will empty itself. If \( RT \) \( mn \) be the vessel, it may be shown in the same manner, that the time in which it will empty itself will be \( \frac{\sqrt{PU}}{\sqrt{16.087}} \times \frac{DE}{A} \), \( DE \) being equal to \( RT \). But the difference between the time in which the vessel \( AB \) \( m \ n \) empties itself, and the time in which the vessel \( RT \) \( mn \) empties itself, will be equal to the time required in the proposition, during which the surface \( AB \) descends to \( RT \). This time therefore will be

\[ T = \frac{\sqrt{PG}}{\sqrt{16.087}} \times \frac{DE}{A} \times \frac{\sqrt{PU}}{\sqrt{16.087}} \times \frac{DE}{A} \times \frac{\sqrt{PG} - DE}{\sqrt{16.087}} \]

Hence

\[ T = \frac{DE \times \sqrt{PG} - \sqrt{PU}}{A \sqrt{16.087}} \]

\[ PU = \left( \frac{T}{A} \right) \frac{\sqrt{16.087}}{DE} - \frac{\sqrt{PG}}{DE} \]

\[ PG = \left( \frac{T}{A} \right) \frac{\sqrt{16.087}}{DE} + \frac{\sqrt{PU}}{DE} \]

\[ PG - PU \text{ or } UG = \frac{2T \times A \times DE \times \sqrt{PG} \times 16.087 - T \times A^2 \times 16.087}{DE^2} \]

As the quantity of fluid discharged while the surface \( AB \) descends to \( RT \) is equal to \( DE \times UG \), we shall have

\[ W = DE \times \frac{2T \times A \times DE \times \sqrt{PG} \times 16.087 - T \times A^2 \times 16.087}{DE^2} \]

\[ A = \frac{DE \times \sqrt{PG} \times PU}{T \sqrt{16.087}} \]

\[ DE = \frac{T \times A \sqrt{16.087}}{\sqrt{PG} - \sqrt{PU}} \]

5A2

PROP.
HYDRODYNAMICS.

PROP. VI.

157. If two cylindrical vessels are filled with water, the time in which their surfaces will descend through similar heights will be in the compound ratio of their bases, and the difference between the square roots of the altitudes of each surface at the beginning and end of its motion, directly, and the area of the orifices inversely.

Let \( A'B' = \text{the two vessels} \); then, by the last proposition, the time \( T \), in which the surface \( AC \) of the first descends to \( RT \), will be to the time \( T' \) in which the surface \( A'B' \) of the second descends to \( R'T' \) as \( \frac{DE \times \sqrt{PG} \times \sqrt{PU}}{A' \times 16.587} \) to \( \frac{DE' \times \sqrt{PG} - \sqrt{PU'}}{A \times 16.587} \), or, by dividing by \( \sqrt{16.587} \), as \( \frac{DE \times \sqrt{PG} - \sqrt{PU}}{A} \) to \( \frac{DE' \times \sqrt{PG} - \sqrt{PU'}}{A} \). Q. E. D.

158. Cor. Hence the time in which two cylindrical vessels full of water will empty themselves, will be in the compound ratio of their bases and the square roots of their altitudes directly, and the area of the orifices inversely; for in this time the surfaces \( AB, A'B' \) descend to \( mn, m'n' \) respectively, and therefore \( \sqrt{PG} - \sqrt{PU} \),

For since the velocity with which the surface \( AB \) descends, the area of that surface being always the same, is as the square roots of its altitude above the orifice (Prop. I. Cor. 6); and since the velocities are as the times of description, the times will also be as the square roots of the altitudes, that is, when

12 11 10 9 &c. are the times

144 121 100 81 will be the altitudes of the surface. Q. E. D.

PROP. VII.

159. To explain the theory and construction of clesypdres or water-clocks.

A clesypdra or water-clock, is a machine which, filled with water, measures time by the descent of the fluid surface. See Part III. on Hydraulic Machinery.

It has already been demonstrated in Prop. IV, that the times in which the surface \( AB \) descends to \( DE \) and \( RT \), &c. are as the areas \( GM \times RH \), \( GM \times IU \), &c. If such a form therefore is given to the vessel that the areas \( GM \times RH \), \( GM \times IU \), &c. increase uniformly as the times, or are to one another as the numbers 1, 2, 3, 4, 5, &c. the time in which the surface \( AB \) descends to \( DE \), and \( RT \), &c. will be in the same ratio, and the vessel will form a machine for measuring time. If the vessel is cylindrical and empties itself in 12 hours, its altitude may be divided in such a manner that the fluid surface may take exactly an hour to descend through each division. Let the cylindrical vessel, for example, be divided into 144 equal parts, then the surface of the water, when the twelve hours begins to run, will be 144 parts above the bottom of the vessel; when one hour is completed, the surface will be 121 parts above the bottom, and so on in the following manner.

Water in the vessel \( CDG \) will be carried off by the current \( EC \), which communicates its motion to the adjacent fluid. In the same way, when a stream of water runs through air, it drags the air along with it, and produces wind. Hence we have the water blowing machine \( \text{which conveys a blast to furnaces, and which shall be described in a future part of this article. The lateral communication of motion, whether the surrounding fluid be air or water, is well illustrated by the following beautiful experiments of Venturi's. In the side of the reservoir \( AB \), insert the horizontal line \( F \) about as inch and a half in diameter, and five inches long. At the point \( o \) of this pipe, about seven-tenths of an inch from the reservoir, fasten the bent glass tube, of \( \text{mm. whose cavity communicates with that of the pipe, whilst its other extremity is immersed in coloured water contained in the small vessel \( F \). When water is poured into the reservoir \( AB \), having no connection with the pipe \( C \), so that it may issue from the horizontal pipe, the red liquor will rise towards \( m \) in the curved tube \( o \text{mm}. If the descending leg of this glass syphon be six inches and a half longer than the other, the red liquor will rise to the very top of the syphon, enter the pipe \( P \), and running out with the other water will in a short time leave the vessel \( F \) empty. Now the cause of this phenomenon is evidently this: When the water begins to flow from the pipe \( P \), it communicates with the air in the syphon \( o \text{mm. and drag}
HYDRODYNAMICS.

471. The air in the syphon is constantly going on as long as the water runs through the horizontal pipe. The equilibrium between the external air pressing upon the fluid in the vessel P, and that included in the syphon, being thus destroyed, the red liquor will rise in the syphon, till it communicates with the issuing fluid, and is dragged along with it through the orifice of the syphon P, till the vessel P is emptied.

Prop. IX.

161. To find the horizontal distance to which fluids will spout from an orifice perforated in the side of a vessel, and the curve which it will describe.

Let A B be a vessel filled with water, and C an orifice in its side, so inclined to the horizon as to discharge the fluid in the direction CP. If the issuing fluid was influenced by no other force except that which impels it out of the orifice, it would move with an uniform motion in the direction CP. But immediately upon its exit from the orifice C it is subject to the force of gravity, and is therefore influenced by two forces, one of which impels it in the direction CP, and the other draws it downwards in vertical lines. Make CE equal to EG, and CP double of CS the altitude of the fluid. Draw PL parallel to CK and join SL. Draw also EF, GH parallel to CN, and FM, HN parallel to CG, and let CM, CN represent the force of gravity, or the spaces through which it would cause a portion of fluid to descend in the time that this portion would move through CE, CG respectively by virtue of the impulsive force. Now, it follows from the composition of forces, (Dynamics, 136,) that the fluid at C, being solicited in the direction CE by a force which would carry it through CE in the same time that the force of gravity would make it fall through CM, will describe the diagonal CE of the parallelogram CEFM, and will arrive at F in the same time that it would have reached E by its impulsive force, or M by the force of gravity; and for the same reason the portion of the fluid will arrive at H in the same time that it would have reached G by the one force, and N by the other. The fluid therefore being continually deflected from its rectilinear direction by CP with the force of gravity, will describe a curve line CEPF, which will be a parabola: for since the motion along CP must be uniform, CE, CG will be to one another as the times in which they are described; and may therefore represent the times in which the fluid would arrive at E and G, if influenced by no other force. But in the time that the fluid has described CE gravity has made it fall through EF, and in the time that it would have described

CG, gravity has caused it to fall through GH. Now, Motion of space is as the squares of the times in which Fluids, &c. they are described, (Dynamics, 37. 2.) we shall have

\[ EF : GH = CE^2 : CG^2. \]

But on account of the parallelograms CEFM, CGHN, EF and GH are equal to CM and CN respectively, and MF, NE to CE, CG respectively; therefore CM : CN = MF^2 : NH^2, which is the property of the parabola, CM, CN being the abscissa, and ME, NH the ordinates (Conic Sections, Part I. Prop. IX. Cor.).

162. On account of the parallels LP, CX, LC, GX, the triangles LCP, GCX are similar, and therefore (Geometrical Theory, XX.) CG = FC x PL and GX = CL x PL. Hence CG = \( \frac{FX x PC}{PL} \), and GX = \( \frac{CX x CL}{PL} \), but since PC = 2 CS, we have CG = \( \frac{FX x CL}{PL} \), and since GX = GX - HX, we shall have

\[ GH = \frac{FX x CL}{PL} - HX. \]

But as the property of the parabola CRK is equal to ½ CS (1), we have, by the property of this conic section, \( NH^2 = CN \times 4 CS \), or \( CG^2 = 4 GH \times CS \), therefore, by substituting in this equation the preceding values of CG and GH, we shall have

\[ FX^2 x CS = FX x CL x PL - HX \times PL. \]

Now, it is evident, from this equation, that HX is nothing, or vanishes when \( CX = 0 \), or when \( CX = \frac{CL \times PL}{CS} \), for

\[ HX = 0, \text{ then } FX \times PL = \frac{CL \times PL}{CS}. \]

But when \( CX \) vanishes towards \( K \), \( CX \) is equal to \( CK \), consequently \( CK = \frac{CL \times PL}{CS} \). Bisect \( CK \) in \( T \), then \( CT = \frac{CL \times PL}{2CS} \), and \( CT = \frac{CL \times PL}{2CS} \). Draw TR perpendicular to \( CK \), and \( TR \) will be found = \( \frac{CL^2}{4CS} \).

Then if \( H \) be drawn at right angles to \( HX \), we shall have \( CX = CT - H = \frac{CL \times PL}{2CS} - Hm \) and \( HX = Hm \times \frac{PL}{4CS} - Rm. \) After substituting these values of \( CX \) and \( HX \) in the equation \( 2FX^2 \times CS = FX \times CL \times PL - HX \times PL \), it will become, after the necessary reductions, \( Hm^2 = \frac{PL^2}{CS} \times Rm. \) The curve CRK is

(1) The parameter of the parabola described by the issuing fluid, is equal to four times the altitude of the fluid above the orifice. For since the fluid issues at \( C \) with a velocity equal to that acquired by falling through SC, if this velocity were continued uniform, the fluid would move through 2 CS or CP, in the same time that a heavy body would fall through SC. Draw PQ parallel to CS, and QW to CP; then since Q is in the parabola, the fluid would describe CP uniformly in the same time that it falls through CW by the force of gravity, therefore \( CW = CS \). Now \( CP = 2 \text{ CS}, \) and \( CP^2 = 4 \text{ CS}^2 - 4 \text{ CS} \times \text{ CS} = 4 \text{ CS} \times CW; \) but it is a property of the parabola, that the square of the ordinate WQ or CP is equal to the product of the abscissa CW and the parameter, therefore 4 CS is the parameter of the parabola.
HYDRODYNAMICS.

163. Hence we have the following construction. With $\frac{1}{2}CS$ as radius, describe the semicircle $SCG$, which is the direction $CR$ of the jet or issuing fluid meets in $G$. Draw $GN$ perpendicular to $CS$, and having prolonged it towards $R$, make $GR$ equal to $GN$. From $R$ let fall $RT$ perpendicular to $CR$ and meeting it in $T$, and upon $RT$, $CT$ describe the parabola $CRK$ having its vertex in $R$, this parabola shall be the course of the issuing fluid. For by the construction $NC$ or $CT$ is equal to $2GN$, and on account of the similar triangles $GSC$, $CGN$, $SCG=CGN$; hence $SG:SN=SG:CG$, or $2GN$, or $CT=\frac{2SG\times CG}{SC}$.

But from the similarity of triangles $CSG=CGN$ and $CSG=CGN$, the equation $CT=\frac{2SG\times CG}{SC}$, we have $CT=\frac{2SG\times CG}{SC}$, and $CG=\frac{CS\times n}{R}$.

But substituting these values of $SG$ and $CG$ in the equation $CT=\frac{2SG\times CG}{SC}$, we have $CT=\frac{2SG\times CG}{SC}$, and $CG=\frac{CS\times n}{R}$.

Therefore the parameter $P$ of the parabola $CRK$ is equal to $\frac{CG}{RT}$, because it is a third proportional to the abscissa and its ordinate, therefore $P=\frac{4a^2\times mn^2}{R^2}$. Now $RT=GN$, and $CG=NG=\frac{m}{n}$, because $CG:NG=mn:n$, or $CG=\frac{m}{n}$, by substituting the preceding value of $NG$. Therefore the parameter $P=\frac{(4a^2\times mn^2)}{R^2}+\frac{4a^2}{R^2}$, which is the same value of the parameter as was found in the preceding article, and therefore verifies the construction.

164. COR. Since $NG=GR$ and $CT=TK$, the amount of the fluid that shall flow through $CT$ is equal to $\frac{4a^2}{R^2}$. Now as each particle of fluid which successively reaches the extremity $DH$ of the pipe, has a tendency to move with the velocity $\sqrt{A}$, while it moves only with the velocity $\frac{\sqrt{A}}{a^2}$, the extremity $D$ of the pipe will sustain a pressure equal to the difference of the pressures produced by the velocities $\sqrt{A}$ and $\frac{\sqrt{A}}{a^2}$, that is, by...
HYDRODYNAMICS.

SECT. I. On the Quantity of Water discharged from Vessels constantly full by Orifices in thin Plates.

172. In the following experiments, which were frequently repeated in various ways, the orifice was pierced in a plate of copper about half a line thick. When the discharged orifice is in the bottom of the vessel, it is called a horizontal orifice; and when it is in the side of it, it is called a lateral orifice.

173. From the results contained in the preceding table, we may draw the following conclusions.

1. That the quantities of water discharged in equal times by different apertures, the altitudes of the fluid being the same, are very nearly as the areas of the orifices. That is, if $A$ or $a$ represent the areas of the orifices, and $W$, $w$ the quantities of water discharged,

2. The quantities discharged in equal times by the same aperture, the altitude of the fluid being different, are to one another very nearly as the square roots of the altitudes of the water in the reservoir, reckoning from the centres of the orifices. That is, if $H$, $h$ be the different altitudes of the fluid, we shall have

$$W : w = \sqrt{H} : \sqrt{h}.$$ 

3. Hence we may conclude in general that the quantities discharged in the same time by different apertures, and under different altitudes in the reservoir, are in the compound ratio of the areas of the orifices, and the square roots of the altitudes. Thus, if $W$, $w$ be the quantities discharged in the same time from the orifices $A$, $a$, under the same altitude of water; and if $W'$, $w'$ be the quantities discharged in the same time by the same aperture $a$ under different altitudes, $H$, $h$: then by the first of the two preceding articles,

$$W : W' = A \sqrt{H} : a \sqrt{h}.$$ 

Multiplying these analogies together, gives us

$$W w : W'w = A \sqrt{H} : a \sqrt{h},$$

and dividing by $w$,

$$W : W' = A \sqrt{H} : a \sqrt{h}.$$
HYDRODYNAMICS:

This rule is sufficiently correct in practice; but when great accuracy is required, the following remarks must be attended to.

4. Small orifices discharge less water in proportion than great ones, the altitude of the fluid being the same. The circumference of the small orifices being greater in proportion to the issuing column of fluid than the circumferences of greater ones, the friction, which increases with the area of the rubbing surfaces, will also be greater, and will therefore diminish the velocity, and consequently the quantity discharged.

5. Hence of several orifices whose areas are equal, that which has the smallest circumference will discharge more water than the rest under the same altitude of fluid in the reservoir, because in this case the friction will be less.—Circular orifices, therefore, are the most advantageous of all, for the circumference of a circle is the shortest of all lines that can be employed to inclose a given space.

6. In consequence of a small increase which the contraction of the vein of fluid undergoes, in proportion as the altitude of the water in the reservoir augments, the quantity discharged ought also to diminish a little as that altitude increases.

By attending to the preceding observations, the results of theory may be so corrected, that the quantities of water discharged in a given time may be determined with the greatest accuracy possible.

174. The abbé Bossut has given the following table containing a comparison of the theoretical with the real discharges, for an orifice one inch diameter, and for different altitudes of the fluid in the reservoir. The real discharges were not found immediately by experiment, but were determined by the precautions pointed out in the preceding articles, and may be regarded as being equal as if direct experiments had been employed. The fourth column was computed by M. Prony.

</table>

175. It is evident from the preceding table, that the theoretical, as well as the real discharges, are nearly proportional to the square roots of the altitudes of the fluid in the reservoir. Thus, if we take the altitudes 1 and 4, whose square roots are as 1 to 2, the real discharges taken from the table are 2722, 5436, which are to one another very nearly as 1 to 2, their real ratio being as 1 to 1.997.

The fourth column of the preceding table also shows us that the theoretical are to the real discharges nearly in the ratio of 1 to 0.62, or more accurately, as 1 to 0.61938; therefore 0.62 is the number by which we must multiply the discharges as found by the formula in the preceding chapter, in order to have the quantities of water actually discharged.

176. In order to find the quantities of fluid discharged by orifices of different sizes, and under different altitudes of water in the reservoir, we must use the table in the following manner. Let it be required, for example, to find the quantity of water furnished by an orifice three inches in diameter, the altitude of the water in the reservoir being 30 feet. As the real discharges are in the compound ratio of the area of the orifices, and the square roots of the altitudes of the fluid, (art. 173, N°3) and as the theoretical quantity of water discharged by an orifice one inch in diameter, is by the second column of the table 16918 cubic inches in a minute, we shall have this analogy, \( \sqrt{15} : 9 : \sqrt{30} = 16918 : 215661 \) cubic inches, the quantity required. This quantity being diminished in the ratio of 1 to 0.62, being the ratio of the theoretical to the actual discharges, gives 133896 for the real quantity of water discharged by the given orifice. But (by N° 5 of art. 173) the quantity discharged ought to be a little greater than 133896, because greater orifices discharge more than small ones; and by N° 5, the quantity ought to be less than 133896, because the altitude of the fluid is double that in the table. These two causes therefore having a tendency to increase and diminish the quantity deduced from the preceding table, we may regard 133896 very near the truth. Had the orifice been less than one inch, or the altitude less than 15 feet, it would have been necessary to diminish the preceding answer by a few cubic inches. Since the velocities of the issuing fluid are as the quantities discharged, the preceding results may be employed also to find the real velocities from those which are deduced from theory.

177. As the velocity of falling bodies is 16.87 feet per second, the velocity due to 16.87 feet per second, and as the velocities are as the square roots of the height, we shall have \( \sqrt{16.87} : \sqrt{H} = 32.147 : \sqrt{H} \) the velocity due to any other height, consequently \( V = \frac{32.147 \sqrt{H}}{16.87} \) and \( H = \frac{32.147 V}{16.87} \), so that 8.016 is the coefficient by which we must always multiply the altitude of the fluid in order to have its theoretical velocity.

178. According to the experiments of M. Eyth-Reinhold, published at Berlin in 1801, in his treatise 'Handbuch der Mechanik und der Hydraulik,' the following are the ratios between the theoretical and actual discharges, and the coefficients by which the height may be multiplied in order to find the velocities of the issuing fluid.

M. Eytelwein has likewise shown, that the quantity of water discharged from rectangular orifices in the side of a reservoir extending to the surface, may be found by taking two-thirds of the velocity due to the mean height, and allowing for the contraction according to the form of the orifice.

Sect. II. On the Quantity of Water discharged from Vessels constantly full, by small Tubes adapted to Circular Orifices.

179. The difference between the natural discharges, and those deduced from theory, arises from the contraction of the fluid vein, and from the friction of the water against the circumference of the orifice. If the operation of any of these causes could be prevented, the quantities of water actually discharged would approach nearer the theoretical discharges. There is no probability of diminishing friction in the present case by the application of unguents; but if a short cylindrical tube be inserted in the orifice of the vessel, the water will follow the sides of the tube, the contraction of the fluid vein will be in a great measure prevented, and the actual discharges will approximate much nearer to those deduced from theory, than when the fluid issues through a simple orifice.

180. The difference between the variable lengths of the tubes, expressed in lines, and the cubic inches discharged in a minute.

</table>

The experiments in the preceding table were made with tubes inserted in the bottom of the vessel. When the tubes were fixed horizontally in the side of the reservoir, they furnished the very same quantities of fluid, their dimensions and the altitude of the fluid remaining the same.

It appears from the preceding results, that the quantities of water discharged increase with the length of the tube, and that these quantities are very nearly as the square roots of the altitudes of the fluid above the interior orifice of the vertical tube.

We have already seen that the theoretical are to real discharges, as 1 to 0.62, or nearly as 16.1 to 10. But by comparing the two last experiments in the preceding table, it appears that the quantity of fluid discharged by a cylindrical tube where the water follows its sides, is to the quantity discharged by the same tube when the venae contractae is formed, as 13 to 10; and since the same quantity must be discharged by the latter method as by a simple orifice, we may conclude...

| 14 | 16393 | 13177 | 0.82382 |
| 15 | 16968 | 13620 | 0.82370 |

By comparing the preceding table with that at art. 174. we shall find that cylindrical tubes discharge a much greater quantity of water than simple orifices of the same diameter, and that the quantities discharged are as 8x to 6x nearly. This is a serious phenomenon, and will be afterwards explained.

185. The application of this table to other additional tubes under different altitudes of the fluid, not contained in the first column, is very simple. Let it be required, for example, to find the quantity of water discharged by a cylindrical tube, 4 inches in diameter, and 8 inches long, the altitude of the fluid in the reservoir being 25 feet. In order to resolve this question, we may make use of the table (by art. 176.) and make the theoretical quantity discharged which in the present instance will be 350490 cubic inches, and this number diminished in the ratio of 1 to 0.8x will give 284773 for the quantity required. The length of the tube in this example was made 8 inches, because, when the length of the tube is less than twice its diameter, the water does not easily follow its interior circumference. If the tube were longer than 8 inches, the quantity of fluid discharged would be less greater, because it uniformly increases with the length of the tube; the greatest length of the tube being always small, in comparison with the altitude of the fluid in the reservoir.

187. Hilberto we have supposed the tube to be exactly cylindrical. When its interior surface, however, is conical, the quantities discharged undergo a considerable variation, which may be estimated from the following experiments of the marquis Polo, published in his work De Castellis per quae derivatitur fusionem aper, &c. which appeared at Padua in 1718.

</table>

From these experiments we are authorised to conclude, 1. That the real discharges are less than those deduced from theory, which in the present case is 27425 cubic inches in a minute, and 2. That when the interior orifice of the tube is enlarged to a certain degree, the quantity discharged is increased; but that when this enlargement is too great, a contraction takes place without the exterior orifice, and the quantity discharged suffers a diminution. If the smallest base of the conical tube be inserted in the side of the reservoir, it will furnish more water than a cylindrical tube whose diameter is equal to the smallest diameter of the conical tube; for the dexterity of its sides changes the oblique motion which the particles would otherwise have had, when passing from the reservoir into the tube.

188. The experiments of Poleni and Bossut having been made only with tubes of a conical and cylindrical form, M. Venturi was induced to institute a set of experiments, in which he employed tubes of the various forms exhibited in fig. 4. The results of his researches are contained in the following table, for which we have computed the columns containing the number of cubic inches discharged in one minute, in order that the experiments of the Italian philosopher may be more easily compared with those which are exhibited in the preceding tables. The constant altitude of the water in the reservoir was 32.5 French inches, or 34.642 English inches. The quantity of water which flowed out of the vessel in the times contained in the first column was 4 French cubic feet, or 4.845 English cubic feet. The measures in the table are all English, unless the contrary be expressed.

Important acts deducible from Venturi's experiments...
HYDRODYNAMICS.

Part I.

190. M. Venturi also found, that the quantities of water discharged out of a straight tube, a curved tube forming a quadrant of a circle, and an elbowed tube with an angle of 90°, each branch having a horizontal position, are to one another nearly as the numbers 70, 50, 45. Hence we see the disadvantages of sinuosities and bends in conduit pipes. In the construction of hydraulic machines, any variation in the internal diameter of the pipe ought to be carefully avoided, excepting those alterations at the extremities which we have recommended in the preceding paragraph.

191. It appears from the researches of Eytelwein, that when the shortest tube that will make the water follow its sides is applied to the reservoir, the quantity discharged will be to that deduced from theory, as 0.810 to 1.000, and the multiplier for finding the velocity will be 6.5. When the lengths of the tubes are increased from two to four times their diameter, the ratio of the actual and theoretical discharge will be 0.822 to 1.000, and the constant multiplier for finding the velocity will be 6.6. In employing a conical tube approaching to the figure of the *vena contracta*, the ratio of the discharges was as 0.92 to 1.00, and when its edges were rounded off, as 0.98 to 1.00 computing from its least section. He found also that the smallest quantity of water was discharged, when the interior extremity of the tube projected within the reservoir, the quantity furnished in this case being reduced to one half of what was discharged when the tube had its proper position.

192. When a cylindrical tube is applied to an orifice, the oblique motion of the particles which enter it is diminished; the vertical velocity of the particles, therefore, is increased, and consequently the quantity of water discharged. M. Venturi maintains that the pressure of the atmosphere increases the expense of water through a simple cylindrical tube, and that in conical tubes, the pressure of the atmosphere increases the expenditure in the ratio of the exterior section of the tube to the section of the contracted vein, whatever be the position of the tube.

193. Of all the tubes that can be employed for discharging water, that is the most advantageous which has the form of a contracted vein. Hence, it will be a truncated cone with its greatest base next the reservoir, having its length equal to half the diameter of that base, and the area of the two orifices as 8 to 5, or their diameters in the subduplicate ratio of these numbers, viz. as \( \sqrt[4]{8} : \sqrt{5} \).

Sect. III. Experiments on the Exhaustion of Vessels.

194. It is almost impossible to determine the exact time in which any vessel of water is completely exhausted. When the surface of the fluid has descended within a few inches of the orifice, a kind of conical funnel is formed immediately above the orifice. The pressure of the supernumerous column being therefore removed, the time of exhaustion is prolonged. The water falls in drops; and it is next to impossible to determine the moment when the vessel is empty. Instead, therefore, of endeavouring to ascertain the time in which vessels are completely exhausted, the abbé Bosset has determined the times in which the superior surface of the fluid descends through a certain vertical height, and his results will be found in the following table.

| TABLE IX. Showing the times in which Vessels are partly exhausted. |
|-----------------|-----------------|-----------------|-----------------|-----------------|
| Primitive altitude of the water in the vessel. | Constant area of a section of the orifice. | Diameter of the orifice of the fluid. | Depression of the upper surface of the fluid. | Time in which this depression takes place. |
| 11.6666 | 9 | 1 | 4 | 7 25' |
| 1 | 2 | 9 20' |
| 2 | 2 | 9 20' |
| PG | DE | \( \sqrt[4]{A/78.54} \) | PG-PU | T |

195. In order to compare these experimental results with those deduced from theory, we must employ the following formula (in Prop. V. 176.) where the time in which the surface descends through any height is given by:

\[ T = \frac{D \times \sqrt{PG-PU}}{A \times 16.87} \]

where \( D \) is the area of the section of the vessel, \( PG \) the primitive altitude of the surface above the centre of the orifice, \( PU \) the altitude of the surface after the time \( T \) is elapsed, \( A \) the area of the orifice, and 16.87 the space through which a heavy body descends in one second of time. That the preceding formula may be corrected, we must substitute 0.62 \( A \) or \( \frac{5A}{8} \), instead of \( A \), in the formula, 0.62 \( A \) being the area of the *vena contracta*; and as the measures in the preceding table are in Paris feet, we must use 15.085 instead of 16.87, the former being the distance in Paris feet, and the latter the distance in English feet, which falling bodies describe in a second. The formula, therefore, will become:

\[ T = \frac{DE \times \sqrt{PG-PU}}{0.62A \times 15.085} \]

and when the computations are made for the different diameters of the orifices and the different depressions of the fluid surface, the results will be had, which are exhibited in the last column of the following table, containing the values of \( T \), according to theory and experience.

| TABLE X. Comparison of the results of Theory with those of Experience. |
|-----------------|-----------------|-----------------|-----------------|-----------------|
| Diameter of the orifice of the fluid. | Depression of the upper surface of the fluid. | Time of the depression of the surface by the experiment. | Time of the depression of the surface by the formula. | Difference between the theory and the experiment. |
| 1 | 4 | 7 25' | 7 22-36 | 3-14 |
| 2 | 4 | 1 32' | 1 50-59 | 1-41 |
| 1 | 9 | 20 24' | 20 16 | 8-50 |
| 2 | 9 | 5 6 | 5 4 | 2-20 |

</tbody>
</table>

197. It appears, from the three first experiments of the preceding table, that great jets rise higher than small ones; and from the three last experiments, that small jets rise higher than great ones when the horizontal tube is very narrow. There is therefore a certain proportion between the diameter of the horizontal tube and that of the adjutage or orifice, which will give a maximum height to the jet. This proportion may be found in the following manner. Let \( D \) be the diameter of the tube, \( d \) that of the adjutage, \( a \) the altitude \( B \) of the reservoir, \( b \) the velocity along the tube; and as the velocity at the adjutage is constant, it may be expressed by \( \sqrt{a} \). Now (art. 150, note) the velocity in the tube is to the velocity at the adjutage as the area of their respective sections, that is, as the square of the diameter of the one is to the square of the diameter of the other. Therefore, \( \sqrt{a} : b = D^2 : d^2 \), and consequently \( b = \frac{d^2 \sqrt{a}}{D^2} \). If there is another tube and another adjutage, the corresponding quantities may be the same letters in the Greek character, viz. \( \Delta \), \( \rho \), \( \alpha \), \( \beta \), and we shall have \( \frac{\rho^2}{\alpha^2} = \frac{\Delta^2}{\delta^2} \). If we wish, therefore, that the two jets be furnished in the same manner, then if the velocity in the first tube leaves to the first jet all the height possible, the velocity in the second tube leaves also to the second jet all the height possible, and we shall have \( \delta = \beta \), or \( \frac{d^2}{D^2} = \frac{\rho^2}{\alpha^2} \). Hence \( D^2 : \Delta^2 = \frac{d^2}{\rho^2} : \frac{\alpha^2}{\beta^2} \). The sum \( \frac{d^2}{\rho^2} : \frac{\alpha^2}{\beta^2} \), that is, the squares of the diameters of the horizontal tubes, ought to be to one another in the compound ratio of the squares of the diameters of the adjutages, and the square roots of the altitudes of the reservoirs.
HYDRODYNAMICS.

Part 1.

Experiments on the Motion of Fluids.

Now, it appears from the experiments of Mariotte (Traité de mouvement des eaux), that when the altitude of the reservoir is 16 feet, and the diameter of the adjutage six lines, the diameter of the horizontal tube ought to be 28 lines and a half. By taking this as a standard, therefore, the diameters of the horizontal tube may be easily found by the preceding rule, whatever be the altitude of the reservoir and the diameter of the adjutage.

It results from the three last experiments, that the jets rise to the smaller height when the adjutage is a cylindrical tube (see D fig. 6), that a conical adjutage throws the fluid very much higher, and that when the adjutage is a simple orifice the jet rises highest of all.

By comparing the preceding experiments with those of Mariotte, it appears, that the differences between the heights of vertical jets, and the heights of the reservoir, are nearly as the squares of the heights of the jets. Thus, $a : b = c : d = E : F : Fd^2$. Therefore, if $ab$ be known by experiment, we shall have $cd = \frac{E}{a} b$, and by adding $cd$ to $Fd$, we shall have the altitude of the reservoir. But if $Fc$ were given, and it were required to find $Fd$, the height of the jet, we have, by the preceding analogy, $F d = \frac{E b \times cd}{ab}$. But $cd$ is an unknown quantity, and is equal to $Fc\cdot Fd$, therefore, by substitution, $F d = \frac{E b \times Fc}{ab}$, or $F d = \frac{E b \times Fc}{ab}$, which is evidently a quadratic equation, which, after reduction, becomes $F d = \frac{\sqrt{E b \times Fc} - \frac{E b}{\sqrt{ab}}}{2}$.

A small inclination of the jet increases its altitude.

The jet rises higher than the reservoir at its commencement.

 risen with the tube, the velocity of the issuing fluid must be considerable, and will raise it higher than the reservoir. But as the jet is resisted by the air, and retarded by the descending fluid, its altitude diminishes, and the simple pressure of the fluid becomes the only permanent source of its velocity. The preceding phenomenon was first noticed by Tartesius, who seems to have been the first to ascribe the diminution in the altitude of the jet to the gravity of the descending particles.

200. The following table exhibits all that is necessary in the formation of jets. The two first columns are taken from Mariotte, and show the altitude of the reservoir requisite to producing a jet of a certain height. The third column contains, in Paris pints, the quantity of water discharged in a minute by an orifice six lines in diameter. The fourth column, computed from the hypothesis in art. 197, contains the diameters of the horizontal tubes for an adjutage six lines in diameter, relative to the altitudes in the second column. The thickness of the horizontal tubes will be determined in a subsequent section.

(k) This was also observed by Wolfius, Opera Mathematica, tom. i. p. 802. Schol. iv.
considerable source of retardation, unless when the jet rises to a great altitude. We must seek therefore for another cause of obstruction to the rising jet, which, when combined with these, may be adequate to the effect produced. Wolfius * has very properly ascribed the diminution in the altitude of the jet to the gravity of the falling water. When the velocity of the foremost particles is completely spent, those immediately behind by impinging against them lose their velocity, and, in consequence of this constant struggle between the ascending and descending fluid, the jet continues at an altitude less than that of the reservoir. Hence we may discover the reason why an inclination of the jet increases its altitude; for the descending fluid falling a little to one side does not encounter the rising particles, and therefore permits them to reach a greater altitude, than when their ascension is in a vertical line. Wolfius observes, in proof of his remark that the diminution is occasioned also by the weight of the ascending fluid, that mercury rises to a less height than water: but this cannot be owing to the greater specific gravity of mercury; for though the weight of the mercurial particles is greater than that of water, yet the momentum with which they ascend is proportionally greater, and therefore the resistance which opposes their tendency downwards, has the same relation to their gravity, as the resistance in the case of water has to the weight of the aqueous particles.

202. The theory of oblique jets has already been discussed in Prop. IX. art. 161. The two following experiments of Bossut contain all that is necessary to be known in practice. When the height NS of the reservoir AB was 9 feet, and the diameter of the adjutage at N, 6 lines, a vertical abscissa CN of 4 feet 3 inches and 7 lines, answered to a horizontal ordinate CT of 11 feet 3 inches and 3 lines. When the altitude NS of the reservoir was 4 feet, the adjutage remaining the same, a vertical abscissa CN of 4 feet 3 inches, and 7 lines, corresponded with a horizontal ordinate CT of 8 feet 2 inches and 8 lines. The real amplitudes, therefore, are less than those deduced from theory; and both are very nearly as the square roots of the altitudes of the reservoirs. Hence, to find the amplitude of a jet when the height of the reservoir is 10 feet, and the vertical ab-

Sect. V. Experiments on the Motion of Water in Conduit Pipes.

203. The experiments of the chevalier de Buat, will be given at great length in the article Water-Works, for which we have been indebted to the late learned Dr Robison. That the reader, however, may be in possession of every thing valuable on a subject of such public importance, we shall at present give a concise view of the experiments of Couplet and Bossut, and of the practical conclusions which they authorize us to form.

204. It must be evident to every reader, that, when water is conducted from a reservoir by means of a long horizontal pipe, the velocity with which the water enters the pipe will be much greater than the velocity with which it issues from its farther extremity; and, that if the pipe has various flexures or bendings, the velocity with which the water leaves the pipe will be still farther diminished. The difference, therefore, between the initial velocity of the water, and the velocity with which it issues, will increase with the length of the pipe and the number of its flexures. By means of the theory, corrected by the preceding experiments, it is easy to determine with great accuracy the initial velocity of the water, or that with which it enters the pipe; but on the obstructions which the fluid experiences in its progress through the pipe, and on the causes of these obstructions, theory throws but a feeble light. The experiments of Bossut afford much instruction on this subject; and it is from them that we have arranged the following table, containing the quantities of water discharged by pipes of different lengths and diameters, compared with the quantities discharged from additional tubes.

</table>

#### Deductions from the preceding table.

204. The third column of the preceding table contains the quantity of water discharged through an additional cylindrical tube 16 lines in diameter, or the quantity discharged from the reservoir into a conduit pipe of the same diameter; and the fourth column contains the quantity discharged by the conduit pipe. The fifth column, therefore, which contains the ratio between these quantities, will also contain the ratio between the velocity of the water at its entrance into the conduit pipe, which we shall afterwards call its initial velocity, and its velocity when it issues from the pipe, which shall be denominated its final velocity; for the velocities are as the quantities discharged, when the orifices are the same. The same may be said of the 6th, 7th, and 8th columns, with this difference only, that they apply to a cylindrical tube and a conduit pipe 24 lines in diameter.

#### Cause of the Retardation of Water in Moving Pipes.

206. By examining some of the experiments in the foregoing table, it will appear, that the water sometimes loses six-ths of its initial velocity. The velocity thus lost is consumed by the friction of the water on the sides of the pipe, as the quantities discharged, and consequently the velocities, diminish when the length of the pipe is increased. In simple orifices, the friction is in the inverse ratio of their diameter; and it appears from the table, that the velocity of the water is more retarded in the pipe 16 lines in diameter, than in the other, which has a diameter of 24 lines. But though the velocity decreases when the length of the tube is increased, it by no means decreases in a regular arithmetical progression, as some authors have maintained. This is obvious from the table, from which it appears, that the differences between the quantities discharged, which represent also the differences between the velocities, always decrease, whereas the differences would have been equal, had the velocities decreased in an arithmetical progression. The same truth is capable of a physical explanation. If every filament of the fluid rubbed against the sides of the conduit pipe, then, since in equal times they all experience the same degree of friction, the velocities must diminish in the direct ratio of the lengths of the tubes, and will form a regular arithmetical progression, of which the first term will be the final, and the last the initial velocity of the water. But it is only the lateral filaments that are exposed to friction. This retards their motion; and the adjacent filaments which do not touch the pipe, by the adhesion to those which do touch it, experience also a retardation, but in a less degree, and go on with the rest, each filament sustaining a diminution of velocity inversely proportional to its distance from the sides of the pipe. The lateral filaments alone, therefore, provided they always remain in contact with the sides of the pipe, will have their velocities diminished in arithmetical progression, while the velocities of the central filaments will not decrease in a much slower progression; consequently, the mean velocity of the fluid, or that in which the quantities discharged are proportional, will decrease less rapidly than the terms of an arithmetical progression.

207. When the altitude of the reservoir was two feet, the diminution of discharge, and consequently of velocity, was greater than when the height of the reservoir was only one foot. The cause of this is manifest. Friction increases with the velocity, because a greater number of obstructions are encountered in a certain time, and consequently the velocities are as the square roots of the altitudes; therefore friction must also be as the square roots of the altitudes of the reservoir. On some occasions Coulomb found that the friction of solid bodies diminished with an augmentation of velocity, but there is no ground
HYDRODYNAMICS.

for supposing that this takes place in the case of fluids.

208. When the pipe is inclined to the horizon, as CGF, the water will move with a greater velocity than in the horizontal tube CGHF. In the former case, the relative gravity of the water, which is to its absolute gravity as F to CF, or as the height of the inclined plane to its length, accelerates its motion along the tube. But this acceleration takes place only when the inclination is considerable; for if the angle which the direction of the pipe forms with the horizon were no more than one degree, the retardation of friction would completely counterbalance the acceleration of gravity. Thus when the pipe CF, 16 lines in diameter, was 177 feet, and was divided into three equal parts in the points D and E, so that CD was 59 feet, CE 118 feet; and when CF was to EF as 2124 to 241, the quantity of water discharged at F was 575 cubic inches in a minute, the quantity discharged at E was 580 cubic inches in a minute, and the quantity at D 580 cubic inches. The quantities discharged therefore, and consequently the velocities, decreased from C to F; whereas if there had been no friction, and no adhesion between the aqueous particles, the velocities would have increased along the line CF in the subduplicate ratio of the frictional altitudes CB, D m, E n, and F o; AB being the surface of the water in the reservoir. The preceding increase of numbers, representing the quantities discharged at F, E, and D, decrease very slowly; consequently by increasing the inclination the relative gravity of the water, that is, by inclining the pipe the tube more to the horizon, the effects of friction may be exactly counterbalanced. This happens when the angle FCE is about 6° 31', or when FFF is the eighth or ninth part of CF. The quantities discharged at C, D, E, and F, will then be equal, and friction will have consumed the velocity arising from the relative gravity of the included water.

209. In order to determine the effects produced by flexures or sinuosities in conduit pipes, M. Bosso made the following experiments.

<p>| Table XIV. Showing the Quantities of Water discharged by rectilinear and curvilinear Pipes 50 Feet long, and 1 Inch in Diameter. |

</table>

210. The two first experiments of the foregoing table shew, that the quantities discharged diminish as the altitude of the reservoir. This arises from an increase of velocity, which produces an increase of friction.

2. The four first experiments shew, that a curvilinear pipe, in which the flexures lie horizontally, discharges less water than a rectilinear pipe of the same length. The friction being the same in both cases, this difference must arise from the impulse of the fluid against the angles of the tube; for if the tube formed an accurate curve, it is demonstrable that the curvature would not diminish the velocity of the water.

3. By comparing the 2nd and 5th, and the 2d and 6th experiments, it appears, that when the flexures are vertical, the quantity discharged is diminished. This also arises from the imperfection of curvature.

4. It appears from a comparison of the 3d and 5th, with the 4th and 6th experiments, that when the flexures are vertical, the quantity discharged is less than when they are horizontal. In the former case, the motion of the fluid arises from the central impulsion of the Vol. X. Part II. water, retarded by its gravity in the ascending parts of the pipe, and accelerated in the descending parts; whereas the motion, in the latter case, arises wholly from the central impulsion of the fluid. To these points of difference the diminution of velocity may somehow or other be owing.

When a large pipe has a number of contrary flexures, the air sometimes mixes with the water, and occupies the highest parts of each flexure as at B and C, fig. 9, fig. 9. By this means the velocity of the fluid is greatly retarded, and the quantities discharged much diminished. This ought to be prevented by placing small tubes at B and C, having a small valve at their top.

211. A set of valuable experiments on a large scale, were made by M. Couplet upon the motion of water in conduits pipes, and are detailed in the Memoirs of the Academy for 1732, in his paper entitled Des Recherches sur le mouvement des eaux dans les tuyaux de conduite. These experiments are combined with those of the Abbé Bosquet in the following table, which gives a distinct view of all that they have done on this subject, and will be of great use to the practical hydraulist.

Application and use of the preceding table: 212. In order to shew the application of the preceding results, let us suppose, that a spring, or number of springs combined, furnishes 40,000 cubic inches of water in one minute; and that it is required to conduct it to a given place 4 feet below the level of the spring, and so situated that the length of the pipe must be 2400 feet. It appears from Table VI. art. 185. that the quantity of water furnished in a minute by a short cylindrical tube, when the altitude of the fluid in the reservoir is 4 feet, is 7070 cubic inches; and since the quantities furnished by two cylindrical pipes under the same altitude of water are as the squares of their diameters, we shall have by the following analogy the diameter of the tube necessary for discharging 40,000 cubic inches in a minute; \( \sqrt[3]{7070} : \sqrt[3]{40000} = 12 \) lines or 1 inch : 28.5 lines, the diameter required. But by comparing some of the experiments in the preceding table, it appears, that when the length of the pipe is nearly 2400 feet, it will admit only about one-eighth of the water, that is, about 5000 cubic inches. That the pipe, however, may transmit the whole 4000 cubic inches, its diameter must be increased. The following analogy, therefore, will furnish us with this new diameter; \( \sqrt[3]{5000} : \sqrt[3]{40000} = 28.54 \) lines : 80.73 lines, or 6 inches.
HYDRODYNAMICS.

Chap. II.

Sect. VI. Experiments on the Pressure exerted upon Pipes by the water which flows through them.

213. The pressure exerted upon the sides of conduit pipes by the included water, has been already investigated theoretically in Prop. X. Part II. The only way of ascertaining by experiment the magnitude of this lateral pressure is to make an orifice in the side of the pipe, and find the quantity of water which it discharges in a given time. This lateral pressure is the force which impels the water through the orifice; and therefore the quantity discharged, or the effect produced, must be always proportional to that pressure as its producing cause, and may be employed to represent it.

The following table, founded on the experiments of Bossut, contains the quantities of water discharged from a lateral orifice about 3/4 lines in diameter, according to theory and experiment.

</table>

It appears from the preceding table, that the real lateral pressure in conduit pipes differs very little from that which is computed from the formula; but in order that this accordance may take place, the orifice must be so perforated, that its circumference is exactly perpendicular to the direction of the water, otherwise a portion of the water discharged would be owing to the direct motion of the included fluid.

Sect. VII. Experiments on the Motion of Water in Canals.

214. Among the numerous experiments which have been made on this important subject, those of the Abbé Bossut seem entitled to the greatest confidence. His experiments were made on a rectangular canal 105 feet long, 5 inches broad at the bottom, and from 8 to 9 inches deep. The orifice which transmitted the water from the reservoir into the canal was rectangular, having its horizontal base constantly 5 inches, and its vertical height sometimes half an inch, and at other times an inch. The sides of this orifice were made of copper, and rising perpendicularly from the side of the reservoir they formed two vertical planes parallel to each other. This projecting orifice was fitted into the canal, which was divided into 5 equal parts of 21 feet each, and also into 3 equal parts of 35, and the time was noted which the water employed in reaching these points of division. The arrival of the water at these points was signified by the motion of a very small water wheel placed at each, and impelled by the stream. When the canal was horizontal, the following results were obtained.

215. It appears from column 1st, that the times successively employed to run through spaces of 21 feet each, are as the numbers 2, 3-, 5, 6, 7+-, which form nearly an arithmetical progression, whose terms differ nearly by 1, so that by continuing the progression, we may determine very nearly the time in which the fluid would run through.
HYDRODYNAMICS.

Experiments on the Motion of Fluids.

If we compute theoretically the time which the water should employ in running through the whole length of the canal, or 105 feet, we shall find, that under the circumstances of each column of the preceding table the times, reckoning from the first column, are 6.35, 7.34, 11.35, 6.35, 7.34, 11.35. It appears, therefore, by comparing these times with those found by experiment, that the velocity of the stream is very much retarded by friction, and that this retardation is less as the breadth of the orifice is increased; for since a greater quantity of water issues in this case from the reservoir, it has more power to overcome the obstacles which obstruct its progress. The signs + and — affixed to the numbers in the preceding table indicate, that these numbers are a little too great or too small.

216. The following experiments were made on inclined canals with different declivities, and will be of the greatest use to the practical hydraulist. The inclination of the canal is the vertical distance of one of its extremities from a horizontal line which passes through its other extremity.

Time in which the number of feet in the last column is run through by the water.
Chapter II.

HYDRODYNAMICS.

217. In the preceding experiments the velocity of the first portion of water that issues from the reservoir was only observed; but when the current is once established, and its velocity permanent, it moves with greater rapidity, and there is always a fixed proportion between the velocity of the first portion of water and the permanent velocity of the established current. The cause of this difference Bossut does not seem to have thoroughly comprehended, when he ascribes it to a diminution of friction when the velocity becomes permanent. The velocity of the first portion of water that issues from the reservoir was measured by its arrival at certain divisions of the canal, consequently the velocity thus determined was the mean velocity of the water. The velocity of the established current, on the contrary, was measured by light bodies floating upon its surface, at the centre of the canal, therefore the velocity thus determined was the superficial velocity of the stream. But the velocity of the superficial central filaments must be the greatest of all, because being at the greatest distance from the sides and bottom of the canal they are less affected by friction than any of the adjacent or inferior filia to a different extent: the perincumbent fluid. The superficial velocity of the superficial current must of consequence be greater than its mean city having velocity, or, in other words, the velocity of the established current must exceed the velocity of the first-said portion of water. The following table contains the experiments of Bossut on this subject; the canal being of only the mean velocity, as in the former experiments, but 600 feet long, and its inclination one-tenth of the whole, or city in the 59.702 feet.

218. In all the experiments related in this chapter, and in those of the Chevalier Boat, which are given in the article Water-Works, the temperature of the water employed has never been taken into consideration. That the fluidity of water is increased by heat can scarcely admit of a doubt. Professor Leslie, in his ingenious paper on Capillary Action, has proved by experiment that a jet of warm water will spring much higher than a jet of cold water, and that a syphon which discharges cold water only by drops, will discharge water of a high temperature in a continued stream. A similar fact was observed by the ancients. Plutarch (1) says in particular assures us, that the clepsydras or water clocks went slower in winter than in summer, and be cold water. The ancients were of opinion that the quantities of fluid discharged from the syphon, were less with cold water, and, as they were of opinion, that the temperature of the fluid, being greater, increased the fluidity of the fluid. It is therefore obvious, that warm water will issue from a syphon with greater velocity than cold water, and that the quantities of fluid discharged from the same orifice, and under the same pressure, will increase with the temperature of the fluid. Hence we may discover the cause of the great discrepancy between the experiments of different philosophers on the motion of fluids.

(1) Ελάχιστα γεγονότα προσέχοντα τού άει οὐκ εἶναι κατάλληλα, ἢ ἡ σχετικὴς κατάλογος, ἢ τὸν ἁναφόρον συνεργὸν, ὅτι οὕτως ἐνεργεῖ ἡ φυσικὴ. Αὐγαμὸς εἰς κειστὸν ὅτι τὸς ἐκ τοῦ κελευθρίδου, μεταφρασθεὶς, άρης τὸν τρόπον ἔκχωρον. Tardius enim trahunt, koyne quam aequae.

Plutarch, Quaest. Natural.
HYDRODYNAMICS.

219. The writer of this article has a set of experiments in view, by which he expects to determine the precise effects of heat upon the motion of fluids, and to furnish the practical hydraulicist with a more correct formula than that of the Chevalier Buat, for finding, under any given circumstances, the velocity of water and the quantities discharged. He hopes also to be able to determine whether or not the friction of water in conduit pipes varies, as in the case of solid bodies, with the nature of the substances of which the pipes are formed; and to ascertain the effects of different natures of fluids in diminishing the resistance of friction. The result of these experiments will probably be communicated in a subsequent article of this work.

CHAP. III. On the Resistance of Fluids.

220. In the article Resistance of Fluids, the reader will find that important subject treated at great length, and with great ability, by the late learned Dr Robison. The researches of preceding philosophers are there given in full detail; their different theories are compared with experiments, and the defects of these minutely considered. Since that article was composed, this intricate subject has been investigated by other writers, and though they have not enriched the science of hydraulics with a legitimate theory of the resistance of fluids, the results of their labours cannot fail to be interesting to every philosopher.

221. The celebrated Coulomb has very successfully employed the principle of torsion, to determine the cohesion of fluids, and the laws of their resistance in very slow motions. His experiments are new, and were performed with the greatest accuracy; and the results which he obtained were perfectly conformable to the deductions of theory. We shall therefore endeavour to give the reader some idea of the discoveries which he has made.

222. When a body is struck by a fluid with a velocity exceeding eight or nine inches per second, the resistance has been found proportional to the square of the velocity, whether the body in motion strikes the fluid at rest, or the body is struck by the moving fluid. But when the velocity is so slow as not to exceed four-tenths of an inch in a second, the resistance is represented by two terms, one of which is proportional to the simple velocity, and the other to the square of the velocity. The first of these sources of resistance arises from the cohesion of the fluid particles which separate from one another, the number of particles thus separated being proportional to the velocity of the body. The other cause of resistance is the inertia of the particles, which, when struck by the fluid, acquire a certain degree of velocity proportional to the velocity of the body; and as the number of these particles is also proportional to that velocity, the resistance generated by the inertia must be proportional to the square of the velocity.

223. When Sir Isaac Newton was determining the resistance which the air opposed to the oscillatory motion of a globe in small oscillations, he employed a formula of three terms, one of them being as the square of the velocity, the second the square root of the velocity, and the third as the simple velocity; and in another part of the work he reduces the formula to two terms, one of which is as the square of the velocity, and the other constant. D. Bernouilli (Comment. Petropol. tom. iii. 1737 and 1742) also supposes the resistance to be represented by two terms, one as the square of the velocity, and the other constant. M. Gravesend (Elements of Nat. Phil. art. 1751), has found that the pressure of a fluid in motion against a body at rest, is partly proportional to the simple velocity, and partly to the square of the velocity. But when the body moves in a fluid at rest, he found (art. 1755) the resistance proportional to the square of the velocity, and to a constant quantity. When the body is in motion, therefore, meets the fluid at rest, these three philosophers have agreed, that the formula which represents the resistance of fluids consists of two terms, one of which is as the square of the velocity, and the other constant. The experiments of Coulomb, however, incontestably prove, that the pressure which the moving body in this case sustains, is represented by two terms, one proportional to the simple velocity, and the other to its square, and that if there is a constant quantity, it is so very small as to escape detection.

224. In order to apply the principle of torsion to the resistance of fluids, M. Coulomb made use of the apparatus represented in fig. 1. On the horizontal arm LK, which may be supported by a vertical stand, is fixed the small circle /e, perforated in the centre, so as to admit the cylindrical pin 0. Into a slit in the extremity of this pin is fastened, by means of a screw, the brass wire a, whose force of torsion is to be compared with the resistance of the fluid; and its lower extremity is fixed in the same way into a cylinder of copper g d, whose diameter is about four-tenths of an inch. The cylinder g d is perpendicular to the disc DS, whose circumference is divided into 480 equal parts. When this horizontal disc is at rest, which happens when the torsion of the brass wire is nothing, the index RS is placed upon the point o, the zero of the circular scale. The small rule R m may be elevated or depressed at pleasure round its axis 8, and the stand GH which supports it may be brought into any position round the horizontal disc. The lower extremity of the cylinder g d is immersed about two inches in the vessel of water MNP, and to the extremity d is attached the plate, or the bodies whose resistance is to be determined when they oscillate in the fluid by the torsion of the brass wire. In order to produce these oscillations, the disc DS, supported by both hands, must be turned gently round to a certain distance from the index, without disturbing the vertical position of the suspended wire. The disc is then left to itself; the force of torsion causes it to oscillate, and the successive diminutions of these oscillations are carefully observed. A simple formula gives in weights the force of torsion that produces the oscillations; and another formula well known to geometers, determines what an approximation sufficiently accurate in practice (by means of the successive diminution of the oscillations compared with their amplitude, what is the law of the resistance, relative to the velocity, which produces these diminutions.

225.
Chap. III.

HYDRODYNAMICS.

225. The method employed by Coulomb, in reducing his experiments, is similar to that adopted by Newton and other mathematicians, when they wished to determine the resistance of fluids, from the successive diminutions of the oscillations of a pendulum moving in a resisting medium; but it is much better fitted for detecting the small quantities which are to be estimated in such researches. When the pendulum is employed, the specific gravity of the body, relative to that of the fluid, must be determined; and the least error in this point leads to very uncertain results. When the pendulum is in different points of the arc in which it oscillates, the wire or pendulum rod is plunged more or less in the fluid; and the alterations which may result from this are frequently more considerable than the small quantities which are the object of research. It is only in small oscillations, too, that the force which brings the pendulum from the vertical, is proportional to the angle which the pendulum rod, in different positions, forms with this vertical line; a condition which is necessarily before the formula can be applied. But small oscillations are attended with great disadvantages; and their successive diminutions cannot be determined but by quantities which it is difficult to estimate exactly, and which are changed by the smallest motion either of the fluid in the vessel, or of the air in the chamber. In small velocities, the pendulum rod experiences a greater resistance at the point of floatation than at any other part. This resistance, too, is very changeable; for the water rises from its level along the pendulum rod to greater or less heights, according to the velocity of the pendulum.

226. These and other inconveniences which might be mentioned, are so inseparable from the use of the pendulum, that Newton and Bernoulli have not been able to determine the laws of the resistance of fluids in very slow motions. When the resistance of fluids is compared with the force of torsion, these disadvantages do not exist. The body is in this case entirely immersed in the fluid; and as every point of its surface oscillates in a horizontal plane, the relation between the density of the fluid and the oscillating body has no influence whatever on the moving force. One or two circles of amplitude may be given to the oscillations; and their duration may be increased at pleasure, either by diminishing the diameter of the wire, or increasing its length; or, which may be more convenient, by segmenting the momentum of the horizontal disc. Coulomb, however, found that when each oscillation was so long as to continue about 100 seconds, the least motion of the fluid, or the tremor occasioned by the passing of a carriage, produced a sensible alteration on the results. The oscillations best fitted for experiments of this kind, continued from 20 to 30 seconds, and the amplitude of those that gave the most regular results, was comprehended between 480 degrees, the entire division of the disc, and 8 or 10 divisions reckoned from the zero of the scale. From these observations it will be readily seen, that it is only in very slow motions that an oscillating body can be employed for determining the resistance of fluids. In small oscillations, or in quick circular motions, the fluid struck by the body is continually in motion; and when the oscillating body returns to its former position, its velocity is either increased or retarded by the motion communicated to the fluid, and not extinguished.

227. In the first set of experiments made by Coulomb, he attached to the lower extremity of the cylinder a circular plate of white iron, about 155 milli. velocity in metres in diameter, and made it move so slowly, that very small, the part of the resistance proportional to the square of the velocity, wholly disappeared. For it, in any particular case, the part of the resistance proportional to the square of the simple velocity, should be equal to the portion that the square is proportional to the square of the velocity when the velocity has a velocity of one-tenth of an inch per second; then, when the velocity is 100 tenths of an inch per second, the part proportional to the square of the velocity will be a hundred times greater than that proportional to the simple velocity; but if the velocity is only the 100th part of the tenth of an inch per second, then the part proportional to the simple velocity will be 100 times greater than the part proportional to the square of the velocity.

228. When the oscillations of the white iron plate result of were so slow, that the part of the resistance which varies with the second power of the velocity was greatly inferior to the other part, he found, from a variety of experiments, that the resistance which diminished the oscillation of the horizontal plate was uniformly proportional to the simple velocity, and that the other part of the plate moving round the resistance, which follows the ratio of the square of its centre in the velocity, produced no sensible change upon the motion of the plate of the white iron disc.—He found also, in its superposition with theory, that the moments of resistance in different circular plates moving round their centre in a fluid, are as the fourth power of the diameters of these circles; and that, when a circle of 195 millimetres (6.577 English inches) in diameter, moved round its centre in water, so that its circumference had a velocity of 140 millimetres (5.512 English inches) per second, the momentum of resistance which the fluid opposed to its circular motion was equal to one-tenth of a gramma (1.454 English troy grains) placed at the end of a lever 143 millimetres (5.63 English inches) in length.

229. M. Coulomb repeated the same experiments with the same object, in clarified oil, at the temperature of 16 degrees of Reseumur. He found, as before, that the moments of the resistance of different circles, moving round their centre in the plane of their supericies, were ratio be as the fourth power of their diameters; and that the difficulty with which the same horizontal plate, moving with the same velocity, separated the particles of oil, was to the difficulty with which it separated the particles of oil, waters, as 17.5 to 1, which is therefore the ratio and the mutual cohesion that the mutual cohesion of the particles of oil has to the mutual cohesion of the particles of water.

230. In order to ascertain whether or not the resistance of a body moving in a fluid was influenced by the resistance of its surface, M. Coulomb anointed the surface of the white iron plate with tallow, and wiped it partially by the edge of a linters plate, so that the thickness of the plate might not be sensibly increased. The plate was then made to move in the oscillating in water, and the oscillations were found to diminish in the same manner as before the application of the tallow. Over the surface of the tallow upon the plate, he afterwards scattered, by means of a sieve, a quantity
quantity of coarse sand which adhered to the greasy surface; but when the plate, thus prepared, was caused to oscillate, the augmentation of resistance was so small, that it could scarcely be appreciated. We may therefore conclude, that the part of the resistance which is proportional to the simple velocity, is owing to the mutual adhesion of the particles of the fluid, and not to the adhesion of these particles to the surface of the body.

232. If the part of the resistance varying with the simple velocity were increased when the white iron plate was immersed at greater depths in the water, we might suppose it to be owing to the friction of the water on the horizontal surface, which, like the friction of solid bodies, should be proportional to the superincumbent pressure. In order to settle this point, M. Coulomb made the white iron plate oscillate at the depth of two centimetres (7.87 English inches), and also at the depth of 50 centimetres (19.6855 English inches), and found no difference in the resistance; but as the surface of the water was loaded with the whole weight of the atmosphere, and as an additional load of 50 centimetres of water could scarcely produce a perceptible augmentation of the resistance, M. Coulomb employed another method of deciding the question. Having placed a vessel full of water under the receiver of an air-pump, the receiver being furnished with a rod and collar of leather at its top, he fixed to the hook, at the end of the rod, a harp-shaped wire, numbered 7 in commerce, and suspended to it a cylinder of copper, like the one in fig. 1, which plunged in the water of the vessel, and under this cylinder he fixed a circular plane, whose diameter was 101 millimetres (3.976 English inches). When the oscillations were finished, and consequently the force of torsion nothing, the zero of torsion was marked by the aid of an index fixed to the cylinder. The rod was then made to turn quickly round through a complete circle, which gave to the wire a complete circle of torsion, and the successive diminutions of the oscillations were carefully observed. The diminution for a complete circle of torsion was found to be nearly a fourth part of the circle for the first oscillation, but always the same whether the experiment was made in a vacuum or in the atmosphere. A small pallet 50 millimetres long (1.969 English inches) and 10 millimetres broad, (0.3937 English inches) which struck the water perpendicular to its plane, furnished a similar result. We may therefore conclude, that when a submerged body moves in a fluid, the pressure which it sustains, measured by the altitude of the superior fluid, does not perceptibly increase the resistance; and consequently, that the part of this resistance proportional to the simple velocity, can in no respect be compared with the friction of solid bodies, which is always proportional to the pressure.

233. The next object of M. Coulomb was to ascertain the resistance experienced by cylinders that moved very slowly, and perpendicular to their axes; but as the particles of fluid struck by the cylinder necessarily partook of its motion, it was impossible to neglect the part of the resistance proportional to the square of the velocity, and therefore he was obliged to perform the experiments in such a manner that both parts of the resistance might be computed. The three cylinders which he employed were 249 millimetres (9.803 English inches) long. The first cylinder was 0.87 millimetres (0.0342 English inches or \(\frac{1}{12}\) of an inch) in circumference; the second 11.2 millimetres (0.4409 English inches); and the third 21.1 millimetres (0.8307 English inches). They were fixed by their middle in the cylinder, piece of glass, so as to form two horizontal radii, whose length was 124.5 millimetres (4.901 English inches) or half the length of each cylinder.

After making the necessary experiments and computations, he found that the part of the resistance proportional to the simple velocity, which, to avoid confusion we shall call \(r\), did not vary with the circumstances of the cylinders. The circumferences of the first and third cylinders were to one another as 24:1; whereas the resistances were in the ratio of 3:1. The same conclusion was deduced by comparing the experiments made with the first and second cylinder.

234. In order to explain these results, M. Coulomb very justly supposes, that in consequence of the mutual adhesion of the particles of water, the motion of the cylinder is communicated to the particles at a small distance from it. The particles which touch the cylinder have the same velocity as the cylinder, those at a greater distance have a less velocity, and at the distance of about one-tenth of an inch the velocity ceases entirely, so that it is only at that distance from the cylinder that the mutual adhesion of the fluid molecules ceases to influence the resistance. The resistance \(r\) therefore should not be proportional to the circumference of the real cylinder, but to the circumference of a cylinder whose radius is greater than the real radius by one-tenth of an inch. It consequently becomes a matter of importance to determine with accuracy the quantity which must be added to the real radius in order to have the radius of the cylinder to which the resistance \(r\) is proportional, and from which it must be computed. Coulomb found the quantity by which the radius should be increased to be 1.5 millimetres (\(\frac{1}{32}\) of an English inch) so that the diameter of the augmented cylinder will exceed the diameter of the real cylinder by double that quantity, or \(\frac{1}{16}\) of an inch.

235. The part of the resistance varying with the square of the velocity, or that arising from the inertia of the fluid, which we shall call \(R\), was likewise found to be proportional to the circumferences of the cylinder; but the augmentation of the radii amounts in this case only to \(\frac{1}{32}\) of an inch, which is only one-fifth of the augmentation necessary for finding the resistance \(r\). The reason of this difference is obvious; all the particles of the fluid when they are separated from each other acquire the same resistance, whatever be their velocity; consequently as the value of \(r\) depends only on the adhesion of the particles, the resistances due to this adhesion will reach to the distance from the cylinder where the velocity of the particles is 0. In comparing the different values of \(R\), the part of the resistance which varies as the square of the velocity, all the particles are supposed to have a velocity equal to that of the cylinder; but as it is only the particles which touch the cylinder that have this velocity, it follows that the augmentation of the diameter necessary for finding \(R\) must be less than the augmentation necessary for finding \(r\).
HYDRODYNAMICS.

On the resistance of fluids. The result may be deduced from theory; for supposing each cylinder divided into any number of parts, the length of each part will be proportional to the whole length. The velocity of the corresponding parts will be as these lengths, and also as the distance from the parts from the centre of rotation. The theory likewise proves, that the momentum of resistance depending on the square of the velocity, in two cylinders of the same diameter but of different lengths, is proportional to the fourth power of the length of the cylinder.

236. When the cylinder is 0.9803 inches in length, and 0.04406 inches in circumference, was made to oscillate in the fluid with a velocity of 5.51 inches per second, the part of the resistance was equal to 58 milligrams, or 0.00414 grammes, of 0.677 Troy grains.

237. The preceding experiments were also made in the oil formerly mentioned; and it likewise appeared, from their results, that the mutual adhesion of the particles of oil was to the mutual adhesion of the particles of water as 17 to 1. But though this be the case, Mr. Coulomb discovered that the quantity by which the radii of the cylinder must be augmented in order to have the resistance of the cylinder oscillated in water. This result was very unexpected, as the greater adhesion between the particles of oil might have led us to anticipate a much greater augmentation. When the cylinders oscillated both in oil and water with the same velocity, the part of the resistance produced by the inertia of the fluid particles which the cylinder put in motion, was almost the same in both. As this part of the resistance depends on the quantity of particles put in motion, and not on their adhesion, the resistance due to the inertia of the particles will be in different fluids as their densities.

238. In a subsequent memoir, Coulomb proposes to determine numerically the part of the resistance proportional to the square of the velocity, and to ascertain the resistance of globes with plain, convex, and concave surfaces. He has found in general that the resistance of solids not entirely immersed in the fluid is much greater than that of bodies which are wholly immersed; and he promises to make further experiments upon this point.

We intended on the present occasion to have given the reader a more complete view of the researches of this ingenious philosopher; but these could not well be understood without a knowledge of his investigations respecting the force of torsion, which we have not yet had an opportunity of communicating. In the article MECHANICS, however, we shall introduce the reader to this interesting subject; and may afterwards have an opportunity of making him farther acquainted with those researches of Coulomb, of which we have at present given only a general view.

239. The subject of the resistance of fluids has been recently treated by the learned Dr. Hutton of Woolwich, of Dr. Hutton's experiments were made in air, with bodies of various forms, moving with different velocities, and inclined at various angles to the direction of their motion. The following table contains the results of many interesting experiments. The numbers in the 9th column represent the exponents of the power of the velocity which the resistances in the 8th column bear to each other.

Vol. X, Part II.
HYDRODYNAMICS.

On the Resistance of Fluids.

Results of the preceding experiments.

1. That the resistance is nearly proportional to the surfaces, a small increase taking place when the surfaces and the velocities are great.
2. The resistance to the same surface moving with different velocities, is nearly as the square of the velocity, but it appears from the 9th column that the resistance increases with the velocity.
3. The round and sharp ends of solids sustain a greater resistance than the flat ends of the same diameter.
4. The resistance to the base of the hemisphere is to the resistance on the convex side, of the whole sphere, as $2^{3/4}$ to 1, instead of 2 to 1, as given by theory.
5. The resistance on the base of the cone is to the resistance on the vertex nearly as 2 to 1; and in the same ratio is radius to the sine of half the angle at the vertex. Hence in this case the resistance is directly as the sine of the angle of incidence, the transverse section being the same.
6. The resistance of the base of a hemisphere, the base of a cone, and the base of a cylinder, are all different, though these bases be exactly equal and similar.

244. The following table contains the resistance sustained by a globe 1.065 inches in diameter. The fourth column is the quotient of the resistance by experiment, divided by the theoretical resistance.

242. It appears from a comparison of the 2d, 3d, and 4th columns, that when the velocity is small the resistance by experiment is nearly equal to that deduced from theory; but that as the velocity increases, the former gradually exceeds the latter till the velocity is 1300 feet per second, when it becomes twice as great. The difference between the two resistances then increase, and reaches its maximum between the velocities of 1600 and 1700 feet. It afterwards decreases gradually as the velocity increases, and at the velocity of 2000 the resistance by experiment is again double of the theoretical resistance. By considering the numbers in column 5th it will be seen, that in slow motions the resistances are nearly as the squares of the velocities; that this ratio increases gradually, though not regularly, till at the velocity of 1500 or 1600 feet it arrives at its maximum. It then gradually diminishes as the velocity increases.

Conclusions similar to these were deduced from experiments made with globes of a larger size.

243. The following table contains the resistance of a plane inclined at various angles, according to experiment, and according to a formula deduced from the experiments.

244. The plane with which the preceding experiments were performed was 32 square inches, and always moved with a velocity of 12 feet per second. The resistances which this plane experienced are contained in column 2d. From the numbers in that column Dr. Hutton deduced the formula $\frac{8R^2\sin^2\theta}{3}$, where $\theta$ is the sine, and $c$ is the cosine of the angles of inclination in the first column. The resistances computed from this formula are contained in column 3d, and agrees very nearly.
Chap. III.

HYDRODYNAMICS.

On the Resistance of Fluids.

The 4th column contains the sines of the angles in the first column to a radius .84, in order to compare them with the resistances which have obviously no relation either to the sines of the angles or to any power of the sines. From the angle of 0° to about 60° the resistances are less than the sines; but from 60° to 90° they are somewhat greater.

245. The experiments of Mr. Vince were made with bodies at a considerable depth below the surface of water; and he determined the resistance which they experienced, both when they moved in the fluid at rest, and when they received the impulse of the moving fluid. In the experiments contained in the following table, the body moved in the fluid with a velocity of 0.66 feet in a second. The angles at which the planes struck the fluid are contained in the first column. The second column shows the resistance by experiment in the direction of their motion in troy ounces. The third column exhibits the resistance by theory, the perpendicular distance being supposed the same as by experiment. The fourth column shows the power of the sine of the angle to which the resistance is proportional, and was computed in the following manner. Let \( \theta \) be the sine of the angle, \( r \) the radius being \( x \), and \( r \) the resistance at that angle. Suppose \( r \) to vary as \( \theta ^{n} \), then we have \( r^{n} = 0.2321 : r ; \) hence \( n = \frac{\log r}{\log 0.2321} \), and therefore \( n = \frac{\log r}{\log 0.2321} \), and by substituting their corresponding values, instead of \( r \) and \( n \) we shall have the values of \( m \) or the numbers in the fourth column.

246. According to the theory the resistance should vary as the cube of the sine, whereas from an angle of 90° it decreases in a less ratio, but not as any constant power, nor as any function of the sine and cosine. Hence the actual resistance always exceeds that which is deduced from theory, assuming the perpendicular resistance to be the same. The cause of this difference is partly owing to our theory neglecting that part of the force which acts upon the plane.

247. Mr. Vince made also a number of experiments on the resistance of hemispheres, globes, and cylinders, moved with a velocity of 0.542 feet per second. He found that the resistance to the spherical side of a hemisphere was to the resistance of a cylinder of the same diameter, and moving with the same velocity, as 0.083393 is to 0.08339; that the resistance to a complete globe is to the resistance of a cylinder of the same diameter, and with the same velocity, as 1 : 2.23.

248. The following results were obtained, when the Determining-plane was struck by the moving fluid. The 2d column of the following table contains the resistance by experiment, and the 3d column the resistance by theory from one body is the perpendicular force, supposing it to vary as the sine struck by of the inclination.

249. It appears from the preceding results, that the resistance varies as the sine of the angle at which the fluid strikes the plane, the difference between theory and experiment being such as might be expected from the necessary inaccuracy of the experiments.

By comparing the preceding table with Table IV. it will be found that the resistance of a plane moving in a fluid is to the resistance of the same plane when struck by the fluid in motion as 5 to 6. In both these cases the actual effect on the plane must be the same, and therefore the difference in the resistance can arise only from the action of the fluid behind the body in the former case.

Chap. IV. On the Oscillation of Fluids, and the Undulation of Water.

Prop. I.

250. The oscillations of water in a syphon, consisting of two vertical branches and a horizontal cilia of one, are isochronous, and have the same duration in a syphon.
HYDRODYNAMICS.

Oscillation of Fluids, &c.

Plate CCLXIX.

Fig. 2.

Into the tube MNOP, having its internal diameter everywhere the same, introduce a quantity of water. When the water is in equilibrio, the two surfaces AB, CD will be in the same horizontal line AD. If this equilibrio be disturbed by making the syphon oscillate round the point y, the water will rise and fall alternately in the vertical branches after the syphon is at rest. Suppose the water to rise to EF in the branch MO, it will evidently fall to GH in the other branch, so that CG is equal to AE. Then it is evident, that the force which makes the water oscillate, is the weight of the column EFKL, which is double the column EABF; and that this force is to the whole weight of the water, as $2AE$ is to $AOPD$. Now, let $P$ be a pendulum, whose length is equal to half the length of the oscillating column $AOPD$, and which describes to the lowest point $S$ arches $PS$, equal to $AE$; then $2AE: AOPD=AE:QP$, because $AE$ is one-half of $2AE$, and $QP$ one-half of $AOPD$. Consequently, since $AOPD$ is a constant quantity, the force which makes the water oscillate is always proportional to the space which it runs through, and its oscillations are therefore isochrones. The force which makes the pendulum describe the arch $PS$, is to the weight of the pendulum as $PS$ is to $PQ$, or as $AE$ is to $PQ$, since $AE=PS$; but the force which makes the water oscillate, is to the weight of the whole water in the same ratio; consequently, since the pendulum $P$, and the column $AOPD$, are influenced by the very same force, their oscillations must be performed in the same time. Q. E. D.

251. Cor. As the oscillations of water and of pendulums are regulated by the same laws, if the oscillating column of water is increased or diminished, the time in which the oscillations are performed will increase or diminish in the subduplicate ratio of the length of the pendulum.

Scholium.

254. The explanation of the oscillation of waves contained in the two preceding propositions, was first given by Sir Isaac Newton, in his Principia, lib. ii. Prop. 44.

He considered it only as an approximation to the truth, since it supposes the waves to rise and fall perpendicularly like the water in the vertical branches of the syphon, while their real motion is partly circular. The theory of Newton was, nevertheless, adopted by succeeding philosophers, and gave rise to many analogous discussions respecting the undulation of waves. Very recently, however, an attempt has been made by M. Flaugergues, to overturn the theory of Newton. From a number of experiments on the motion and figure of water waves, an account of which may be seen in the Journal des Scavans, for October 1789, M. Flaugergues concludes, that a wave is not the result of a motion in the particles of water, by which they ascend and descend alternately in a serpentine line, when moving from the place where the water received the shock; but that it is an intumescence which this shock occasions around the place where it is received, by the depression that is there produced. This intumescence afterwards propagates itself circularly, while it removes from the place where the shock first raised it above the level of the stagnant water. A portion of the stagnant water then flows from all sides into the hollow formed at the place where the shock was received; this hollow is thus heaped with fluid, and the water is elevated so as to produce all around another intumescence, or a new wave, which propagates itself circularly as before. The repetition of this effect produces on the surface of the water a number of concentric rings, successively elevated and depressed, which have the appearance of an undulatory motion. This interesting subject has also been discussed by M. La Grange, in his Mécanique Analytique, to which we must refer the reader for further information. See also some excellent remarks on this subject, in Mr Leslie's Essay on Heat, p. 223, and note 29.

PART II. The undulations of waves are performed in the same time as the oscillations of a pendulum whose length is equal to the breadth of a wave, or to the distance between two neighbouring cavities or eminences.

Fig. 4.

In the waves ABCDE, the undulations are performed in such a manner, that the highest parts A, C, E become the lowest; and as the force which depresses the eminences A, C, E, is always the weight of water contained in these eminences, it is obvious, that the undulations of waves are of the same kind as the undulations or oscillations of water in a syphon. It follows, therefore, from Prop. I., that if we take a pendulum, whose length is one-half BM, or half the distance between the highest and lowest parts of the wave, the highest parts of each wave will descend to the lowest parts during one oscillation of the pendulum, and in the time of another oscillation will again become the highest parts. The pendulum, therefore, will perform two oscillations in the time that each wave performs one undulation, that is, in the time that each wave describes the space AC or BD, between two neighbouring eminences or cavities, which is called the breadth of the wave. Now if a pendulum, whose length is one-half BM, performs two oscillations in the above time, it will require a pendulum four times that length to perform only one oscillation in the same time, that is, a pendulum whose length is AC or BD, since $4 \times \frac{1}{2} BM = 2BM = AC$ or $BD$. Q. E. D.
HYDRODYNAMICS.

PART III. ON HYDRAULIC MACHINERY.

255. TO describe the various machines in which water is the impelling power, would be an endless and unprofitable task. Those machines which can be driven by wind, steam, and the force of men or horses, as well as they can be driven by water, do not properly belong to the science of hydraulics. By hydraulic machinery, therefore, we are to understand those various contrivances by which water can be employed as the impelling power of machinery; and those machines which are employed to raise water, or which could not operate without the assistance of that fluid.

CHAP. I. On Water-Wheels.

Different kinds of water-wheels.

256. WATER-WHEELS are divided into three kinds, overshot-wheels, breast-wheels, and undershot-wheels, which derive their names from the manner in which the water is delivered upon their circumferences.

Sect. I. On Overshot-Wheels.

Description of an overshot-wheel Plate CCLXIX. Fig. 1.

257. An overshot-wheel is a wheel driven by the weight of water, conveyed into buckets disposed on its circumference. It is represented in fig. 5, where ABC is the circumference of the wheel furnished with a number of buckets. The canal MN conveys the water into the bucket from the top A or. The equilibrium of the wheel is therefore destroyed; and the power of the bucket A or, to turn the wheel round its centre of motion O, is the same as if the weight of the water in the bucket were suspended at m, the extremity of the lever O m, c being the centre of gravity of the bucket, and O m a perpendicular let fall from the fulcrum O to the direction c m, in which the force is exerted. In consequence of this destruction of equilibrium, the wheel will move round in the direction AB, the bucket A or will be at d, and the empty bucket b will take the place of A or, and receive water from the spout N. The force acting on the wheel is now the water in the bucket d acting with a lever n O, and the water in the bucket A or acting with a lever m O. The velocity of the wheel will therefore increase with the number of loaded buckets, and with their distance from the vertex of the wheel; for the lever by which they tend to turn the wheel about its axis, increases as the buckets approach to c, when their power, represented by c O, is a maximum. After the buckets have passed c, the lever by which they act gradually diminishes, they lose by degrees a small portion of their water; and as soon as they reach B it is completely discharged. When the wheel begins to move, its velocity will increase rapidly till the quadrant of buckets b e is completely filled. While these buckets are descending through the inferior quadrant e P, and the buckets on the left hand of b are receiving water from the spout, the velocity of the wheel will still increase; but the increments of velocity will be smaller and smaller, since the levers by which the inferior buckets act are gradually diminishing. As soon as the highest bucket A c has reached the point B where it is emptied, the whole se-
HYDRODYNAMICS.

On Water-Wheels.

259. In the construction of **overshot-wheels**, it is of great importance to determine what should be the diameter of the wheel relatively to the height of the fall. It is evident that its diameter cannot exceed the height of the fall. Some mechanical writers have demonstrated that, in theory, an **overshot-wheel** will produce a maximum effect when its diameter is two-thirds of that height, the water being supposed to fall into the buckets with the velocity of the wheel. But this rule is palpably erroneous, and directly repugnant to the results of experiment. For if the height of the fall be 48 feet, the diameter of the wheel will, according to this rule, be 32 feet; and the water having to fall through 16 feet before it reaches the buckets, will have a velocity of 32 feet per second, which, according to the hypothesis, must also be the velocity of the wheel's circumference. But Smeaton has proved, that a maximum effect is produced by an overshot-wheel of any diameter, when its velocity is only three feet per second. The chevalier de Borda has shown, that overshot-wheels will produce a maximum effect when their diameter is equal to the height of the fall; and this is completely confirmed by Mr. Smeaton's experiments. From a great number of trials, Mr. Smeaton has concluded, "that the higher the wheel is in proportion to the whole descent, the greater will be the effect." Nor is it difficult to assign the reason of this. The water which is conveyed into the buckets can produce very little effect by its impulse, even if its velocity be great; both on account of the obliquity with which it strikes the buckets, and in consequence of the loss of water occasioned by a considerable quantity of the fluid being dashed over their sides. Instead, therefore, of expecting an increase of effect from the impulse of the water occasioned by its fall through one-third of the whole height, we should allow it to act through this height by its gravity, and therefore make the diameter of the wheel as great as possible. But a disadvantage attends even this rule; for if the water is conveyed into the buckets without any velocity, which must be the case when the diameter of the wheel equals the height of the fall, the velocity of the wheel will be retarded by the impulse of the buckets against the water, and much power would be lost by the water dashingly over them. In order, therefore, to avoid all inconveniences, the distance of the spout from the receiving bucket should, in general, be about two or three inches, that the water may be delivered with a velocity a little greater than that of the wheel; or, in other words, the diameter of an overshot-wheel should be two or three inches less than the greatest height of the fall; and yet it is no uncommon thing to see the diameters of these wheels scarcely one-half of that height. In such a construction the loss of power is prodigious.

3. When the large cylinders were used, the velocity of the wheel was smaller, because the resistances are proportional to their diameter, the weight being the same. Hence, it appears, by comparing the four results in column 2d with one another, and also the four results in column 3d, that when the wheel turns more slowly, the effect, which is in this case measured by the elevation of the weight, always increases. When the weight of 24 ounces was used, the resistance was twice as great, and the velocity twice as slow, as when the 12 ounce weight was employed. But by comparing the results in column 2d with the corresponding results in column 3d, it appears, that when the 24 ounce weight was employed, and the velocity was only one-half of what it was when the 12 ounce weight was used, the effect was more than one-half, the numbers in the 3d column being more than one-half the numbers in the 2d. Hence we may conclude, that the slower an overshot-wheel moves, the greater will be its performance.

262. These experiments of Deparcieux presented such unexpected results, as to induce other philosophers to examine them with care. The chevalier d'Arcy, in particular, considered them attentively. He maintained that there was a determinate velocity when the effect of the wheel reached its maximum; and he has shewn, by comparing the experiments of Deparcieux with his own formula, that the overshot-wheel which Deparcieux employed never moved with such a small velocity as corresponded with the maximum effect, and that [if]
HYDRODYNAMICS.

On Water-Wheels.

263. The reasoning of the chevalier d'Arcy is completely confirmed by the experiments of Smeaton. This celebrated engineer concludes with Deparcieux that, ceteris paribus, the less the velocity of the wheel, the greater will be its effect. But he observes, on the contrary, that when the wheel of his model made about 30 turns in a minute, the effect was nearly the greatest; when it made 30 turns, the effect was diminished about one-twentieth part; and that when it made 40 it was diminished about one-fourth; when it made less than 18½ turns, its motion was irregular, and when it was loaded so that it could not make 18 turns, the wheel was overpowered by its load. Mr. Smeaton likewise observes, that when the circumferences of overshot wheels, whether high or low, move with the velocity of three feet per second, and when the other parts of the work are properly adapted to it, they will produce the greatest possible effect. He allows, however, that high wheels may deviate farther from this rule before losing their power than low ones can be permitted to do; and assures us that he has seen a wheel 24 feet high moving at the rate of six feet per second, without losing any considerable part of its power, and likewise a wheel 33 feet high moving very steadily and well with a velocity but little exceeding two feet.

264. The experiments of the abbé Bossut may also be brought forward in support of the same reasoning. He employed a wheel 3 feet in diameter, furnished with 48 buckets, having each three inches of depth, and four inches of width. The canal which conveyed the water into the buckets was perfectly horizontal, and was five inches wide. It furnished uniformly 1194 cubic inches of water in a minute. The resistance to be overcome was a variety of weights fixed to the extremity of a cord, which, after passing over a pulley as in Deparcieux's experiments, wound round the cylindrical axle of the wheel. The diameter of this cylinder was two inches and seven lines, and that of the gudgeons or pivots of the wheel two lines and a half. The number of turns which the wheel made in a minute was not reckoned till its motion became uniform, which always happened when it had performed five or six revolutions. When the wheel was unloaded it made 40½ turns in a minute.

</tbody>
</table>

265. It appears evidently from the last column, which we have computed on purpose, that the effect increases as the velocity diminishes; but that the effect is a maximum when the number of turns is 8½ in a minute, being then 139½. When the velocity was farther diminished by adding an additional pound to the resistance, the effect was diminished to 138, and when the velocity was still less, the wheel ceased to move.

Now since the wheel was three feet in diameter, and 9.42 feet in circumference, the velocity of its circumference will be about one foot four inches per second, when it performs 8½ turns in a minute, or when the maximum effect is produced. With Mr. Smeaton's model, the maximum effect was produced when the velocity of the wheel's circumference was two feet per second. So that the experiments both of Smeaton and Bossut concur to prove, that the power of overshot wheels increases as the velocity diminishes; but that there is a certain velocity, between one and two feet per second, when the wheel produces a maximum effect. Since when the wheel was unloaded it turned 40½ times in a minute, and performed only 8½ revolutions when its power was a maximum, the velocity of the wheel when unloaded will be to its velocity when the effect is the greatest, as five to one, nearly.

266. The chevalier de Borda maintains that an overshot wheel will raise through the height of the fall a foot of quantity of water equal to that by which it is driven, overshot. And Albert Euler has shown that the effect of these wheels is very much inferior to the momentum or force which imparts them. It appears, however, from Mr. Smeaton's experiments, that when the work performed was a maximum, the ratio of the power to the effect was as four to three, when the height of the fall
HYDRODYNAMICS.

On Water-wheels.

On Water, fall and the quantities of water expended were the least; but that it was as four to two when the heights of the fall and the quantities discharged were the greatest. By taking a mean between these ratios, we may conclude, in general, that in overshot wheels the power is to the effect as three to one. In this case the power is supposed to be computed from the whole height of the fall; because the water must be raised to that height in order to be in a condition of producing the same effect a second time. When the power of the water is estimated only from the height of the wheel, the ratio of the power to the effect was more constant, being nearly as five to four.

Investigations of Albert Euler.

267. The theory of overshot wheels has been ably discussed by Albert Euler, and Lambert. The former of these philosophers has shown that the altitude of the wheel should be made as great as possible; that the buckets should be made as capacious as other circumstances will permit; that their form should be such as to convey the water as near the lowest point of the wheel as can be conveniently done; and that the motion of the wheel should be slow, that the buckets may be completely filled. He has likewise shown that the effect of the wheel increases as its velocity is diminished; and that overshot wheels should be used only when there is a sufficient height of fall. The results of Lambert's investigations are less consonant with the experiments of Smeaton. By examining the following table, which contains these results, it will appear at once that he makes the diameter of the wheel much smaller than it ought to be.

SECT. II. On Breast Wheels.

268. A breast wheel partakes of the nature both of an overshot and an undershot wheel, and is driven partly by the impulse, but chiefly by the weight of the water. A water wheel of this kind is represented in fig. 6. where MC is the stream of water falling on the floatboard α, with a velocity corresponding to the altitude m m, and afterwards acting by its weight on the floatboards between o and B. The mill course o B is made concentric with the wheel, which is fitted to it in such a manner that very little water is allowed to escape at the sides and extremities of the floatboards. According to Mr. Smeaton, the effect of a wheel driven in this manner is equal to the effect of an undershot wheel whose head of water is equal to the difference of level between the surface of water in the reservoir, and the point where it strikes the wheel, added to that of an overshot whose height is equal to the difference of level between the point where it strikes the wheel and the level of the tail water (m). That is, the effect of the wheel A is equal to that of an undershot wheel driven by a fall of water equal to m m, added to that of an overshot wheel whose height is equal to n D.

269. Mr. Lambert of the academy of sciences at Ber- lin (n) has shown that when the floatboards arrive at the position Ω, they ought to be horizontal: the point p should be lower than Ω, in order that the whole space between any two adjacent floatboards may be filled with water; and that C m should be equal to the depth of the floatboards. He observes also, that a breast wheel should be used when the fall of water is above four feet in height, and below ten. The following table is calculated from Lambert's formulæ, and exhibits at one view the results of his investigations.

</table>

270. It appears from the preceding table, that when the altitude of the fall of water is below three feet, there is such an unsuitable proportion between the depth and width of the floatboards, that a breast wheel cannot well be employed. It is also evident, on the other hand, that when the height of the fall approaches ten feet, the depth of the floatboards is too small in relation to their width. These two extremes, therefore, ought to be avoided in practice. The eleventh column of the table contains the quantity of water necessary to drive the wheel; but the total quantity of water should always exceed this, by the quantity, at least, that escapes between the mill course and the sides and extremities of the floatboards (0).

### Sect. III. On Undershot Wheels

272. An undershot wheel is a wheel with a number of floatboards disposed on its circumference, which receive the impulse of the water conveyed to the lowest point of the wheel by an inclined canal. It is represented in fig. 1, where WW is the water wheel, and ABDFHKMV the canal or mill course, which conveys the water to K, where it strikes the plane floatboards n, &c. and makes the wheel revolve about its axis.

273. In order to construct the mill course to the greatest advantage, we must give but a very small declivity to the canal which conducts the water from the river. It will be sufficient to make AB slope about one inch in 200 yards, making the declivity, however, about half an inch for the first 48 yards, in order that the water may have sufficient velocity to prevent it from falling back into the river. The inclination of the fall, represented by the angle GCR, should be 25° 30', or CR the radius should be to GR, the tangent of this angle, as 100 to 28, or as 25 to 12; and since the surface of the water 8b is bent from a b into a c before it is precipitated down the fall, it will be necessary to incurate the upper part BCD of the course into BD, that the water in the bottom may move parallel to the water at the surface of the stream. For this purpose take the points B, D about 12 inches distant from C, and raise the perpendiculars BE, DE. The point of intersection E will be the centre from which the arch BD is to be described; the radius being about 10½ inches. Now, in order that the water may act more advantageously upon the floatboards of the wheel WW, it must assume a horizontal direction, with the same velocity which it would have acquired when it came to the point G. But, if the water were allowed to fall from C to G, it would dash upon the horizontal part HG, and thus

---

**Dimensions of a Breast Wheel:**

271. The following are the dimensions of an excellent breast water wheel, differing very little from that which is represented in fig. 6. The water, however, instead of falling through the height c n which is 16 inches, is delivered on the floatboard o p, through an adjutage six inches and a half high. The height n D is four feet two inches; and therefore the whole height CD must be five feet and a half. The radius of the wheel AB is six feet and a half, the breadth of each floatboard six inches and a half, and their depth 28 inches. The point P of the wheel moves with the velocity of 7.588 feet in a second. The quantity of water discharged in a second is 3.266 cubic feet, and the force of impulse upon the floatboards 356 pounds avoidopias. On some occasions buckets have been used in breast wheels instead of floatboards; but this is evidently a disadvantage, as the height through which the water acts is diminished by the number of inches through which the water must fall in order to acquire the velocity of the wheel, and also by the versed sine of the arch above the lowest point of the wheel which may be considered as not loaded with water.

---

HYDRODYNAMICS.

273. It has been disputed among philosophers, whether the wheel should be furnished with a small or a great number of floatboards. M. Pitot has shown that when the floatboards have different degrees of obliquity, the force of impulsion upon the different surfaces will be reciprocally as their breadths. Thus in fig. 3, the force of impulsion upon $\alpha e$ will be to the force upon DO, as DO to $\alpha e$ ($p$). Hence he concludes that the distance between the floatboards should be equal to one-half of the immersed arch, or that wise one floatboard is at the bottom of the wheel, and perpendicular to the current, as DE, the preceding floatboard BC should be just leaving the stream, and the succeeding one FG just immersing into it. For when the three floatboards FG, DE, BC have the same position as in the figure, the whole force of the current NM will act upon DE when it is in the most advantageous position for receiving it, whereas, if another floatboard $de$ were inserted between FG and DE, the part $fg$ would cover DO, and by thus substituting an oblique for a perpendicular surface, the effect would be diminished in the proportion of DO to $fg$. Hence it is evident that, upon this principle, the depth of the floatboard DE should be always equal to the versed sine of the arch EG ($q$).

274. Notwithstanding the plausibility of this reasoning, it will not be difficult to shew that it is destined to a mercenary foundation. It is evident from fig. 3, that when one of the floatboards DE is perpendicular to the stream, it receives the whole impulse of the water in the most advantageous manner. But when it arrives at the position $de$, and the succeeding one $FG$ at the position $fg$, so that the angle $eAg$ may be bisected by the perpendicular $AE$; the situation of these floatboards will be the most disadvantageous, for a great part of the water will escape between the extremities $g$ and $e$ of the floatboards without striking them, and the part $y$ of the floatboard, which is really impelled, is less than DE, and oblique to the current. The wheel, therefore, must move irregularly, sometimes quick and sometimes slowly, according to the position of the floatboards with respect to the stream: and this inequality will increase with the arch plunged in the water. The reasoning of M. Pitot, indeed, is founded on the supposition, that if another floatboard $fg$ were placed between FG and DF it would annihilate the force of the water that impels it, and prevent any of the fluid from striking the corresponding part DO of the preceding floatboard. But this is not the case. For when the water has acted upon $fg$, it still retains a part of its motion, and after bending round the extremity $g$ strikes DE with its remaining force. We are entitled, therefore, to conclude that advantage must be gained by using more floatboards than are recommended by Pitot.

275. It is evident from the preceding remarks, that in order to remove any inequality of motion in the wheel and prevent the water from escaping below the extremities of the floatboards, the wheel should be furnished with the greatest possible number of floatboards, without loading it too much, or enforcing the rim on which they are

---

(q) A table containing the number of floatboards for wheels of different diameters, and founded on this principle, has been computed by Mr Brewster. See Appendix to Ferguson's Lectures, vol. ii. p. 149. 2d Edit.
Chapter I.

HYDRODYNAMICS.

In Water-works. This rule was first given by M. Dupérite, and it is easily perceived, that the mill-wheel should be in using too many floatboards, this error in excess will be perfectly trifling, and that a much greater loss of power would be occasioned by an error in defect.

276. The section of the floatboards ought not to be rectangular like abcd in fig. 3, but should be bevelled like a b c. For if they were rectangular, the extremity b n would interrupt a portion of the water which would otherwise fall on the corresponding part of the preceding floatboard. In order to find the angle abm, subtract from 180 degrees the number of degrees contained in the immersed arch c eg, and the half of the remainder will be the angle required.

277. It has been maintained by M. Pitot and other philosophers, that the floatboards should be a continuation of the radius, or perpendicular to the rim, as in fig. 1. This indeed is true in theory; but it appears from the most unquestionable experiments, that they should be inclined to the radius. This important fact was discovered by Deprazier in 1753, and proved by several experiments. When the floatboards are inclined, the water heeps up on their surface, and acts not only by its impulse but also by its weight. The same truth has also been confirmed by the abbé Bossut, the most accurate of whose experiments are contained in the following table. The wheel that was employed was immersed four inches vertically in the water, and it was furnished with 12 floatboards.

278. It is obvious, from the preceding table, that the wheel made the greatest number of turns, or moved with the greatest velocity, when the number of floatboards was between 15 and 30. When the water-wheels are placed on canals that have little declivity, and in which the water can escape freely after its impulse upon the floatboards, it would be proper to make the floatboards a continuation of the radius. But when they move an inclined mill-course, an augmentation of velocity may be expected from an inclination of the floatboards.

279. Having thus pointed out the most scientific method of constructing the wheel, and delivering the water upon its floatboards, we have now to determine the velocity with which it should move. It is evident, that the velocity of the wheel must be always less than that of the water which impels it, even when there is no Water-work to be performed; for a part of the impelling power is necessarily spent in overcoming the inertia of the wheel and the resistance of friction. It is likewise obvious, that when the wheel has little or no velocity, its performance will be very trifling. There is, consequently, a certain proportion between the velocity of the water and the wheel, when its effect is a maximum. By the reasoning which is employed in the section on undershot wheels in the article Water-Works, Parent and Pinot found, that a maximum effect was produced when the velocity of the wheel was one-third of the velocity of the water; and Desaguliers (s) Maclaurin (t), Lambert (u), and Atwood (x), have adopted their conclusions. In the calculus from which this result was deduced, it was taken for granted, that the momentum or force of water upon the wheel is in the duplicate ratio of the relative velocity, or as the square of the difference between the velocity of the water and that of the wheel. This supposition, indeed, is perfectly correct, when the water impels a single floatboard; but of a current impelling for as the number of particles which strike the floatboard in a given time, and also the momentum of these, shot-wheel are each as the relative velocity of the floatboards, the is as the relative velocity, that is, $M = M^2$, $M = M^2$, and $M = M^2$.

The relative velocity. But we have seen, in some of the preceding paragraphs, that the water acts on more than one floatboard at a time. Now the number of floatboards acted upon in a given time will be as the velocity of the wheel, or inversely as the relative velocity; for if you increase the relative velocity, the velocity of the water remaining the same, you must diminish the velocity of the wheel. Consequently, we shall have $M = M^2$, or $M = M^2$; that is, the momentum of the water acting upon the wheel, is directly as the relative velocity.

280. Let $V$ be now the velocity of the stream, and $F$ the force with which it would strike the floatboard at rest, and $v$ the velocity of the wheel. Then the relative velocity will be $V - v$; and since the velocity of the water will be to its momentum, or the force with which it would strike the floatboard at rest, as the relative velocity is to the real force which the water exerts against the moving floatboards, we shall have $V : V - v = F : F \times \frac{V - v}{V} = F \times \frac{V - v}{V}$. But the effect of the wheel is measured by the product of the momentum of the water and the velocity of the wheel, consequently the effect of the undershot wheel will be $v \times F \times V = \frac{F \times V}{V} - v$. Now this effect is to be a maximum, and therefore its fluxion must be equal to 0, that is, $v$, being the variable quantity, $V \frac{dV}{dv} - 2v = 0$, or $2v = V$. Dividing by $v$, we have $2v = \frac{5E2}{V}$.

HYDRODYNAMICS.

772

Our Water-Wheels. \( v = \frac{V}{2} \), that is, the velocity of the wheel will be one half the velocity of the fluid when the effect is a maximum.

281. This result, which was first obtained by the chevalier de Borda, has been amply confirmed by the experiments of Mr. Smeaton. The velocity of the stream (say be) varies at the maximum between one-third and one-half that of the water; but in all the cases in which most work is performed in proportion to the water expended, and which approach the nearest to the circumstances of great works, when properly executed, the maximum lies much nearer one-half than one-third, one half seeming to be the true maximum, if nothing were lost by the resistance of the air, the scattering of the water carried up by the wheel, &c."

282. A result, nearly similar to this, was deduced from the experiments of Bossut. He employed a wheel whose diameter was three feet. The number of floatboards was at one time 48, and at another 24, their widths being five inches, and their depth six. The experiments with the wheel, when it had 48 floatboards, were made in an inclined canal, supplied from a reservoir by an arched two inches deep, the velocity being 300 feet in 27 seconds. The experiments with the wheel, when it had 24 floatboards, were made in a canal, contained between two vertical walls, 12 or 13 feet distant. The depth of the water was about seven or eight inches, and its mean velocity about 2740 inches in 40 seconds. The floatboards of the wheel were immersed about four inches in the stream.

</table>

283. As the effect of the machine is measured by the product of the load raised, and the time employed, it will appear, by multiplying the second and third columns, that the effect was a maximum when the load was 34 1/2 pounds, the wheel performing 20 2/3 revolutions in 40 seconds. By comparing the velocity of the centre of impression computed from the diame-

ter of the wheel, and the number of turns which it makes in 40 seconds, with the velocity of the current, we will find, that the velocity of the wheel, when its effect is the greatest possible, is nearly two-fifths that of the stream. From the two last columns of the table, where the effect is a maximum when the load is 60 pounds, the same conclusion may be deduced.

284. The proper velocity of the wheel being thus established, we shall proceed to point out the method of constructing a millwright's table for undershot wheels, taking it for granted, that the velocity of the wheel should be one-half the velocity of the stream, and that water moves with the same velocity as falling bodies.

1. Find the perpendicular height of the fall of water above the bottom of the mill-course, and having diminished this number by one-half the depth of the water at K, call that the height of the fall.

2. Since bodies acquire a velocity of 32.174 feet, by falling through the height of 16.087 feet, and as the velocities of falling bodies are as the square roots of the heights through which they fall, the square root of 16.087 will be to the square root of the height of the fall as 32.174 to a fourth number, which will be the velocity of the water. Therefore the velocity of the water may be always found by multiplying 32.174 by the square root of the height of the fall, and dividing that product by the square root of 16.087. Or it may be found more easily by multiplying the height of the fall by the constant quantity 64.348 = 2 \times 32.174, and extracting the square root of the product. This root, abstracting from the effects of friction, will be the velocity of the water required.

3. Take one-half the velocity of the water, and it will be the velocity which must be given to the floatboards, or the number of feet they must move through in a second, in order to produce a maximum effect.

4. Divide the circumference of the wheel by the velocity of its floatboards per second, and the quotient will be the number of seconds in which the wheel revolves.

5. Divide 60 by the number last found, and the quotient will be the number of revolutions made by the wheel in a minute. — Or the number of revolutions performed by the wheel in a minute may be found, by multiplying the velocity of the floatboards by 60, and dividing the product by the circumference of the wheel.

6. Divide 90, the number of revolutions which a millstone, five feet diameter, should make in a minute, by the number of revolutions made by the wheel in a minute; and the quotient will be the number of turns which the millstone ought to make for one revolution of the wheel.

7. Then as the number of revolutions of the wheel in a minute, is to the number of revolutions of the millstone in a minute, so must the number of staves in the trundle be to the number of teeth in the wheel, in the nearest whole numbers that can be found.

8. Multiply the number of revolutions performed by the wheel in a minute, by the number of revolutions made by the millstone for one of the wheel, and the product will be the number of revolutions made by the millstone in a minute.

285. By these rules, the following table has been completed.
### HYDRODYNAMICS

On Water, computed for a water wheel fifteen feet in diameter, which is a good medium size, the millstone being seven feet in diameter, and revolving 90 times in a minute.

286. The preceding table, computed by Mr. Brewer (Appendix to Ferguson's Lectures, vol. ii. p. 174), supposes, according to theory, that the velocity of the wheel, at the maximum effect, is one-half of that of the stream, which is nearly the case in practice, when the quantities of water discharged by the stream are considerable. When we consider, however, (observes the editor of the work now quoted), that after every precaution has been observed, a small quantity of water will escape between the mill course and the extremities of the floats, and that the effect is diminished by the resistance of the air and the dispersion of water carried up by the wheel, the propriety of making the wheel move with three-sevenths the velocity of the water will appear. The chevalier de Borda supposes it never to exceed three-eighths. Co Water Wheels.

And Mr. Steev hum and the abbe Bossut found two-fifths to be the proper medium (v). With three-sevenths, therefore, as the best medium, which differs only 7/32d from 3/4ths, the numbers in the following table have been computed. In Table I. the water was supposed to move with the same velocity as falling bodies, but owing to its friction on the mill-course, &c. this is not exactly the case. We have therefore deducted the velocity of the water in column second, from the following formula, \( V = \sqrt{\frac{772}{R \times b - \frac{H}{a}}}, \) Fig. 1. 3

in which \( V \) is the velocity of the water, \( R \) the absolute height of the fall, and \( H \) the depth of the water at the bottom of the course. The formula is founded on the experiments of Bossut, from which it appears, that if a canal be inclined one-tenth part of its length, this additional declivity will restore that velocity to the water which was destroyed by friction.

**Table II. A New Mill-Wright's Table, in which the Velocity of the Wheel is three-sevenths of the Velocity of the Water, and the effects of Friction on the Velocity of the stream reduced to computation.**

287. The great hydraulic machine at Marly was found to produce a maximum effect, when its velocity was two-fifths that of the stream.
HYDRODYNAMICS.

On Water-Wheels.

Method of using the table.

287. In order that the wheel may move with a velocity duly adjusted to that of the current, we would not advise the mechanic to trust to the second column of Table II. for the true velocity of the stream, or to any theoretical results, even when deduced from formulae founded on experiments. Bossut, with great justice, remarks, that "it would not be exact in practice to compute the velocity of a current from its declivity. This velocity ought to be determined by immediate experiment in every particular case." Let the velocity of the water, therefore, where it strikes the wheel, be determined by the method in the following paragraph. With this velocity, as an argument, enter column second of either of these tables, according as the velocity of the wheel is to be one-half or three-sevenths of that of the stream, and take out the other numbers from the table.

Different methods of measuring the velocity of the stream.

288. Various methods have been proposed by different philosophers for measuring the velocity of running water; the method, by floating bodies, which Mariotte (z) employed, the bent tube of Pitot (A), the regulator of Guglielmini (B), the quadrant (c), the little wheel (d), and the method proposed by the Abbé Mann (k), have each their advantages and disadvantages. The little wheel was employed in the experiments of Bossut. It is the most convenient mode of determining the superficial velocity of the water; and, when constructed in the following manner, will be more accurate, it is hoped, than any instrument that has hitherto been used. The small wheel WW should be formed of the lightest materials. It should be about 10 or 12 inches in diameter, and furnished with 14 or 16 floatboards. This wheel moves upon a delicate screw a B, passing through its axle b b; and when impelled by the stream it will gradually approach towards D, each revolution of the wheel corresponding with a thread of the screw. The number of revolutions performed in a given time are determined upon the scale m a, by means of the index O H fixed at O, and moveable with the wheel, each division of the scale being equal to the breadth of a thread of the screw, and the extremity h of the index O h coinciding with the beginning of the scale, when the shoulder b of the wheel is screwed close to a. The parts of a revolution are indicated by the bent index m u pointing to the periphery of the wheel, which is divided into 100 parts. When this instrument is to be used, take it by the handles C, D, or when great accuracy is required, make it rest on the handles C, D; and screw the shoulder n of the wheel close to a, so that the indices may both point to o the commencement of the scales. Then, by means of a stop-watch or pendulum, find how many revolutions of the wheel are performed in a given time. Multiply the mean circumference of the wheel (or the circumference deduced from the mean radius, which is equal to the distance of the centre of the water-impulsion or impression from the axis b B) by the number of revolutions, and the product will be the number of feet through which the water moves in the given time. On account of the friction of the screw, the resistance of the air, and the weight of the wheel, its centre of impression will revolve with a little less velocity than that of the stream; but the diminution of velocity, arising from these causes, may be estimated with sufficient precision for all the purposes of the practical mechanic. (Appendix to Ferguson's Lectures, vol. ii. p. 177.)

289. It appears, from a comparison of the numerous roads of Smeaton's and accurate experiments of Mr Smeaton, that, in undershoot wheels, the power employed to turn the wheel is to the effect produced as 3 to 1; and that the load which the wheel will carry at its maximum, is to the load which will totally stop it, as 3 to 4. The same experiments inform us, that the impulse of the water on the wheel, in the case of a maximum, is more than double of what is assigned by theory, that is, instead of four-sevenths of the column, it is nearly equal to the whole column. In order to account for this, Mr Smeaton observes, that the wheel was not, in this case, placed in an open river, where the natural current, after it had communicated its impulse to the float, has room on all sides to escape; as the theory supposes; but in a conduit or race, to which the float being adapted, the water could not otherwise escape than by moving along with the wheel. He likewise remarks, that when a wheel works in this manner, the water, as soon as it meets the float, receives a sudden check, and rises up against it like a wave against a fixed object; insomuch, that when the sheet of water is not a quarter of an inch thick before it meets the float, yet this sheet will act upon the whole surface of a float, whose height is three inches. Were the float, therefore, no higher than the thickness of the sheet of water, as the theory supposes, a great part of the force would be lost by the water dashing over it. In order to try what would be the effect of diminishing the number of floatboards, Mr Smeaton reduced the floatboards, which were originally 24, to 12. This change produced a diminution of the effect, as a greater quantity of water escaped between the floats and the floor. But when a circular sweep was adapted to the floor, and made of such a length that one float entered the curve before the preceding one quitted it, the effect came so near to the former, as to afford no hopes of increasing it by augmenting the number of floats beyond 24 in this particular wheel. Mr Smeaton likewise deduced, from his experiments, the following maxima.

1. That the virtual or effective head being the same, the effect will be nearly as the quantity of water expended.

2. That

HYDRODYNAMICS.

2. That the expense of water being the same, the effect will be nearly as the height of the virtual or effective head.

3. That the quantity of water expended being the same, the effect is nearly as the square of the velocity.

4. The aperture being the same, the effect will be nearly as the cube of the velocity of the water.

290. We have hitherto supposed the floatboards, though inclined to the radius, to be perpendicular to the plane of the wheel. Undershoot-wheels, however, have sometimes been constructed with floatboards inclined to the plane of the wheel. A wheel of this kind is represented in fig. 5, where AB is the wheel, and CDEFGH the oblique floatboards. The horizontal current MN is delivered on the floatboards, so as to strike them perpendicularly. On account of the size of the floatboards, every filament of the water contributes to turn the wheel; and therefore its effect will be greater than in undershot wheels of the common form. Albert Euler imagines that the effect will be twice as great, and observes, that in order to produce such an effect, the velocity of the centre of impression should be to the velocity of the water, as radius is to triple the sine of the angle by which the floatboards are inclined to the plane of the wheel. If this inclination, therefore, be $60^\circ$, the velocity of the wheel at the centre of impression ought to be to the velocity of the impelling fluid as 1 to $\frac{3\sqrt{3}}{2}$, that is, as 5 to 13 nearly, because $\sin A = \frac{5.67 \sqrt{H}}{2}$, where $H$ represents the height of the fall, and $A$ the angle which the direction of the fall makes with a vertical line. But as the quantity $\frac{5.67 \sqrt{H}}{2 \sin A}$ evidently increases as the sine of $A$ decreases, it follows, that without lessening the effect of these wheels, we may diminish the angle $A$, and thus augment considerably the velocity of the floatboards, according to the nature of the machinery employed; whereas, in vertical wheels, there is only one determinate velocity which produces a maximum effect.

291. In wheels of this kind, the floats may also be advantageously inclined to the radius. In this case, the stream, which still strikes them perpendicularly, is inclined to the horizon. If the angle formed by the common section of the wheel and floatboards with the radius of the wheel, be $= m$; and if the angle by which the floatboards are inclined to the plane of the wheel be $= n$, then the angle which the floatboards should form with the direction in which the wheel moves, will be $= \cos m \times \sin n$. In order, therefore, that the stream may strike the floatboards with a perpendicular impulse, its inclination to the horizon must be $= m$, and its inclination to the plane of the wheel $= 90^\circ - n$. The less that the velocity of the water is, the greater should be the angle $m$; for there is, in this case, no danger that the celerity of the wheel be too great. The area of the floatboards ought to be much greater than the section of the current; and the interval between two adjacent floatboards should be so great, that before the one completely withdraws itself from the action of the water, the other should begin to receive its impulse.

292. Horizontal water-wheels have been much used on the continent, and are strongly recommended to our notice by the simplicity of their construction. In fig. 6. AB is the large water-wheel which moves horizontally upon its arbor CD. This arbor passes through the immovable millstone EF at D, and being fixed to the upper one GH, carries it once round for every revolution of the great wheel. The mill-course is constructed in the same manner for horizontal as for vertical wheels, with this difference only, that the part on Water-mill, fig. 2, of which KL in fig. 1. is a section, instead of being rectilinear like $m \ n$, must be circular like $m \ P$, and concentric with the rim of the wheel, sufficient room being left between it and the tips of the floatboards for the play of the wheel. In this construction, where the water moves in a horizontal direction before it strikes the wheel, the floatboards should be inclined about $23^\circ$ to the plane of the wheel, and the same number of degrees to the radius, so that the lowest and outermost sides of the floatboards may be farthest up the stream.

293. Instead of making the canal horizontal before it delivers the water on the floatboards, they are frequently inclined in such a manner as to receive the impulse perpendicularly, and in the direction of the declivity of the mill-course. When this construction is adopted, the maximum effect will be produced when the velocity of the floatboards is not less than $\frac{5.67 \sqrt{H}}{2 \sin A}$, where $H$ represents the height of the fall, and $A$ the angle which the direction of the fall makes with a vertical line. But as the quantity $\frac{5.67 \sqrt{H}}{2 \sin A}$ evidently increases as the sine of $A$ decreases, it follows, that without lessening the effect of these wheels, we may diminish the angle $A$, and thus augment considerably the velocity of the floatboards, according to the nature of the machinery employed; whereas, in vertical wheels, there is only one determinate velocity which produces a maximum effect.

294. In the southern provinces of France, where horizontal wheels are generally employed, the floatboards are made of a curvilinear form, so as to be concave towards the stream. The Chevalier de Borda observes, that in theory a double effect is produced when the floatboards are concave; but that the effect is diminished in practice, from the difficulty of making the fluid enter and leave the curve in a proper direction. Notwithstanding this difficulty, however, and other defects which might be pointed out, horizontal wheels with concave floatboards are always superior to those in which the floatboards are plane, and even to vertical wheels, when there is a sufficient fall of water. When the floatboards are plane, the wheel is driven merely by the impulse of the stream; but when they are concave, a part of the water acts by its weight and increases the velocity of the wheel. If the fall of water be 5 or 6 feet, a horizontal wheel with concave floatboards may be erected, whose maximum effect will be to that of the ordinary vertical wheels as 3 to 2.

295. An advantage attending horizontal wheels is, that the water may be divided into several canals, and delivered upon several floatboards at the same time. Each stream will heap up on its corresponding floatboard, and produce a greater effect than if the force of the water had been concentrated on a single floatboard. Horizontal wheels may be employed with greatest advantage when a small quantity of water falls through a considerable height.

296. It has been disputed among mechanical philosophers, whether overshot or undershot wheels produce the wheels so greatest effect. M. Belidor maintained that the former were inferior to the latter, while a contrary opinion undershot was.
HYDRODYNAMICS.

Part III. Machines driven by the Reaction of Water.

Sect. I. On Dr Barker's Mill.

300. This machine, which is sometimes called Pa De B's mill, is represented in fig. 3, where A is the canal that conveys the water into the upright tube B, which communicates with the horizontal arm C. The water will therefore descend through the upright tube into this arm, and will exert upon the inside of it a pressure proportioned to the height of the fall. But if two orifices d and e be perforated at the extremities of the arm, and on contrary sides, the pressure upon these orifices will be removed by the efflux of the water, and the unbalanced pressure upon the opposite sides of the arm will make the tube and the horizontal arm revolve upon the spindle D as an axis. This will be more easily understood, if we suppose the orifices to be shut up, and consider the pressure upon a circular inch of the arm opposite to the orifice, the orifice being of the same size. The pressure upon this circular inch will be equal to a cylinder of water whose base is one inch in diameter, and whose altitude is the height of the fall; and the same force is exerted upon the shut-up orifice. These two pressures, therefore, being equal and opposite, the arm C will remain at rest. But as soon as you open the orifice, the water will issue with a velocity due to the height of the fall: the pressure upon the orifice will of consequence be removed; and as the pressure upon the circular inch opposite to the orifice still continues, the equilibrium will be destroyed, and the arm C will move in a retrograde direction.

301. The upright spindle D, on which the arm revolves, is fixed in the bottom of the arm, and screwed to it below by the nut g. It is fixed to the upright tube by two cross bars at f, so as to move along with it. If a corn mill is to be driven, the top of the spindle is fixed into the upper millstone H. The lower quiescent millstone I rests upon the floor K, in which is the hole L, to let the meal pass into a trough about M. The bridge or support GF, which supports the millstone, tube, &c. is moveable on a pin at A, and its other end is supported by an iron rod fixed into it, the top of the rod going through the fixed bracket c, furnished with a nut o. By screwing this nut, the millstone may be raised or lowered at pleasure. If any other kind of machinery is to be driven, the spindle D must be prolonged to X, and a small wheel W fixed to its extremity, which will communicate its motion to any species of mechanism. An improvement on this machine by M. Mathon de la Cour, and some excellent observations on the subject by Professor Robinson, will be found in the article Water-Works.

302. Mr Waring of the American Philosophical Society, has given a theory of Barker's mill with the improvement of M. Mathon de la Cour, which he has strangely ascribed to a Mr Ramsey about 20 years after it was published in Rossier's Journal de Physique, Jan. and August 1775. Contrary to every other philosopher, he makes the effect of the machine equal only to that of a good undershot-wheel, moved with the same quantity of water, falling though the same height. The following...
Chap. II.

HYDRODYNAMICS.

1. Make the arm of the rotatory tube or arm \( C \), from the centre of motion to the centre of the aperture, of any convenient length, not less than one-third (one-ninth according to Mr Gregory (1), who has corrected some of Waring's numbers) of the perpendicular height of the water's surface above their centres.

2. Multiply the length of the arm in feet by \( .614 \), and take the square root of the product for the proper time of a revolution in seconds, and adapt the other parts of the machinery to this velocity; or, if the time of a revolution be given, multiply the square of this time by \( 1.63 \) for the proportional length of the arm.

3. Multiply together the breadth, depth, and velocity per second, of the race, and divide the last product by \( 18.47 \) times (14.37 according to Mr Gregory) the square root of the height, for the area of either aperture.

4. Multiply the area of either aperture by the height of the fall of water, and the product by \( 41 \frac{1}{3} \) pounds (55.775 according to Mr Gregory), for the moving force estimated at the centres of the apertures in pounds avoirdupois.

5. The power and velocity at the aperture may be easily reduced to any part of the machinery by the simplest mechanical rules.

6. This machine consists of two vessels, the lowest of which EEFF is moveable round the vertical axis OO, while the higher vessel remains immovable. The form of the lowest vessel, which is represented by itself in Fig. 5, is similar to that of a truncated cone, which is fastened by the cross beams \( m, n \) to the axis O so as to move along with it. The annular cavity \( h \) terminates at \( e \) in several tubes \( e \), \( e \), \( e \), \( e \), diverging from the axis through the lower extremities of these tubes, which are bent into a right angle, the water flowing from the cavity \( h \) issues with a velocity due to the altitude of its surface in \( h \), \( h \), and produces by its reaction a rotatory and retrograde motion round the axis OO. The cavity of the ring \( h \), \( h \) receives the water from the superior vessel GGHH, similar to the inferior vessel in Fig. 6, but not connected with the axis OO. This vessel has also an annular cavity PP, into which the water is conveyed from a reservoir by the canal R. Around the lower part HH of the cavity, this vessel is divided into several apertures \( a \), \( a \), placed obliquely that the water may descend with proper obliquity into the inferior vessel. The width of the higher vessel at HH ought to be equal to the width of the lower vessel at EE, that the water which issues from the former may exactly fill the annular cavity \( h \), \( h \), \( h \).

When the machine is constructed in this way, its maximum effect will be equal to the power, provided all its parts be proportioned and adjusted according to the results in the following table, computed from the formula of Albert Euler. In the table,

\[ Q \] = the quantity of water, or number of cubic feet of water furnished in a second.

\[ T \] = the time, or number of seconds in which the lower vessel revolves.

\[ B \] = the breadth of the annular orifice in inches.

**Explanation of the Table:**

The determinations in the preceding table are exhibited in a general manner, that the machine may be accommodated to local circumstances. The time of a revolution \( T \), for instance, is left undetermined, because upon this time depends the magnitude of the machine; and \( T \) may be assumed of such a value that the dimensions of the machine may be suitable to the given place, or to the nature of the work to be performed.

**Example:**

In order to show the application of the preceding table, let it be required to construct the machine when the height of the fall is five feet, and when the reservoir furnishes one cubic foot of water in a second. In this case \( Q = 1 \), and therefore, by column 3d, the sum of the areas of the orifices will be 11.52 square inches. Consequently, if there are twelve orifices, the area of each orifice will be \( \frac{11.52}{12} = 0.96 \) of a square inch. Suppose the time of a revolution to be 2 second or \( T = 1 \), then the 4th column will give the mean radius of the annular orifice \( = 1.9894 \) feet, or nearly two feet. Let the breadth of the annular orifice or \( B = \frac{1}{2} \) an inch, then the difference between the altitude of
HYDRODYNAMICS.

On Machines for raising Water.

308. The subject of pumps has been fully and ably discussed by Dr. Robison under the article PUMP, to which we must refer the reader for a complete view of the theory of the machine. In that article, however, a reference is made to the present for a description of the ancient pump of Ctesibius, and of those in common use to which it has given rise. To these subjects, therefore, we must now confine our attention.

309. The pump was invented by Ctesibius, a mathematician of Alexandria, who flourished under Ptolemy Sichones, about 120 years before Christ. In its original state it is represented in fig. 1, where $ABCD$ is a brass cylinder with a valve $L$ in its bottom. It is furnished with a piston $MK$ made of green wood, so as not to swell in water, and adjusted to the bore of the cylinder by the interposition of a ring of leather. The tube $C I$ connects the cylinder $ABCD$ with another tube $N H$, the bottom of which is furnished with a valve $I$ opening upwards. Now when the extremity $D C$ of the cylinder is immersed in water, and the piston $MK$ is depressed, the pressure of the water upon the valve $L$ from below will be proportional to the depth below the surface $(41)$. The valve will therefore open and admit the water into the cylinder. But when the piston is depressed, it will force the water into the tube $C I$, and through the valve $I$ into the tube $N H$. As soon as the portion of water that was admitted into the cylinder $A B C D$, is thus impelled into the tube $N H$, the valve $I$ will close. A second elevation of the piston will admit another quantity of fluid into the cylinder, and a second depression will force it into the tube $N H$; so that, by continuing the motion of the piston, the water may be elevated to any altitude in the tube. From this pump of Ctesibius are derived the three kinds of pumps now commonly used, the sucking, the forcing, and the lifting pump.

310. The common sucking pump is represented in Description fig. 2, where $ICBL$ is the body of the pump immersed in the water at $A$. The movable piston $DG$ is composed of the piston rod $D d$, the piston or bucket $D$, and the valve $a$. The bucket $H$, which is fixed to the body of the pump, is likewise furnished with a valve $b$, which, like the valve $a$, should by its own weight be closed upon the hole in the bucket till the working of the engine commences. The valves are made of brass, and have their lower surface covered with leather, in order to fill the holes in the bucket more exactly. The movable bucket $G$ is covered with leather, so as to suit exactly the bore of the cylinder, and to prevent any air from escaping between it and the pump. The piston $DG$ may be elevated or depressed by the lever $D Q$, whose fulcrum is $r$, the extremity of the bent arm $R r$.

311. Let us now suppose the piston $G$ to be depressed so that its inferior surface may rest upon the valve $b$, the operation then if the piston is raised to $C$, there would have been a vacuum between $H$ and $G$ if the valve $b$ were immoveable. But as the valve $b$ is moveable, and as the pressure of the air is removed from its superior surface, the air in the tube $H L$ will, by its elasticity, force open the valve $b$, and expand itself through the whole cavity $L C$. This air, however, will be much rarer than that of the atmosphere; and since the equilibrium between the external air and that in the tube $L H$ is destroyed by the rarefaction of the latter, the pressure of the atmosphere on the surface of the water in the vessel $K$ will predominate, and raise the water to about $e$ in the suction pipe $H L$, so that the air formerly included in the space $L C$ will be condensed to the same state as that of the atmosphere. The elasticity of the air both above and below the valve $b$ being now equal, that valve will fail by its own weight. Let the piston $D G$ be now depressed to $b$. The air would evidently resist its descent, did not the valve $a$ open and give a free exit to the air in the space $C H$, for it cannot escape through the inferior valve $b$. When the piston reaches $b$, the valve $a$ will fall by its weight; and when the piston is again elevated, the incumbent air will press the valve $a$ firmly upon its orifice. During the second ascent of the piston to $C$ the valve $b$ will rise, the air between $e$ $H$ will rush into $H C$; and in consequence of its rarefaction, and inability to counteract the pressure of the atmosphere, the water will rise to $f$. In the same way it may be shown, that at the next stroke of the piston the water will rise through the box $H$ to $B$. 

...
HYDRODYNAMICS.

4. The barrel AB is fixed in the immovable frame KILM, the lower part of which is immersed in the water to be raised. The frame GQHO consists of two strong iron rods EQ, GH which move through holes in IK and LM, the upper and lower ends of the pump. To the bottom GH of this frame is fixed an inverted piston with its bucket and valve uppermost at D. An inclined branch KH, either fixed to the top of the barrel, or movable by a ball and socket, as represented at F, must be fitted to the barrel so exactly as to resist the admission both of air and water. The branch KH is furnished with a valve C opening upwards. Let the pump be now plunged in the water to the depth of D. Then if the piston frame be thrust downwards into the fluid, the piston will descend, and the water by its upward pressure will open the valve at D and gain admission above the piston. When the piston frame is elevated, it will raise the water above D along with it, and forcing it through the valve, it will be carried off by the spout.

315. An ingenious pump, invented by De la Hire, is here represented in fig. 5. It raises water equally quickly by its descent as by the ascent of the piston. The pipe B, C, E, F, all communicate with the barrel MD, and have each a valve at their top, viz. at b, s, r, f. The piston rod LM and plunger K never rise higher than K, nor descend lower than D, KD being the length of the stroke. When the plunger K is raised from D to K, the pressure of the atmosphere forces the water through the valve b, and fills the barrel up to the plunger, in the very same way as in the forcing pump. When the plunger K is depressed to D, it forces the water between K and b up the pipe E and through the valve e into the box G, where it issues at the orifice O. During the descent of the plunger K the valve f falls, and covers the top of the pipe F; and as the piston rod LM moves in a collar of leather at M, and is air-tight, the air above the plunger, between Q and M, will be rarefied, and likewise the air in the pipe CS, which communicates with the rarefied air by the valve S. The pressure of the air therefore will raise the water in CS, force it through the valve S, and fill the space above the plunger, expelling the rarefied air through the valve f. When the piston is raised from D to K, it will force the water through the bent pipe F into the box G, so that the same quantity of water will be discharged at O through the pipe F, during the ascent of the piston, as was discharged through the pipe E during the piston's descent. Above the pipe O is a close air-vessel P, so that when the water is driven above the spout O, it compresses the air in the vessel P, and this air acting by its elasticity on the surface of the water, forces it out at O in a constant and nearly equal stream. As the effect of the machine depends on a proper proportion between the height O of the spout above the surface of the well, and the diameter of the barrel, the following table will be of use to the practical mechanic.
When the proportions in the preceding table are observed, a man of common strength will raise water much higher than he could do with a pump of the common construction.

316. A very simple pump which furnishes a continued stream is represented in fig. 6. It was invented by Mr. Noble, and consists of a working barrel AB with two pistons C and D B, which are moved up and down alternately by the rods fixed to the lever EMN. The rod of the piston H passes through the piston C, and the piston C moves upon the rod AB. When the piston rod D is depressed and elevated, it will make the water rise in the barrel A, in the same way as in the sucking pump, whether the valve C be movable or not. Let us now suppose that the water is raised to A. Then if the piston D is elevated by depressing the extremity N of the lever, the water at A will be raised higher in the barrel, and issue at the spout P, and when the same piston B is depressed by elevating the end N of the lever, the piston C is evidently raised, and the water above it will be expelled at P. This pump, therefore, will give a continued stream, for as the pistons ascend and descend alternately, one of them must always be forcing the water out at P. The pistons are elevated and depressed by means of toothed arches c and d, working in the teeth of a rack, at the extremities a, b, of the piston rod.

317. The pump invented by Mr. Buchanan is shown in fig. 7. In the vertical section DGA, A is the suction barrel, D the working barrel, E the piston, G the spout, B the inner valve, and C the outer valve. These valves are of the kind called clack valves, and have their hinges generally of metal. It is easily seen that when the piston E is raised, the water will rise through the suction barrel A, into the working barrel D, in the same way as in the sucking pump; and that when the piston E is depressed, it will force the water between it and the valve B, through the valve C, and make it issue at C. The points of difference between this pump and those of the common form, are,—that it discharges the water below the piston, and has its valves lying near each other. Hence the sand or mud which may be in the water, is discharged without injuring the barrel or the piston leathers; and as the valves B, C may be of any size, they will transmit, without being choked, any rubbish which may rise in the suction barrels. If any obstruction should happen to the valves, they are within the reach of the workman’s hand, and may be cleared without taking the pump to pieces. This simple machine may be quickly converted into a fire engine, by adding the air-vessel H, which is screwed like a hosepipe, and by fixing in the spout G a perforated stopple fitted to receive such pipes as are employed in fire engines. When these additions are made, the water, as in the case of the forcing pump, will be driven into the air vessel H, and repelled through the perforated stopple G, by the elasticity of the included air.

318. A simple method of working two pumps at once by means of a balance, is exhibited in fig. 8, where AB is the balance, having a large iron ball at each end, Figs. 8 & 9, placed in equilibrium on the two spindles C, see fig. 9. The person who works the pump stands on two boards L, I, nailed to two cross pieces fastened to the axis of the machine, and supports himself by a cross bar D of joined to the two parts D, E. At the distance of ten inches on each side of the axis are suspended the iron rods M, N, to which the pistons are attached. The workman, by bearing alternately on the right and left foot, puts the balance in motion. The pistons M, N are alternately elevated and depressed, and the water raised in the barrel of each, is driven into the pipe HH, in which it is elevated to a height proportional to the diameter of the valves, and the power of the balance. In order to make the oscillations of the balance equal, and prevent it from acquiring too great a velocity, iron springs F, G are fixed to the upright posts, which limit the length of its oscillations.

319. The chain pump is represented in fig. 1. It consists of a chain MTHG, about 30 feet long, carrying a number of flat pistons M, N, O, P, Q, which are made to revolve in the barrels ABCD and GH, by driving the wheel F. When the flat pistons are at the lower part of the barrel T, they are immersed in the water RR, and as they rise in the barrel GH, they bring up the water along with them into the reservoir MG, from which it is conveyed by the spout S. The teeth of the wheel F are so contrived as to receive one-half of the flat pistons, and let them fold in; and sometimes another wheel like F is fixed at the bottom D. The distance of the pistons from the side of the barrel is about half an inch; but as the machine is generally worked with great velocity, the ascending pistons bring along with them into the reservoir as much water as fills the cavity GH. Sometimes chain pumps are constructed without the barrels ABCD and GH. In this case, the flat pistons are conveyed into buckets connected with a chain, which dip in the water with their mouths downwards, and convey it to the reservoir. The buckets are moved by hexagonal axles, and the distance between each is nearly equal to the depth of the buckets. Chain pumps are frequently in an inclined position, and in this position they raise the greatest quantity of water when the distance of the flat pistons is equal to their breadth, and when the inclination of the barrels is about 24° 21′.

320. The hair-rope machine, invented by the Sieur Vena, operates on the same principle as the chain pump, machine of the Sieur Vena; the hair rope is substituted. The part of the rope at T, is lowest always dips in the water, which adhering to the rope is raised along with it. When the rope reaches the top at G and M, it passes through two small tubes, which being fixed in the bottom of the reservoir.
HYDRODYNAMICS.

Sect. II. On Engines for Extinguishing Fire.

321. The common fire engine which discharges water in successive jets is represented in fig. 2, and is only a modification of the lifting pump. In the vessel $AB$, full of water, is immersed the frame $DC$ of a common lifting pump. This frame, and consequently the piston $N$, is elevated and depressed by means of the levers $E$, $F$, and the water which is raised is forced through the pipe $G$, which may be moved in any direction by means of the elastic leather pipe $H$, or by a baulk and socket screwed on the top of the pump. While the piston $N$ is descending, the stream at $G$ is evidently discontinued, and issues only at each elevation of the piston. The vessel $AB$ is supplied with water by buckets, and the pump is prevented from being choked by the strainer $LK$ which separates from the water any mud that it may happen to contain.

322. As this fire engine does not afford a continued stream, it is not so useful in case of accidents as when the stream is uninterrupted. An improved engine of this sort is represented in fig. 3, where $D$, $E$, are two forcing pumps connected with the large vessel $OG$, and wrought by the levers $F$, $G$, moving upon $H$ as a fulcrum. This apparatus is plunged and fastened in the vessel $AB$ partly filled with water, and by means of the forcing pump $DE$, the operation of which has already been described, the water is driven through the valves $I$, $L$ into the large vessel $OG$, where the included air is condensed. Into this vessel is inserted the tube $PO$ communicating with the leather pipe $ORQS$. The elasticity of the condensed air in the vessel $OG$ pressing upon the surface of the water in that vessel, forces it up through the tube $PO$ into the leather pipe, from whose extremity $S$, it issues with great force and velocity; and as the condensed air is continually pressing upon the water in the vessel $OG$, the stream at $S$ will be constant and uniform.

323. A section of the fire engine, as improved by Mr. Newham, is represented in fig. 4, where $TU$ and $WX$ are the forcing pumps corresponding with $D$ and $C$ in fig. 3. $YZ$ the large vessel corresponding with $OG$, and $EF$ the tube corresponding with $PO$. The vessels $TU$, $WX$, $YZ$, the horizontal canal $ON$, $QP$, $ML$, and the vertical canal $EE$, all communicate with each other by means of four valves $O$, $I$, $K$, $P$, opening upwards, and the vertical pipe is immersed in the water to be raised. When the piston $R$ is raised by means of the double lever $a$, a vacuum would be made in the barrel $TU$, if the water at $R$ were prevented from rising; but as this barrel communicates with the vessel of water below $EF$, on the surface of which the pressure of the atmosphere is exerted, the water will rise through $EF$, force open the valve $H$, and follow the piston $R$. By depressing the piston $R$, however, the water is driven down the barrel, closes the valve $H$, and rushes through the valve $I$ into the air vessel $YZ$. The very same operation is going on with the pump $WX$, which forces the water into the air vessel through the valve $K$. By these means the air vessel is constantly filling with water, and the included air undergoing continual condensation. The air thus compressed, reacts upon the surface $YZ$ of the water, and forces it through the tube $EF$ to the stop-cock $e$, where after turning the cock, the water passes into the tube $A$, fixed to a bell and socket, by which it may be discharged in any direction.

324. The fire engine has undergone various alterations and improvements from Bramah, Dickenson, Simpkin, the engineer Raventree, Philips and Forst, an account of whose engines may be seen in the Repertory of Arts, &c. A very simple and cheap fire engine has been invented by Mr. B. Dearborn, and is described in the American Transactions for 1794, and in Gregory's Mechanias, vol. ii. p. 177.

325. Mr. Whitehurst was the first who suggested the ingenious idea of raising water by means of its momentum. A machine upon the same principle as Mr. Whitehurst's, but in an improved form, has lately made its appearance in France, and excited considerable attention both on the continent and in this country. Whatever credit, therefore, has been given to the inventor of the hydraulic ram, justly belongs to our countryman Mr. Whitehurst, and Montgolfier is entitled to nothing more than the merit of an improver.

326. Mr. Whitehurst's machine, which was actually executed at Oulton in Cheshire, is represented in fig. 1, where $AM$ is the original reservoir having its surface in the same horizontal line with the bottom of the reservoir $BN$. The diameter of the main pipe $AE$ is one inch and a half, and its length about 200 yards; and the branch pipe $EF$ is of such a size that the height of the surface $M$ of the reservoir is nearly 16 feet above the cock $F$. In the valve box $D$ is placed the valve $a$, and into the air vessel $C$ are inserted the extremities $m$, $n$, of the main pipe, bent downwards to prevent the air from being driven out, when the water is forced into it. Now as the cock $F$ is 16 feet below the reservoir $AM$, the water will issue from $F$ with a velocity of nearly 30 feet per second. As soon as the cock $F$ therefore is opened, a column of water 200 yards long is put in motion, and though the aperture of the cock $F$ be small, this column must have a very considerable momentum. Let the cock $F$ be now suddenly stopped, and the water will rush through the valve $a$ into the air vessel $C$, and condense the included air. This condensation must take place every time the cock is shut, and the imprisoned air being in a state of high compression, will react upon the water in the air vessel, and raise it into the reservoir $BN$.

327. A section of the hydraulic ram of Montgolfier is exhibited in fig. 2. Where $R$ is the reservoir, $RS$ the vertical height of the fall, and $ST$ the horizontal canal which conveys the water to the engine $ABHTC$. $E$ and $D$ are two valves, and $FG$ a pipe reaching within a very little of the bottom $CB$. Let us now suppose that wa

HYDRODYNAMICS.

On Machines for raising Water.

Chap. III.

On Machines for raising Water.

On Machines for raising Water.

This condensed air will consequently react upon the surface of the water, and raise it in the pipe FG to an altitude proportioned to the elasticity of the included air. The external appearance of the engine, drawn from one in the possession of Professor Leslie, is represented in fig. 3, where ABC is the air vessel, F the valve box, G the extremity of the valve, and M, N screws for fixing the horizontal canal to the machine. When the engine is employed to form a jet of water, a piece of brass, A, with a small aperture, is screwed upon the top of the tube FG, which, in that case, rises no higher than the top of the air vessel. From this description it will be seen, that the only difference between the engines of Montgolfier and Whitehurst, is, that the one requires a person to turn the cock, while the other has the advantage of acting spontaneously. Montgolfier (c) assures us, that the honour of this invention does not belong to England, but that he is the sole inventor, and did not receive a hint from any person whatever. We leave the reader to determine the degree of credit to which these assertions are entitled.—It would appear from some experiments made by Montgolfier, that the effect of the water ram is equal to between a half and three-fourths of the power expended, which renders it superior to most hydraulic machines. Appendix to Ferguson's Lectures, p. 19.

Sect. IV. On Archimedes' Screw Engine.

Description of Archimedes' screw-engine.

328. The screw engine invented by Archimedes is represented in fig. 4, where AB is a cylinder with a flexible pipe, CEHGF, wrapped round its circumference like a screw. The cylinder is inclined to the horizon, and supported at one extremity by the bent pillar IR, while its other extremity, furnished with a pivot, is immersed in the water. When, by means of the handle K, the cylinder is made to revolve about its axis, the water which enters the lower orifice of the flexible pipe is raised to the top, and discharged at D. On some occasions, when the water is to be raised moves with a considerable velocity, the engine is put in motion by a number of floatboards fixed at I, and impelled by the current; and if the water is to be raised to a great height, another cylinder is immersed in the vessel D, which receives the water from the first cylinder, and is driven by a pinion fixed at I. In this way, by having a succession of screw engines, and a succession of reservoirs, water may be raised to any altitude. An engine of this kind is described in Ferguson's Lectures, vol. ii. p. 113.

329. In order to explain the reason why the water rises in the spiral tube, let AB be a section of the engine, BC DE the spiral tube, BF a horizontal line or the surface of the stagnant water which is to be raised, and AB F the angle which the axis of the cylinder makes with the horizon. Then, the water which enters the extremity B of the spiral tube will descend to C, and remain there as long as the cylinder is at rest. But if a motion of rotation is communicated to the cylinder, so that the lowest part C of the spiral triangle move towards B, and the points D, E towards C, and become successively the lowest parts of the spiral, the water must occupy successively the points D, E, F, and therefore rise in the tube; or, which is the same thing, when the point C moves to c, the point d will be at C; and as the water at C cannot rise along with the point C to c, on account of the inclination of C c to the horizon, it must occupy the point d of the spiral, when C has moved to c; that is, the water has a tendency to occupy the lower parts of the spiral, and the rotatory motion withdraws this part of the spiral from the water, and causes it to ascend to the top of the tube. By wrapping a cord round the cylinder, and inclining it to the horizon, so that the angle ABC may be greater than the angle ABF, and then making it revolve upon its axis, the preceding remarks will be clearly illustrated.—If the direction of the spiral BC should be horizontal, that is, if it should coincide with the line BF, the water will have no tendency to move towards C, and therefore cannot be raised in the tube. For a similar reason, it will not rise when the point C is above the horizontal line BF. Consequently, in the construction of this engine, the angle ABC, which the spiral forms with the side of the cylinder, must always be greater than the angle ABF, at which the cylinder is inclined to the horizon. In practice, the angle of inclination ABF should generally be about 50°, and the angle ABC about 65°.

Sect. V. On the Persian Wheel.

331. The Persian wheel is an engine which raises water to a height equal to its diameter. It is shown in fig. 6, where CDE is the wheel driven by the stream of water AB acting upon floatboards fixed on one side of its rim. Fig. 6. A number of buckets, a, a, a, a, are disposed on the opposite side of the rim, and suspended by strong pins, b, b, b, b, &c. When the wheel is in motion, the descending buckets immerse into the stream, and ascend full

(c) Cette invention n'est point originaire d'Angleterre, elle appartient toute entière à la France. Je déclare que j'en suis le seul inventeur, et que l'idée ne m'en a été fournie par personne. Journal des Mines, vol. xiii. No 73;
HYDRODYNAMICS.

332. On some occasions the Persian wheel is made to raise water only to the height of its axle. In this case, instead of buckets, its spokes c, d, e, f, g, h, are made of a spiral form, and hollow within, so that their inner extremities all terminate in the box N on the axle, and their outer extremities in the circumference of the wheel. When the rim CDEF, therefore, is immersed in the stream, the water runs into the tubes C, D, E, F, &c. rises in the spiral spokes c, d, &c. and is discharged from the orifices at O into the reservoir Q, from which it may be conveyed in pipes.

SECT. VI. On the Zurich Machine.

333. This machine is a kind of pump invented and erected by H. Andreas Wirtz, an ingenious tin-plate worker in Zurich, and operates on a principle different from all other hydraulic engines. The following description of it, written by Dr. Robison, is transferred to this part of the work for the sake of uniformity.

Plate LXXIV.

Fig. 7.

334. Fig. 7. is a sketch of the section of the machine, as it was first erected by Wirtz at a dye-house in Limmat, in the suburbs or vicinity of Zurich. It consists of a hollow cylinder, like a very large grindstone, turning on a horizontal axis, and partly plunged in a cistern of water. The axis is hollow at one end, and communicates with a perpendicular pipe CBZ, part of which is hid by the cylinder. This cylinder or drum is formed into a spiral canal by a plate coiled up within it like the main spring of a watch in its box; only the spires are at a distance from each other, so as to form a conduit for the water of uniform width. This spiral partition is well joined to the two ends of the cylinder, and no water escapes between them. The outermost turn of the spiral begins to widen about three-fourths of a circumference from the end, and this gradual enlargement continues from Q to S nearly a semicircle: this part may be called the Horn. It then widens suddenly, forming a Scoop or Shovel SS'. The cylinder is supported so as to dip several inches into the water, whose surface is represented by VV.

335. When this cylinder is turned round its axis in the direction ABFO, as expressed by the two darts, the scoop SS' dips at V and takes up a certain quantity of water before it immerses again at V. This quantity is sufficient to fill the taper part SQ, which we have called the Horn; and this is nearly equal in capacity to the outermost uniform spiral round.

336. After the scoop has emerged, the water passes along the spiral by the motion of it round the axis, and drives the air before it into the rising-pipe, where it escapes.—In the mean time, air comes in at the mouth of the scoop; and when the scoop again dips into the water, it again takes in some. Thus there is now a part filled with water and a part filled with air. Continuing this motion, we shall receive a second round of water and another of air. The water in any turn of the spiral will have its two ends on a level; and the air between the successive columns of water will be in its natural state; for since the passage into the rising pipe or Main is open, there is nothing to force the water and air into any other position. But since the spiral gradually diminishes in their length, it is plain that the column of water will gradually occupy more and more of the circumference of each. At last it will occupy a complete turn of some spiral that is near the centre; and when sent farther in, by the continuance of the motion, some of it will run back over the top of the succeeding spiral. Thus it will run over at K 4 into the right-hand side of the third spiral. Therefore it will push the water of this spire backwards, and raise its other end, so that it also will run over backwards before the next turn be completed. And this change of disposition will last reach the first or outermost spiral, and some water will run over into the horn and scoop, and finally into the cistern.

337. But as soon as water gets into the rising pipe, and rises a little in it, it stops the escape of the air when the next scoop of water is taken in. Here are now two columns of water acting against each other by hydrostatic pressure and the intervening column of air. They must compress the air between them, and the water and air-columns will now be unequal. This will have a general tendency to keep the whole water back, and cause it to be higher on the left or rising side of each spire than on the right descending side. The excess of height will be just such as produces the compression of the air between that and the preceding column of water. This will go on increasing as the water mounts in the rising pipe; for the air next to the rising pipe is compressed at its inner end with the weight of the whole column in the main. It must be as much compressed at its outer end. This must be done by the water column without it; and this column exerts this pressure partly by reason that its outer end is higher than its inner end, and partly by the transmission of the pressure on its outer end by air, which is similarly compressed from without. And thus it will happen that each column of water, being higher at its outer than at its inner end, compresses the air on the water column beyond or within it, which transmits this pressure to the air beyond it, adding to it the pressure arising from its own want of levels at the ends. Therefore the greatest compression, viz. that of the air at the main, is produced by the sum of all the transmitted pressures; and these are the sum of all the differences between the elevations of the inner ends of the water columns above their outer ends: and the height to which the water will rise in the main will be just equal to this sum.

338. Draw the horizontal lines K K 1, K K 2, K K 3, &c. and m m, m m, m m, &c. Suppose the left-hand spaces to be filled with water, and the right-hand spaces to be filled with air. There is a certain gradation of compression which will keep things in this position. The spaces evidently decrease in arithmetical progression; so do the hydrostatic heights and pressures of the water columns. If therefore the air be dense in the same progression, all will be in hydrostatical equilibrium.
manner of working most evident, namely, which contained the same material quantity of air in each turn of the spiral, more and more compressed as it approaches to the rising pipe. We should otherwise have been obliged to investigate in great detail the gradual progress of the water, and the frequent changes of its arrangement, before we could see that one arrangement would be produced which would remain constant during the working of the machine. But this is not the best construction. We see that, in order to raise water to the height of a column of 34 feet, which balances the atmosphere, the air in the last spire is compressed into half its bulk; and the quantity of water delivered into the main at each turn is but half of what was received into the first spire, the rest flowing back from spire to spire, and being discharged at the spout.

343. But it may be constructed so as that the quantity of water in each spire may be the same that was received into the first; by which means a greater quantity (double in the instance now given) will be delivered into the main, and raised to the same height by very nearly the same force. This may be done by another proportion of the capacity of the spires, whether by a change of their caliber or of their diameters. Suppose the bore to be the same, the diameter must be made such that the constant column of water, and the column of air, compressed to the proper degree, may occupy the whole circumference. Let A be the column of water which balances the atmosphere, and A the height to which the water is to be raised. Let A be to A+1+h as 1 to m.

344. It is plain that m will represent the density of the air in the last spire, if its natural density be 1, because it is pressed by the column A+1+h, while the common air is pressed by A. Let r represent the constant water column, and therefore nearly equal to the air column in the first spire. The whole circumference of the last spire must be 1+ m, in order to hold the water 1, and the air compressed into the space \( \frac{1}{m} \) or A.

A+1+h

345. The circumference of the first spire is 1+1 or 2. Let D and d be the diameters of the first and last spires; we have 2 : 1+1 = D : d, or 2 m : m+1 = D : d. Therefore if a pipe of uniform bore be lapped round a cone, of which D and d are the end diameters, the spirals will be very nearly such as will answer the purpose. It will not be quite exact, for the intermediate spirals will be somewhat too large. The conoidal frustum should be formed by the revolution of a curve of the logarithmic kind. But the error is very trifling.

With such a spiral, the full quantity of water which was confined in the first spiral will find room in the last, and will be sent into the main at every turn. This is a very great advantage, especially when the water is to be much raised. The saving of power by this change of construction is always in proportion to the greatest compression of the air.

The great difficulty in the construction of any G of
HYDRODYNAMICS.

Part II

On Machines for raising Water.

346. Let ABO (fig. 2) represent the first or outermost round of the spiral, of which the axis is C. Suppose it immersed up to the axis in the water \( V V \), we have seen that the machine is most effective when the surfaces KB and ON of the water columns are the whole diameter BO of the spiral. Therefore let the pipe be first supposed of equal calibre to the very mouth Ex, which we suppose to be just about to dip into the water. The surface ON is kept there, in opposition to the pressure of the water column BAQ, by the compressed air contained in the quadrant OE, and in the quadrant which lies behind EB. And this between the spire and the rising pipe. But the air in the outermost quadrant EB is in its natural state, communicating as yet with the external air. When, however, the mouth Ex has come round to A, it will not have the water standing in it in the same manner, leaving the half space BEO filled with compressed air; for it took in and confined only what filled the quadrant BE. It is plain, therefore, that the quadrant BE must be so shaped as to take in and confine a much greater quantity of air; so that when it has come to A, the space BEO may contain air sufficiently dense to support the column AO. But this is not enough: For when the wide mouth, now at A, rises up to the top, the surface of the water in it rises also, because the part AO of is more capacious than the cylindric part OEo which succeeds it, and which cannot contain all the water that it does. Since, then, the water in the spire rises above A, it will press the water back from ON to some other position \( m' n' \), and the pressing height of the water-column will be diminished by this rising on the other side of O. In short, the horn must begin to widen, not from B, but from A, and must occupy the whole semicircle ABE; and its capacity must be to the capacity of the opposite cylindric side as the sum of BO, and the height of a column of water which balances the atmosphere to the height of that column. For then the air which filled it, when the common density, will fill the uniform side BEO, when compressed so as to balance the vertical column BO. But even this is not enough; for it has not taken in enough of water. When it dipped into the cistern at E, it carried air down with it, and the pressure of the water in the cistern caused the water to rise into it a little way; and some water must have come over at B from the other side, which was drawing narrower. Therefore when the horn is in the position EO A, it is not full of water. Therefore when it comes into the situation OAB, it cannot be full nor balance the air on the opposite side. Some will therefore come out at O, and rise up through the water. The horn must therefore, 1st, Extend at least from O to B, or occupy half the circumference; and, 2dly, It must contain at least twice as much water as would fill the side BEO. It will do little harm though it be much larger; because the surplus of air which it takes in at E will be discharged, as the end Eo of the horn rises from O to B, and it will leave the precise quantity that is wanted. The overplus water will be discharged as the horn comes round to dip again into the cistern. It is possible, but requires a discussion too intricate for this place, to make it of such size and shape, that while the mouth moves from E to B, passing through O and A, the surface of the water in it shall advance from E to O m, and be exactly at O when the beginning or narrow end of the horn arrives there.

347. We must also secure the proper quantity of water. When the machine is so much immersed as to be up to the axis in water, the capacity which thus secures the proper quantity of air will also take in the proper quantity of water. But it may be erected so as that the spires shall not even reach the water. In this case it will answer our purpose if we join to the end of the horn a scoop or shovel QRBB (fig. 3), which is so formed as to take in at least as much water as will fill the horn. This is all that is wanted in the beginning of the motion along the spiral, and more than is necessary when the water has advanced to the succeeding spire; but the overplus is discharged in the way we have mentioned. At the same time, it is needless to load the machine with more water than is necessary, merely to throw it out again. We think that if the horn occupies fully more than one-half of the circumference, and contains as much as will fill the whole round, and if the scoop lifts as much as will certainly fill the horn, it will do very well.

N. B. The scoop must be very open on the side next the axis, that it may not confine the air as soon as it enters the water. This would hinder it from receiving water enough.

348. The following dimensions of a machine erected at Florence, and whose performance corresponded extremely well with the theory, may serve as an example.

The spiral is formed on a cylinder of 10 feet diameter, and the diameter of the pipe is six inches. The smaller end of the horn is of the same diameter; it occupies three-fourths of the circumference, and is 7 7/8ths inches wide at the outer end. Here it joins the scoop, which rises as much water as fills the horn, which contains 4340 Swedish cubic inches, each = 1.377 English. The machine makes six turns in a minute, and raises 1354 pounds of water, or 22 cubic feet, 10 feet high in a minute.

349. The above account will, we hope, sufficiently explain the manner in which this singular hydraulic machine produces its effect. When every thing is executed by the maxims which we have deduced from its principles, we are confident that its performance will correspond to the theory; and we have the Florentine machine as a proof of this. It raises more than four-sixteens of what the theory promises, and it is not perfect. The spiral is of equal caliber, and is formed on a cylinder. The friction is so inconsiderable in this machine, that it need not be minded: but the great excellency is, that whatever imperfection there may be in the arrangement of the air and water columns, this only affects the elegance of the execution, causing the water to make a few more turns in the spiral before it can mount to the height required; but wastes no power, because the power employed is always in proportion to the sum of the vertical columns of water in the rising side of the machine: and the height to which the water is raised by it is in the very same proportion. It should be
HYDRODYNAMICS.

On Machines for raising Water.

be made to move very slow, that the water be not al-
ways dragged up by the pipes, which would cause
more to run over from each column, and disturb
the pressure of the remainder.

If the rising-pipe be made wide, and thus room
be made for the air to escape freely up through the
water, it will rise to the height assigned; but if it be ne-
now, so that the air cannot get up, it rises almost as
slow as the water, and by this circumstance the water
is raised to a much greater height mixed with air, and
this with hardly any more power. It is in this way that
we can account for the great performance of the Flo-
rentine machine, which is almost triple of what a man
can do with the finest pump that ever was made:
indeed the performance is so great, that one is apt to sus-
pect some inaccuracy in the accounts. The entry into
the rising-pipe should be no wider than the last part of
the spiral; and it would be advisable to divide it into
four channels by a thin partition, and then to make the
rising-pipe very wide, and to put into it a number of
slender rods, which would divide it into slender chan-
nels that would completely entangle the air among the
water. This will greatly increase the height of the be-
terogeneous column. It is surprising that a machine
that is so very promising should have attracted so little
notice. We do not know of any being erected out of
Switzerland, except at Florence in 1778. The account
of its performance was in consequence of a very publi-
trial in 1779, and honourable declaration of its merits,
by Sig. Lorenzo Gini, who erected another, which
fully equalled it. It is shortly mentioned by Professor
Sulzer of Berlin, in the Sammlungen Versuchten Schrif-
ten for 1754. A description of it is published by the
Philosophical Society at Zurich in 1766, and in the des-
criptions published by the Society in London for the
encouragement of Arts in 1776. The celebrated Da-
aniel Bernouilli has published a very accurate theory of
it in the Petersburgh Commentaries for 1772, and the
machines at Florence were erected according to his in-
structions. Baron Alstromer in Sweden caused a glass
model of it to be made, to exhibit the internal motions
for the instruction of artists, and also ordered an opera-
tive engine to be erected; but we have not seen any
account of its performance. It is a very intricate ma-
achine in its principles; and an ignorant engineer, may
the most intelligent, may erect one which shall hardly
do any thing; and yet by a very trifling change, may
become very powerful. We presume that failures of
this kind have turned the attention of engineers from
it; but we are persuaded that it may be made very ef-
effective, and we are certain that it must be very durable.

351. The water blowing machine consists of a reservoir, of water AB, into the bottom of which the bent of the wa-
tered pipe ECH is inserted; of a condensing vessel DE, into whose top the lower extremity H of the pipe
is fixed, and of a pedestal P resting on the bottom of
this vessel. When the water from the reservoir AB is
descending through the part CH of the pipe, it is in
contact with the external air by means of the orifices or
tubes m, n, o, p, and by the principle of the lateral
communication of motion in fluids (art. 160.), the air
is dragged along with the water. This combination of
air and water issuing from the aperture H, and impi-
ging upon the surface of the stone pedestal P, is disper-
sed in various directions. The air being thus separated
from the water, ascends into the upper part of the vessel,
and rushes through the opening F, whence it is con-
voyed by the pipe FG to the fire at G, while the water
drops to the lower part of the vessel, and is discharged
by the openings M, N,—That the greatest quantity of
air may be driven into the vessel DE, the water should
begin to fall at C with the least possible velocity; and
the height of the lowest tubes above the extremity H
of the pipe should be three-elevenths of the length of
the vertical tube CH, in order that the air may move
in the pipe FG with sufficient velocity.

352. Fabri and Dietrich imagined that the wind is Way in
produced by the decomposition of the water, or which the
transformation into gas, in consequence of the agitation wind is ge-
and percussion of its parts. But M. Venturi, to whom
we owe the first philosophical account of this machine,
has shewn that this opinion is erroneous, and that the
wind is supplied from the atmosphere, for no wind was
generated when the lateral openings m, n, o, p were
shut. The principal object, therefore, in the construc-
tion of water blowing machines, is to combine as much
air as possible with the descending current. For this
purpose the water is often made to pass through a kind
of cullender placed in the open air, and performed with
a number of small triangular orifices. Through these
apertures the water descends in many small streams;
and by exposing a greater surface to the atmosphere, it
carries along with it an immense quantity of air. The
water is then conveyed to the pedestal P by a pipe CH
opened and enlarged at C, so as to be considerably
wider than the end of the tube which holds the cullen-
der.

353. It has been generally supposed that the water-
fall should be very high; but Dr Lewis has shewn, by
a variety of experiments, that a fall of four or five feet
is sufficient, and that when the height is greater than
this, two or more blowing machines may be erected, by
conducting the water from which the air is extricated,
into another reservoir, from which it again descends, and

5 G 2  generates
HYDRODYNAMICS.

Part III.

SECTION III. On Clepsydra or Water-Clocks.

354. The storm wind is produced in the same way as the blast of air in water blowing machines. When the drops of rain impinge upon the surface of the sea, the air which they drag along with them often produces a heavy squall, which is sufficiently strong to carry away the mast of a ship. The same phenomenon happens at land, when the clouds empty themselves in alternate showers. In this case, the wind proceeds from that quarter of the horizon where the shower is falling. The common method of accounting for the origin of the winds by local rarefaction of the air appears pregnant with insuperable difficulties; and there is reason to think that these agitations in our atmosphere ought rather to be referred to the principle which we have now been considering. For farther information on this subject, the reader is referred to Lewis's Commoner of Arts, Wolfii Opera Mathematica, tom. i. p. 380. Journal des Mines, No. xii. or Nicholson's Journal, vol. xii. p. 48.

SECTION II. Bramah's Hydrostatic Press.

355. The machine invented by Mr Bramah of Piccadilly, depends upon the principle, that any pressure exerted upon a fluid mass is propagated equally in every direction (art. 111.). It is represented in fig. 6, where A is a strong metallic cylinder, furnished with a piston B perfectly water-tight. Into the bottom of this cylinder is inserted the end of the bent tube C, the interior orifice of which is closed by the valve D. The other extremity of the tube communicates with the forcing pump E, by which water or other fluids may be driven into the cylinder A. Then, if any pressure is exerted upon the surface of the water in the cylinder E by means of the lever H, this pressure will be propagated to the cylinder A, and exert a certain force on the piston B, varying with the respective areas of the sections of each cylinder. If the diameter of the cylinder E is equal to the diameter of the cylinder A, and if a force of 10 pounds is exerted at the handle H, then the piston B will be elevated with a force of 10 pounds; if the diameter of E be one-half that of A, the piston B will be raised with a force of 40 pounds, because the area of the one piston is four times the area of the other. Or, in general, if D be the diameter of the cylinder A, d that of the cylinder E, and F the force exerted at the lever H, we shall have

\[ d^2 = \frac{D^2 F}{d^2}, \]

which is the force exerted upon the piston B.

Thus, if \( d = 2 \) inches, \( D = 24 \) inches, and \( F = 10 \) pounds, then

\[ d^2 = \frac{10 \times 24 	imes 24}{2 \times 2} = 1440 \text{ pounds}, \]

the force with which the piston B is elevated. Now, as this force increases as \( d^2 \) diminishes, or as \( F \) and \( D^2 \) increase, there is no limit to the power of the engine; for the diameter of the cylinder A may be made of any size, and that of the cylinder E exceedingly small, while the power may be still farther augmented by lengthening the lever H. The same effects may be produced by injecting air into the pipe C by means of a large globe fixed at its extremity. Upon the same principles the power and motion of one machine may be communicated to another; for we have only to connect the two machines by means of a pipe filled with water, inserted at each extremity into a cylinder furnished with a piston. By this means the power which depresses one of the pistons will be transferred along the connecting pipe, and will elevate the other piston. In the same way water may be raised out of wells of any depth, and at any distance from the place where the power is applied; but we must refer the reader, for a detailed account of these applications, to the specification of the patent obtained by Mr Bramah, or to Gregory's Mechanics, vol. ii. p. 130.

356. A clepsydra or water-clock, derived from Greek αἰλων, "to steal," and ὕδωρ, "water," is a machine which measures time by the motion of water (art. 115.). The invention of this machine has been ascribed to Scipio Nasica, the cousin of Scipio Africanus, who flourished about 200 years before the Christian era. It was well known, however, at an earlier period, among the Egyptians, who employed it to measure the course of the sun. It is highly probable that Scipio Nasica had only the merit of introducing it into his native country. These machines were in use for a very long period, and continued to be employed as measurers of time till the invention of the pendulum clock enriched the arts and sciences.

357. The clepsydra, invented by Ctesibius of Alexandria, was an interesting machine. The water which in Greek αἰλων indicated the progress of time by the gradual descent of its surface, flowed in the form of tears from the eyes of a human figure. Its head was bent down with age: Its look was dejected, while it seemed to pay the last tribute of regret to the fleeting moments as they passed.

The water which was thus discharged was collected in a vertical reservoir, where it raised another figure holding in its hand a rod, which, by its gradual ascent, pointed out the hours upon a vertical column. The same fluid was afterwards employed in the interior of the pedestal, as the impelling power of a piece of machinery which made this column revolve round its axis in a year, so that the months and the days were always shown by this index, whose extremity described a vertical line divided according to the relative lengths of the hours of day and night. Among the longest the length of the hours varied every day, and even the hours of the day differed in length from those of the night: for the length of the day, or the interval between sunrise and sunset, was always divided into twelve equal parts, while the length of the night, or the interval between sunset and sunrise, was divided into the same number of parts, for hours. A farther description of this beautiful machine, and others of the same nature, may be seen in Perrault's Vitruvius.

358. The method of constructing clepsydras, when the vessel from which the fluid issues is cylindrical or of any other form, has been shown in Prop. VII. Part II. Instead of dividing the sides of the vessel, for a scale to ascertain the descent of the fluid surface, the following
HYDRODYNAMICS.

The following method may be adopted. In the bottom of the cylindrical vessel $ABCD$, which is about 12 inches high, and four inches in diameter, is inserted a small glass adjutage $E$, which discharges the water in the vessel by successive drops. A hole $F$, about half an inch in diameter, is perforated in the cover $AB$, so as to allow the glass tube $CG$, about 16 inches long, and half an inch in diameter, to move up and down without experiencing any resistance. To the extremity of this tube is attached the ball $I$, which floats on the surface of the water in the vessel, and is kept steady, either by introducing a quantity of mercury into its cavity, if it be hollow, or by suspending a weight of a solid which does not sink in water. When the vessel is filled with water, the ball $I$ will be at the top $A$; then, in order to conduct the tube $C$, let the water flow out at $E$, and by means of a watch mark the points on the tube which descend to $F$ after the lapse of every hour, every half hour, and every quarter, and the instrument will be finished. In order to use this hydroscope or water-clock, pour water into the vessel $ABCD$ till the hour of the day is about to descend below $F$; and when this is done, it will point out any succeeding hour till the vessel is emptied.

Hamilton's clepsydra.

359. The clepsydra, invented by the honourable Mr. Charles Hamilton, is represented in fig. 7. An open canal $e$, supplied with a constant and equal stream by the syphon $d$, has at each end $f$, open pipes $f_1, f_2$ of exactly equal bores, which deliver the water that runs along the canal $e$, alternately into the vessels $g_1, g_2$, in such a quantity as to raise the water from the mouth of the tantaulus $t$, exactly in an hour. The canal $e$ is equally poised by the two pipes $f_1, f_2$, upon a centre $r$; the ends of the canal $e$ are raised alternately, as the cups $z$ are depressed, to which they are connected by lines running over the pulleys $l$. The cups $z$ are fixed at each end of the balance $m$, which moves up and down upon its centre $v$. $a_1, a_2$, are the edges of two wheels or pulleys, moving different ways alternately, and fitted to the cylinder $o$ by oblique teeth both in the cavity of the wheel and upon the cylinder, which, when the wheel moves one way, that is, in the direction of the minute-hand, meet the teeth of the cylinder and carry the cylinder along with it, and slip over those of the cylinder when it moves the contrary way, the teeth not meeting, but receding from each other. One or other of these wheels moves continually moves $o$ in the same direction, with an equal and uninterrupted motion. A fine chain goes twice round each wheel, having at one end a weight $X$, always out of the water, which equiperponders with $y$ at the other end, and, when kept floating on the surface of the fluid in the vessel $g$, which $y$ must always be; the two cups $z$, $z$, one at each end of the balance, keep it in equilibrio, till one of them is forced down by the weight and impulse of the water, which it receives from the tantaulus $t$. Each of these cups $z$, $z$, has likewise a tantaulus of its own $b, h$, which empties it after the water has run from $g$, and leaves the two cups again in equilibrio: $q$ is a drain to carry off the water. The dial-plate, &c. needs no description. The motion of the clepsydra is effected thus: As the end of the canal $e$, fixed to the pipe $f_1$, is the lowest in the figure, all the water supplied by the syphon runs through the pipe $f_1$, into the vessel $g_1$, till it runs over the top of the tantaulus $t$; when it immediately runs out at $i$ into the cup $Z$, at the end of the balance $m$, and forces it down; the balance moving on its centre $v$. When one side of $m$ is brought down, the string which connects it to $f_1$, running over the pulley $l$, raises the end $f_2$ of the canal $e$, which turns up its centre $r$, higher than $f_2$; consequently, all the water which runs through the syphon $d$ passes through $f_2$ into $g_2$, till the same operation is performed in that vessel, and so on alternately. As the height to which the water rises in $g$ in an hour, viz. from $S$ to $t$, is equal to the circumference of $n$, the float $y$ rising through that height with the water, allows the weight $X$ to act upon the pulley $m$, which carries with it the cylinder $o$; and this, making a revolution, causes the index $k$ to describe an hour on the dial-plate. This revolution is performed by the pulley $n$; the next is performed by $n_1$, whilst $n_1$ goes back, as the water in $g_1$ runs out through the tantaulus; for $y$ must follow the water, as its weight increases, out of it. The axis $o$ always keeps moving the same way; the index $p$ describes the minutes; each tantaulus must be wider than the syphon, that the vessels $g, g'$ may be emptied as low as $z$, before the water returns to them.

of the quantities of water discharged according to theory and experiment, 174.

of the results of Eydelwein's experiments, 178.

of the quantities of water discharged by cylindrical tubes, 182.

of the quantities discharged by cylindrical tubes, according to theory and experiment, 185.

of the quantities discharged by conical tubes, 187.

of the quantities discharged by orifices of various forms, 188.

showing the time in which vessels are partly exhausted, 194, 195.

showing the altitudes, &c. of jets, 196.

of the quantities of water discharged by conduit pipes, 204—211.

showing the pressure exerted upon pipes, 213.

of the velocity of water in canals, 214, 215.

showing the resistance of hemispheres, cones, globes, and cylinders, 239.

showing the resistance of globes, 241.

showing the resistance of plane surfaces, 243, 245.

Torrizelli discovers an important proposition in hydraulics, 7.

Torsion, the principle of, employed by Coulomb to determine the resistance of fluids, 221.

Tubes, cylindrical, discharge more water than simple orifices, 180.

conical, Poleni's experiments with, 187.

of various forms, Venturi's experiments with, 188.

capillary, how to measure their diameters, 120.

U

Undershoot wheels, 272.

number of their float boards, 272—275.

form of their float boards, 276.

position of their float boards, 277.

velocity of, 279.

maximum effect of, according to theory, 280.

maximum effect of, according to Smeaton, 281.

maximum effect of, according to Bousset, 282.

tables for, 285, 286.

how to construct them, 284.

Smeaton's experiments on, 289.

Undulation of waves, 253.

Velocity of fluids issuing from orifices, 137.

Vena contracta, discovered by Newton, 138.

quantity of its contraction according to different authors, 171.

Venturi discovers the lateral communication of motion in fluids, 23.

Vessels, time in which they are exhausted, 155—177.

Vera's hair-ropes machine, 320.

W

Waring's rules for Barker's mill, 302.

Water blowing machine, 351.

clocks, theory and construction of, 159.

clocks move faster in summer than winter, 218.

fluidity of, increased by electricity and by heat, 121.

running, method of measuring its velocity, 288.

instrument for, 288.

Water.
HYDRODYNAMICS.

END OF THE TENTH VOLUME.
