When men are once engaged in active life, and find that wealth and power, generally called interest, are the great avenues to every kind of enjoyment, they are apt to throw in many engaging moral forms to the object of their pursuit, in order to justify their passion, and varnish over the measures they take to gratify it, as indecency on the sides or passions of others, provision and security to themselves and friends, prudent economy or well-placed charity, social communication, superiority to their enemies, who are all villains, honourable service, and many other ingredients of merit. To attain such capacities of usefulness or enjoyment, what arts, nay, what meannesses, can be thought blameable by those cool pursuers of interest?—Nor have they whom the gay world is pleased to indulge with the title of men of pleasure, their imaginations less pregnant with moral images, with which they never fail to enoble, or, if they cannot do that, to palliate their gross pursuits. Thus admiration of evil, of sentiments and merit, friendship, love, generous sympathy, mutual confidence, giving and receiving pleasure, are the ordinary ingredients with which they season their gallantry and pleasurable entertainments; and by which they impose on themselves, and endeavour to impose on others, that their amours are the joint issue of good sense and virtue.

These associations, variously combined and proportioned by the imagination, form the chief private passions, which govern the lives of the generality, as the love of action, of pleasure, power, wealth, and fame; they influence the defensive, and affect the public passions, and raise joy or sorrow as they are gratified or disappointed. So that in effect these associations of good and evil, beauty and deformity, and the passions they raise, are the main hinges of life and manners, and the great sources of our happiness or misery. It is evident, therefore, that the whole of moral culture must depend on giving a right direction to the leading passions, and duly proportioning them to the value of the objects or goods pursued, under what name soever they may appear.

Now, in order to give them this right direction and due proportion, it appears from the foregoing detail, that those associations of ideas, upon which the passions the mind depend, must be duly regulated; that is to say, as an exorbitant passion for wealth, pleasure, or power, from an association or opinion, that more beauty and good, whether natural or moral, enters into the enjoy-ment or possession of them, than really belongs to ei-ther; therefore, in restoring those passions to their just proportion, we must begin with correcting the opinion, or breaking the false association, or, in other words, we must compound the complex phantom of happiness or good, which we fondly admire; disunite those ideas that have no natural alliance; and separate the original idea of wealth, power, or pleasure, from the foreign mixtures, incorporated with it, which enhance its value, or give it its chief power to enchant and seduce the mind.

For instance, let it be considered how poor and inconsiderable a thing wealth is, if it be disjoined from real use, or from ideas of capacity in the possessor to do good, from independence, generosity, protection for a family or friends, and social communication with others. By this standard let its true value be fixed; let its misapplication, or unbenevolent enjoyment, be accounted sordid and infamous; and nothing worthy or estimable be ascribed to the mere possession of it, which is not borrowed from its generous use.

If that complex form of good which is called pleasure engages us, let it be analyzed into its constituent principles, or those allurements it draws from the heart and imagination, in order to heighten the low part of the indulgence; let the separate and comparative moment of each be distinctly ascertained and deduced from that gross part, and this remainder of the accumulated enjoyment will dwindle down into a poor, insipid, trasiory thing. In proportion as the opinion of the good pursued abates, the admiration must decay, and the passions lose strength of course. One effectual way to lower the opinion, and consequently to weaken the habit founded upon it, is to practise lesser pieces of selfishness, or to abstain, to a certain pitch, from the pursuit or enjoyment of the favourite object; and, that this may be the more easily accomplished, one must avoid those occasions, that company, those places, and other circumstances, that inflamed one and endeared the other. And, as a counter-process, let higher or even different enjoyments be brought in view, other passions played upon the former, different places frequented, other exercises tried, company kept with persons of a different or more correct way of thinking both in natural and moral subjects.

As much depends on our setting out well in life, let the youthful fancy, which is apt to be very florid and luxuriant, be early accustomed by instruction, example, and significant moral exercises, nay, by looks, gestures, and every other testimony of just approbation or blame, to annex ideas of merit, honour, and happiness, not to birth, dress, rank, beauty, fortune, power, popularity, and the like outward things, but to moral and truly virtuous qualities, and to those enjoyments which spring from a well-informed judgment and a regular conduct of the affections, especially those of the social and disinterested kind. Such dignified forms of beauty and good, often suggested, and, by moving pictures and examples warmly recommended to the imagination, enforced by the authority of conscience, and demonstrated by reason to be
MORAL PHILOSOPHY.

The surest means of enjoyment, and the only independent, undependable, and durable goods, will be the best counterbalance to meaner passions, and the firmest foundation and security of virtue.

It is of great importance to the forming a just taste, or our large conceptions of happiness, to study and understand human nature well, to remember what a complicated system it is, particularly to have deeply imprinted on our minds that Gratitude of sense, faculties, and powers of enjoyment formerly mentioned, and the subordination of goods resulting from the notion, which nature points out, and the experience of mankind confirms. When, then we think seriously, and are not under the immediate influence of some violent prejudice or passion, prefer not the pleasures of action, contemplation, society, and most exercises and joys of the moral kind, as friendship, natural affection, and the like, to all sensual gratifications whatsoever? Where the different species of pleasure are blended into one complex form, let them be accurately distinguished, and be referred each to its proper faculty and sense, and examined apart what they have peculiar, what common with others, and what foreign and adventitious. Let wealth, grandeur, luxury, love, fame, and the like, be tried by this test, and their true alloy will be found out.

It be further considered, whether the mind may not be easy and enjoy itself greatly, though it want many of those elegancies and superfluities of life which some possess, or that load of wealth and power which others eagerly pursue, and under which they groan. Let the difficulty of attaining, the precariousness of possessing, and the many abatements in enjoying overgrown wealth and envied greatness, of which the weary possessors so frequently complain, as the hurry of business, the burden of company, of paying attendance to the few, and giving it to many, the cares of keeping, the fears of losing, and the desires of increasing what they have, and the other troubles which accompany this pitiful drudgery and pompous servitude; let these and the like circumstances be often considered, that are conducive to the removing or lessening the opinion of such goods, and the attendant passion or set of passions will decay of course.

Let the peculiar bent of our nature and character be observed, whether we are most inclined to form associations and relish objects of the sensible, intellectual, or moral kind. Let that which has the ascendant be particularly watched; let it be directed to right objects, be improved by proportioned exercises, and guarded by proper checks from an opposite quarter. Thus the sensible turn may be exalted by the intellectual, and a taste for the beauty of the fine arts, and both may be made subservient to convey and rivet sentiments highly moral and public-spirited. This inward survey must extend to the strength and weaknesses of one's nature, one's conditions, connections, habits, fortunes, studies, acquaintance, and the other circumstances of one's life, from which every man will form the justest estimate of his own dispositions and character, and the best rules for correcting and improving them. And in order to do this with more advantage, let those times or critical seasons be watched when the mind is best disposed towards a change; and let them be improved by rigorous resolutions, promises, or whatever else will engage the mind to persevere in virtue. Let the conduct, in fine, be often reviewed, and the causes of its corruption or improvement be carefully observed.

It will greatly conduce to refine the moral taste and strengthen the virtuous temper, to accustom the mind to frequent exercise of moral sentiments and determinations; by reading history, poetry, particularly of the picturesque and dramatic kind, the study of the fine arts; by conversing with the most eminent for good sense and virtue; but above all, by frequent and repeated acts of humanity, compassion, friendship, politeness, and hospitality. It is exercise that gives health and strength. He that reasons most frequently becomes the wisest, and most enjoys the pleasures of wisdom. He who is most often affected by objects of compassion in poetry, history, or real life, will have his soul most open to pity, and its delightful pains and duties. So he also who practices most diligently the offices of kindness and charity, will by it cultivate that disposition from whence all his pretensions to personal merit must arise, his present and his future happiness.

An useful and honourable employment in life will by an honest administration of a thousand opportunities of this kind, and the next employment; greatly strengthen a sense of virtue and good affections, which must be nourished by light training, as well as our understandings. For such an employment, by enlarging one's experience, giving a habit of attention and caution, or obliging one, from necessity or interest, to keep a guard over the passions, and study the outward decencies and appearances of virtue, will by degrees produce good habit, and at length insinuate the love of virtue and honesty for its own sake.

It is a great inducement to the exercise of benevolence to view human nature in a favourable light, to men and observe the character and circumstances of mankind on the fairest sides, to put the best constructions on their actions they will bear, and to consider them as the result of partial mistaken rather than ill affections, or, at worst, as the excesses of a pardonable self-love, seldom or never the effect of pure malice.

Above all, the nature and consequences of virtue and by consideration, their consequences being the law of our nature and rational animals, and will of heaven; the light in which they appear to our supreme Parent and Lawgiver, and the reception they will meet with from him, must be often attended to. The exercises of piety, as adoration and praise of the divine excellency, invocation of and dependence on his aid, confession, thanksgiving, and resignation, are habitually to be indulged, and frequently performed, not only as medicinal, but highly improving to the temper.

To conclude: It will be of admirable efficacy to the wards eradicating bad habits, and implanting good views of human life, ones, frequently to contemplate human life as the great and its crusts our future and immortal existence, as that state of probation in which we are to be educated for a divine life: to remember, that our virtues or vices will be immortal as ourselves, and influence our future as well as our present happiness—and therefore, that every disposition and action is to be regarded as pointing beyond the present to an immortal duration.—An habitual attention to this wide and important connexion will give a vast compass and dignity to our sentiments and actions, a noble...
MORAL PHILOSOPHY.

Part III.

Motives to Virtue.

We have already considered our obligations to the practice of virtue, arising from the constitution of our nature, by which we are led to approve a certain order and economy of affections, and a certain course of action correspondent to it. But, besides this, there are several motives which strengthen and secure virtue, though not themselves of a moral kind. These are, its tendency to personal happiness and the contrary tendency of vice. "Personal happiness arises either from the state of a man's own mind, or from the state and disposition of external causes towards him."

We shall first examine the "tendency of virtue to happiness with respect to the state of a man's own mind." This is a point of the utmost consequence in morals, because, unless we can convince ourselves, or show to others, that by doing our duty, or fulfilling our moral obligations, we consult the greatest satisfaction of our own mind, or our highest interest on the whole, it will raise strong and often unsurmountable prejudices against the practice of virtue, especially whenever there arise any appearances of opposition between our duty and our satisfaction or interest. To creatures so desirous of happiness, and averse to misery, as we are, and often so oddly situated amidst contending passions and interests, it is necessary that virtue appear not only an honourable but a pleasing and beneficient form. And in order to justify our choice to ourselves as well as before others, we must ourselves feel and be able to see in the face of the whole world, that her ways are ways of pleasantness, and her paths the paths of peace. This will show, beyond all contradiction, that we not only approve, but can give a sufficient reason for what we do.

Let any man in a cool hour, when he is disengaged from business, and undisturbed by passion (as such cool hours will sometimes happen), sit down, and seriously reflect with himself what state or temper of mind he would choose to feel and indulge, in order to be easy and to enjoy himself. Would he choose, for that purpose, to be in a constant dissipation and hurry of thought; to be disturbed in the exercise of his reason; to have various and often interfering phantoms of good playing before his imagination, soliciting and distracting him by turns, now soothing him with amusing hopes, then torturing him with anxious fears; and to approve this minute what he shall condemn the next? Would he choose to have a strong and painful sense of every petty injury; quick apprehensions of every impending evil; incessant and irremissible desires of power, wealth, honour, pleasure; an irreconcilable antipathy against all competitors and rivals; insolent and tyrannical dispositions to all below him; fawning, and at the same time envious, dispositions to all above him; with dark suspicions and jealousies of every mortal? Would he choose neither to love nor be beloved of any; to have no friend in whom to confide, or with whom to interchange his sentiments or designs; no favourite, on whom to bestow his kindness, or vent his passions; in fine, to be conscious of no merit with mankind, no esteem from any creature, no good affection to his Maker, no concern for, nor hopes of, his approbation; but in stead of all these, to hate, and know that he is hated, to condemn, and know that he is condemned by all; by the good, because he is so unlike; and by the bad because he is so like themselves; to hate or to dread the very Being that made him; and, in short, to have his breast the seat of pride and passion, petulance and revenge, deep melancholy, coal malignity, and all the other furies that ever possessed and tortured mankind?—Would our calm inquirer after happiness pitch on such a state, and such a temper of mind, as the most likely means to put him in possession of his desired ease and self-enjoyment?

Or would he rather choose a serene and easy flow of thought; a reason clear and composed; a judgment unbiassed by prejudice, and undistracted by passion; a sober and well-governed fancy, which presents the images of things true, and unmixed with delusive and unnatural charms, and therefore administers no improper or dangerous fuel to the passions, but leaves the mind free to choose or reject, as becomes a reasonable creature; a sweet and sedate temper, not easily ruffled by hopes or fears, prone neither to suspicion nor revenge, apt to view men and things in the fairest lights, and to bend gently to the humours of others rather than obstinately to contend with them? Would he choose such moderation and continence of mind, as neither to be ambitious of power, fond of honours, covetous of wealth, nor a slave to pleasure; a mind of course neither elated with success, nor dejected with disappointment; such a modest and noble spirit as supports power without insolence, wears honour without pride, uses wealth without profusion or parsimony; and rejoices more in giving than in receiving pleasure; such fortitude and equanimity as rises above misfortunes, or turns them into blessings; such integrity and greatness of mind, as neither flatters the vices, nor triumphs over the follies of men; as equally spurns servitude and tyranny, and will neither engage in low designs, nor abet them in others? Would he choose, in fine, such mildness and benignity of heart as takes part in all the joys, and refuses none of the sorrows, of others; stands well affected to all mankind; is conscious of meriting the esteem of all, and of being beloved by the best; a mind which delights in doing good without any show, and yet arrogates nothing on that account; rejoices in loving and being beloved by its Maker, acts ever under his eye, resigns itself to his providence, and triumphs in his approbation? Which of these dispositions would be his choice in order to be contented, serene, and happy? The former temper is vice, the latter virtue. Where one prevails, there misery prevails, shamed by the generality is acknowledged to prevail. Where the other reigns, there happiness reigns, and by the confession of mankind is acknowledged to reign. The perfection of either temper is misery or happiness in perfection. Therefore, every approach to either extreme is an approach to misery or to happiness; i.e. every degree of vice or virtue is accompanied with a proportionable degree of misery or happiness.

The principal alleviations of a virtuous man's calamities are these:—That though some of them may be...
MORAL PHILOSOPHY.

feeling state of men of pleasure, ambition, or interest, from Happiness.

and compares it with the serene and gentle state of a
mind at peace with itself, and friendly to all mankind,
unruffled by any violent emotion, and sensible to every
good-natured and alluring joy.

It were easy, by going through the different sets of the private
affections mentioned formerly, to show, that it is only passions
by maintaining the proportion settled there, that the mind arrives at true repose and satisfaction. If fear
exceeds that proportion, it sinks into melancholy and
dejection. If anger passes just bounds, it ferments into
rage and revenge, or subsides into a sullen cowering
gloom, which embitters every good, and renders one
exquisitely sensible to every ill. The private passions,
the love of honour especially, whose impulses are more
generous, as its effects are more diffuse, are instru-
ments of private pleasure; but if they are disproportio-
tioned to our wants, or to the value of their several
objects, or to the balance of other passions equally ne-
necessary and more amiable, they become instruments
of intense pain and misery. For, being now destitute of
that counterpoise which held them at a due pitch,
they grow turbulent, peevish, and revengeful, the cause
of constant restlessness and torment, sometimes flying
out into a wild delirious joy, at other times settling
in a deep splanchnic grief. The concert between rea-
son and passion is then broke: all is dissonance and
distraction within. The mind is out of frame, and feels
an agony proportioned to the violence of the reigning
passion.

The case is much the same, or rather worse, when in the pa-
any of the particular kind affections are out of their
natural order and proportion; as happens in the case of
effeminate pity, exorbitant love, parental dotage, or
any party passion, where the joint regards to society are
supplanted. The more social and disinterested the pa-
ssion is, it breaks out into the wider excesses, and makes
the more dreadful havoc both within and abroad; as
is but too apparent in those cases where a false species
of religion, honour, zeal, or party-rage, has seized on
the natural enthusiasm of the mind, and worked it up
to madness. It breaks through all ties natural and ci-
civil, disregards the most sacred and solemn obligations,
silences every other affection whether public or private,
and transforms the most gentle natures into the most
savage and inhuman.

Whereas, the man who keeps the balance of affection
Happiness even, is easy and serene in his motions; mild, and yet of well pro-
portioned affectionate; uniform and consistent with himself: is not liable to disagreeable collisions of interests and pas-
sions; gives always place to the most friendly and hu-
mankind affections, and never to dispositions or acts of re-
sentment, but on high occasions, when the security of the
private, or welfare of the public system, or the great
interests of mankind, necessarily require a noble indigna-
tion; and even then he observes a just measure in wrath;
and last of all, he proportions every passion to the
value of the object he affects, or to the importance of the
end he pursues.

To sum up this part of the argument, the honest and
good man has eminently the advantage of the know-
ledge and selfish wretch in every respect. The pleasures
which the last enjoys flow chiefly from external ad-
vantages and gratifications; are superficial and transi-
tory; dashed with long intervals of satiety, and fre-
quent

Nor do those generous affections stop any other na-
tural source of joy whatever, or deaden his sense of
any innocent gratification. They rather keep the
several senses and powers of enjoyment open and diseng-
gaged, intense and uncorrupted by riot or abuse; as
is evident to any one who considers the dissipate, un-
feeling state of men of pleasure, ambition, or interest, from Happiness.

and compares it with the serene and gentle state of a

vantages and gratifications; are superficial and transi-
tory; dashed with long intervals of satiety, and fre-
quent
MORAL PHILOSOPHY.

Part III.

Motives to Virtue.

He may have equal abilities, equal industry, equal attention to business; and in other respects he has greatly the advantage of him. People love better to deal with him; they can trust him more; they know he will not impose on them, nor take advantage of them, and can depend more on his word than on the oath or strongest securities of others. Whereas what is commonly called cunning, which is the offspring of ignorance, and constant companion of knavery, is not only a mean-spirited, but a very short-sighted talent, and a fundamental obstacle in the road of business. It may indeed procure immediate and petty gains; but it is attended with dreadful abatements, which do more than overbalance them, both as it sinks a man’s credit when discovered, and cramps that largeness of mind which extends to the remotest as well as the nearest interest, and takes in the most durable equality with the most transient gains. It is therefore easy to see how much a man’s credit and reputation, and consequently his success, depend on his honesty and virtue.

With regard to security and peace with his neighbours, it may be thought, perhaps, that the man of a quiet forgiving temper, and a flowing benevolence and courtesy, is much exposed to injury and affronts from every proud or peevish mortal, who has the power or will to do mischief. If we suppose, indeed, this quietness and gentleness of nature accompanied with cowardice and pusillanimity, this may often be the case; but in reality the good man is bold as a lion, and so much the bolder for being the calmer. Such a person will hardly be a butt to mankind. The ill natured will be afraid to provoke him, and the good natured will not incline to do it. Besides, true virtue, which is conducted by reason, and exerted gracefully and without parade, is a most insinuating and commanding thing; if it cannot disarm malice and resentment at once, it will wear them out by degrees, and subdue them at length. How many have, by favours and prudently yielding, triumphed over an enemy, who would have been inflamed into tenfold rage by the fiercest opposition! In fine, goodness is the most universally popular thing that can be.

To conclude; the good man may have some enemies, but he will have more friends; and, having given so many marks of private friendship or public virtue, he can hardly be destitute of a patron to protect, or a sanctuary to entertain him, or to protect or entertain his children when he is gone. Though he should have little else to leave them, he bequeaths them the fairest, and generally the most uneviend, inheritance of a good name, which, like good seed sown in the field of futurity, will often raise up unsolicited friends, and yield a benevolent harvest of unexpected charities. But should the fragrance of the parent’s virtue prove offensive to a perverse or envious age, or even draw persecution on the friendless orphans, there is one in heaven who will be more than a father to them, and recompense their parent’s virtues by showering down blessings on them.

CHAP. III. Motives to Virtue from the Being and Providence of God.

Besides the interesting motive mentioned in the last Chapter, there are two great motives of virtue, and strictly
MORAL PHILOSOPHY.

III.

Strictly connected with human life, and resulting from the very constitution of the human mind. The first is the BEING and PROVIDENCE of God; the second is the IMMORTALITY of the Soul, with future rewards and punishments.

It appears from Chap. IV. of Part II. that man, by the constitution of his nature, is designed to be a RELIGIOUS CREATURE. He is intimately connected with the Deity, and necessarily dependent on him. From that connection and necessary dependence result various obligations and duties, without fulfilling which, some of his sublimest powers and affections would be incomplete and abortive. If be be likewise an IMMORTAL creature, and if his present conduct shall affect his future happiness in another state as well as in the present, it is evident that we take only a partial view of the creature; if we leave out this important property of his nature; and make a partial estimate of human life, if we strike out of the account, or overlook, that part of his duration which runs out into eternity.

It is evident from the above-mentioned Chapter, that "to have a respect to the Deity in our temper and conduct, to venerate and love his character, to adore his goodness, to depend upon and resign ourselves to his providence, to seek his approbation, and act under a sense of his authority, is a fundamental part of moral virtue, and the completion of the highest destination of our nature."

But as piety is an essential part of virtue, so likewise it is a great support and enforcement to the practice of it. To contemplate and admire a Being of such transcendent dignity and perfection as God, must naturally and necessarily open and enlarge the mind, give a freedom and ampleness to its powers, and a grandeur and elevation to its aims. For, as an excellent divine observes, "the greatness of an object, and the excellency of the act of any agent about a transcendent object, doth mightily tend to the enlargement and improvement of his faculties." Little objects, mean company, mean cares, and mean business, cramp the mind, contract its views, and give it a creeping air and deportment. But when it soars above mortal cares and mortal pursuits into the regions of divinity, and converses with the greatest and best of Beings, it spreads itself into a wider compass, takes higher flights in reason and goodness, becomes godlike in its air and manners. Virtue is, if one may say so, both the effect and cause of largeness of mind. It requires that one think freely, and act nobly. Now what can conduct more to freedom of thought and dignity of action, than to conceive worthily of God, to reverence and adore his unrivalled excellency, to imitate and transcribe that excellency into our own nature, to remember our relation to him, and that we are the images and representatives of his glory to the rest of the creation? Such feelings and exercises must and will make us scorn all actions that are base, unhandsome, or unworthy our state; and the relation we stand in to God will irradiate the mind with the light of wisdom, and ennoble it with the liberty and dominion of virtue.

The influence and efficacy of religion may be considered in another light. We all know that the presence of a friend, a neighbour, or any number of spectators, but especially an august assembly of them, uses to be a considerable check upon the conduct of one who is not lost to all sense of honour and shame, and contributes to restrain many irregular sallies of passion. In the same manner we may imagine, that the awe of some superior mind, who is supposed privy to our secret conduct, and armed with full power to reward or punish, will impose a restraint on us in such actions as fall not under the control or animadversion of others. If we go still higher, and suppose our inmost thoughts and darkest designs, as well as our most secret actions, to lie open to the notice of the supreme and universal Mind, who is both the spectator and judge of human actions, it is evident that the belief of so august a presence, and such awful inspection, must carry a restraint and weight with it proportioned to the strength of that belief, and be an additional motive to the practice of many duties which would not have been performed without it.

It may be observed farther, that "to live under an habitual sense of the Deity and his great administration, is to be conversant with wisdom, order, and beauty, in the highest subjects, and to receive the delightful reflections and benign feelings which these excite while they irradiate upon him from every scene of nature and providence." How improving must such views be to the mind, in dilating and exalting it above those puny interests and competitions which agitate and inflame the bulk of mankind against each other!

CHAP. IV. Motive to Virtue from the Immortality of the Soul, &c.

The other motive mentioned was the immortality of the soul, with future rewards and punishments. The metaphysical proofs of the soul's immortality are commonly drawn from—its simple, uncompounded, and indivisible nature; from whence it is concluded, that it cannot be corrupted or extinguished by a dissolution or destruction of its parts:—from its having a beginning of motion within itself; whence it is inferred, that it cannot discontinue and lose its motion:—from the different properties of matter and mind, the sluggishness and inactivity of the one, and the immense activity of the other; its prodigious flight of thought and imagination; its penetration, memory, foresight, and anticipations of futurity; from whence it is concluded, that a being of so divine a nature cannot be extinguished. But as these metaphysical proofs depend on intricate reasonings concerning the nature, properties, and distinctions of body and mind, with which we are not very well acquainted, they are not obvious to ordinary understandings, and are seldom so convincing even to those of higher reach, as not to leave some doubts behind them. Therefore perhaps it is not so safe to rest the proof of such an important article on what many may call the subtilties of school learning. Those proofs which are brought from analogy, from the moral constitution and phenomena of the human mind, the moral attributes of God, and the present course of things, and which therefore are called the moral arguments, are the plainest and generally the most satisfying. We shall select only one or two from the rest.

In tracing the nature and destination of any being, Moral we form the surest judgment from his powers of action, proof from the and the scope and limits of these, compared with his analogy.
MORAL PHILOSOPHY.

Part III

Virtue.

Motives to state, or with that field in which they are exercised. If this being passes through different states, or fields of action, and we find a succession of powers adapted to the different periods of his progress, we conclude that he was destined for those successive states, and reckon his nature progressive. If, besides the immediate set of powers which fix him for action in his present state, we observe another set which appear superfluous if he were to be confined to it, and which point to another or higher one, we naturally conclude, that he is not designed to remain in his present state, but to advance to that for which those supernumerary powers are adapted. Thus we argue, that the insect, which has wings forming or formed, and all the apparatus proper for flight, is not destined always to creep on the ground, or to continue in the torpid state of adhering to a wall, but is designed in its season to take its flight in air. Without this farther destination, the admirable mechanism of wings and the other apparatus would be useless and absurd. The same kind of reasoning may be applied to man, while he lives only a sort of vegetative life in the womb. He is furnished even there with a beautiful apparatus of organs, eyes, ears, and other delicate senses, which receive nourishment indeed, but are in a manner folded up, and have no proper exercise or use in their present confinement. Let us suppose some intelligent spectator, who never had any connexion with man, nor the least acquaintance with human affairs, to see this odd phenomenon, a creature formed after such a manner, and placed in a situation apparently unsuitable to such various machinery: must he not be strangely puzzled about the use of his complicated structure, and reckon such a profusion of art and admirable workmanship lost on the subject; or reason by way of anticipation, that a creature endowed with such various yet unexerted capacities, was destined for a more enlarged sphere of action, in which those latent capacities shall have full play? the vast variety and yet beautiful symmetry and proportions of the several parts and organs with which the creature is endowed, and their apt cohesion with, and dependence on, the curious receptacle of their life and nourishment, would forbid his concluding the whole to be the birth of chance, or the bungling effort of an unskilful artist; at least would make him demur a while at so harsh a sentence. But if, while he is in this state of uncertainty, we suppose him to see the babe, after a few successful struggles, throwing off his fetters, breaking loose from his little dark prison, and emerging into open day, then unfolding his recluse and dormant powers, breathing in air, gazing at light, admiring colours, sounds, and all the fair variety of nature, immediately his doubts clear up, the propriety and excellency of the workmanship dawn upon him with full lustre, and the whole mystery of the first period is unravelled by the opening of this new scene. Though in this second period the creature lives chiefly a kind of animal life, i.e., of sense and appetite, yet by various trials and observations he gains experience, and by the gradual evolution of the powers of imagination he ripens space for a higher life, for exercising the arts of design and imitation, and of those in which strength or dexterity are more requisite than acuteness or reach of judgment. In the succeeding rational or intellectual period, his understanding, which formerly crept in a lower, mounts into a higher sphere, canvases the nature, judges of the relations of things, forms schemes, imagines, deduces consequences from what is past, and from present as well as past collects future events. By this succession of states, and of correspondent culture, he grows up to an intelligent moral, a social, and a political creature. This is the last period at which we perceive him to arrive in this his mortal career. Each period is introductory to the next succeeding one; each life is a field of exercise and improvement for the next higher one; the life of the infant is for that of the child, the life of the child for that of the youth, and all the lower for the highest and best. But is this the last period of Nature's progress? Is this the utmost extent of her dominions? Part I, plot, where she winds up the drama, and dismisses the actor into eternal oblivion? Or does he appear to be invested with supernumerary powers, which have not full exercise and scope even in the last scene, and reach not that maturity or perfection of which they are capable; and therefore point to some higher scene, where he is to sustain another and more important character than he has yet sustained? If any such there are, may we not conclude by analogy, or in the same way of anticipation as before, that he is destined for that after part, and is to be produced upon a more august and solemn stage, where his sublimer powers shall have proportioned action, and his nature attain its completion.

If we attend to that curiosity, or prodigious thirst of knowledge, which is natural to the mind in every period of its progress, and consider withal the endless round of business and care, and the various hardships to which the bulk of mankind are chained down; it is invidious, that in this present stage it is impossible to expect the gratification of an appetite at once so insatiable and so noble. Our senses, the ordinary organs by which knowledge is let into the mind, are always imperfect, and often fallacious; the advantages of assisting or correcting them are possessed by few; the difficulties of finding out truth amidst the various and contradictory opinions, interests, and passions of mankind, are many; and the wants of the creature, and of those with whom he is connected, numerous and urgent: so that it may be said of most men, that their intellectual organs are as much shut up and secluded from proper nourishment and exercise in that little circle to which they are confined, as the bodily organs are in the womb. Nay, those who to an aspiring genius have added all the assistances of art, leisure, and the most liberal education, what narrow prospects can even they take of this unbounded scene of things from that little eminence on which they stand? and how eagerly do they still grasp at new discoveries, without any satisfaction or limit to their ambition?

But should it be said that man is made for action, and not for speculation, or fruitless searches after knowledge, we ask, For what kind of action? Is it only for bodily exercises, or for moral, political, and religious ones? Of all these he is capable; yet, by the unavoidable circumstances of his lot, he is tied down to the former, and has hardly any leisure to think of the latter, or, if he has, wants the proper instruments of exercising them. The love of virtue, of one's friends and country, the generous sympathy with mankind, and heroic zeal of doing good, which are all so natural to great and good
MORAL PHILOSOPHY.

a divine elasticity in the free air of heaven. He will not then peep at the universe and its glorious Author through a dark grate or a gross medium, nor receive the reflections of his glory through the strait openings of sensible organs: but will be all eye, all ear, all ethereal and divine feeling*. Let one part, however, of the analogy be attended to: That as in the womb we receive our original constitution, form, and the essential stamina of our being, which we carry along with us into the light, and which greatly affect the succeeding periods of our life; so our temper and condition in the future life will depend on the conduct we have observed, and the character we have formed, in the present life. We are here in miniature what we shall be at full length hereafter. The first rude sketch or outlines of reason and virtue must be drawn at present, to be afterwards enlarged to the stature and beauty of angels.

This, if duly attended to, must prove not only an immortal guard, but an admirable incentive to virtue. For he who faithfully and ardently follows the light of knowledge, and pants after higher improvements in virtue, will be wonderfully animated and inflamed in that pursuit by a firm conviction that the scene does not close with life—that his struggles, arising from the weakness of nature and the strength of habit, will be turned into triumphs—that his career in the track of wisdom and goodness will be both swifter and smoother—and those generous arduous with which he glows towards heaven, i.e. the perfection and immortality of virtue, will find their adequate object and exercise in a sphere proportionably enlarged, incorruptible, immortal. On the other hand, what an inexpressible damp must it be to the good man, to dread the total extinction of that light and virtue, without which life, nay, immortality itself, were not worth a single wish?

Many writers draw their proofs of the immortality of soul, and of a future state of rewards and punishments, from the unequal distribution of these here. Any of present calamities cannot be dissembled that wicked men often escape the outward punishment due to their crimes, and do not feel the inward in that measure, the demerit seems to require, partly from the callousness induced upon their nature by the habits of vice, and partly from the dissipation of their minds abroad by pleasure or business—and sometimes good men do not reap all the natural and genuine fruits of their virtue, through the many unforeseen or unavoidable calamities in which they are involved. To the smallest reflection, however, it is obvious that the natural tendency of virtue is to produce happiness; that if it were universally practised, it would, in fact, produce the greatest sum of happiness which human nature is capable; and that this tendency is defeated only by numerous individuals, who, forsaking the laws of virtue, injure and oppress those who steadily adhere to them. But the natural tendency of virtue is the result of that constitution of things which was established by God at the creation of the world. This being the case, we must either conclude, that there will be a future state, in which all the moral obliquities of the present shall be made straight; or else admit, that the designs of infinite wisdom, goodness, and power, can be finally defeated by the perverse conduct of human weakness. But this last supposition is so extravagantly absurd,
MORAL PHILOSOPHY.

Part III

403

Motives to Virtue.

Belief of immortality, &c. a great support amidst trials.

that the reality of a future state, the only other possible alternative, may be pronounced to have the evidence of perfect demonstration.

Virtue has present rewards, and vice present punishments annexed to it; such rewards and punishments as make virtue, in most cases that happen, far more eligible than vice: but, in the infinite variety of human contingencies, it may sometimes fall out, that the inflexible practice of virtue shall deprive a man of considerable advantages to himself, his family, or friends, which he might gain by a well-timed piece of roguery; suppose by betraying his trust, voting against his conscience, selling his country, or any other crime where the security against discovery shall heighten the temptation. Or, it may happen, that a strict adherence to his honour, to his religion, to the cause of liberty and virtue, shall expose him, or his family, to the loss of every thing, nay, to poverty, slavery, death itself, or to torments far more intolerable. Now what shall secure a man's virtue in circumstances of such trial? What shall enforce the obligations of conscience against the allurements of so many interests, the dread of so many and so terrible evils, and the almost unsurmountable aversion of human nature to excessive pain? The conflict is the greater, when the circumstances of the crime are such as easily admit a variety of alleviations from necessity, natural affection, love to one's family or friends, perhaps in indigence: these will give it even the air of virtue. Add to all, that the crime may be thought to have few bad consequences,—may be easily concealed,—or imagined possible to be retrieved in a good measure by future good conduct. It is obvious to which side most men will lean in such a case; and how much need there is of a balance in the opposite scale, from the consideration of a God, of a Providence, and of an immortal state of retribution, to keep the mind firm and uncorrupted in those or like instances of singular trial or distress.

In the general course of a governing Mind, and a persuasion that virtue is not only befriended by him here, but will be crowned by him hereafter with rewards suitable to its nature, vast in themselves, and immortal in their duration, must be not only a mighty support and incentive to the practice of virtue, but a strong barrier against vice. The thoughts of an Almighty Judge, and of an impartial future reckoning, are often alarming, expressibly so, even to the stoutest offenders. On the other hand, how supporting must it be to the good man, to think that he acts under the eye of his friend, as well as judge! How improving, to consider the present state as connected with a future one, and imagine every relation in which he stands as a school of discipline for his affections; every trial as the exercise of some virtue; and the virtuous deeds which result from both, as introductory to higher scenes of action and enjoyment! Finally, How transporting is it to view death as his discharge from the warfare of mortality, and a triumphant entry into a state of freedom, security, and perfection, in which knowledge and wisdom shall break upon him every quarter; where each faculty shall have its proper object: and his virtue, which was often damped or defeated here, shall be enshrined in undisturbed and eternal empire?

On reviewing this short system of morals, and the motives which support and enforce it, and comparing it both with the Christian scheme, what light and vigour do they borrow from thence! How clearly and fully do Christianity lay open the connections of our nature, both material and immaterial, and future as well as present! What an ample and beautiful detail does it present of the duties we owe to God, to society, and ourselves, promulgated in the most simple, intelligible, and popular manner; divested of every partiality of sect or nation; and adapted to the general state of mankind! With what bright and alluring examples does it illustrate and recommend the practice of those duties: and with what mighty sanctions does it enforce that practice! How strongly does it describe the corruptions of our nature; the deviations of our life from the rule of duty, and the causes of both! How marvelous and benevolent a plan of redemption does it unfold, by which those corruptions may be remedied, and our nature restored from its deviations to transcendent heights of virtue and piety! Finally, What a fair and comprehensive prospect does it give us of the administration of God, of which it represents the present state only as a small period, and a period of warfare and trial! How solemn and unbounded are the scenes which it opens beyond it! the resurrection of the dead, the general judgment, the equal distribution of rewards and punishments to the good and the bad; and the full completion of divine wisdom and goodness in the final establishment of order, perfection, and happiness! How glorious then is that Scheme of Religion, and how worthy of affection as well as of admiration, which, by making such discoveries, and affording such assistance, has disclosed the unfading fruits and triumphs of virtue, and secured its interests beyond the power of time and chance.

MOR.

Moral Sense, that whereby we perceive what is good, virtuous, and beautiful, in actions, manners, and characters. See Moral Philosophy.

MORALITY. See Moral Philosophy.

Morant-Point, the most easterly point or promontory of the island of Jamaica, in America. W. Long. 75° 56'. N. Lat. 17° 56'.

MORASS, a marsh, fen, or low moist ground, which receives the waters from above without having any descent to carry them off again. Somner derivation the word from the Saxon merse, "lake;" Salinas from mor, "a collection of waters;" others from the German meras "a muddy place;" and others from moris, of mariscum, à maris, i.e. rushes. See Drain. Agriculture Index.

In Scotland, Ireland, and the north of England, there is a particular kind of morasses called moors, or peat-mosses, whence the country people dig their peat or turf for firing. See Moss.

MORAT, or Murten, a considerable town of Switzerland,
Switzerland, capital of a bailiwick of the same name, belonging to the cantons of Bern and Friburg. It is situated on the lake Morat, on the road from Avenches to Bern, 10 miles west of Bern and 10 miles north-east of Friburg. The lake is about six miles long and two broad, and the country about it pleasant and well cultivated. The lakes of Morat and Neuchâtel are parallel to each other, but the latter is more elevated, discharging itself by means of the river Broye into the lake of Neuchâtel. According to M. de Luc, the former is 15 French feet above the level of Neuchâtel at the level of Bienne, seem formerly to have extended considerably beyond their present limits, and from the position of the country appear to have once united. Formerly the large fish named *sulisus glanis*, or the salut, frequented these lakes, but has not been caught in them for a long time past. The environs of this town and lake were carefully examined by Mr. Coxe, during his residence in Switzerland, who made several excursions across the lake to a ridge of hills situated between it and Neuchâtel. Here are many delightful prospects; particularly one from the top of Mount Vuilly, which, he says, is perhaps the only central spot from which the eye can at once comprehend the vast amphitheatre formed on one side by the Jura stretching from the environs of Geneva as far as Bâle, and, on the other, by that stupendous chain of snowy Alps which extend from the frontiers of Italy to the confines of Germany, and is lost at each extremity in the horizon. Morat is celebrated for the obstinate defence it made against Charles the Bold, duke of Burgundy, and for the battle which afterwards followed on the 22d of June 1476, where the duke was defeated, and his army almost entirely destroyed. Not far from the town, and adjoining to the high road, there still remains a monument of this victory. It is a square building, filled with the bones of Burgundian soldiers who were slain at the siege and in the battle; the number of which appears to have been very considerable. There are several inscriptions in the Latin and German languages commemorating the victory.

MORA, OLYMPIA FULVIA, an Italian lady, distinguished for her learning, was born at Ferrara, in 1526. Her father, after teaching the belles lettres in several cities of Italy, was made preceptor to the two young princes of Ferrara, the sons of Alphonso. The uncommon abilities he discovered in his daughter determined him to give her all the advantages of education. Meanwhile the princess of Ferrara studying polite literature, it was judged expedient that she should have a companion in the same pursuit; and Morata being called, she was heard by the astonished courtiers to declaim in Latin, to speak Greek, and to explain the paradoxes of Cicero. Her mother dying, she was obliged to return home to take upon her the management of family affairs, and the education of her brother and three sisters; both which she executed with the greatest diligence and success. In the meantime Andrew Grunthler, a young German physician, had married her, and with him she went to Germany, taking her brother along with her, whom she instructed in the Latin and Greek tongues; and after staying a short time at Augsburg, went to Schweinfurt in Franconia, where her husband was born: but they had not been there long before that town was unhappily besieged and burnt; however, escaping the flames, they fled in the utmost distress to Hambühl. This place they were also obliged to quit, and were reduced to the last extremities, when the elector Palatine invited Grunthler to be professor of physic at Heidelberg. He entered on his new office in 1554; but they no sooner began to taste the sweets of repose, than a disease, occasioned by the distresses and hardships they had suffered, seized upon Morata, who died in 1555, in the 20th year of her age; and her husband and brother did not long survive her. She composed several works, great part of which were burnt with the town of Schweinfurt; the remainder, which consist of orations, dialogues, letters, and translations, were collected and published under the title of *Olympia Fulviae Moratae, iamae doctissima*, et *plani divinae, opera omnia quae haeceterni mevri potuviunt; quibus Caetiii secundus curiosi epistolae ac orationes accessorunt*.

MORAVIA, a river of Turkey in Europe, which rises in Bulgaria, runs north through Servia by Nissa, and falls into the Danube at Scemendra, to the eastward of Belgrade.

MORAVIA, a marquisate of Germany, derives the name of *Mahera*, as it is called by the Germans, and of *Mauravia*, as it is called by the natives, from the river of that name, which rises in the mountains of the county of Glats, and passes through the middle of it. It is bounded to the south by Austria; to the north by Silesia and Hungary; being about 120 miles in length and 10 in breadth. Its surface is about 80,000 square miles. In 1775 its population, according to official returns, was 1,143,674, of whom 23,382 were Jews; but in 1801 has been computed to be 1,400,000 (Mentelle et Malte Brun). Olmutz, formerly the chief town, contains 11,000 inhabitants; Brunn, now the seat of government, contains 14,000; and there are several other considerable towns.

A great part of this country is overrun with woods and mountains, where the air is very cold, but much wholesomer than in the low grounds, which are full of bogs and lakes. The mountains, in general, are barren; but the more champaign parts tolerably fertile, yielding corn, with plenty of hemp and flax, good saffron, and pasture. Nor is it altogether destitute of wine, red and white, fruits, and garden stuff. Moravia also abounds in horses, black cattle, sheep, and goats. In the woods and about the lakes there is plenty of wild fowl, game, venison, bees, honey, hares, foxes, wolves, beavers, &c. This country affords marble, alum, iron, sulphur, saltpetre, and vitriol, with mineral waters, and warm springs, but salt is imported. Its rivers, of which the March, Morawa, or Morau, are the chief, abound with trout, crayfish, barbels, eel, perch, and many other sorts of fish.

The language of the inhabitants is a dialect of the Slavonic, differing little from the Bohemian; but the nobility and citizens speak German and French. Moravia was anciently inhabited by the Quadi, who were driven out by the Scali. Its kings, who were once powerful and independent, afterwards became dependent on, and tributary to, the German emperors and kings. At last, in the year 908, the Moravian kingdom was parcelled out among the Germans, Poles, &c.
and Hungarians. In 1066, that part of it properly called Moravia was declared a marquisate by the German king Henry IV, and united with Bohemia, to whose dukes and kings it hath ever since been subject. The states of the country consist of the clergy, lords, knights, and burgesses; and the diets, when summoned by the regency, are held at Brunn. The marquisate is still governed by its own peculiar constitutions, under the directorium in publicis et cameralibus, and the supreme judiciary at Vienna. It is divided into six circles, each of which has its captain, and contributes to its sovereign one-third of what is exacted from Bohemia. Towards the expenses of the military establishment of the whole Austrian hereditary countries, its yearly quota is 1,856,490 florins. Seven regiments of foot, one of cuirassiers, and one of dragoons, are usually quartered in it.

Christianity was introduced into this country in the 9th century; and the inhabitants continued attached to the church of Rome till the 15th, when they espoused the doctrine of John Huss, and threw off Popery: but after the defeat of the elector Palatine, whom they had chosen king, as well as the Bohemians, the emperor Ferdinand II. re-established Popery; though there are still some Protestants in Moravia. The bishop of Olmutz, who stands immediately under the pope, is at the head of the ecclesiastics in this country. The supreme ecclesiastical jurisdiction, under the bishop, is vested in a consistory.

The commerce of this country is considerable. Of what they have, Brunn enjoys the principal part. At Iglaub and Trebitz are manufactures of cloth, paper, gunpowder, etc. There are also some iron works and glass houses in the country.

The inhabitants of Moravia in general are open-hearted, not easy to be provoked or pacified, obedient to their masters, and true to their promises; but credulous of old prophecies, and much addicted to drinking, though neither such sots or bigots as they are represented by some geographers. The boors, indeed, upon the river Hanc, are said to be a thriftless, unpolished, brutal race. The sciences now begin to lift up their heads a little among the Moravians, the university of Olmutz having been put on a better footing; and a riding academy, with a learned society, has been lately established there.

MORAVIAN BROTHERS. See HEBREUTHERS, and UBITAS FRATRUM.

MORAV, or MORA, a large river of Germany, which has its source on the confines of Bohemia and Silesia. It traverses the whole of Moravia, waters Olmutz and Hradisch, and receiving the Taya from the confines of Lower Hungary and Upper Austria, separates these two countries as far as the Danube, into which it falls.

MORBID, among physicians, signifies "diseased or corrupt;" a term applied either to an unsound constitution, or to those parts or humours that are affected by a disease.

MORBUS COMITIAE, a name given to the epilepsy; because if on any day when the people were assembled in comitia upon public business, any person suddenly seized with this disorder should fall down, the assembly was dissolved, and the business of the comitia, however important, was suspended. See COMITIA.
Sir Thomas replied, "I thank our lord, son Roper, I find his grace my very good lord indeed, and believe he doth as singularly favour me as any subject within this realm: howbeit, I must tell thee, I have no cause to be proud thereof; for if my head would win him a castle in France, it would not fail to go off." From this anecdote it appears, that Sir Thomas knew his grace to be a villain.

In 1526 he was sent with Cardinal Wolsey and others, on a joint embassy to France, and in 1529 with Bishop Tostal to Cambray. The king, it seems, was so well satisfied with his services on these occasions, that in the following year, Wolsey being disgraced, he made him chancellor; which seems the more extraordinary, when we are told that Sir Thomas had repeatedly declared his disapprobation of the king's divorce, on which the great defensor fidei was so positively bent. Having executed the office of chancellor about three years, with equal wisdom and integrity, he resigned the seals in 1533, probably to avoid the danger of his refusing to confirm the king's divorce. He now retired to his house at Chelsea; dismissed many of his servants; sent his children with their respective families to their own houses (for hitherto, he had, it seems, maintained all his children, with their families, in his own house, in the true style of an ancient patriarch; and spent his time in study and devotion: but the capricious tyrant would not suffer him to enjoy his tranquillity. Though now reduced to a private station, and even to indigence, his opinion of the legality of the king's marriage with Anne Boleyn was deemed of so much importance, that various means were tried to procure his approbation; but all persuasion proving ineffectual, he was, with some others, attainted in the house of lords of misprision of treason, for encouraging Elizabeth Barton, the nun of Kent, in her treasonable practices. His innocence in this affair appeared so clearly, that they were obliged to strike his name out of the bill. He was then accused of other crimes, but with the same effect; till, refusing to take the oath enjoined by the act of supremacy, he was committed to the Tower, and, after 15 months imprisonment, was tried at the bar of the king's bench for high treason, in denying the king's supremacy. The proof rested on the sole evidence of Rich the solicitor general, whom Sir Thomas, in his defence, sufficiently discredited; nevertheless the jury brought him in guilty, and he was condemned to suffer as a traitor. The merciful Harry, however, indulged him with simple decollation; and he was accordingly beheaded on Tower hill, on the 8th of July 1535. His body, which was first interred in the Tower, was begged by his daughter Margaret, and deposited in the chancel of the church at Chelsea, where a monument, with an inscription written by himself, had been some time before erected. This monument with the inscription is still to be seen in that church. The same daughter, Margaret, also procured his head after it had remained 14 days upon London bridge, and placed it in a vault belonging to the Roper family, under a chapel adjoining to St Dunstan's church in Canterbury. Sir Thomas More was a man of some learning, and an upright judge; a very priest in religion, yet cheerful, and even affectedly witty.
witty (α). He wanted not sagacity, where religion was out of the question; but in that his faculties were so enveloped, as to render him a weak and credulous enthusiast. He left one son and three daughters; of whom Margaret, the eldest, was very remarkable for her knowledge of the Greek and Latin languages. She married a Mr Roper of Welhall in Kent, whose life of Sir Thomas More was published by Mr Hearne at Oxford in 1716. Mrs Roper died in 1544; and was buried in the vault of St Dunstan's in Canterbury, with her father's head in her arms.

Sir Thomas was the author of various works, though his Utopia is the only performance that has survived in the esteem of the world; owing to the rest being chiefly of a polemic nature: his answer to Luther has only gained him the credit of having the best knack of any man in Europe, at calling bad names in good Latin. His English works were collected and published by order of Queen Mary, in 1557; his Latin, at Basel, in 1565, and at Louvain, in 1566.

MOREA, formerly called the Peloponnesus, is a peninsula to the south of Greece, to which it is joined by the isthmus of Corinth. Its form resembles a mulberry leaf, and its name is derived from the great number of mulberry trees which it produces. It is about 420 miles in length, and 110 in breadth. The air is temperate, and the land fertile, except in the middle, where it is full of mountains, and is watered by a great number of rivers. It is divided into three provinces; Scania, Belvedera, and Breedoo-Mains. It was taken from the Turks by the Venetians in 1687; but they lost it again in 1715. The population of the Morea is estimated by Dr Clarke at 300,000. See GRECIA and PELOPONNESUS.

MOREL, the name of several celebrated printers to the kings of France, who, like the Stephens, were also men of great learning.

Frederic Morel, who was interpreter in the Greek and Latin tongues, as well as printer to the king, was heir to Vascoan, whose daughter he had married. He was born in Champagne, and he died in an advanced age at Paris, 1583. His sons and grandsons trode in his steps; they distinguished themselves in literature, and maintained also the reputation which he had acquired by printing. The edition of St Gregory of Nyssa, by his son Claude Morel, is held in great estimation by the learned.

Morel, Frederic, son of the preceding, and still more celebrated than his father, was professor and interpreter to the king, and printer in ordinary for the Hebrew, Greek, Latin, and French languages. He was so devoted to study, that when he was told his wife was at the point of death, he would not stir till he had finished the sentence which he had begun. Before it was finished, he was informed that she was actually dead; I am sorry for it, (replied he coldly), she was an excellent woman. This printer acquired great reputation from the works which he published, which were very numerous and beautifully executed. From the manuscripts in the king's library, he published several treatises of St Basil, Theodoret, St Cyril; and he accompanied them with a translation. His edition of the works of Oecumenius and Aetæus, in 2 vol. folio, is much esteemed. In short, after distinguishing himself by his knowledge in the languages, he died June 27, 1630, at the age of 78. His sons and grandsons followed the same profession.

Morél, William, regius professor of Greek, and director of the king's printing house at Paris, died 1564. He composed a Dictionnaire Grec-Latin François, which was published in quarto in 1622, and some other works which indicate very extensive learning. His editions of the Greek authors are exceedingly beautiful. This great scholar, who was of a different family from the preceding, had a brother named John, who died in prison (where he had been confined for heresy) at the age of 20, and whose body was dug out of the grave, and burnt, Feb. 27. 1559. They were of the parish of Tilleul, in the county of Mortain in Normandy.

Morena, in Ancient Geography, a district or division of Mycia, in the Hither Asia. A part of which was occupied by Cleo, formerly at the head of a band of robbers, but afterwards priest of Jupiter Abrettenus, and enriched with possessions, first by Antony, and then by Caesar.

Moresque, Moresk, or Morsko, a kind of painting, carving, &c. done after the manner of the Moors; consisting of several grotesque pieces and compartments promiscuously intermingled, not containing any perfect figure of a man, or other animal, but a wild resemblance of birds, beasts, trees, &c. These are also called arabesques, and are particularly used in embroidery, damask work, &c.

Moresque Dances, vulgarly called Morrice dances, are those altogether in imitation of the Moors, as sarabands, chacones, &c. and are usually performed with castanets, tambours, &c.

There are few country places in England where the morrice dance is not known. It was probably introduced about, or a little before, the reign of Henry VIII. and is a dance of young men in their shirts, with bells at their feet, and ribbands of various colours tied round their arms and flung across their shoulders.

Morgagna. See Fata.

Morgagni, John Baptist, doctor of medicine, first professor of anatomy in the university of Padua, and member of several of the most eminent societies of learned men in Europe, was born in the year 1683, at Forli, a town in the district of La Romagna in Italy. His

(A) This last disposition, we are told, he could not restrain even at his execution. The day being come, he ascended the scaffold, which seemed so weak that it was ready to fall; whereupon, "I pray (said he) see me safe up, and for my coming down let me shift for myself." His prayers being ended, he turned to the executioner, and with a cheerful countenance said, "Pluck up thy spirits, man, and be not afraid to do thy office; my neck is very short, take heed therefore thou strike not awry for saving thy honesty." Then laying his head upon the block, he bade him stay until he had put aside his beard, saying, "That had never committed any treason."
His parents, who were in easy circumstances, allowed him to follow that course in life his genius dictated. He began his studies at the place of his nativity; but soon after removed to Bologna, where he obtained the degree of Doctor of Medicine, when he had but just reached the 16th year of his age. Here his peculiar taste for anatomy found an able preceptor in Valsalva, who bestowed on him the utmost attention; and such was the progress he made under this excellent master, that at the age of 20 he himself taught anatomy with high reputation. Soon, however, the fame of his prelections, and the number of his pupils, excited the jealousy of the public professors, and gave rise to invincible persecutions. But his abilities and prudence gained him a complete triumph over his enemies; and all opposition to him was finally terminated from his being appointed by the senate of Bologna to fill a medical chair, which soon became vacant. But the duties of this office, although important, neither occupied the whole of his time, nor satisfied his anxious desire to afford instruction. He still continued to labour in secret on his favourite subject, and soon after communicated the fruits of these labours to the public in his Adversaria Anatomica, the first of which was published in the year 1706, the second and third in 1717, and the three others in 1719. The publication of this excellent work spread the fame of Morgagni far beyond the limits of the state of Bologna. Such was his reputation, that the wise republic of Venice had no hesitancy in making him an offer of the second chair of the theory of medicine in the university of Padua; but it was vacated by the death of M. Molinetti; and, to ensure his acceptance, they doubled the emoluments of that appointment. While he was in this department, he published his treatise, entitled Nova Institutionem medicarum idea, which first appeared at Padua in the year 1712. From this work his former reputation suffered no diminution. And soon after he rose, by different steps, to be first professor of anatomy in that celebrated university. Although Morgagni was thus finally settled at Padua, yet he gave evident proofs of his gratitude and attachment to Bologna, which he considered as his native country with respect to the sciences. He exerted his utmost efforts in establishing the academy of Bologna, of which he was one of the first associates; and he enriched their publications with several valuable and curious papers. Soon after this, the Royal Societies of London and Paris received him among their number. Not long after the publication of his Adversaria Anatomica, he began, much upon the same plan, his Epistolas Anatomicae, the first of which is dated at Padua in the beginning of April 1726. The works of Morgagni which have already been mentioned, are to be considered, in a great measure, as strictly anatomical: but he was not more eminent as an-anatomist, than as a learned and successful physician. In the year 1750, when he was not far distant from the 80th year of his age, he published his large and valuable work De causis et sedibus morborum per anatomen indagatis. This last and most important of all his productions will afford convincing evidence of his industry and abilities to latest posterity. Besides these works, he published, at different periods of his life, several miscellaneous pieces, which were afterwards collected into one volume, and printed under his own eye at Padua, in the year 1765. It does not appear that he had in view any future publications; but he intended to have favoured the world with a complete edition of all his works, which would probably have been augmented with many new observations. In this he was engaged when, on the 5th of December 1771, after he had nearly arrived at the 90th year of his age, death put a period to his long and glorious career in the learned world.

MORGANA, or MORGAGNA, Fata. See FATA.

MORGES, a town of Switzerland in the canton of Berne, a place of some trade, and situated on the lake of Geneva, five miles from Lausanne. E. Long. 6° 42'. N. Lat. 46° 29'.

MORGO, anciently Amorgos, an island in the Archipelago, which produces wine, oil, and corn. It is well cultivated, and the inhabitants are affable, and generally of the Greek church. The best parts belong to a monastery. The greatest inconvenience in this island is the want of wood. It is 30 miles in circumference. E. Long. 26° 15'. N. Lat. 36° 30'.

MORIAH, one of the eminences of Jerusalem; on which Abraham went to offer his son, and David wanted to build the temple, which was afterwards executed by Solomon: the threshold floor of Araunah; originally narrow, so as scarce to contain the temple, but enlarged by means of ramps; and surrounded with a triple wall, so as to add great strength to the temple, (Josephus). It may be considered as a part of Mount Zion, to which it was joined by a bridge and gallery. (Id.).

MORILLES, a kind of mushroom, about the size of a walnut, pierced with holes like a honey-cob, and said to be good for creating an appetite. It is often used in sauces and ragouts.

MORINA, a genus of plants belonging to the diandria class; and in the natural method ranking under the 48th order, Aggregata. See BOTANY INDEX.

MORINORUM CASTELLUM, in Ancient Geography, simply Castellum (Antoine); situated on an eminence, with a spring of water on its top, in the territory of the Morini. Now Mont Cassel, in Flanders.

MORINDA, a genus of plants belonging to the pentandria class, and in the natural method ranking under the 48th order, Aggregata. See BOTANY INDEX.

MORISON, Robert, physician and professor of botany at Oxford, was born at Aberdeen in 1620, bred at the university there, and taught philosophy for some time in it; but having a strong inclination to botany, made great progress in that science. The civil wars obliged him to leave his country; which, however, he did not do till he had first signalized his zeal for the interest of the King, and his courage, in a battle fought between the inhabitants of Aberdeen and the Presbyterian troops on the bridge of Aberdeen, in which he received a dangerous wound on the head. As soon as he was cured of it, he went into France; and fixing at Paris, he applied assiduously to botany and anatomy. He was introduced to the duke of Orleans, who gave him the direction of the royal gardens at Blois. He exercised the office till the death of that prince, and afterwards went over to England in 1660. Charles II. to whom the duke of Orleans had presented him at Blois, sent for him to London, and gave him the title of
of his physician, and that of professor royal of botany, with a pension of 220l per annum. The Praelection Botanicum, which he published in 1669, procured him so much reputation, that the university of Oxford invited him to the professorship of botany in 1669; which he accepted, and acquitted himself in it with great ability. He died at London in 1683, aged 63. He published a second and third part of his History of Plants, in 2 vols. folio; with this title, Plantarum Historia Oxonensis Universalis. The first part of this excellent work has not been printed; and it is not known what has become of it.

MORISONIA, a genus of plants belonging to the monadelphia class, and in the natural method ranking under the 25th order, Pulmonariae. See Botany Index.

MORIACHIA, a mountainous country of Dalmatia. The inhabitants are called Morlacks or Morlacchi; they inhabit the pleasant valleys of Koter, along the rivers Kerha, Cettina, Narenta, and among the inland mountains of Dalmatia. The inhabitants are by some said to be of Walachian extraction, as is indicated by their name; Morlachia being a contraction of Mauro Walachia, that is, Black Walachia; and the Walachians are said to be descendants of the ancient Roman colonies planted in these countries. This, however, is denied by the Abbé Fortis, who published a volume of travels into that country. He informs us that the origin of the Morlacci is involved in the darkness of barbarous ages, together with that of many other nations, resembling them so much in customs and language, that they may be taken for one people, dispersed in the vast tracts from the Adriatic sea to the Frozen ocean.

With regard to the etymology of the name, the Abbé observes, that the Morlacci generally call themselves, in their own language, Vlassi; a national term, of which no vestige is found in the records of Dalmatia till the 13th century. It signifies powerful men, or men of authority; and the denomination of Moro Vlassi, corruptly Morlacchi, as they are now called, may perhaps point out the original of the nation. This word may possibly signify the conquerors that came from the sea; mor, in all the dialects of the Slavonian language, signifying the sea.

With regard to the character of these people, we are informed that they are much injured by their maritime neighbours. The inhabitants of the sea coast of Dalmatia tell many frightful stories of their avarice and cruelty: but these, in our author’s opinion, are all either of an ancient date, or if any have happened in latter times, they ought rather to be ascribed to the corruption of a few individuals, than to the bad disposition of the nation in general; and though thievish tricks are frequent among them, he informs us, that a stranger may travel securely through their country, where he is faithfully escorted, and hospitably treated.

As to the Morlacci themselves, they are represented as open and sincere to such a degree, that they would be taken for simpletons in any other country; and by means of this quality they have been so often duped by the Italian, that the faith of an Italian and the faith of a Morlack are synonymous among the Morlacci. They are very hospitable to strangers; and their hospitality is equally conspicuous among the rich and poor. Morlacks.

The rich prepares a roasted lamb or sheep, and the poor with equal cordiality offers whatever he has; nor is this generosity confined to strangers, but generally extends itself to all who are in want. When a Morlack is on a journey, and comes to lodge at a friend’s house, the eldest daughter of the family, or the new married bride, if there happen to be one, receives and kisses him when he alights from his horse or at the door of the house: but a foreigner is rarely favoured with these female civilities; on the contrary the women, if they are young, hide themselves, and keep out of his way.

The Morlacci in general have little notion of domestic economy, and readily consume in a week as much as would be sufficient for several months, whenever any occasion of merriment presents itself. A marriage, the holiday of the saint protector of the family, the arrival of relations or friends, or any other joyful incident, consumes of course all that there is to eat and to drink in the house. Yet the Morlack is a great economist in the use of his wearing apparel; for rather than spoil his new cap, he takes it off, let it rain ever so hard, and goes bareheaded in the storm. In the same manner he treats his shoes, if the road is dirty and they are not very old. Nothing but an absolute impossibility hinders a Morlack from being punctual; and if he cannot repay the money he borrowed at the appointed time, he carries a small present to his creditor, and requests a longer term.

Friendship is lasting among the Morlacci. They have even made it a kind of religious point, and tie the sacred bond at the foot of the altar. The Slavonian ritual contains a particular benediction for the solemn union of two male or two female friends in the presence of the congregation. The male friends thus united are called Pobratimi, and the female Posestreme, which means half-brothers and half-sisters. From these consecrated friendships among the Morlacci and other nations of the same origin, it should seem that the sworn brothers arose; a denomination frequent enough among the common people of Italy and in many parts of Europe. The difference between these and the Pobratimi of Morlachia consists not only in the want of the ritual ceremony, but in the design of the union itself. For, among the Morlacci, the sole view is reciprocal service and advantage; but such a brotherhood among the Italians is generally commenced by bad men, to enable them the more to hurt and disturb society.

But as the friendships of the Morlacci are strong and sacred, so their quarrels are commonly unextinguishable. They pass from father to son; and the mothers fail not to put their children in mind of their duty to revenge their father if he has had the misfortune to be killed, and to show them often the bloody shirt and arms of the dead. And so deeply is revenge rooted in the minds of this nation, that all the missionaries in the world would not be able to eradicat it. A Morlack is naturally inclined to do good to his fellow creatures, and is full of gratitude for the smallest benefit; but implacable if injured or insulted.

A Morlack who has killed another of a powerful family, is commonly obliged to save himself by flight, and
The Morlackee, whether they happen to be of the Roman or of the Greek church, have very singular ideas about religion: and the ignorance of their teachers daily augments this monstrous evil. They are as firmly persuaded of the reality of witches, fairies, en-chantment, nocturnal apparitions, and sorceries, as if they had seen a thousand examples of them. Nor do they make the least doubt about the existence of vampires: and attribute to them, as in Transylvania, the sucking the blood of infants. Therefore, when a man dies suspected of becoming a vampire, or "vukodlak," as they call it, they cut his hands, and prick his whole body with pins; pretending that, after this operation he cannot walk about. There are even instances of Morlachchi, who, imagining that they may possibly thirst for children's blood after death, entreat their heirs, and sometimes oblige them to promise, to treat them as vampires when they die.

A most perfect discord reigns in Morlachchi, as it generally does in other parts, between the Latin and Greek communion, which their respective priests fall not to foment, and tell a thousand little scandalous stories of each other. The churches of the Latins are poor, but not very dirty; those of the Greeks are equally poor, and shamefully ill kept. Our author has seen the curate of a Morlachchi village sitting on the ground in the churchyard, to hear the confession of women on their knees by his side: a strange posture indeed! but a proof of the innocent manners of those good people, who have the most profound veneration for their spiritual pastors, and a total dependence upon them; who, on their part, frequently make use of a discipline rather military, and correct the bodies of their offending flock with the cudgel.

Innocence, and the natural liberty of pastoral ages, are still preserved among the Morlachchi, or at least many traces of them remain in the places farthest distant from our settlements. Pure cordiality of sentiment is not there restrained by other regards, and displays itself without any distinction of circumstances. A young handsome Morlack girl, who meets a man of her district on the road, kisses him affectionately, without the least imputation of impropriety; and M. Fortis has seen all the women and girls, all the young men and old, kissing one another as they came into the churchyard on a holiday; so that they looked as if they all belonged to one family. He often observed the same thing on the road, and at the fairs in the ma-ritime towns, where the Morlachchi came to sell their commodities.

The dress of the unmarried women is the most complex and whimsical, in respect to the ornaments of the head; for when married they are not allowed to wear anything else but a handkerchief, either white or coloured tied about it. The girls use a scarlet cap, to which they commonly hang a veil falling down on the shoulders, as a mark of their virginity. The better sort adorn their caps with strings of silver coins, among which are frequently seen very ancient and valuable ones; they have moreover ear-rings of very curious work, and small silver chains with the figures of half moons fastened to the ends of them. But the poor are forced to content themselves with plain caps; or if they have any ornaments, they consist only of small exotic shells, round glass beads, or bits of tin. The principal merit of these caps, which constitute the good taste as well as vanity of the Morlack young ladies, is to attract and fix the eyes of all who are near to them by the multitude of ornaments, and the noise they make on the least motion of their heads.

Most old and young women wear about the neck large strings of round glass beads, of various size and colour; and many rings of brass, tin, or silver, on their fingers. Their bracelets are of leather covered with wrought tin or silver; and they embroider their stomachers, or adorn them with beads or shells. But the use of stays is unknown, nor do they put whale-bone or iron in the stomacher. A broad woollen girdle surrounds their petticoat, which is commonly decked with shells, and of blue colour, and therefore called "modrina." Their gown as well as petticoat, is of a kind of serge; and both reach near to the ankle: the gown is bordered with scarlet, and called "sedak." They use no modrina in summer, and only wear the sedak without sleeves over a linen petticoat or shift.

The girls always wear red stockings; and their shoes are like those of the men, called "opanke." The sole is of undressed ox hide, and the upper part of sheep's skin thongs knotted, which they call "opute;" and these they fasten above the ankles, something like the ancient cor-thurnae. The unmarried women, even of the richest families, are not permitted to wear any other sort of shoes; though after marriage, they may, if they will, lay aside the opanke, and use the Turkish slippers. The girls keep their hair dressed under their caps, but when married they let it fall dishevelled on the breast; sometimes they tie it under the chin; and always have medals, beads, or bored coins, in the Tartar or American mode twisted amongst it.

Nothing is more common among the Morlacchi than marriages concluded between the old people of the respective families, especially when the parties live at a great distance, and neither see nor know each other; and the ordinary motive of these alliances is the ambition of being related to a numerous and powerful family, famous for having produced valiant men. A denial in such cases is very rare; nor does the father of the maid inquire much into the circumstances of the family that asks her. Sometimes a daughter of the master is given in marriage to the servant or tenant, as was usual in patriarchal times; so little are the women regarded in this country. But on these occasions, the Morlacchi girls enjoy the privilege of refusal. For he
Morlacchi, who acts by proxy, having obtained his suit, is obliged to go and bring the bridegroom: and, if on seeing each other, the young people are reciprocally content, the marriage is concluded, but not otherwise. In some parts it is the custom for the bride to go to see the house and family of the proposed husband, before she gives a definitive answer; and if the place or persons are disagreeable to her, she is at liberty to annul the contract.

The bride is conducted to a church, veiled, and surrounded by the friends of the bridegroom, or scavi, as they are called, on horseback; and the sacred ceremony is performed amidst the noise of muskets, pistols, barbaric shouts and acclamations, which continue till she returns to her father's house or to that of her husband, if not far off. The first day's entertainment is sometimes made at the bride's house, but generally at the bridegroom's, whether the svati hasten immediately after the nuptial benediction; and at the same time three or four men run on foot to tell the good news; the first who gets to the house has a kind of a towel embroidered at the ends, as a premium. The domachin, or head of the house, comes out to meet his daughter-in-law; and a child is handed to her, before she alights, to caress it; and if there happen to be none in the house, the child is borrowed from one of the neighbours. When she alights, she kneels down, and kisses the threshold.

Then the mother-in-law, or in her place some other female relation, presents a corn sieve, full of different kinds of grain, nuts, almonds, and other small fruits, which the bride scatters upon the svati, by handfuls, behind her back. The bride does not sit at the great table the first day, but has one apart for herself, the two divers, and the stachoe. The bridegroom sits at table with the svati; but in all that day, consecrated to the matrimonial union, he must neither unlock nor cut any thing whatever. The knave carves his meat, and eats his bread. It is the domachin's business to give the toast; and the stari-svati is the first who pledges him.

Generally the bukkara, a very large wooden cup, goes round, first to the saint protector of the family; next to the prosperity of the holy faith; and sometimes to the name the most sublime and venerable. The most extravagant abundance reigns at these feasts; and each of the svati contributes, by sending a share of provisions. The dinner begins with fruit and cheese; and the soup comes last, just contrary to our custom. All sorts of domestic fowls, kid, lamb, and sometimes venison, are heaped in prodigal quantities upon their tables.

These nuptial feasts, called adrove by the ancient Huns, are by the Morlacchi called adrovico, from whence the Italian word adrovise is undoubtedly derived. They continue three, six, eight, or more days, according to the ability or prodigal disposition of the family where they are held. The new married wife gets no inconsiderable profit in these days of joy; and it usually amounts to much more than all the portion she brings with her, which often consists of nothing but her own clothes and perhaps a cow; nay, it happens sometimes that the parents, instead of giving money with their daughter, get something from the bridegroom by way of price. The bride carries water every morning, to wash the hands of her guests as long as the feasting lasts; and each of them throws a small piece of money into the bason after performing the Morlacchi function, which is a very rare one among them, excepting on such occasions.

The Morlacchi pass their youth in the woods, attending their flocks and herds; and in that life of quiet and leisure they often become dexterous in carving with a simple knife: they make wooden cups, and whistles adorned with fanciful bas reliefs, which are not void of merit, and at least show the genius of the people.

Mornay, Philippe de, seigneur du Plessis Marly, was born at Bubly or Bisbrey in Upper Normandy in France, in 1549, and was educated at Paris. What was then thought a prodigy in a gentleman, he made a rapid progress in the belles lettres, in the learned languages, and in theology. He was at first destined for the church; but the principles of Calvinism, which he had imbibed from his mother, effectually excluded him from the ecclesiastical preferments to which he was entitled by his interest, abilities, and birth. After the horrible massacre of St Bartholomew, Philippe de Mornay made the tour of Italy, Germany, England, and the Low Countries; and he was equally improved and delighted by his travels. Mornay afterwards joined the king of Navarre, at that time leader of the Protestant party, and so well known since by the name of Henry IV. This prince sent Mornay, who employed his whole abilities, both as a soldier and a writer, in defence of the Protestant cause, to conduct a negotiation with Elizabeth, queen of England; and left him wholly to his own discretion in the management of that business. He was successful in almost every negotiation, because he conducted it like an able politician, and not with a spirit of intrigue. He tenderly loved Henry IV. and spoke to him on all occasions as to a friend. When he was wounded at Anzale, he wrote to him in these words: "Sire, You have long enough acted the part of Alexander, it is now time you should act that of Caesar. It is our duty to die for your majesty, &c. It is glorious for you, Sire, that I dare venture to tell you it is your duty to live for us." This faithful subject did every thing in his power to raise Henry to the throne. But when he deserted the Protestant faith, he reproached him in the bitterest manner, and retired from court. Henry still loved him; and was extremely affected with an insult which he received in 1597 from one Saint Phal, who beat him with a cudgel, and left him for dead. Mornay demanded justice from the king, who gave him the following answer, a proof as well of his spirit as of his goodness of heart. "Monsieur Duplessis, I am exceedingly offended at the insult you have received; and I sympathize with you both as your sovereign and your friend. In the former capacity, I shall do justice to you and to myself; and had I sustained only the character of your friend, there are few perhaps who would have drawn their sword or sacrificed their life more cheerfully in your cause. Be satisfied, then, that I will act fully the part of a king, a master, and friend." Mornay's knowledge, probity, and valour, made him the soul of the Protestant party, and procured him the contemptuous appellation of the Pope of the Huguenots. He defended their doctrines both by speech and writing. One of his books on the Iniquity of the Mass, having stirred up all the Catholic divines, he refused to

Moroc

Morocco.

To make any reply to their censures and criticisms except in a public conference. This was accordingly appointed to be held A.D. 1652, at Fountainebleau, where the court then was. The two champions were, Du Perron bishop of Evreux, and Morey. After many arguments and replies on both sides, the victory was adjudged to Du Perron. He had boasted that he would point out to the satisfaction of every one five hundred errors in his adversary's book, and he partly kept his word. The Calvinists did not fail to claim the victory on this occasion, and they still continue to do so. This conference, instead of putting an end to the differences, was productive of new quarrels among the controversialists, and of much profane wit among the libertines. A Huguenot minister, who was present at the conference, observed with great concern to a captain of the same party, "The bishop of Evreux has already driven Morey from several strong holds." "No matter (replied the soldier), provided he does not drive him from Saumur." This was an important place on the river Loire, of which Duplessis was governor. He retired, his attention being constantly occupied in defending the Huguenots, and in making himself formidable to the Catholics. When Louis XIII. was making preparations against the Protestants, Duplessis wrote him a letter, dissuading him from such a measure. After employing the most plausible arguments, he concludes in the following manner: "To make war on the subject, is an indication of weakness in the government. Authority consists in the quiet submission of the people, and is established by the prudence and justice of the governor. Force of arms ought never to be employed except in repelling a foreign enemy. The late king would have sent the new ministers of state to learn the first elements of politics, who like unskilful surgeons would apply violent remedies to every disease, and advise a man to cut off an arm when his finger aches." These remonstrances produced no other effect than the loss of the government of Saumur, of which he was deprived by Louis XIII. in 1621. He died two years after, November 11, 1623, aged 74, in his barony de la Forest-Sure in Poitou. The Protestant cause never had an abier supporter, or one who did more credit by his virtues and abilities.

Cenecur de courtoisin, mais à la cour aimé; Fier ennemi de Rome, et de Rome aimé. — HENRIADE.

The following is a list of his works: 1. Un Traité de l'Eucharistie, 1604, in folio. 2. Un Traité de la vérité de la Religion Chrétienne, 8vo. 3. A book entitled La Mysteres d'Iniquité, 4to. 4. Un discours sur le droit pretendu par ceux de la maison du Guiye, 8vo. 5. Curious and interesting Memoirs from the year 1572 to 1629, 4 vols. 4to. valuable. 6. Letters; which are written with great spirit and good sense. David des Liques has given us his life in quarto; a book more interesting for the matter than the manner.

MORNE-GAROU, a very remarkable volcanic mountain on the island of St Vincent's in the West Indies. It was visited by Mr James Anderson surgeon in the year 1764. See St Vincent.

MOROC, or MAROC, a beautiful bird of Abyssinia, described by Mr Bruce, who thinks its name is derived from mar, "honey," though he says that he never heard it was further concerned in the honey than destroying bees. It seems to pursue those insects out of enmity or diversion as well as for food, leaving great numbers dead on the ground, besides those which it devours for food.

The moroc resembles the cuckoo in size and shape, but differs in other respects. Its mouth is very wide, the opening reaching almost to its eyes; the inside of the mouth and throat yellow, the tongue sharp-pointed, and capable of being drawn almost half its length out of the mouth beyond the point of its beak, and is very flexible. The head and neck are brown, without any mixture of other colours; there are likewise a number of very small and scarcely visible hairs at the root of the beak.

This seems to be the bird mentioned by Sparman under the name of cuculus indiculator, which (he says) has the singular property of discovering the nests of wild bees, and leading travellers by a certain cry to the place where the treasure is deposited. According to Sparman's account, it makes known these discoveries by the same cry to foxes as well as to the human species; but Jerome Lobo, who mentions the Abyssinian bird, takes no notice of the foxes, though he mentions its singing melodiously when it arrives at the place where the honey is deposited. Both these accounts are severely criticised by Mr Bruce, who says, that honey is so abundant on every hillock and every tree, that a bird possessing this faculty could be of no use to man or to any other animal in that country, and that having never heard of such a bird in Abyssinia, he considers the account of it as a fiction.

MORNING, the beginning of the day, or the time of the sun rising. The astronomers reckon morning, mane, from the time of midnight to that of mid-day. Thus an eclipse is said to begin at 11 o'clock in the morning, &c.

MORNING star, is the planet Venus, when a little to the westward of the sun; that is, when she rises a little before. In this situation she is called by the Greeks Phosphorus; by the Latins Lucifer, &c.

MOROCCO, an empire of Africa, comprehending a considerable part of the ancient Mauritania, is bounded on the west by the Atlantic ocean; on the east by the river Volva, which separates it from Algiers; on the north by the Mediterranean; and on the south by Mount Atlas, or rather by the river Sus, which divides it from the kingdom of Taghilt. Its greatest length is from the north-east to the south-west, amounting to above 500 miles; its breadth is not above 260 where broadest, and in the narrowest places it is not above half that breadth.

The ancient history of Morocco has been already given under the article MAURITANIA. It continued under the dominion of the Romans upwards of 400 years. On the decline of that empire it fell under the Goths, who held it till about the year 600, when the Goths were driven out by the Vandals, the Vandals by the Greeks, and they in their turn by the Saracens, who conquered not only this empire, but we may say the whole continent of Africa; at least their religion, one way or other, is to be found in all parts of it. The Saracen empire did not continue long united under one head, and many princes set up for themselves in Africa as well as elsewhere, through whose dissensions the Almoravides were at length raised.
Morocco. raised to the sovereignty, as related under the article Algiers, No. 2. Yusef, or Joseph, the second monarch of that line, built the city of Morocco, conquered the kingdom of Fez, and the Moorish dominions in Spain; all which were lost by his grandson Abbu Halli, who was defeated and killed by the Spaniards. On this prince's death the crown passed to the Mohejians, or Almohedes, with whom it had not continued above three generations, when Mohammed the son of Al Mansur lost the famous battle of Sierra Morena, in which 200,000 Moors were slain, and in consequence of which Alphonso X. retook a great many of the Moorish conquests immediately after.

Mohammed died soon after this disgrace, and left several sons, between whom a civil war ensued, during which the viceroy of Fez, Tunis, and Tremesen, found means to establish themselves as independent princes. At length one of the princes of the royal blood of Tremesen having defeated the Almohedes, made himself master of the kingdoms of Morocco and Fez, and entailed them on his own family. In a short time, however, this family was expelled by the Merini, the Merini by the Oatazes, and these by the Sharifs of Hassen, who have kept the government ever since.

Nothing can be conceived more unjust and despotic than the government of Morocco, and nothing more degenerate than the character of the people. The emperor is allowed to have not only an uncontrorollable power over the lives and fortunes of his subjects, but a great measure over their consciences, inasmuch as he is the only person who, as the successor of the prophet, has a right to interpret the Koran; and appoints all the judges under him, of whom those of Morocco and Fez are the chief, whose business it is to explain and dispense all matters relating to their religion; and who, being his creatures and dependents, dare not steer otherwise than as he directs. Whenever therefore the laws are enacted by him, and proclaimed by his governors in all the provinces, as is commonly done, that none may plead ignorance, they are everywhere received with an implicit and religious submission. On the other hand, the subjects are bred up with a notion, that those who die in the execution of his command are entitled to an immediate admittance into paradise, and those who have the honour to die by his hand to a still greater degree of happiness in it. After this we need not wonder at finding so much cruelty, oppression, and tyranny on the one side, and so much submission, passiveness and misery on the other.

This latter, however, extends no farther than the Moors: for as to the mountaineers, the subjection and tribute they pay to those tyrants was always involuntary; and as for the negroes, their zeal and attachment is owing merely to the great sway and power which they have gained in the government, on various accounts. They were first introduced, or rather their importation increased, by the policy of Muley Ishmael, a late emperor, at a period when there was a great decrease of population in the empire, occasioned in some degree by the enormous cruelties exercised by his former sovereigns, who have been known not unfrequently, through a slight disgust, to abandon a whole town or province to the sword. In the character of Muley Ishmael were found the most singular inconsistencies; for it is certain, that although a tyrant, yet in other respects, as if to repair the mischief which he committed, Muley he left nothing undone for the encouragement of population.—He introduced large colonies of negroes from Guinea; built towns for them, many of which are still remaining, assigned them portions of land, and encouraged their increase by every possible means. He soon initiated them in the Mahometan faith; and had his plan been followed, the country by this time would have been populous, and probably flourishing. As the negroes are of a more lively, active and enterprising disposition than the Moors, they might soon have been taught the arts of agriculture; and their singular ingenuity might have been directed to other useful purposes. It is true, Muley Ishmael, when he adopted this plan, had more objects in view than that of merely peopling his dominions. He saw plainly that his own subjects were too capricious a disposition to form soldiers calculated for his tyrannical purposes. They had uniformly manifested an inclination to change their sovereigns, though more from the love of variety than to reform the government, or restrain the abuses of tyranny. Muley Ishmael had discernment enough to see, that by forming an army of slaves, whose sole dependence should rest upon their master, he could easily train them in such a manner as to act in the strictest conformity to his wishes. He soon learnt that the great object with the negroes was plenty of money and liberty of plunder; in these he liberally indulged them, and the plan fully answered his expectations. Though, however, Muley Ishmael had no great merit in introducing subjects for the purposes of tyranny, yet the good effects of this new colonization were very generally experienced. By intermarrying among themselves, and intermixing among the Moors (for the Moors will keep negro women as concubines, though they seldom marry them), a new race of people started up, who became as useful subjects as the native inhabitants, and brought the empire into a much more flourishing state than it had ever been in since their great revolution.

Sidi Mahomet, his grandson and successor, had different views, and was actuated by different motives. From his inordinate avarice, he ceased to act towards his black troops in the generous manner which had distinguished his predecessor Muley Ishmael; and they soon showed themselves discontented with his conduct. They offered to place his eldest son Muley Ali, on the throne; but this prince, not unmindful of the duty which he owed his father and sovereign, declined their offer. They next applied to Muley Yazid, who, at first accepted of the assistance they tendered, but in a short time relinquished the plan. Sidi Mahomet, disgusted with this conduct of the negroes, determined to curb their growing power, by disbanding a considerable part of these troops, and banishing them to distant parts of the empire.

A most flagrant species of despotism, which renders the emperors more formidable to their subjects, is their power of making themselves their sole heirs, and, in virtue of that power, seizing upon all their effects, and making only such provision for their families as they think proper; and often, on some frivolous pretence, leaving them destitute of any, according to the liking or dislike they bear to the deceased; so that, upon the whole, they are the only makers, judges, and interpreters, and in many instances, likewise the executioners, of their own laws, which have
MOR

no other limits than their own arbitrary will. The titles which the emperors of Morocco assume, are those of Most glorious, mighty, and noble emperor of Afric; king of Fez and Morocco, Taflet, Sus, Dorka, and all the Algarte, and its territories in Afric; grand Sharif (or, as others write it, Xarif), that is, successor, or vicegerent, of the great Prophet Mohammed, &c.

The judges or magistrates who act immediately under the emperor are either spiritual or temporal, or rather ecclesiastical and military. The muftis and the cadis are judges of all religious and civil affairs; and the bashaws, governors, alcaides, and other military officers, of those that concern the state or the army: all of them the most obsequious creatures and slaves of their prince, and no less the rapacious tyrants of his subjects, and from whom neither justice nor favour can be obtained but by mere dint of money and extortionate bribery, from the highest to the lowest. Neither can it indeed be otherwise in such an arbitrary government, where the highest posts must not only be bought of the prince at a most extravagant price, and kept only by as exorbitant a tribute, which is yearly paid to him, but where no one is sure to continue longer than he can bribe some of the courtiers to insinuate to the monarch that he pays to the utmost of his power and much beyond what was expected from him. There are instances of the sultan elevating at once a common soldier to the rank of a bashaw, or making him a confidential friend; the following day he would perhaps imprison him, or reduce him again to the station of private soldier. Yet such is the disposition of these people, that they have an unbounded thirst for rank and power with all their uncertainties, and what is more extraordinary, when they have obtained a high station, they seldom fail to afford their sovereign a plea for ill treating them, by abusing in some way or other their trust.

From what has been said, it may be reasonably concluded that the revenue arising to the emperor from the last mentioned source, that of bribery, extortion, and confiscation, must be very considerable, though there is no possibility to make any other conjecture of its real amount than that it must be an immense one. Another considerable branch is the piratical trade, which brings the greater income into his treasury, as he is not at any expense either for fitting out of corsair vessels, or maintaining their men; and yet has the tenth of all the cargo and of all the captives; besides which, he appropriates to himself all the rest of them, by paying the captors 50 crowns per head, by which means he engrosses all the slaves to his own service and advantage. This article is indeed a very considerable addition to his revenue, not only as he sells their ransom at a very high rate, but likewise as he has the profit of all their labour, without allowing them any other maintenance than a little bread and oil, or any other assistance when sick, than what medicines a Spanish convent, which he tolerates there, gives them gratis; and which, nevertheless is forced to pay him an annual present for that toleration, besides furnishing the court with medicines, and the slaves with lodging and diet when they are not able to work. Another branch of his revenue consists in the tenth part of all cattle, corn, fruits, honey, wax, hides, rice, and other products of the earth, which is exacted of the Arabs and Brebes, as well as of the natives; and these are levied, or rather farmed, by the bashaws, governors, alcaides, &c. with all possible severity. The Jews and Christians likewise pay an income or capitation, the former of six crowns per head on all males from 15 years and upwards, besides other arbitrary imposts, fines, &c. That on the Christians, for the liberty of trading in his dominions, rises and falls according to their number, and the commerce they drive; but which, whatever it may bring yearly into his coffers, is yet detrimental to trade in general, seeing it discourages great numbers of settlers there, notwithstanding the artful invitations which the emperors and their ministers make use of to invite them to it; for, besides those arbitrary exactions, there is still another great hardship attending them, viz. that they cannot leave the country without forfeiting all their debts and effects to the crown. The duties on all imports and exports is another branch of his income, the amount of which, it is said, does not exceed 165,000l. per annum.

The climate of the empire of Morocco is in general sufficiently temperate, healthy, and not so hot as its situation might lead us to suppose. The chain of mountains which form Atlas, on the eastern side, defends it from the east winds, that would scorch up the earth were they frequent. The summit of these mountains is always covered with snow; and their abundant descending streams spread verdure through the neighbourhood, make the winter more cold, and temper the heats of summer. The sea on the west side, which extends along the coast from north to south, also refreshes the land with regular breezes, that seldom vary according to their seasons. At a distance from the sea, within in land, the heat is so great, that the rivulets become dry in summer; but as in hot countries dew are plentiful, the nights are there always cool. The rains are tolerably regular in winter; and are even abundant, though the atmosphere is not loaded with clouds as in northern latitudes. Those rains which fall by intervals are favourable to the earth, and increase its fertility. In January the country is covered with verdure, and enamelled with flowers. Barley is cut in March, but the wheat harvest is in June. All fruits are early in this climate; and in forward years the vintage is over in the beginning of September. Though in general there is more uniformity and less variation in hot than in northern climates, the first are nevertheless exposed to the intemperance of weather: too heavy rains often impede the harvest; and drought has still greater inconveniences, for it ensures the propagation of locusts.

The soil of Morocco is exceedingly fertile. It is, and most so in the inland provinces. On the western coast it is in general light and stony, and is better adapted to the vine and olive than the culture of wheat. They annually burn, before the September rains, the stubble, which is left rather long; and this and the dung of cattle, every day turned to pasture, form the sole nurture the land receives. The soil requires but little labour and the ploughing is so light that the furrows are scarcely six inches deep; for which reason, in some provinces, wooden ploughshares are used for cheapness.

The empire of Morocco might supply itself with all produce-necessaries, as well from the abundance and nature of its products, as from the few natural or artificial wants of the Moors occasioned by climate or education. Its wealth consists in the fruitfulness of its soil: its corn, fruits,
Morocco. 

Fruits, flocks, flax, salt, gums, and wax, would not only supply its necessities, but yield a superflux, which might become an object of immense trade and barter with other nations. Such numerous exports might return an inexhaustible treasure, were its government fixed and secure, and did subjects enjoy the fruits of their labour and their property in safety. The increase of corn in Morocco is often as sixty to one, and thirty is held to be but an indifferent harvest.

The Moors, naturally indolent, take little care of the culture of their fruits. Oranges, lemons, and thick skinned fruits, the trees of which require little nurture, grow in the open fields; and there are very large plantations of them found, which they take the trouble to water in order to increase their product. Their vines, which yield excellent grapes, are planted as far as the 33rd degree, as in the southern provinces of France, and are equally vigorous. But at Morocco, where they yield a large and delicious grape, they are supported by vine poles five and eight feet above the ground; and off they are obliged to be watered, the little wine made there is seldom preserved. Figs are very good in some parts of the empire, but toward the south they are scarcely ripe before they are full of worms; the heats and night dews may, perhaps, contribute to this speedy decay. Melons, for the same reason, are rarely edible; they have but a moment of maturity; which passes so rapidly that it is with difficulty seized. Water melons are everywhere reared, and in some provinces are excellent. Apricots, apples, and pears, are in tolerable plenty in the neighbourhood of Fez and Mequinez, where water is less scarce and the climate more temperate. But in the plain, which extends along the western coast, these delicate fruits are very indifferent, have less juice or taste, and the peaches there do not ripen. The tree called the prickly pear, or the Barbary fig, is plentifully found in the empire of Morocco; and is planted round vineyards and gardens, because its thick and thorny leaves, which are wonderfully prolific, form impeneetrable hedges. From these leaves a fruit is produced, covered with a thorny skin, that must be taken off with care. This fruit is mild, and full of very hard, small kernels. The olive is everywhere found along the coast, but particularly to the south.

In the province of Sus, between the 25th and 30th degrees, the inhabitants have an almond harvest, which varies little because of the mildness of the climate; but the fruit is small, for which reason they take little care of the trees, and they degenerate with time. The palm-tree is common in the southern provinces of Morocco; but dates ripen there with difficulty, and few are good except in the province of Sus and toward Taflet. On the coast of Salle and Mamora there are forests of oak, which produce acorns near two inches long. They taste like chestnuts, and are eaten raw and roasted. Salt abounds in the empire, and in some places on the coast requires only the trouble of gathering. Independent of the salt pits formed by the evaporation of the soft water, there are pits and lakes in the country whence great quantities are obtained. It is carried as far as Tombut, whence it passes to the interior parts of Africa.

The Moors cultivate their lands only in proportion to their wants; hence two-thirds of the empire at least lie waste. Here the down, that is, the fan or wild palm tree, grows in abundance: and from these people, when necessity renders them industrious, find great advantage. The shepherds, mule-drivers, camel-drivers, and travellers, gather the leaves, of which they make mats, fringes, baskets, hats, shawris or large wallets to carry corn, wine, ropes, girths, and covers for their pack saddles. This plant, with which also they heat their ovens, produces a mild and resinous fruit that ripens in September and October. It is in form like the raisin, contains a kernel, and is astrignent and very proper to temper and counteract the effects of the watery and laxative fruits, of which these people in summer make an immoderate use.

Unacquainted with the sources of wealth of which their ancestors were possessed, the Moors pretend there are gold and silver mines in the empire, which the emperors will not permit to be worked, lest their subjects should thus find means to shake off their yoke. It is not improbable but that the mountains of Atlas may contain unexplored riches; but there is no proof that they have ever yielded gold and silver. There are known iron mines in the south; but the working of them has been found so expensive, that the natives would rather use imported iron, notwithstanding the heavy duty it pays, by which its price is doubled. There are copper mines in the neighbourhood of Santa Cruz, which are not only sufficient for the small consumption of the empire, where copper is little used, but are also an object of exportation, and would become much more so were the duties less immoderate.

Neither the elephant nor the rhinoceros is to be found in this or the other states of Barbary; but the deserts abound with lions, tigers, leopards, hyenas, and monstrous serpents. The Barbary horses were formerly very valuable, and thought equal to the Arabian. Though the breed is now said to be decayed, yet some very fine ones are occasionally imported into England. Camels and dromedaries, asses, mules, and kamals (a most serviceable creature, begot by an ass upon a cow), are their beasts of burden. Their cows are but small, and barren of milk. Their sheep yield but indifferent fleeces, but are very large, as are their goats. Bears, porcupines, foxes, serpents, hares, rabbits, weasels, moles, chameleons, and all kinds of reptiles, are found here. Partridges and quails, eagles, hawks, and all kinds of wild fowl, are frequent on the coast.

The principal mountains form the chain which goes under the name of Mount Atlas, and runs the whole length of Barbary from east to west, passing through Morocco, and abutting upon that ocean which separates the eastern from the western continent, and is from this mountain called the Atlantic Ocean. See ATLAS. The principal rivers, besides the Malva or Malvya above mentioned, which rises in the deserts, and running from south to north divides Morocco from the kingdom of Algiers, are the Suz, Ommirribili, Rabba, Larche, Darodit, Sebon, Gueeron, and Tensilt, which rise in Mount Atlas, and fall into the Atlantic ocean.

The traffic of the empire by land is either with Arabia or with the countries to the north; Mecca, they send caravans, consisting of several thousand camels, horses, and mules, twice every year, partly for traffic, and partly on a religious account; for numbers of pilgrims take that opportunity of paying their devotions to their great prophet. The goods they carry to the east are woolen manufactures,
The coins of this empire are a fucce, a blanquill, and ducat. The fucose is a small copper coin, 20 whereof make a blanquill, of the value of twopence sterling. The blanquill is of silver, and the ducat of gold, not unlike that of Hungary, and worth about nine shillings. Both these pieces are so liable to be clipped and filed by the Jews, that the Moors always carry scales in their pockets to weigh them; and when they are found to be much diminished in their weight, they are recouped by the Jews, who are masters of the mint, by which they gain a considerable profit; so they do also by exchanging the light pieces for those that are full weight. Merchants accounts are kept in ounces, 10 of which make a ducat; but in payments to the government, it is said they reckon 17½ one-half for a ducat.

With respect to religion, the inhabitants of Morocco are Mohammedans, of the sect of Ali; and have a mufti or high-priest, who is also the supreme civil magistrate, and the last resort in all cases ecclesiastical and civil. They have a great veneration for their hermits, and for idiots and madmen; as well as for those who by their tricks have got the reputation of wizards: all whom they look upon as inspired persons, and not only honour as saints while they live, but build tombs and chapels over them when dead; which places are not only religiously visited by their devotees far and near, but are esteemed inviolable sanctuaries for all sorts of criminals except in cases of treason.

Notwithstanding the natives are zealous Mohammedans, they allow foreigners the free and open profession of their religion, and their very slaves have their priests and chapels in the capital city; though it must be owned that the Christian slaves are here treated with the utmost cruelty. Here, as in all other Mohammedan countries, the Alcoran and their comments upon it are their only written laws; and though in some instances their califs and other civil magistrates are controlled by the arbitrary determinations of their princes, bashaws, generals, and military officers, yet the latter have generally a very great deference and regard for their laws. Murder, theft, and adultery, are commonly punished with death; and their punishments for other crimes, particularly those against the state, are very cruel; as impaling, dragging the prisoner through the streets at a mule's heels till all his flesh is torn off, throwing him from a high tower upon iron hooks.

The inhabitants of the empire of Morocco, known by the name of Moors, are a mixture of Arabian and African nations formed into tribes; with the origin of whom we are but imperfectly acquainted. These tribes, each strangers to the other, and ever divided by traditional hatred or prejudice, seldom mingle. It seems probable that most of the castes who occupy the provinces of Morocco have been expelled from the eastern to the western Africa, during those different revolutions by which this part of the world has been agitated; that they have followed the standard of their chiefs, whose names they have preserved; and that by those they, as well as the countries they inhabit, are distinguished. At present those tribes are called cellite or cables, from the Arabic word khebile; and they are so numerous, that it is impossible to have a knowledge of them all.
The native subjects of the empire of Morocco may be divided into two principal classes; the Brebes and the Moors.

The etymology of the name, and the origin of the people, of the first class, are equally unknown. Like the Moors, at the time of the invasion by the Arabs, they may have adopted the Mahometan religion, which is consonant to their manners and principal usages; but they are an ignorant people, and observe none of the precepts of that religion, but the assignation it enjoins against other modes of worship.

Confined to the mountains, the Brebes preserve great animosity against the Moors, whom they confound with the Arabs, and consider as usurpers. They thus contract in their retreats a ferocity of mind, and a strength of body, which makes them more fit for war and every kind of labour than the Moors of the plain in general are. The independence they boast of gives even a greater degree of expression to their countenance. The prejudices of their religion make them submit to the authority of the emperors of Morocco; but they throw off the yoke at their pleasure, and retire into the mountains, where it is difficult to attack or overcome them. The Brebes have a language of their own, and never marry but among each other. They have tribes or cafiles among them who are exceedingly powerful both by their number and courage.

The Moors of the plains may be distinguished into those who lead a pastoral life, and those who inhabit the cities.

The former live in tents; and that they may allow their ground a year's rest, they annually change the place of their encampments, and go in search of fresh pasture; but they cannot take this step without acquainting their governor. Like the ancient Arabs, they are entirely devoted to a pastoral life: their encampments, which they call doucchars, are composed of several tents, and form a crescent; or they are ranged in two parallel lines, and their flocks, when they return from pasture, occupy the centre.

The tents of the Moors, viewed in front, are of a conical figure; they are from 8 to 10 feet high, and from 20 to 25 feet long; like those of high antiquity, they resemble a boat reversed. They are made of cloth composed of goats and camel's hair, and the leaves of the wild palm, by which they are rendered impervious to water; but at a distance their black colour gives them a very disagreeable look.

The Moors, when encamped, live in the greatest simplicity, and exhibit a faithful picture of the inhabitants of the earth in the first ages of the world. The nature of their education, the temperature of the climate, and the rigour of the government, diminish the wants of the people, who find in their plains, in the milk and wool of their flocks, every thing necessary for food and clothing. Polygamy is allowed among them; a luxury so far from being injurious to a people who have few wants, that it is a great convenience in the economy of these societies, because the women are intrusted with the whole care of the domestic management. In their half-closed tents, they are employed in milking the cows for daily use; and when the milk abounds, in making butter, in picking their corn, their barley, and pulse, and grinding their meal, which they do daily in a mill composed of two stones about 18 inches in diameter, the uppermost having a handle, and turning on an axis fixed in the under one; they make bread likewise every day, which they bake between two earthen plates, and often upon the ground after it has been heated by fire. Their ordinary food is the couscoosoo; which is a paste made with their meal in the form of small grains like Italian paste. This couscoosoo is dressed in the vapour of boiling soups, in a hollow dish perforated with many small holes in the bottom, and the dish is enclosed in a kettle where meat is boiled; the couscoosoo, which is in the hollow dish, grows gradually soft by the vapour of the broth, with which it is from time to time moistened. This simple food is very nourishing, and even agreeable when one has got the better of the prejudices which every nation entertains for its own customs. The common people eat it with milk or butter indiscriminately; but those of higher rank, such as the governors of provinces and lieutenants, who live in the centre of the encampments, add to it some succulent broth, made with a mixture of mutton, poultry, pigeons, or hedgehogs, and then pour on a sufficient quantity of fresh butter.

The women in their tents spin wool, and weave it into cloth on looms suspended the whole length of the tent. Each piece is about five ells long, and one and a half broad; it is neither dressed nor dyed, and it has no seam; they wash it when it is dirty; and as it is the only habit of the Moors, they wear it night and day. It is called hack, and is the true model of the ancient draperies.

The Moors of the plain wear nothing but their woollen stuff; they have neither shirts nor drawers. Linen among these people is a luxury known only to those of the court or the city. The whole wardrobe of a country Moor in easy circumstances consists in a hack for winter, another for summer, a red cap, a hood, and a pair of slippers. The common people both in the country and in towns wear a kind of tunic of woollen cloth, white, gray, or striped, which reaches to the middle of the leg, with great sleeves and a hood; it resembles the habit of the Carthusians.

The women's dress in the country is likewise confined to a hack, which covers the neck and the shoulders, and is fastened with a silver clasp. The ornaments they are fond of are ear rings, which are either in the form of rings or crescents, made of silver, bracelets, and rings for the small of the leg; they wear these trinkets at their most ordinary occupations; less out of vanity than because they are unacquainted with the use of caskets or cabinets for keeping them. They also wear necklaces made of coloured glass beads or cloves strung on a cord of silk.

The Moors consider their wives less in the light of companions than in that of slaves destined to labour. Except in the business of village, they are employed in every servile operation; nay, in some of the poorer quarters a woman is often seen yoked in a plough along with a mule, an ass, or some other animal. When the Moors remove their doucahars, all the men seat themselves in a circle on the ground; and with their elbows resting on their knees, pass the time in conversation, while the women strike the tents, fold them up into bundles, and place them on the backs of their camels or oxen. The old women are then each loaded with a parcel, and the young carry the children on their shoulders.
prayer, a public market in the different quarters of each province. The Moors of the neighbourhood assemble to sell and buy cattle, corn, pulse, dried fruits, carpets, haikas, and in short all the productions of the country. This market, which is called Soc, resembles our fairs. The battle of the people who go and come, gives a better idea of the manner of life of the Moors than can be had in the cities. The alcades, who command in the neighbourhood, always attend these markets with soldiers to keep the peace; as it frequently happens that the grudges which these tribes harbour against one another break out upon such occasions into open violence.

The Moors who inhabit the cities differ from the others only in having a little more urbanity and a more easy deportment. Though they have the same origin with those of the plains, they affect to decline all intercourse with them. Some writers, without any foundation, have given the name of Arabs to the inhabitants of the towns, and that of Moors to those of the plains. But the greater part of the cities of this empire are more ancient than the invasion of the Arabs, who themselves lived in tents.

The houses in most of the towns in this empire appear at a little distance like vaulted tombs in a churchyard; and the entrance into the best of them has but a mean appearance. The rooms are generally on the ground floor, and whitened on the outside. As the roofs are quite flat, they serve as verandas, where the Moorish women commonly sit for the benefit of the air; and in some places it is possible to pass nearly over the whole town without having occasion to descend into the street.

As the best apartments are all backwards, a stable, or perhaps something worse, is the place to which visitors are first introduced. Upon entering the house, the stranger is either detained in this place, or in the street, till all the women are despatched out of the way; he is then allowed to enter a square court, into which four narrow and long rooms open by means of large folding doors, which, as they have no windows, serve likewise to introduce light into the apartments. The court has generally in its centre a fountain; and if it is the house of a Moor of property, it is floored with blue and white chequered tiling. None of the chambers have fire places; and their virtuals are always dressed in the court-yard in an earthen stove heated with charcoal. When the visitor enters the room, where he is received by the master of the house, he finds him sitting cross-legged and barefooted on a mattress, covered with fine white linen, and placed on the floor or else on a common mat. This, with a narrow piece of carpeting, is in general the only furniture he will meet with in Moorish houses, though they are not destitute of other ornaments.

The wardrobe of the inhabitants of cities is but little Dress of the different from that of those who live in tents.—Like the men, latter, they have a haik, and a hood more or less fine, and have also a hood of coarse European cloth of dark blue for the winter. What farther distinguishes them from the country Moors is, that they wear a shirt and linen drawers, and an upper garment of cotton in summer, and of cloth in winter, which they call a caylan. The white or blue hood, the purpose of which seems to be to guard against bad weather, and which is called

Vol. XIV. Part II.
The Moorish women who live in cities are, as in other nations, more addicted to show and finery in dress than those of the country; but as they generally leave the house only one day in the week, they seldom dress themselves. Not allowed to receive male visitors, they remain in their houses employed in their families, and so totally in deshabille that they often wear only a shift, and another coarser shift over the first, tied round their waist, with their hair plaited, and sometimes with, though often without, a cap. When dressed, they wear an ample and fine linen shift, the bosom embroidered in gold; a rich caftan of cloth, stuff, or velvet, worked in gold; and one or two folds of gauze, streaked with gold and silk, round the head, and tied behind so as that the fringes, intermingled with their tresses, descend as low as the waist; to which some add a ribbon of about two inches broad, worked in gold or pearls, that encircles the forehead in form of a diadem. Their caftan is bound round their waist by a crimson velvet girdle, embroidered in gold, with a buckle of gold or silver, or else a girdle of tamboured stuff, manufactured at Fez.

The women have yellow slippers, and a custom of wearing a kind of stocking of fine cloth somewhat large, which is tied below the knee and the ankle, over which it falls in folds. This stocking is less calculated to show what we call a handsome leg, than to make it appear thick; for to be fat is one of the rules of beauty among the Moorish women. To obtain this quality, they take infinite pains, feed when they become thin on a diet somewhat like forced meat balls, a certain quantity of which is given them daily; and in fine, the same care is taken among the Moors to fatten young women as in Europe to fatten fowls.

The Negroes, who constitute a large proportion of the emperor's subjects, are better formed than the Moors; and as they are more lively, daring, and active, they are intrusted with an important share in the executive part of government. They constitute in fact the most considerable part of the emperor's army, and are generally appointed to the command of provinces and towns. This circumstance naturally creates a jealousy between them, and the Moors, the latter considering the negroes as usurpers of a power which they have no right to assume. Besides these negroes which form the emperor's army, there are a great many others in the country, who either are or have been slaves to private Moors: every Moor of consequence, indeed, has his proportion of them in his service. To the disgrace of Europe, the Moors treat their slaves with humanity, employing them in looking after their gardens, and in the domestic duties of their houses. They allow them to marry among themselves; and after a certain number of years, spontaneously present them with the invaluable boon of liberty. They soon are initiated in the Mahometan persuasion, though they sometimes intermix with it a few of their original superstitions customs. In every other respect they copy the dress and manners of the Moors.

Among the inhabitants of Morocco there is another class, of whom we must not omit to make mention. These are the Renegades, or foreigners, who have renounced their religion for the sake of gaining profit. Of these there are a great number who have been originally Jews: they are held in little estimation by the Moors; and would be held in abhorrence by the Jews, if they did not freely express their aversion. The families of these apostates are called Touaregs: not having at any time married with the Moors, they still preserve their ancient characteristics, and are known almost at sight to be the progeny of those who formerly embraced the Mahometan religion. The Christian renegades are not few; and generally are fugitive peculators of Spain, or men fallen from power, who have been deprived of their influence, or, in despair, quit one unfortunate situation for another much more deplorable.

The Jews were formerly very numerous in this empire. After being proscribed in Spain and Portugal, multitudes of them passed over to Morocco, and spread themselves through the towns and over the country. By the relations they themselves give, and by the extent of the places assigned to them to dwell in, it would appear there were more than 10,000 families, of whom at present there is scarcely a residue of one-twelfth; the remainder either having changed their religion, sunk under their sufferings, or fled from the vexations they endured, and the arbitrary taxes and tolls imposed upon them. The Jews possess neither lands nor gardens, nor can they enjoy their fruits in tranquillity: they must wear only black; and are obliged, when they pass near mosques, or through streets in which there are sanctuaries, to walk barefoot. The lowest among the Moors imagines he has a right to ill-treat a Jew; nor dares the latter defend himself, because the Koran and the judge are always in favour of the Mahometan. Notwithstanding this state of oppression, the Jews have many advantages over the Moors: they better understand the spirit of trade; they act as agents and brokers, and profit by their own cunning and the ignorance of the Moors.

The Moors, who derive their language and religion from the Arabs, seem not in any manner to have participated of their knowledge. United and confounded as those of Morocco have been with the Moors of Spain, the latter of whom cultivated the arts and gave birth to Averrosse, and many other great names, the Moors of this empire have preserved no traces of the genius of their ancestors. They have no conception of the speculative sciences. Education consists merely in learning to read and write; and as the revenues of the learned are derived from these talents, the priests and talbes among them are the sole depositories of that much knowledge: the children of the Moors are taught in their schools to read and repeat some sixty lessons, selected from the Koran, which for the sake of economy are written upon small boards.

The Moors who formerly inhabited Spain gave great application to physic and astronomy; and they have left manuscripts behind them which still remain monuments of their genius. The modern Moors are infinitely degenerate; they have not the least inclination to the study of science; they know the properties of some simples; but as they do not proceed upon principle, and are ignorant of the causes and effects of diseases, they generally make a wrong application of their remedies. Their most useful physicians are their talbes, their fa-
Notwithstanding the Moors have occupied themselves little in the study of astronomy, they have been eager after astrology. This imaginary science, which made so rapid a progress at Rome in spite of the edicts of the emperors, may be conceived to make still greater advances among a people wholly stupid and ignorant, and ever agitated by the dread of present evils, or the hope of a more happy futurity. Magic, the companion of astrology, has here also found its followers, and is particularly studied by the talbes in the southern parts, who successfully use it in imposing upon Moorish credulity with strange dreams and ambiguous forebodings and prophecies.

The Moorish manufactures are—The hack, which as was before observed, is a long garment composed of white wool and cotton, or cotton and silk woven together, and is used by the Moors for the purpose of covering their under dress when they go abroad, which they do by totally wrapping themselves in it in a careless but easy manner; silk handkerchiefs of a particular kind, prepared only at Fez; silks chequered with cotton; carpeting, little inferior to that of Turkey; beautiful matting, made of the palm tree; paper of a coarse kind; cordovan, commonly called Morocco leather; gunpowder of an inferior nature; and long-barreled muskets, made of Biscay iron. The Moors are unacquainted with the mode of casting cannon: and therefore those few which are now in the country are obtained from Europeans. The manufacture of glass is likewise unknown to them; as indeed they make great use of earthen ware, and have few or no windows to their houses, this commodity may be of less importance to them than many others. They make butter, by putting the milk into a goat skin, with its outward coat turned inwards, and shaking it till the butter collects on the sides, when it is taken out for use. From this operation it proves always full of hairs, and has an insipid flavour. Their cheese consists merely of curds hardened and dried, and has uniformly a disagreeable taste. The bread in some of the principal towns, particularly at Tangier and Salé, is remarkably good, but in many other places it is coarse, black, and heavy.

Their looms, forges, ploughs, carpenters tools, &c. are much upon the same construction with the unimproved instruments of the same kind which are used at this time in some parts of Europe, only still more clumsily finished. In their work, they attend more to strength than neatness or convenience; and, like all other ignorant people, they have no idea that what they do is capable of improvement. It is probable, indeed, that the Moors have undergone no very material change since the revolution in their arts and sciences, which took place soon after their expulsion from Spain. Previous to that period, it is well known they were an enlightened people, at a time when the greater part of Europe was involved in ignorance and barbarism; but owing to the weakness and tyranny of their princes, they gradually sunk into the very opposite extreme, and may now be considered as but a few degrees removed from a savage state.

Their mosques or places of public worship are usually large square buildings, composed of the same materials as the houses. The building consists of broad and lofty piazzas, opening into a square court, in a manner in some degree similar to the Royal Exchange of London. In the centre of the court is a large fountain; and a small stream surrounds the piazzas, where the Moors perform the ceremony of ablution. The court and piazzas are floored with blue and white chequered tiling; and the latter are covered with matting, upon which the Moors kneel while repeating their prayers. In the most conspicuous part of the mosque facing the east, stands a kind of pulpit, where the talbe or priest occasionally preaches. The Moors always enter this place of worship barefooted, leaving their slippers at the door. On the top of the mosque, is a square steeple with a flag staff, whither at stated hours the talbe ascends, boasts a white flag, and calls the people to prayers, for they have no bells. From this high situation the voice is heard at a considerable distance; and the talbes have a monotonous mode of enunciation, the voice sinking at the end of every short sentence, which in some measure resembles the sound of a bell. The moment the flag is displayed, every person forsakes his employment, and goes to prayers. If they are near a mosque, they perform their devotions within it, otherwise immediately on the spot where they happen to be, and always with their faces towards the east, in honour of their prophet Mahomet, who it is well known was buried at Medina.

Their Sabbath is on our Friday, and commences from six o'clock the preceding evening. On this day they use a blue flag instead of the white one. As it has been prophesied that they are to be conquered by the Christians on the Sabbath day, the gates of all the towns and of the emperor's palaces are shut when at divine service on that day, in order to avoid being surprised during that period. Their talbes are not distinguished by any particular dress.

The Moors have three solemn devotional periods in the course of the year. The first, which is named Aid de Cabier, is held in commemooration of the birth of Mahomet. It continues seven days; during which period, every person who can afford the expense kills a sheep as a sacrifice, and divides it among his friends. The second is the Ramadum. This is held at the season when Mahomet disappeared in his flight from Morocco to Medina. Every man is obliged at that period to fast (that is, to abstain from animal food from sunrise to sunset each day) for 30 days; at the expiration of which time a feast takes place, and continues a week. The third is named Lashere, and is a day set apart by Mahomet for every person to compute the value of his property, in order for the payment of zakat, that is, one-tenth of their income to the poor, and other pious uses. Although this feast only lasts a single day, yet it is celebrated with far greater magnificence than either of the others.

The Moors compute time by lunar months, and count the days of the week by the first, second, third, &c. beginning from our Sunday. They use a common reed for writing, and begin their manuscripts from right to left.

The Moors of the empire of Morocco, as well as those to the northern limits of Africa, speak Arabic; but this language is corrupted in proportion as we recede farther from Asia, where it first took birth; the intermixture
intermixture which has happened among the African nations, and the frequent transmigrations of the Moors, during a succession of ages, have occasioned them to lose the purity of the Arabic language; its pronunciation has been vitiated, the use of many words lost, and other foreign words have been introduced without thereby rendering it more copious; the pronunciation of the Africans, however, is softer to the ear and less guttural than that of the Egyptians. The language, when written, is in effect much the same at Morocco as at Cairo, except that there are letters and expressions among the Moors which differ from those of the Oriental Arabs, who, however, understand the Moors in conversation, notwithstanding their vitiated manner of pronouncing. They mutually read each other's writings with some difficulty.

The Moors are naturally of a grave and pensive disposition, fervid in professions of friendship, but very insincere in their attachments. They have no curiosity, no ambition of knowledge; an indolent habit, united to the want of mental cultivation, renders them perhaps even more cullous than other unenlightened people to every delicate sensation; and they require more than ordinary excitement to render them sensible of pleasure or of pain. This languor of sentiment is, however, unaccompanied with the smallest spark of courage or fortitude. When in adversity, they manifest the most abject submission to their superiors; and in prosperity their tyranny and pride are inseparable.

Personal cleanliness has been considered as one of those circumstances which serve to mark and determine the civilization of a people. It was in vain that Mahomet enjoined the frequency of ablution as a religious duty to the Moors. Their dress, which should be white, is but seldom washed; and their whole appearance evinces that they perform this branch of their religious ceremonies in a slovenly manner. With this degree of negligence as to their persons, we may be justly surprised to find united a most scrupulous nicety in their habitations and apartments. They enter their chambers barefooted, and cannot bear the slightest degree of contamination near the place where they are to eat. This delicacy again is much confined to the insides of their houses. The streets receive the whole of their rubbish and filth; and by these means the ground is so raised in most parts of the city of Morocco, that the new buildings always stand considerably higher than the old.

With respect to the hours for eating, the people of this country are remarkably regular. Very soon after daybreak they take their breakfast, which is generally a composition of flour and water boiled thin, together with an herb which gives it a yellow tinge. The male part of the family eat in one apartment and the female in another. The children are not permitted to eat with their parents, but take their meals afterwards with the servants; indeed in most other respects they are treated exactly as servants or slaves by their parents. The mess is put into an earthen bowl, and brought in upon a round wooden tray. It is placed in the centre of the guests, who sit cross-legged either on a mat or on the floor, and who form a circle for the purpose. Having previously washed themselves, a ceremony always performed before and after meals, each person with his spouse attacks vigorously the bowl, while they diversify the entertainment by eating with it fruit or bread. At twelve o'clock they dine, performing the same ceremonies as at breakfast. For dinner, from the emperor down to the peasant, their dish is universally couscous, the mode of preparing which has been already described. The dish is brought in upon a round tray and placed on the floor, round which the family sit as at breakfast, and with their fingers commit a violent assault on its contents; they are at the same time, however, attended by a slave or domestic, who presents them with water and a towel occasionally to wash their hands. From the want of the simple and convenient invention of knives and forks, it is not uncommon in this country to see three or four people pulling to pieces the same piece of meat, and afterwards with their fingers stirring up the paste or couscous, of which they often take a whole handful at once into their mouth. At sunset they sup upon the same dish; and indeed supper is their principal meal.

But the common people must content themselves with a little bread and fruit instead of animal food, and sleep in the open streets. This kind of existence seems so calculated to endure even in an imitative state; far more severe must it therefore be to those who exercise the laborious employment of couriers in this country, who travel on foot a journey of three hundred or four hundred miles, at the rate of between thirty or forty miles a-day, without taking any other nourishment than a little bread, a few figs, and some water, and who have no better shelter at night than a tree. It is wonderful with what alacrity and perseverance these people perform the most fatiguing journeys at all seasons of the year. There is a regular company of them in every town, who are ready to be dispatched at a moment's warning to any part of the country their employers may have occasion to send them.

As the Moors are not fond of admitting men into their houses, except upon particular occasions, if the weather be fine they place a mat, and sometimes a carpet, on the ground before the door, seat themselves upon it cross-legged, and receive their friends, who form a circle, sitting in the same manner with their foreheads on the ground. Upon these occasions they either drink tea or coffee and converse. The streets are sometimes crowded with parties of this kind; some engaged in playing at an inferior kind of chess or draughts, at which they are very expert; but the majority in conversation. The people of this country, indeed, are so decidedly averse to standing up, or walking about, that if only two or three people meet, they squat themselves down in the first clean place they can find, if the conversation is to hold but for a few minutes.

The Moors have in general but few amusements; the sedentary life they lead in cities is little varied except by the care they take of their gardens, which are rather kept for profit than pleasure. Most of these gardens are planted with the orange, the lemon tree, and the cedar, in rows, and in such great quantities, that the appearance is rather that of a forest than that of a garden. The Moors sometimes, though rarely, have music in these retreats; a state of slavery but ill agrees with the love of pleasure; the people of Fez alone, either from a difference in education, or because their organs and sensibility are more delicate, make
The Moors go to the markets, where all in which countries seem to be the rendezvous of newsmongers. These shops are surrounded by benches; on which the customer, the inquisitive, and the idle, seat themselves, and when there are no more places vacant, they crouch on the ground like monkeys.

A common diversion in the towns where there are soldiers, as well as in the country, is what the Moors call the game of gunpowder; a kind of military exercise, that is the more pleasing to these people, inasmuch as, by the nature of their government, they all are, or are liable to become, soldiers, therefore all have arms and horses. By explosions of powder too, they manifest their festivity on their holidays. Their game of gunpowder consists in two bodies of horse, each at a distance from the other, galloping in successive parties of four and four, and firing their pieces charged with powder. Their chief art is in galloping up to the opposite detachment, suddenly stopping, firing their muskets, facing about, charging, and returning to the attack; all which manoeuvres are imitated by their opponents. The Moors take great pleasure in this amusement, which is only an imitation of their military evolutions.

The common topics for conversation among the Moors, are the occurrences of the place, religion, their women, but above all their horses. This last topic, indeed, appears to occupy by far the greatest portion of their attention. These animals are seldom kept in stables in Morocco. They are watered and fed only once a-day, the former at one o'clock at noon, and the latter at sunset: and the only mode which they use to clean them is by washing them all over in a river two or three times a-week, and suffering them to dry themselves.

Like all barbarous nations, the Moors are passionately fond of music, and some few have a taste for poetry. Their slow airs, for want of that variety which is introduced when the science has attained a degree of perfection, have a very melancholy sameness; but some of their quick tunes are beautiful and simple, and partake in some degree of the characteristic melody of the Scotch airs. The poetry of their songs, the constant subject of which is love, though there are few nations perhaps who are less sensible of that passion, has certainly less merit than the music.

Their instruments are a kind of hautboy, which differs from ours only in having no keys; the mandoline, which they have learnt to play upon from their neighbours the Spaniards; another instrument, bearing some resemblance to a violin, and played upon in a similar manner, but with only two strings; the large drum, the common pipe, and the tabour. These, united, and accompanied with a certain number of voices, upon many occasions form a band, though sole music is more common in this uncivilized country.

The Moors marry very young, many of their females not being more than 12 years of age at their cunipials. As Mahometans, it is well known that their religion admits of polygamy to the extent of four wives, and as many concubines as they please; but if we except the very opulent, the people seldom avail themselves of this indulgence, since it entails on them a vast additional expense in house-keeping, and in providing for a large family. In contrasting marriage, the parents of both parties are the only agents; and the intended bride and bridegroom never see each other till the ceremony is performed. The marriage settlements are made before the cadi; and then the friends of the bride produce her portion, or if not, the husband agrees to settle a certain sum upon her in case she should die, or divorce her on account of barrenness, or any other cause. The children of the wives have all an equal claim to the effects of the father and mother, but those of the concubines can each only claim half a share.

When the marriage is finally agreed upon, the bride is kept at home eight days, to receive her female friends, who pay congratulatory visits every day. At the same time a tabbe attends upon her, to converse with her relative to the solemn engagement on which she is about to enter: on these occasions he commonly accompanies his admonitions with a pious hymn, which is adapted to the solemnity. The bridegroom, on the other hand, receives visits from his male friends in the morning, and in the evening rides through the town accompanied by them, some playing on hautboys and drums, while others are employed in firing volleys of musketry. In all their festivals the discharge of musketry indeed forms a principal part of the entertainment. Contrary to the European mode, which particularly aims at firing with exactness, the Moors discharge their pieces as irregularly as possible, so as to have a continual succession of reports for a few minutes.

On the day of the marriage, the bride in the evening is put into a square or octagonal cage about twelve feet in circumference, which is covered with fine white linen, and sometimes with gauzes and silks of various colours. In this vehicle, which is placed on a mule, she is paraded round the streets, accompanied by her relations and friends, some carrying lighted torches, others playing on the hautboys, and a third party again firing volleys of musketry. In this manner she is carried to the house of her intended husband, who returns about the same time from performing similar ceremonies. On her arrival, she is placed in an apartment by herself, and her husband is introduced to her alone for the first time, who finds her sitting on a silk or velvet cushion (supposing her to be a person of consequence), with a small table before her, upon which are two wax candles lighted. Her shirt, or more properly skirt, hangs down like a train behind her, and over it is a silk or velvet robe with close sleeves, which at the breast and wrists is embroidered with gold; this dress reaches something lower than the calf of the leg. Round her head is tied a black silk scarf, which hangs behind as low as the ground. Thus attired, the bride sits with her hands over her eyes, when her husband appears, and receives her as his wife without any further ceremony: for the agreement made by the friends before the cadi is the only specific contract which is thought necessary.

If the husband should have any reason to suspect that his wife has not been strictly virtuous, he is at liberty to divorce her and take another. For some time after marriage, the family and the friends are engaged in much
MOROCCO [ 422 ]

Morocco. — much feasting, and a variety of amusements, which last a longer or shorter time according to the circumstances of the parties. It is usually customary for the man to remain at home eight days and the women eight months after they are first married; and the woman is at liberty to divorce herself from her husband, if she can prove that he does not provide her with a proper subsistence.

Women suffer but little inconvenience in this country from child-bearing; they are frequently up the next day, and go through all the duties of the house with the infant upon their backs. In celebrating the rite of circumcision, the child is dressed very sumptuously, and carried on a mule, or, if the parents are in poor circumstances, on an ass, accompanied with flags and musicians playing on hautbois and beating drums. In this manner they proceed to the mosque, where the ceremony is performed. Children, as soon as they are sent to school and are sent to the various kinds of labour adapted to their age and strength. Others, whose parents are in better circumstances, are sometimes sent to school; and these who are intended for the church, usually continue their studies till they have nearly learnt the Koran by rote. In that case, they are enrolled among the talbes, or learned men of the law; and upon leaving school are paraded round the streets on a horse, accompanied by music and a large concourse of people.

When any person dies, a certain number of women are hired for the purpose of lamentation; in the performance of which, nothing can be more grating to the ear, or more unpleasant, than their frightful moans, or rather howlings: at the same time, these mercenary mourners beat their heads and breasts, and tear their cheeks with their nails. The bodies are usually buried a few hours after death. Previous to interment, the corpse is washed very clean, and sewed up in a shroud, with the right hand under the head, which is pointed towards Mecca: it is carried on a bier supported upon men's shoulders, to the burying place, which is always, with great propriety, on the outside of the town, for they never bury their dead in the mosques, or within the bounds of an inhabited place.

MOROCCO, a city of the kingdom of Morocco in Barbary, lying about 120 miles to the north of Tarudant, 90 to the east of Mogodore, and 350 to the south of Tangier. It is situated in a beautiful valley, formed by a chain of mountains on the northern side, and those of Atlas, from which it is distant about 20 miles, on the south and east. The country which immediately surrounds it is a fertile plain, beautifully diversified with clumps of palm trees and shrubs, and watered by small and numerous streams which descend from Mount Atlas. The emperor's out gardens, which are situated at the distance of about five miles to the south of the city, and are large plantations of olives walled in, add considerably to the beauty of the scene.

Morocco, though one of the capitals of the empire (for there are three, Morocco, Mequinez, and Fez), has nothing to recommend it but its great extent and the royal palace. It is enclosed by remarkably strong walls built of tabby, the circumference of which is about eight miles. On these walls there are no guns mounted; but they are flanked with square towers, and surrounded by a wide and deep ditch. The city has a number of entrances, consisting of large double gates in porches of tabby in the Gothic style, the gates of which are regularly shut every night at certain hours. As polygamy is allowed by the Mahometan religion, and is supposed in some degree to affect population, it would be difficult to form any computation near the truth with respect to the number of inhabitants which this city may contain. The mosques, which are the only public buildings except the palace worth noticing at Morocco, are more numerous than magnificent; one of them is ornamented with a very high and square tower, built of cut stone, which is visible at a considerable distance from the city. The streets are very narrow, dirty, and irregular, and many of the houses are uninhabited and falling to ruin. Those which are decent and respectable in their appearance are built of tabby, and enclosed in gardens. That of the effendi or prime minister (according to Mr. Lempriere, from whose Tour this account is transcribed), was among the best in Morocco. This house, which consisted of two stories, had elegant apartments both above and below, furnished in a style far superior to any thing our author ever saw in that country. The court, into which the lower apartments opened, was very neatly paved with glazed blue and white tiling, and had in its centre a beautiful fountain. The upper apartments were connected together by a broad gallery, the balusters of which were painted of different colours. The hot and cold baths were very large, and had every convenience which art could afford. Into the gardens, which was laid out in a tolerably neat style, opened a room adjoining to the house, which had a broad arched entrance but no door, beautifully ornamented with chequered tiling; and at both ends of the apartment the walls were entirely covered with looking glass. The flooring of all the rooms was covered with beautiful carpeting, the walls ornamented with large and valuable looking glasses, intermixed with watches and clocks in glass cases. The ceiling was carved wood, painted of different colours; and the whole was in a superior style to the Moorish grandeur. This and a few others are the only decent habitations in Morocco. The generality of them serve only to impress the traveller with the idea of a miserable and deserted city.

The Elbasiarias is a particular part of the town where stuffs and other valuable articles are exposed to sale. It consists of a number of small shops, formed in the walls of the houses, about a yard from the ground, of such a height within as just to admit a man to sit in one of them cross-legged. The goods and wares are so arranged round him, that when he serves his customers, who are standing all the time out in the street, he can reach down any article he wants without being under the necessity of moving. These shops, which are found in all the other towns of the empire, are sufficient to afford a striking example of the indolence of the Moors. There are three daily markets in different parts of the town of Morocco where provisions are sold, and two weekly fairs or markets for the disposal of cattle. The city is supplied with water by means of wooden pipes connected with the neighbouring streams, which empty themselves into reservoirs placed for the purpose in the suburbs, and some few in the centre of the town.

The castle is a large and ruinous building, the outer walls...
wells of which enclose a space of ground about three miles in circumference. It has a mosque, on the top of which are three large balls, formed, as the Moors allege, of solid gold. The castle is almost a town of itself; it contains a number of inhabitants, who in some department or other are in the service of the emperor, and all under the direction of a particular alcaide, who is quite independent of the governor of the town. On the outside of the castle, between the Moorish town and the Jewry, are several small distinct pavilions, enclosed in gardens of orange trees, which are intended as occasional places of residence for such of the emperor's sons or brothers as happen to be at Morocco. As they are covered with coloured tiling, they have at a small distance rather a neat appearance; but upon approaching or entering them, that effect in a great measure ceases.

The Jews, who are at this place pretty numerous, have a separate town to themselves, walled in, and under the charge of an alcaide, appointed by the emperor. It has two large gates, which are regularly shut every evening about nine o'clock; after which time no person whatever is permitted to enter or go out of the Jewry till they are opened again the following morning. The Jews have a market of their own; and when they enter the Moorish town, castle, or palace, they are always compelled to be barefooted.

The palace is an ancient building, surrounded by a square wall, the height of which nearly excludes from the view of the spectator the other buildings. Its principal gates are constructed with Gothic arches, composed of cut stone, which conduct to several open and spacious courts; through these it is necessary to pass before we reach any of the buildings. These open courts were used by the late emperor for the purposes of transacting public business and exercising his troops. The habitable part consists of several irregular square pavilions, built of tabby, and whitened over; some of which communicate with each other, others are distinct, and most of them receive their names from the different towns of the empire. The principal pavilion is named by the Moors the Douhar, and is more properly the palace or seraglio than any of the others. It consists of the emperor's place of residence and the harem, forming altogether a building of considerable extent. The other pavilions are merely for the purposes of pleasure or business, and are quite distinct from the douhar. The Mogul-e pavilion, so named from the late emperor's partiality to that town, has by far the fairest claim to grandeur and magnificence. This apartment was the work of Sidi Mahomet, and is lofty and square. It is built of cut stone, handsomely ornamented with windows, and covered with varnished tiles of various colours; and its elegance and neatness, contrasted altogether with the simplicity and irregularity of the other buildings, produce a most striking effect. In the inside, besides several other apartments, we find in the pavilion a spacious room floored with blue and white chequered tiling, its ceiling covered with curiously carved and painted wood, and its stucco'd walls variously ornamented with looking glasses and watches, regularly disposed in glass cases. To this pavilion the late emperor manifested an exclusive preference, frequently retiring to it both for the purpose of business and of recreation. The apartments of the emperor have in general a much smaller complement of furniture than those of the Moors in the interior walks of life. Handsome carpeting, a mattress on the ground covered with fine linen, a couch, and a couple of European bedsteads, are the principal articles they contain. The gardens within the walls of the palace, of which he has several, are very neat; they contain orange and olive trees, variously disposed and arranged, and intersected with streams of water, fountains, and reservoirs. Those on the outside are nothing more than large tracts of ground, irregularly planted with olives; having four square walks, and surrounded by walls.

MOROCCO, or Marroquin, the skin of a goat, or some other animal resembling it, dressed in sumach or galls, and coloured at pleasure; much used in bookbinding, &c. The name is commonly derived from the kingdom of Morocco, whence it is supposed the manner of preparing these skins was first borrowed. We have Moroccan skins brought from the Levant, Barbary, Spain, Flanders, and France; red, black, yellow, blue, &c. For the manner of preparing these see LEATHER.

MORON, a town of Spain, in Andalusia, seated in a fertile plain about 30 miles south-east of Seville. W. Long. 5°. 20. N. Lat. 37°. 6.

MORPETH, a handsome town of Northumberland, 14 miles from Newcastle, 286 miles from London, is an ancient borough by prescription, with a bridge over the Wansbeck. It had once an abbey and a castle, now in ruins, situated about a quarter of a mile south of the town and river Wansbeck, on an eminence which overlooks both. The market-place is conveniently situated near the centre of the town; and an elegant townhouse was built by the Carlisle family in 1714, in which the quarter-sessions is held for the county. It is built of hewn stone, with a piazza. The church being a quarter of a mile distant from the town, a tower containing a good ring of bells stands near the market place. Near the bridge is the country gaol, a modern structure. Here are a free grammar school, a chapel near the river, on the site of a chantry that was granted for the support of the foundation of the school, which was part of the old structure, and a hospital for infirm people. In 1215, the townsmen themselves burnt their town, out of pure hatred to King John, that he might find no shelter there. Here is a good market on Saturday for corn, cattle, and all necessary provisions; and there is another on Wednesday, the greatest in England except Smithfield; for live cattle. This is a post town and a borough, with many good inns, and plenty of fish; and here are several mills.—The earl of Carlisle's steward holds a court here twice a year, one of them the Monday after Michaelmas, when four persons are chosen by the free burgesses, who are about 107, and presented to the steward, who names two of them to the bailiffs, who, with seven aldermen, are its governors for the year ensuing. In 1811 the inhabitants amounted to nearly 3244. It has several fairs, and sends two members to parliament. W. Long. 5°. 24. N. Lat. 55°. 12.

MORPHEUS, in fabulous history, the god of sleep, or, according to others, one of the ministers of Somnus. He caused sleepiness, and represented the.
forms of dreams. Ovid styles him the kindest of the deities; and he is usually described in a recumbent posture, and crowned with poppies.

MORRERII, Lewis, author of the Historical Dictionary, was born at Bargo-ment in Provence, in 1642. He learned rhetoric and philosophy at Aix and divinity at Lyons. At 18 years of age he wrote a small piece, entitled Le Pays d'Amour, and a collection of the finest French poems entitled Dous plaisir de la Poesie. He learned Spanish and Italian; and translated out of Spanish into French the book entitled La Perfection Chretienne de Rodrigues. He then refined the Saints Lives to the purity of the French tongue. Being ordained priest, he preached at Lyons, and undertook, when he was but 30 years of age, a new Historical Dictionary, printed at Lyons in one vol. folio, 1673. But his continual labour impaired his health; so that he died in 1680, aged 37. His second volume was published after his death; and four more volumes have since been added. He left some other works behind him.

MORRHINA or MURRHA VASA, were a sort of cups or vases made use of by the ancients for drinking out of, and other purposes. Authors are not agreed as to the substance of which they were made. Some say it was a stone; some assert that it was a fluid condensed by being buried under ground. All that we know concerning it is, that it was known by the name of murmaha, and that Heliospaula's chamber pot was made of it. The word is sometimes written murhina.

MORRISE-DANCES. See Moresque-Dances.

MORS, DEATH, one of the infernal deities, born of Night without a father. She was worshipped by the ancients with great solemnity. She was not represented as an actually existing power, but as an imaginary being. Euripides introduces her in one of his tragedies on the stage. The moderns represent her as a skeleton armed with a scythe and a scimitar.

MORSE. See Tachecus, Mammalia Index.

MORTALITY, a term frequently used to signify a contagious disease, which destroys great numbers of either men or beasts.

Bills of MORTALITY, are accounts or registers specifying the numbers born, married, and buried in any parish, town, or district. In general they contain only these numbers; and, even when thus limited, are of great use, by showing the degrees of healthiness and prolificness, and the progress of population in the places where they are kept. It is therefore much to be wished, that such accounts had been always correctly kept in every kingdom, and regularly published at the end of every year. We should then have had under our inspection the comparative strength of every kingdom, as far as it depends on the number of inhabitants, and its increase or decrease at different periods. But such accounts are rendered more useful, when they include the ages of the dead, and the distempers of which they have died. In this case they convey some of the most important instructions, by furnishing us with the means of ascertaining the law which governs the waste of human life, the values of annuities dependent on the continuance of any lives, or any survivorships between them, and the favourableness and unfavourableness of different situations to the duration of human life. There are but few registers of this kind; nor has this subject, though so interesting to mankind, ever engaged much attention till lately. The first bill containing the ages of the dead were those for the town of Breslaw in Silesia. It is well known what use has been made of these by Dr Halley, and after him by De Moivre. A table of the probabilities of the duration of human life at every age, deduced from them by Dr Halley, has been published in the Philosophical Transactions, see the Abbrigment, vol. iii. p. 699.) and is the first table of that sort that has been ever published. Since the publication of this table similar bills have been established in a few towns of this kingdom; and particularly in London, in the year 1728, and at Northampton in 1735.

Two improvements of these registers have been proposed: the first is, That the sexes of all that die in every period of life should be specified in them, under the denomination of boys, married men, widowers, and bachelors; and of girls, married women, widows, and virgins. The second is, That they should specify the number of both sexes dying of every distemper in every month, and at every age. See the end of the 4th essay in Dr Price's Treatise on Reversionary Payments. Registers of mortality thus improved, when compared with records of the seasons, and with the circumstances that discriminate different situations, might contribute greatly to the increase of medical knowledge; and they would afford the necessary data for determining the difference between the duration of human life among males and females; for such a difference there certainly is much in favour of females, as will appear from the following facts.

At Northampton, though more males are born than females: and nearly the same number die; yet the number of living females appeared, by an account taken in 1746, to be greater than the number of males, in the proportion of 2301 to 1770, or 39 to 30.

At Berlin it appeared, from an accurate account which was taken of the inhabitants in 1747, that the number of female citizens exceeded the number of male citizens in the proportion of 459 to 391. And yet out of this smaller number of males, more had died for 20 years preceding 1751, in the proportion of 19 to 17.

At Edinburgh, in 1743, the number of females was to the number of males as 4 to 3. (See Maitland's History of Edinburgh, p. 220.) But the females that died annually from 1749 to 1758, were to the males in no higher proportion than 3 1/2 to 3.

He that will take pains to examine the accounts in Phil. Trans. A. vol. vii. part iv. p. 46, &c. will find, that though in the town, we enumerated, the proportion of males and females born is no higher than 19 to 18, yet the proportion of boys and girls that die is 8 to 7; and that, in particular, the still-born and chryson males are to the still-born and chryson females as 3 to 2.

In 39 parishes of the district of Vaand in Switzerland, the number of males that died during ten years before 1766 was 8170; of females 8167; of whom the numbers that died under one year of age were 1817 males and 1305 females; and under ten years of age, 3999 males and 2598 females. In the beginning of life, therefore, and before any emigrations can take place, the rate of mortality among males appears to
material parts of them may be found in an essay by Mortality. Dr Price on the Difference between the Duration of Human Life in Towns and in Country Parishes, prefixed in the 5th volume of the Philos. Trans. Part II.

In the fourth essay in Dr Price's Treatise on Reversionary Payments and Life Annuities, the following account is given of the principles on which tables of observation are formed from registers of mortality, and of the proper method of forming them, so as to render them just representations of the number of inhabitants, and the probabilities of the duration of human life in a town or country.

In every place which just supports itself in the number of its inhabitants, without any recruits from other places; or where, for a course of years, there has been no increase or decrease, the number of persons dying every year at any particular age, and above it, must be equal to the number of the living at that age. The number, for example, dying every year at all ages from the beginning to the utmost extremity of life, must, in such a situation, be just equal to the whole number born every year. And for the same reason, the number dying every year at one year of age and upwards, at two years of age and upwards, at three and upwards, and so on, must be equal to the numbers that attain to those ages every year; or which is the same, to the numbers of the living at those ages. It is obvious, that unless this happens, the number of inhabitants cannot remain the same. If the former number is greater than the latter, the inhabitants must decrease; if less, they must increase. From this observation it follows, that in a town or country where there is no increase or decrease, bills of mortality which give the ages at which all die, will show the exact number of inhabitants, and also the exact law according to which human life wastes in that town or country.

In order to find the number of inhabitants, the mean numbers dying annually at every particular age and upwards must be taken as given by the bills, and placed under one another in the order of the second column of the following tables. These numbers will, it has appeared, be the numbers of the living at 1, 2, 3, &c. years of age; and consequently the sum diminished by half the number born annually will be the whole number of inhabitants.

This subtraction is necessary, for the following reason. In a table formed in the manner here directed, it is supposed that the numbers in the second column are all living together at the beginning of every year. Thus the number in the second column opposite to 0 in the first column, the table supposed to be all just born together on the first day of the year. The number, likewise, opposite to 1, it supposes to attain to one year of age just at the same time that the former number is born. And the like is true of every number in the second column. During the course of the year, as many will die at all ages as were born at the beginning of the year, and consequently, there will be an excess of the number alive at the beginning of the year above the number alive at the end of the year, equal to the whole number of the annual births; and the true number constantly alive together, is the arithmetical mean between these two numbers; or a-
MOR [426] MOR

Mortality. According to the rules here given, the sum of the numbers in the second column of the table lessened by half the number of annual births.

In such a series of numbers, the excess of each number above that which immediately follows it will be the number dying every year out of the particular number alive at the beginning of the year; and these excesses set down regularly as in the third column of the table to which we have referred, will show the different rates at which human life wastes through all its different periods, and the different probabilities of life at all particular ages.

It must be remembered, that what has been now said goes on the supposition, that the place whose bills of mortality are given, supports itself by procreation only, in the number of its inhabitants. In towns this very seldom happens, on account of the luxury and debauchery which generally prevail in them. They are, therefore, commonly kept up by a constant accession of strangers, who remove to them from country parishes and villages. In these circumstances, in order to find the true number of inhabitants, and probabilities of life, from bills of mortality containing an account of the ages at which all die, it is necessary that the proportion of the annual births to the annual settlers should be known, and also the period of life at which the latter remove. Both these particulars may be discovered in the following method.

If for a course of years there have been no sensible increase or decrease in a place, the number of annual settlers will be equal to the excess of the annual burials above the annual births. If there be an increase, it will be greater than this excess. If there be a decrease, it will be less.

The period of life at which these settlers remove, will appear in the bills by an increase in the number of deaths at that period and beyond it. Thus in the London bills the number of deaths between 20 and 30 is generally above double, and between 30 and 40 near triple the number of deaths between 10 and 20; and the true account of this, is that from the age of 18 or 20 to 35 or 40, there is an influx of people every year to London from the country, which occasion a great increase in the number of inhabitants at these ages; and consequently raises the deaths for all ages above 20 considerably above their due proportion when compared with the number of deaths before 20.

This is observable in all the bills of mortality for towns with which we are acquainted, not even excepting the Breslaw bills. Dr. Halley takes notice, that these bills gave the number of deaths between 10 and 20 too small. This he considered as an irregularity in them owing to chance; and, therefore, in forming his table of observations, he took the liberty so far to correct it, as to render the proportion of those who die to the living in this division of life nearly the same with the proportion which, he says, he had been informed die annually of the young lads in Christ Church hospital. But the truth is, that this irregularity in the bills was derived from the cause, we have just assigned. During the five years for which the Breslaw bills are given by Dr. Halley, the births did indeed a little exceed the burials; but it appears that this was the effect of some peculiar causes that happened to operate just at that time; for during a complete century, from 1633 to 1734, the annual medium of births was 1089, and of burials 1246. This town, therefore, must have been all along kept up by a number of yearly recruits from other places, equal to about a seventh part of the yearly births.

It appears from the account in the Philosophical Transactions (Abridgement, vol. vii. N° 332, p. 46 &c.), that from 1717 to 1725, the annual medium of births at Breslaw was 1252, of burials 1507; and also that much the greatest part of the births died under 10 years of age. From a table in Susmilch’s work, vol. i. p. 38, it appears that in reality the greater part of all that die in this town are children under five years of age.

What has been now observed concerning the period of life at which people remove from the country to settle in towns, would appear sufficiently probable were there no such evidence for it as has been mentioned; for it might well be reckoned that these people in general must be single persons in the beginning of mature life, who not having yet obtained settlements in the places where they were born, migrate to towns in quest of employments.

Having premised these observations, it will be proper next to endeavour to explain distinctly the effect which these accessions to towns must have on tables of observation formed from their bills of mortality. This is a subject proper to be insisted on, because mistakes have been committed about it; and because the discussion of it is necessary to show how near to truth the value of lives comes as deduced from such tables.

The following general rule may be given on this subject. If a place has for a course of years been maintained in a state nearly stationary, as to number of inhabitants, by recruits coming in every year, to prevent the decrease that would arise from the excess of burials above the births, a table formed on the principle, “that the number dying annually after every particular age, is equal to the number living at that age,” will give the number of inhabitants, and the probabilities of life, too great, for all ages, preceding that at which the recruits cease; and after this it will give them right. If the accessions are so great as to cause an increase in the place, such a table will give the number of inhabitants and the probabilities of life too little after the age at which the accessions cease; and too great if there is a decrease. Before that age it will in both cases give them too great; but most considerably so in the former case, or when there is an increase.

Agreeably to these observations, if a place increases not in consequence of accessions from other places, but of a constant excess of the births above the deaths, a table constructed on the principle that has been mentioned will give the probabilities of life too low through the whole extent of life; because in such circumstances the number of deaths in the first stages of life must be too great in comparison of the number of deaths in the latter stages; and more or less so as the increase is more or less rapid. The contrary in all respects takes place where there is a decrease arising from the excess of the deaths above the births.

For example: Let us suppose that 244 of those born in a town attain annually to 20 years of age, and
show likewise at what parts of life the errors in such tables are most considerable, and how they may be in a great measure corrected.

All this shall be exemplified in the particular case of London.

The number of deaths between the ages of 10 and 20 is always so small in the London bills, that it seems certain few recruits come to London under 20, or at least not so many as before this age are sent out for education to schools and universities. After 20 great numbers come in till 30, and some perhaps till 40 or 50: but at every age after 50, it is probable that more retire from London than come to it. The London tables of observation, therefore, being formed on the principle already mentioned, cannot give the probabilities of life right till 40. Between 30 and 40 they must be a little too high; but more so between 20 and 30, and most of all so before 20. It follows also that these tables must give the number of inhabitants in London much too great.

The first of the following tables is formed in the manner here explained, from the London bills for 10 years, from 1759 to 1768, and adapted to 1000 born as a radix. The sum of the numbers in the second column, diminished by half the number born, is 25777. According to this table, then, for every 1000 deaths in London there are 25½ as many inhabitants; or, in other words, the expectation of a child just born is 25½; and the inhabitants are to the annual burials as 25½ to 1. But it has appeared, that the numbers in the second column, being given on the supposition that all those who die in London were born there, must be too great; and we have from hence a demonstration, that the probabilities of life are given in the common tables of London observations too high for at least the first 30 years of life; and also, that the number of inhabitants in London must be less that 25½ multiplied by the annual burials. The common tables, therefore, of London observations undoubtedly need correction, as Mr. Simpson suggested, and in some measure performed; though too imperfectly, and without going upon any fixed principles, or showing particularly how tables of observation ought to be formed, and how far in different circumstances, and in different ages, they are to be depended on. The way of doing this, and in general the right method of forming genuine tables of observation for towns, may be learned from the following rule:

"From the sum of all that die annually, after any given age, subtract the number of annual settlers after that age; and the remainder will be the number of the living at the given time."

This rule can want no explication or proof after what has been already said.

If, therefore, the number of annual settlers in a town at every age could be ascertained, a perfect table of observations might be formed for that town from bills of mortality, containing an account of the ages at which all die in it. But no more can be learned in this instance from any bills, than the whole number of annual settlers, and the general division of life in which they enter. This, however, may be sufficient to enable us to form tables that shall be tolerably exact. For instance: Suppose the annual deaths in a town which has not increased or decreased, to have been
Mortality has been for many years in the proportion of 4 to 3 to the annual births. It will hence follow, that ⅗ of the persons who die in such a town are settlers, or emigrants from other places, and not natives; and the sudden increase in the deaths after 20 will also show, agreeably to what was before observed, that they enter after this age.

In forming, therefore, a table for such a town, a quarter of all that die at all ages throughout the whole extent of life must be deducted from the sum of all that die after every given age before 20; and the remainder will be the true number living at that given age. And if at 20, and every age above it, the deduction is omitted, or the number of the living at every such age is taken the same with the sum of all that die after it, the result will be (supposing most of the settlers to come in before 30, and all before 40) a table exact till 20; too high between 20 and 30; but nearly right for some years before 40; and after 40 exact again. Such a table, it is evident, will be the same with the table last described at all ages above 20, and different from it only under 20. It is evident also, that on account of its giving the probabilities of life too great for some years after 20, the number of inhabitants deduced from it may be depended on as somewhat greater than the truth; and more or less so, as the annual recruits enter in general later or sooner after 20.

Let us now consider what the result of these remarks will be, when applied particularly to the London bills.

It must be here first observed, that at least one quarter of all that die in London are emigrants or settlers from the country, and not natives. The medium of annual burials for 10 years, from 1779 to 1788, was 23,956; of births 15,712. The excess is 7,244, or near a third of the burials. The same excess during 20 years before 1780 was 10,500, or near half the burials. London was then decreasing. For the last 12 or 15 years it has been increasing. This excess, therefore, agreeably to the foregoing observations, was then greater than the number of annual settlers, and it is now less. It is however here supposed, that the number of annual settlers is now no more than a quarter of the annual burials, in order to allow for more emigrations in the births than the burials; and also, in order to be more sure of obtaining results that shall not exceed the truth.

Of every 1000 then who die in London only 750 are natives, and 250 are recruits who come to it after 18 or 20 years of age; and, consequently, in order to obtain from the bills a more correct table than the first of the following tables, 250 must be subtracted from every one of the numbers in the second column till 20; and the numbers in the third column must be kept the same, the bills always giving these right. After 20, the table is to be continued unaltered; and the result will be, a table which will give the numbers of the living at all ages in London much nearer the truth but still somewhat too high. Such is the second of the following tables. The sum of all the numbers in the second column of this table, diminished by 500, is 20,750. For every 1000 deaths, therefore, in London, there are, according to this table, 20,750 living persons in 12; or for every single death 204 inhabitants. It was before shown, that the number of inhabitants in various London could not be so great as 25½ times the deaths.

It now appears (since the numbers in the second column of this table are too high) that the number of inhabitants of London cannot be so great as even 20½ times the deaths. And this is a conclusion which every one, who will bestow due attention on what has been said, will find himself forced to receive. It will not be amiss, however, to confirm it by the following fact, the knowledge of which is derived from the particular inquiry and information of Mr Harris, the late ingenious master of the royal mathematical school in Christ Church hospital. The average of lads in this school has, for 30 years past, been 831. They are admitted at all ages between 7 and 11; and few stay beyond 16: they are, therefore, in general, lads between the age of 8 and 16. They have better accommodations than it can be supposed children commonly have; and about 300 of them have the particular advantage of being educated in the country. In such circumstances it may be well reckoned, that the proportion of children dying annually must be less than the general proportion of children dying annually at the same ages in London. The fact is, that for the last 30 years 11½ have died annually, or one in 70½.

According to Table II. one in 73 dies between 10 and 20, and one in 70 between 8 and 16. That table, therefore, probably gives the decrements of life in London at these ages, too little, and the numbers of the living too great; and if this is true of these ages, it must be true of all other ages under 20; and it follows demonstrably, in conformity to what was before shewn, that more people settle in London after 20 than the fourth above supposed; and that from 20 to at least 30 or 35, the numbers of the living are given too great, in proportion to the decrements of life.

In this table the numbers in the second column are doubled at 20, agreeably to what really happens in London; and the sum of the numbers in this column, diminished by half the whole number of deaths, gives the expectation of life, not of a child just born, as in other tables, but of all the inhabitants of London at the time they enter it, whether that be at birth or at 20 years of age. The expectations, therefore, and the culures of London lives under 20, cannot be calculated from this table. But it may be very easily fitted for this purpose, by finding the number of births which, according to the given decrements of life, will leave 494 alive at 20; and then adapting the intermediate numbers in such a manner to this radix, as to preserve all along the number of the living in the same proportion to the numbers of the dead. This is done in the third of the following tables; and this table may be recommended as better adapted to the present state of London than any other table. The values of lives, however, deduced from it, are in general nearly the same with those deduced by Mr Simpson from the London bills as they stood forty years ago; the main difference is, that after 52, and in old age, this table gives them somewhat lower than Mr Simpson's table.

The fourth and fifth of the following tables, compared with the two last, will give a distinct and full view of the difference between the rate of human mortality in great towns and in country parishes and villages.

All the bills, from which the following tables are formed, give the numbers dying under 1 as well as under 2 years; and in the numbers dying under 1 are included, in the country parish in Brandenburg and at Berlin, all the stillborns. All the bills also give the numbers dying in every period of five years.

For the probabilities of life at Carlisle, see Annuities, Supplement.

</table>

**Brief of Mortancestry**, in *Sota Law*: anciently the ground of an action at the instance of an heir, in the special case where he had been excluded from the possession of his ancestor's estate by the superior, or other person pretending right.

**Mortar**, a preparation of lime and sand mixed with water, which serves as a cement, and is used by masons and bricklayers in building walls of stone and brick. See *Lime, Chemistry Index*.

**Mortar**, a chemical utensil, very useful for the division of bodies, partly by percussion and partly by grinding. Mortars have the form of an inverted bell. The matter intended to be pounded is to be put into them, and there it is to be struck and bruised by a long instrument called a pestle. The motion given to the pestle ought to vary according to the nature of the substances to be pounded. Those which are easily broken, or which are apt to fly out of the mortar, or which are hardened by the stroke of the pestle, require that this instrument should be moved circularly, rather by grinding or bruising than by striking. Those substances which are softened by the heat occasioned by rubbing.
Mortars, rubbing and percussion, require to be pounded very slowly. Lastly, those which are very hard, and which are not capable of being softened, are easily pounded by repeated strokes of the pestle. They require no bruising but when they are brought to a certain degree of fineness. But these things are better learned by habit and practice than by any directions.

As mortars are instruments which are constantly used in chemistry, they ought to be kept of all sizes and materials; as of marble, copper, glass, iron, gristone, and agate. The nature of the substance to be pounded determines the choice of the kind of mortar. The hardness and dissolving power of that substance are particularly to be attended to. As copper is a metal, which is soluble by almost all menstrua, and hurtful to health, this metal is rarely or never employed for the purpose of making mortars.

One of the principal inconveniences of pulverization in a mortar proceeds from the fine powder which rises abundantly from some substances during the operation. If these substances be precious, the loss will be considerable; and if they be injurious to health, they may hurt the operator. These inconveniences may be remedied, either by covering the mortar with a skin, in the middle of which is a hole, through which the pestle passes; or by moistening the matter with a little water when this addition does not injure it; or, lastly, by covering the mouth and nose of the operator with a fine cloth, to exclude this powder. Some substances, as corrosive sublimate, arsenic, calce of lead, Mortars, cantarides, euphorbium, &c. are so noxious, that all these precautions ought to be used, particularly when a large quantity is pounded.

Large mortars ought to be fixed upon a block of wood, so high, that the mortar shall be level with the middle of the operator. When the pestle is large and heavy, it ought to be suspended by a cord or chain fixed to a movable pole placed horizontally above the mortar: this pole considerably relieves the operator, because its elasticity assists the raising of the pestle.

Mortar-Piece, in the military art, a short piece of ordnance, thick and wide, proper for throwing bombs, carcasses, shells, stones, bags filled with grapeshot, &c. See Gunnery, No. 50.

Land Mortars, are those used in sieges, and of late in battles, mounted on beds made of solid timber, consisting generally of four pieces, those of the royal and howitzer, excepted, which are but one single block; and both mortar and bed are transported on block-carriages. There is likewise a kind of land mortars, mounted on travelling carriages, invented by Count Buckeburg, which may be elevated to any degree; whereas ours are fixed to an angle of 45 degrees, and firmly lashed with ropes. The following table shows the weight of land mortars and shells; together with the quantity of powder the chambers hold when full the weight of the shells, and powder for loading them.

Sea Mortars, are those which are fixed in bomb vessels for bombarding places by sea: and as they are generally fired at a much greater distance than that which is required by land, they are made somewhat longer and much heavier than the land mortars. The following table exhibits the weight of the sea mortars and shells, and also of their full charges.

</table>

'To Charge or Load a Mortar, the proper quantity of gunpowder is put into the chamber, and if there be any vacant space they fill it up with hay; some choose a wooden plug: over this they lay a turf, some a wood-ten-tom-pion fitted to the bore of the piece; and lastly the bomb; taking care that the fuse be in the axis thereof, and the orifice be turned from the muzzle of the piece: what space remains is to be filled up with hay, straw, turf, &c. so as the load may not be exploded without the utmost violence.
The quantity of gunpowder to be used is found by dividing the weight of the bomb by 30; though this rule is not always to be strictly observed.

When the proper quantity of powder necessary to charge a mortar is put into the chamber, it is covered with a wad well beat down with the rammer. After this the fixed shell is placed upon the wad, as near the middle of the mortar as possible, with the fuse hole uppermost, and another wad pressed down close upon it, so as to keep the shell firm in its position. The officer then points the mortar according to the proposed inclination. When the mortar is thus fixed, the fuse is opened; the priming iron is also thrust into the touch-hole of the mortar to clear it, after which it is primed with the finest powder. This done, two of the matrosses or sailors, taking each one of the matches, the first lights the fuse, and the other fires the mortar. The bomb, thrown out by the explosion of the powder, is carried to the place intended: and the fuse, which ought to be exhausted at the instant of the shell’s falling, inflames the powder contained in it, and bursts the shell in splinters; which, flying off circularly, occasion incredible mischief wherever they reach.

If the service of mortars should render it necessary to use pound shots, 200 of them with a wooden bottom are to be put into the 13 inch mortar, and a quantity of powder not exceeding 5 pounds; and 100 of the above shot with 24 pounds of powder, for the 10 inch mortar, or three pounds at most.

To E levate the Mortar so as its axis may make any given angle with the horizon, they apply the artillery level or gunner’s quadrant. An elevation of 70 or 80 degrees is what is commonly chosen for rendering mortars most serviceable in casting shells into towns, forts, &c. though the greatest range be in 45 degrees.

All the English mortars are fixed to an angle of 45 degrees, and lashed strongly with ropes at that elevation. Although in a siege there is only one case in which shells should be thrown with an angle of 45 degrees; that is, when the battery is so far off that they cannot otherwise reach the works; for when shells are thrown out of the trenches into the works of a fortification, or from the town into the trenches, they should have as little elevation as possible, in order to roll along, and not bury themselves; whereby the damage they do, and the terror they occasion, are much greater than if they sink into the ground. On the contrary, when shells are thrown upon magazines or any other buildings, with an intention to destroy them, the mortars should be elevated as high as possible, that the shells may acquire a greater force in their fall, and consequently do greater execution.

If all mortar pieces were, as they ought to be, exactly similar, and their requisites of powder as the cubes of the diameters of their several boxes, and if their shells, bombs, carcasses, &c. were also similar; then, comparing like with like, their ranges on the plane of the horizon, under the same degree of elevation, would be equal; and consequently one piece being well proved, i.e. the range of the grenade, bomb, carcass, &c. being found to any degree of elevation, the whole work of the mortar piece would become very easy and exact.

But since mortars are not thus similar, it is required, Vol. XIV. Part II.
The use of the table is obvious. Suppose, for instance, it be known by experiment, that a mortar elevated 15°, charged with three pounds of powder, will throw a bomb to the distance of 350 fathoms; and it be required, with the same charge, to throw a bomb 200 fathoms farther; seek in the table the number answering to 15 degrees, and you will find it 6100. Then as 350 is to 6100, so is 5000 to a fourth number, which is 6428. Find this number, or the nearest to it, in the table, and against it you will find 20° or 70°; the proper angles of elevation.

MORTGAGE, in Law, (mortuum vadium, or dead pledge), is where a man burrows of another a specific sum (e.g. 200l.), and grants him an estate in fee, on condition that if he, the mortgagor, shall pay the mortgage the said sum of 200l. on a certain day mentioned in the deed, that then the mortgagor may re-enter on the estate so granted in pledge; or, as is now the more usual way, that the mortgagee shall re-convey the estate to the mortgagor: in this case the land which is so put in pledge, is by law, in case of nonpayment, at the time limited, for ever dead and gone from the mortgagee; and the mortgagor's estate in the lauds, is then no longer conditional, but absolute. But so long as it continues conditional, that is, between the time of lending the money and the time allotted for payment, the mortgagee is called tenant in mortgage. But as it was formerly a doubt, whether, by taking such estate in fee, it did not become liable to the wife's dower, and other encumbrances of the mortgage (though that doubt has been long ago overruled by our courts of equity), it therefore became usual to grant only a long term of years, by way of mortgage; with condition to be void on repayment of the mortgage money: which course has been since continued, principally because on the death of the mortgagee such term becomes vested in his personal representatives, who only are entitled in equity to receive the money lent, of whatever nature the mortgagee may happen to be.

As soon as the estate is created, the mortgagee may immediately enter on the lands; but is liable to be dispossessed, upon performance of the condition by payment of the mortgage money at the day limited. And therefore the usual way is to agree that the mortgagor shall hold the land till the day assigned for payment: when, in case of failure, whereby the estate becomes absolute, the mortgagee may enter upon it, and take possession, without any possibility at law of being afterwards evicted by the mortgagor, to whom the land is now for ever dead. But here again the courts of equity interpose; and though a mortgage be thus forfeited, and the estate absolutely vested in the mortgagor at the common law, yet they will consider the real value of the tenements compared with the sum borrowed. And if the estate be of greater value than the sum lent thereon, they will allow the mortgagor at any reasonable time to recall or redeem his estate: paying to the mortgagee his principal, interest, and expenses: for otherwise, in strictness of law, an estate worth 1000l. might be forfeited for non-payment of 100l. or a less sum. This reasonable advantage, allowed to mortgagees, is called the equity of redemption; and this enables a mortgagor to call on the mortgagor, who has possession of his estate, to deliver it back, and account for the rents and profits received on payment of his whole debt and interest, thereby turning the mortgagor into a kind of vivum vadium; (see VADUUM). But, on the other hand, the mortgagee may either compel the sale of the estate, in order to get the whole of his money immediately; or else call upon the mortgagor to redeem his estate presently, or, in default thereof, to be for ever foreclosed from redeeming the same; that is, to lose his equity of redemption without possibility of recal. And also, in some cases of fraudulent mortgages, the fraudulent mortgagor forfeits all equity of redemption whatsoever. It is not, however, usual for mortgagees to take possession of the mortgaged estate, unless where the security is precarious, or small; or where the mortgagor neglects even the payment of interest: when the mortgagor is frequently obliged to bring an ejectment, and take the land into his own hands, in the nature of a pledge, or the primum of the Roman law: whereas, while it remains in the hands of the mortgagor, it more resembles their hypothesa, which was where the possession of the thing pledged remained with the debtor. But by statute 7 Geo. II. c. 20, after payment or tender by the mortgagor of principal, interest, and costs, the mortgagee can maintain no ejectment; but may be compelled to re-assign his securities. In Clavil's time, when the universal method of conveyance was by livery of seisin or corporeal tradition of the lands, no gage or pledge of lands was good unless possession was also delivered to the creditor; si non sequatur ipsum vadi traditio, curia domini regis husumodi privatias conventice tueor non solit: for which the reason given is, to prevent subsequent and fraudulent pledges of the same land; cum in tali casu possidem ex pluribus aliis creditoribus tuum prium tueor posteros invidios. And the frauds which have arisen, since the exchange of these public and notorious conveyances for more private and secret bargains, have well evinced the wisdom of our ancient law.

MORTIER, an ensign of dignity, which was borne by the chancellor and grand presidents of the parliament of France. That borne by the chancellor was a piece of cloth of gold, edged and turned up with ermine; and that of the first president was a piece of black velvet edged with a double row of gold lace.

MORTIFICATION, or GANGRENE. See Medicine and Surgery Index. Mortification, in religion, any severe penance observed on a religious account. See Fast.

MORTISE, or MORTOISE, in carpentry, &c. a kind of joint wherein a hole of a certain depth is made in a piece of timber, which is to receive another piece called a tenon.

MORTMAIN, or ALIENATION in Mortmain (in mortua manu), is an alienation of lands or tenements to any corporation, sole or aggregate, ecclesiastical or temporal; but these purchases having been chiefly made by religious houses, in consequence whereof the lands became perpetually inherent in one dead hand, this hath occasioned the general appellation of mortmain to be applied to such alienations, and the religious houses themselves to be principally considered in forming the statutes of mortmain: in deducing the history of which statutes, it will be more of curiosity to observe the great address and subtile contrivance of the ecclesiastics, in eluding from time to time the laws in being, and the zeal with which successive parliaments have pursued...
them through all their finesses: how new remedies were still the parents of new evasions; till the legislature at last, though with difficulty, hath obtained a decisive victory.

By the common law any man might dispose of his lands to any other private man at his own discretion, especially when the feodal restraints of alienation were worn away. Yet in consequence of this it was always, and is still necessary, for corporations to have a license of mortmain from the crown, to enable them to purchase lands: for as the king is the ultimate lord of every fee, he ought not, unless by his own consent, to lose his privilege of escheat and other feodal profits, by the vesting of lands in tenants that can never be attainted or die. And such licenses of mortmain seem to have been necessary among the Saxons above 60 years before the Norman conquest. But, besides this general license from the crown as lord paramount of the kingdom, it was also requisite, whenever there was a mesne or intermediate lord between the king and the alienor, to obtain his license also (upon the same feodal principles) for the alienation of the specific land. And if no such license was obtained, the king or other lord might respectively enter on the land so alienated in mortmain, as a forfeiture. The necessity of this privilege from the crown was acknowledged by the Constitutions of Clarendon, in respect of advowsons, which the monks always greatly coveted, as being the groundwork of subsequent appropriations. Yet such were the influence and ingenuity of the clergy, that (notwithstanding this fundamental principle) we find that the largest and most considerable donations of religious houses happened within less than two centuries after the Conquest. And (when a license could not be obtained) their contrivance seems to have been this: That as the forfeiture for such alienations accrued in the first place to the immediate lord of the fee, the tenant who wanted to alienate first conveyed his lands to the religious house, and instantly took them back again to hold as tenant to the monastery: which kind of instantaneous seisin was probably held not to occasion any forfeiture: and then, by pretext of some other forfeiture, surrender, or escheat the society entered into those lands in right of such newly acquired signory, as immediate lords of the fee. But when these donations began to grow numerous, it was observed that the feodal services, ordained for the defence of the kingdom, were every day visibly withdrawn; that the circulation of landed property from man to man began to stagnate: and that the lords were curtailed of the fruits of their signories, their escheats, wardships, reliefs, and the like: and therefore, in order to prevent this, it was ordained by the second of King Henry III.'s great charters, and afterwards by that printed in our common statute books, that all such attempts should be void, and the land forfeited to the lord of the fee.

But as this prohibition extended only to religious houses, bishoprics, and other sole corporations were not included therein, and the aggregate ecclesiastical bodies (who, Sir Edward Coke observes, in this were to be commended, that they were half of their counsel the best lease, and that they could not do more than a man was to scrap out of this statute, by buying in lands that were free and void of themselves as lords of the fee, and thereby evading the forfeiture; or by taking long leases for years, which first introduced those extensive terms, for a thousand or more years, which are now so frequent in conveyances. This produced the statute de religiosis, 7 Edw. I.; which provided, that no person, religious or other whatsoever, should buy, or sell, or receive under pretence of a gift, or term of years, or any other title whatsoever, nor should by any art or ingenuity appropriate to himself, any lands or tenements in mortmain; upon pain that the immediate lord of the fee, or, on his default for one year, the lords paramount, and in default of all of them, the king, might enter thereon as a forfeiture.

This seemed to be a sufficient security against all alienations in mortmain; but as these statutes extended only to gifts and conveyances between the parties, the religious houses now began to set up a fictitious title to the land, which it was intended they should have, and to bring an action to recover it against the tenant; who, by fraud and collusion, made no defence, and thereby judgment was given for the religious house, which then recovered the land by a sentence of law upon a supposed prior title. And thus they had the honour of inventing those fictitious adjudications of right, which are since become the great assurance of the kingdom, under the name of common recoveries. But upon this the statute of Westminster the second, 13 Edw. I. c. 32. enacted, that in such cases a jury shall try the true right of the demandants or plaintiffs to the land; and if the religious house or corporation be found to have it, they shall still recover seisin; otherwise it shall be forfeited to the immediate lord of the fee, or else to the next lord, and finally to the king, upon the immediate or other lord's default. And the like provision was made by the succeeding chapter, in case the tenants set up crosses upon their lands (the badges of knights templars and hospitalers) in order to protect them from the feudal demands of their lords, by virtue of the privileges of those religious and military orders. And so careful was this prudent prince to prevent any future evasions, that when the statute of quita emptores, 18 Edw. I. abolished all sub-infeudations, and gave liberty for all men to alienate their lands to be held of their next immediate lord, a proviso was inserted that this should not extend to authorize any kind of alienation in mortmain. And when afterwards the method of obtaining the king's license by writ of ad quod damnum was marked out by the statute 27 Edw. I. st. 2. it was farther provided by statute 34 Edw. I. st. 3. that no such license should be effectual without the consent of the mesne or intermediate lords.

Yet still it was found difficult to set bounds to ecclesiastical ingenuity: for when they were driven out of all their former holds, they devised a new method of conveyance, by which the lands were granted, not to themselves directly, but to nominal feoffees to the use of the religious houses; thus distinguishing between the possession and the use, and receiving the actual profits, while the seisin of the land remained in the nominal feoffee; who was held by the courts of equity (then under the direction of the clergy) to be bound in conscience to act for the use of the grants. The see for the rents and emoluments of the patronate. And it is to these inventions that our practisers are indebted for the introduction of uses and trusts, the foundation
MOR [ 436 ]

Mor\_tality of modern conveyancing. But unfortunately for the inventors themselves, they did not long enjoy the advantage of their new device; for the statute 15 Rich\_ ard II. c. 5, enacts, that the lands which had been so purchased to uses should be amortised by license from the crown, or else be sold to private persons; and that, for the future, uses shall be subject to the statutes of mortmain, and forfeitable like the lands themselves.

And whereas the statutes had been eluded by purchasing large tracts of land adjoining to churches, and consecrating them by the name of churchyards, such subtle imagination is also declared to be within the compass of the statutes of mortmain. And civil or lay corporations, as well as ecclesiastical, are also declared to be within the mischief, and of course within the remedy provided by those salutary laws. And lastly, As during the times of popery lands were frequently given to superstitious uses, though not to any corporate bodies; or were made liable in the hands of heirs and devisees to the charge of obits, chantries, and the like, which were equally pernicious in a well-governed state as actual alienations in mortmain; therefore at the dawn of the Reformation, the statute 23 Hen. VIII. c. 12, declares, that all future grants of lands for any of the purposes aforesaid, if granted for any longer term than 20 years, shall be void.

But, during all this time, it was in the power of the crown, by granting a license of mortmain, to remit the forfeiture, so far as related to its own-rights; and to enable any spiritual or other corporation to purchase and hold any lands or tenements in perpetuity: which prerogative is declared and confirmed by the statute 18 Edw. III. st. 3. c. 3. But as doubts were conceived at the time of the Revolution how far such license was valid, since the king had no power to dispense with the statutes of mortmain by a clause of non obstante, which was the usual course, though it seems to have been unnecessary; and as, by the gradual declension of mesue signories through the long operation of the statute of quia emporos, the rights of intermediate lords were reduced to a very small compass; it was therefore provided by the statute 7 & 8 W. III. c. 37. that the crown for the future at its own discretion may grant licenses to alienate or take in mortmain, of whomsoever the tenements may be held.

After the dissolution of monasteries under Hen. VIII. though the policy of the next popish successor affected to grant a security to the possessors of abbey lands, yet, in order to regain so much of them as either the zeal or timidity of their owners might induce them to part with, the statutes of mortmain were suspended for 20 years by the statute 1 & 2 P. & M. c. 8, and during that time any lands or tenements were allowed to be granted to any spiritual corporation without any license whatsoever. Yet, long afterwards, for a much better purpose, the augmentation of poor livings, it was enacted by the statute 17 Car. II. c. 3, that appropriators may annex the great tithes to the vicarages, and that all benefices under 100l. per annum may be augmented by the purchase of lands, without license of mortmain in either case; and the like provision hath been since made in favour of the governors of Queen Anne's bounty. It hath also been held, that the statute 13 Hen. VIII. before-mentioned, did not extend to any thing but superstitious uses; and that therefore a man may give lands for the maintenance of a school, hospital, or any other charitable uses. But as it Mortmain was apprehended from recent experience, that persons on their deathbeds might make large and imprudent dispositions even for these good purposes, and defeat the political ends of the statutes of mortmain; it is therefore enacted by the statute 9 Geo. II. c. 36. that no lands or tenements, or money to be laid out thereon, shall be given for or charged with any charitable uses whatsoever, unless by deed indented, executed in the presence of two witnesses 12 kalender months before the death of the donor, and enrolled in the court of chancery within six months after its execution (except stocks in the public funds, which may be transferred within six months previous to the donor's death); and unless such gift be made to take effect immediately, and be without power of revocation; and that all other gifts shall be void. The two universities, their colleges, and their scholars upon the foundation of the colleges of Eton, Winchester, and Westminster, are excepted out of this act: but such exemption was not granted with this proviso, that no college shall be at liberty to purchase more advowsons than are equal in number to one moiety of the fellows or students upon the respective foundations.

MORTUARY, in Law, is a sort of ecclesiastical heir\:* being a customary gift claimed by and due to the minister in very many parishes on the death of his parishioners. They seem originally to have been only a voluntary bequest to the church; being intended, as Lyndewode informs us from a constitution of Archbishop Langham, as a kind of expiation and amend to the clergy for the personal tithes, and other ecclesiastical duties, which the laity in their life might have neglected or forgotten to pay. For this purpose, after the lord's heir or best good was taken out, the second best chattel was reserved to the church as a mortuary. And therefore in the laws of King Canute, this mortuary is called soul-scot or symbolun anima. And in pursuance of the same principle, by the laws of Venice, where no personal tithe has been paid during the life of the party, they are paid at his death out of his merchandise, jewels, and other moveables. So also, by a similar policy in France, every man that died without bequeathing a part of his estate to the church, which was called dying without confession, was formerly deprived of Christian burial; or, if he died intestate, the relations of the deceased, jointly with the bishop, named proper arbitrators to determine what he ought to have given to the church, in case he had made a will. But the parliament, in 1499, redressed this grievance.

It was anciently usual in England to bring the mortuary to church along with the corpse when it came to be buried; and thence it is sometimes called a corpse-present: a term which bespeaks it to have been once a voluntary donation. However, in Bracton's time, so early as Henry III. we find it rivetted into an established custom; in so much that the bequests of heriots and mortuaries were held to be necessary ingredients in every testament of chattels. Imprimis autem debet quilibet, qui testamentum fecerit, dominum suum de meliori re quom habuerit recognoscere; et postea ecclesiam de alia meliore: the lord must have the best good left him as a heriot; and the church the second best as a mortuary.
for any one of full age, that is not a housekeeper; nor
for any wayfaring man; but such wayfaring man's mor-
tuary shall be paid in the parish to which he belongs.
And upon this statute stands the law of mortuaries to
this day.

MORUS, the Mulberry Tree, a genus of plants
belonging to the moneccea class, and in the natural me-
thod ranking under the 53d order, Scabridae. See Bo-
tany Index.

MOSEA, in Ancient Geography, a river of Belgica,
rising in the Mount Vosgesus on the borders of the Lingones,
and which, after receiving a part of the Rhine called
Pahals, forms the island of the Batavi, and passes off
into the sea, at the distance of 80 miles. Now called
the Moselle, or Meuse; rising in Champagne, on the
borders of the county of Burgundy, or Franche
Comté, at a village called Meuse, whence the appella-
tion; and running north through Lorraine and Cham-
pagne into the Netherlands: it afterwards directs its
course north-east and then west; and joining the Waal,
rises to Dort, and falls into the German sea, a little be-
low the Brielle.

MOSAE PONS, in Ancient Geography, supposed to be
Maastricht, situated on the Moselle. E. Long. 5 40.
N. Lat. 50 45

MOSAIIC LAW, or the Law of Moses, is the most
ancient that we know of in the world, and is of three
kinds; the moral law, the ceremonial law, and the
judicial law. The different manner in which each of
these was delivered, may perhaps suggest to us a right
idea of their different natures. The moral law, or
ten commandments, for instance, was delivered on the
top of the mountain, in the face of the whole world,
as being of universal influence, and obligatory on all
mankind. The ceremonial was received by Moses in
private in the tabernacle, as being of peculiar concern,
belonging to the Jews only, and destined to cease
when the tabernacle was down, and the vail of the temple
rent. As to the judicial law, it was neither so publicly
nor so audibly given as the moral law, nor yet so
privately as the ceremonial; this kind of law being of
an indifferent nature, to be observed or not observed,
as its rites suit with the place and government under
which we live. The five books of Moses called the
Pentateuch, are frequently styled, by way of emphasis
the Law. This was held by the Jews in such veneration,
that they would not allow it to be laid upon the
bed of any sick person, lest it should be polluted by
touching the dead.

**A TABLE or HARMONY of the MOSAIIC LAW, digested into proper HEADS, with
REFERENCES to the several Parts of the PENTATEUCH where the respective Laws occur.**

MOSAIC, or MOSAIC WORK, an assemblage of little pieces of glass, marble, precious stones, &c. of various colours, cut square, and cemented on a ground of stucco, in such a manner as to imitate the colours and gradations of painting. The critics are divided as to the origin and reason of the name. Some derive
MOS

it from mosaicum, a corruption of mosaicum, as that is of mosaicum, as it was called among the Romans.

Seiler derives it from the Greek mosaic, and imagines the name was given to this sort of works as being very fine and ingenious. Nebrisium is of opinion it was so called, because ex libris picturi or ornamentum mosaicum.

1. Method of performing mosaic work of glass in this: They provide little pieces of glass, of as many different colours and sizes as possible.

Now, in order to apply these several pieces, and cast them to form pictures, they first of all procure a cartoon, or design to be drawn; this is transferred to the ground or plaster by chalkling as in painting in fresco. See Fresco.

As this plaster is to be laid thick on the wall, and therefore will continue fresh and soft a considerable time, so there may be enough prepared as a stock to serve for as much work as will take up three or four days.

This plaster is composed of lime made of hard stone, with brick dust very fine, gum tragacanth, and white of eggs; when this plaster has been thus prepared and laid on the wall, and made the design of what is to be represented, they take out the little pieces of glass with a pair of pincers, and range them one after another, still keeping strictly to the light, shadow, different tints and colours represented in the design before; pressing or fastening them down with a ruler, which serves both to sink them within the ground and to render the surface even.

Thus, in a long time, and with a great deal of labour, they finish the work, which is still the more beautiful, as the pieces of glass are more uniform and ranged at an even height.

Some of these pieces of mosaic work are performed with that exactness, that they appear as smooth as a table of marble, and as finished and masterly as a painting in fresco; with this advantage, that they have a fine lustre, and will last ages.

The finest works of this kind that have remained till our time, and those by whom the moderns have retrieved the art, which was in a manner lost, are those in the church of St Agnes, formerly the temple of Bacchus, at Rome; and some at Pisa, Florence, and other cities of Italy. The most esteemed among the works of the moderns are those of Joseph Pine and the Chevalier Lanfranc, in the church of St Peter at Rome: there are also very good ones at Venice.

2. The method of performing mosaic work of marble is this: The ground of mosaic works, wholly marble, is usually a massive marble either white or black. On this ground the design is cut with a chisel, after it has been first chalked. After it has been cut of a considerable depth, i.e., an inch or more, the cavities are filled up with marble of a proper colour, first fashioned according to the design, and reduced to the thickness of the indentures with various instruments. To make the piece thus inserted into the indentures cleave fast, whose several colours are to imitate those of the design, they use a stucco, composed of lime and marble dust; or a kind of mastick, which is prepared by each workman, after a different manner peculiar to himself. The figures being marked out, the painter or sculptor himself draws with a pencil the colours of the figures not determined by the ground, and in the same manner makes strokes or hatchings in the place where shadows

Vol. XIV. Part II.

MOS

not to be: and after he has engravew the chisel all the strokes thus drawn, he fills them up with a black mastick, composed partly of Burgosy paste poured on hot; taking off afterwards what is superfluous with a piece of soft stone or brick, which, together with water, and beaten cement, takes away the mastick, polishes the marble, and renders the whole so even that one would imagine it only consisted of one piece. This is the kind of mosaic work that is seen in the church of the Invalides at Paris, and the fine chapel at Versailles, with which some entire apartments of the palace are incrustated.

As for mosaic work of precious stones, such as inlays and finer instruments are required than those used in marble; as drills, wheels, &c., used by lapidaries and engravers on stone. As none but the richest marbles and stones enter this work, to make them go the farther, they are sawn into the thinnest leaves imaginable, scarcely exceeding half a line in thickness; the block to be sawn is fastened firmly with cardo on the bench, and only raised a little on a piece of wood, one to two inches high. Two iron pins, which are on one side the block, and which serve to fasten it, are put into a vice con trived for the purpose; and with a kind of saw or bow, made of a fine brass wire, bent on a piece of spongy wood, together with emery steeped in water, the leaf is gradually fashioned by following the stroke of the design made on paper, and glues on the pieces. When there are pieces enough fastened to form an entire flower, or some other part of the design, they are applied to the ground.

The ground which supports this mosaic work is usual of freestone. The matter with which the stones are joined together is a mastick, or kind of stucco, laid very thin on the leaves as they are fashioned; and this being done, the leaves are applied with pincers.

If any centaur, or side of a leaf, be not either squared or rounded sufficiently, so as to fit the place exactly into which it is to be inserted, when it is too large, it is to be brought down with a brass file or rasp; and if it be too little, it is managed with a drill and other instruments used by lapidaries.

Mosaic work of marble is used in large works, as in pavements of churches and palaces; and in the incrustation and veneering of the walls of the same edifices.

As far that of precious stones, it is only used in small works, as ornaments for altar pieces, tables for rich cabinets, precious stones being so very dear.

4. Manner of performing mosaic work of gypsum. Of this stone calcined in a kiln, beaten in a mortar and sifted, the French workmen make a sort of artificial marbles, imitating precious stones; and of these they compose a kind of mosaic work, which does not come far short either of the durability and the vivacity of the natural stones; and which besides has this advantage that it admits of continued pieces or paintings of entire compartments without any visible joining.

Some make the ground of plaster of Paris, others of freestone. If it be of plaster of Paris, they spread it in a wooden frame, of the length and breadth of the work intended, and in thickness about an inch and a half. This frame is so contrived, that the tenons being only joined to the mortises by single pins, they may be taken asunder, and the frame be dissevered when the plaster is dry. The frame is covered on one side with a strong linen cloth, nailed all round; which being placed
Mosaic [442] Mosaic

placed horizontally with the linen at the bottom, is filled with plaster passed through a wide sieve. When the plaster is half dry, the frame is set up perpendicularly, and left till it is quite dry; then it is taken out, by taking the frame to pieces.

In this mosaic, the ground is the most important part. Now in order to the preparation of this gift, which is to be applied on this ground, it is dissolved and boiled in the best English glue, and mixed with the colour that it is to be of; then the whole is worked up into the usual consistence of plaster, and then taken and spread on the ground five or six inches thick. If the work be such, as that mouldings are required, they are formed with gouges and other instruments.

It is on this plaster, thus coloured like marble or precious stone, and which is to serve as a ground to a work, either of lapis, agate, alabaster, or the like, that the design to be represented is drawn: having been first pounced or chalked. To hollow or impress the design, they use the same instruments that sculptors do; the ground wherein they are to work not being much less hard than the marble itself. The cavities being thus made in the ground, are filled with the same gypsum boiled in glue, only differently coloured, and thus are the different colours of the original represented. In order that the necessary colours and tints may be ready at hand, the quantities of the gypsum are tempered with the several colours in pots. After the design has been thus filled and tempered, it is, by half polishing it with brick and soft stone, they go over it again, cutting such plates as are either to be weaker or more shadowed, and filling them with gypsum which work they repeat till all the colours being added one after the other, represent the original to the life. When the work is finished, they scour it with soft stone, sand, and water; after that with a pumice stone; and in the last place polish it with a wooden mullet and emery. Lastly, they give it a lustre, by smearing it over with oil, and rubbing it a long time with the palm of the hand, which gives it a lustre nowise inferior to that of natural marble.

In Clavigero's history of Mexico is described a curious kind of mosaic work, made by the ancient Mexicans of the most delicate and beautiful feathers of birds. They raised for this purpose various species of birds of fine plumage with which that country abounds, not only in the palaces of the king, where there were all sorts of animals, but likewise in private houses; and at certain seasons they carried off their feathers to make use of them on this kind of work, or to sell them at market. They set a high value on the feathers of those wonderful little birds which they call Huirutaiextli, and the Spaniards Picafloros, on account of the smallness, the fineness, and the various colours of them. In these and other beautiful birds, nature supplied them with all the colours which art can produce, and also some which art cannot imitate. At the undertaking of every mosaic work several artists assembled: After having agreed upon a design, and taken their measures and proportions, each artist charged himself with the execution of a certain part of the image, and exerted himself so diligently in it, with such patience and application, that he frequently spent a whole day in adjusting a feather; first trying one, then another, viewing it sometimes one way, then another, until he found one which gave his part that ideal perfection proposed to be attained. When the part which each artist undertook was done, they assembled again to form the entire image from them. If any part was accidentally the least deranged, it was wrought again until it was perfectly finished. They laid hold of the feathers with small pincers, that they might not do them the least injury, and secured them on the cloth with tesnatiiltli, or some other glutinous matter; then they united all the parts upon a little table, or a plate of copper, and flattened them softly until they left the surface of the image so equal and smooth that it appeared to be the work of a pencil.

These were the images so much celebrated by the Spaniards and other European nations. Whoever beheld them was at a loss whether he ought to have praised most the life and beauty of the natural colours, or the dexterity of the artist and the ingenious disposition of art. "These images (says Acosta) are deservedly admired; for it is wonderful how it was possible, with the feathers of birds, to execute works so fine and so equal, that they appear the performance of the pencil; and, what neither the pencil nor the colours in painting can effect, they have, when viewed from a side, an appearance so beautiful, so lively, and animated, that they give delight to the sight. Some Indians, who are able artists, copy whatever is painted with a pencil so perfectly with plumeages, that they rival the best painters of Spain." These works of feathers were even so highly esteemed by the Mexicans as to be valued more than gold. Cortes, Bernal Diaz, Gemara, Torquemada, and all the other historians who saw them, were at a loss for expressions sufficient to praise their perfection. Several works of this kind, our author says, are still preserved in the museums of Europe, and many in Mexico; but few, he apprehends, belong to the 16th century, and still fewer, if any, are of these made before the conquest. The mosaic works also which the Mexicans made of broken shells were extremely curious: this art is still practised in Guatemala. MOSAMBOQUE, a kingdom of Africa, lying south of Quiloa, and taking its name from the chief town, which is situated on an island, at the mouth of a river of the same name, in 15 deg. S. Lat. The island is 30 miles in circumference, and very populous. Though the air is said to be very hot, and the soil in general dry, sandy, and barren; yet they have most of the tropical fruits, with black cattle, hogs, and sheep. There is a kind of fowl here, both the feathers and flesh of which are black, in such mass that, when they are boiled, the broth looks like ink; and yet their flesh is very delicate and good food. The town of Mosambique is regularly fortified, and has a good harbour, defended by a citadel, with several churches and monasteries. The Portuguese shipping to and from India touch here for refreshments. As the island abounds in cattle, the Portuguese slaughter and salt up a great deal of beef, which they afterwards send to the Brazil, or sell to the European shipping. They also barter European goods with the natives for gold, elephants teeth, and slaves. There is another town, called Mongala, situated also on an island, and garrisoned by the Portuguese, being their chief magazine for European goods. The gold they receive from the natives is found near the surface of the earth, or in the
MOSCHION, the name of four different writers, whose compositions, character, and native place, are unknown. Some fragments of their writings remain, some few verses, and a treatise De mulierum affectibus. MOSCHUS, a Grecian poet of antiquity, usually coupled with Bion; and they were both of them contemporaries with Theocritus. In the time of the latter Grecians, all the ancient idylliums were collected and attributed to Theocritus; but the claims of Moschus and Bion have been admitted to some few little pieces; and this is sufficient to make us inquisitive about their characters and story; yet all that can be known about them must be collected from their own remains. Moschus, by composing his delicate elegy on Bion, has given the best memorials of Bion's life. See Bion. Moschus and Theocritus have by some critics been supposed the same person; but there are irrefragable evidences against it: others will have him as well as Bion to have lived later than Theocritus, upon the authority of Suidas: while others again suppose him to have been the scholar of Bion, and probably his successor in governing the poetic school; which, from the elegy of Moschus, does not seem unlikely. Their remains are to be found in all the editions of the Poetae Minores.

MOSCHUS, a genus of quadrupeds, of the order of pectora, having no horns. See Mammalia Index.

MOSCOV, the chief province of the empire of Russia, deriving its name from the river Muscovy, or Moskva, on which the capital is situated. It was from this duchy that the czars of old took the title of dukes of Muscovy. The province is bounded on the north by the dukies of Twere, Rosow, Susdal, and Wlodomer; on the south by Rezan, from which it is separated by the river Oca; on the east by the principality of Kazan, and the same river Oca; partly it from Nis-Niowod; and on the west by the dukies of Rzova, Bielar and Smolensko. It extends about 150 miles in length, by 100 in breadth, and contains 1,120,000 inhabitants on a surface of 10,000 square miles. It is watered by the Moskva, Oca, and Clesma, which fall into the Volga: nevertheless, the soil is not very fertile. The air, though sharp, is salubrious; and this consideration, with the advantage of its being situated in the midst of the best provinces in the empire, induced the czars to make it their chief residence. In the western part of Moscov is a large forest, from whence flows the celebrated river Dnieper, or Byrathenes, which, traversing the duchy of Smolensko, winds in a serpentine course to Ukraine, Lithuania, and Poland.

Moscow, the capital of the above province, and till the beginning of the last century the metropolis of all Russia, is situated in a spacious plain on the banks of the river Moskva. E. Long. 37° 31'. N. Lat. 55° 45'.

The Russian antiquaries differ considerably in their opinions concerning the first foundation of Moscow; the following relation, Mr. Coxe says, is generally esteemed by the best authors the most probable account.

Kief was the metropolis, when George son of Vladimir Monomaka ascended in 1154 the Russian throne. That monarch, being insulted in a progress through his dominions by a rich and powerful nobleman named Stephen Kutchko, put him to death, and confiscated his domains, which consisted of the lands now occupied by the city of Moscow and the adjacent territory. Pleased with the situation of the ground lying at the conflux of the Moskva and Neggina, he laid the foundation of a new town, which he called Moskva from the river of that name. Upon the demise of George, the new town was not neglected by his son Andrew, who transferred the seat of empire from Kief to Vladimir; but it fell into such decay under his immediate successors, that when Daniel, son of Alexander Nevski, received, in the division of the empire, the duchy of Muscovy as his portion, and fixed his residence upon the confluence of the Moskva and Neggina, he may be said to have founded the town. The spot now occupied by the Kremlin was at that time overspread with a thick wood and a moat, in the midst whereof was a small island containing a single wooden hut. Upon this part Daniel constructed churches and monasteries, and various buildings, and enclosed it with wooden fortifications: he first assumed the title of duke of Moscow; and was so attached to this situation, that when in 1304 he succeeded his brother Andrew Alexandrovich in the great duchy of Vladimir, he did not remove his court to Vladimir, but continued his residence at Moscow, which then became the capital of the Russian dominions. His successors followed his example; among whom his son Ivan considerably enlarged the new metropolis, and in 1367 his grandson Demetrius Ivanovitch Donski surrounded the Kremlin with a brick wall. These new fortifications, however, were not strong enough to prevent Tamerlane in 1382, from taking the town after a short siege. Being soon evacuated by that desultory conqueror, it again came into the possession of the Russians; but was frequently invaded and occupied by the Tartars, who in the 14th and 15th centuries overran the greatest part of Russia, and who even maintained a garrison in Moscow until they were finally expelled by Ivan Vasilyevitch I. To him Moscow is indebted for its principal splendour, and under him it became the principal and most considerable city of the Russian empire.

Moscow continued the metropolis of Russia until the beginning of the 18th century, when, to the great dissatisfaction of the nobility, but with great advantage probably to the state, the seat of empire was transferred to Petersburgh.

Notwithstanding the predilection which Peter conceived for Petersburgh, in which all the succeeding sovereigns excepting Peter the II. have fixed their residence, Moscow, according to Mr Coxe, is still the most populous city of the Russian empire. Here the chief nobles who do not belong to the court reside: they here support a large number of retainers; they love to gratify their taste for a ruder and more expensive magnificence in the ancient style of feudal grandeur; and are not, as at Petersburgh, eclipsed by the superior splendour of the court.

Moscow, before its destruction in 1812, was represented as the largest town in Europe; its circumference within the rampart, which encloses the suburbs, being exactly 39 versts or 26 miles; but it was built in so straggling and disjointed a manner, that its population in no degree corresponded to its extent. According to a computation, which Mr Coxe says may be depended upon,

3 K 2
The places of divine worship at Moscow are exceedingly numerous; including chapels, they amount to above 1,000: there are 484 public churches, of which 199 are of brick; and the others of wood; the former are commonly stuccoed or white-washed, the latter painted a red colour. The most ancient churches of Moscow are generally square buildings, with a cupola and four small domes, some of which are of copper or iron girt; others of tin, either plain or painted green. These cupolas and domes are for the most part ornamented with crowns entwined with thin chains or wires. The church of the Holy Trinity, sometimes called the church of Jerusalem, which stands in the Kitaigerod, close to the gate leading into the Kremlin, has a kind of high steeple and nine or ten domes: it was built in the reign of Ivan Vassilievitch II. The inside of the churches is mostly composed of three parts: that called by the Greeks doumo, by the Russians trapeza; the body; and the sanctuary or shrine. Over the door of each church is the portrait of the saint to whom it is dedicated, to which the common people pay their homage as they pass along, by taking off their hats, crossing themselves, and occasionally touching the ground with their heads. The bells, which form no inconsiderable part of public worship in this country, as the length or shortness of their peals uncertain the greater or lesser sanctity of the day, are hung in belfrys detached from the church: they do not swing like our bells; but are fixed immovably to the beams, and are rung by a rope tied to the clapper and pulled sideways. Some of these bells are of a stupendous size; one in the tower of St. Ivan's church weighs 3,551 Russian pounds, or 127,836 English pounds. It has always been esteemed a meritorious act of religion to present a church with bells; and the piety of the donor has been measured by their magnitude. According to this mode of estimation, Boris Godunof, who gave a bell of 288,000 pounds to the cathedral of Moscow, was the most pious sovereign of Russia, until he was surpassed by the empress Anne, at whose expense bells cast weighing 432,000 pounds, and which exceeded in size every bell in the known world. The height of this enormous bell is 19 feet, its circumference at the bottom 21 yards 11 inches; its greatest thickness 23 inches. The bema to which this vast machine was fastened being accidentally burnt, the bell fell down, and a fragment was broken off towards the bottom, which left an aperture large enough to admit two persons abreast without stooping.

The palace, inhabited by the ancient czars, stands at the extremity of the Kremlin. Part of this palace is old, and remains in the same state in which it was built under Ivan Vassilievitch I. The remainder has been successively added at different intervals, without any plan, and in various styles of architecture, which has produced a motley pile of building, remarkable for nothing but the incongruity of the several structures. The top is thickly set with numerous little gilded spires and spires; and a large portion of the front is decorated with the arms of all the provinces which compose the Russian empire. The apartments are in general exceedingly small, excepting one single room called the council chamber, in which the ancient czars used to give audience to foreign ambassadors, and which has been repeatedly described by several English travellers who visited Moscow before the imperial residence was transferred to Petersburgh. The room is large and vaulted, and has in the centre...
The enormous pillar of stone which supports the ceiling. In this palace Peter the Great came into the world, in the year 1672. In that part called the treasury are deposited the crown, jewels, and royal robes, used at the coronation of the sovereign, besides several curiosities relative to the history of the country. Of the great number of churches contained in this city, two in particular, namely, that of St Michael and that of the Assumption of the Virgin Mary, are remarkable; the one for being the place where the sovereigns of Russia were formerly interred, and the other where they are crowned. These edifices, which are situated in the Kremlin, are both in the same style of architecture; and their exterior form, though modelled according to the ancient style of the country, is not absolutely inelegant. In the cathedral of St Michael, which contains the tombs of the Russian sovereigns, the bodies are not, as with us deposited in vaults, or beneath the pavement, but are entombed in raised sepulchres, mostly of brick, in the shape of a coffin, and about two feet in height.

The cathedral of the Assumption of the Virgin Mary, which has long been appropriated to the coronation of the Russian sovereigns, is the most splendid and magnificent in Moscow. The screen is in many parts covered with plates of solid silver and gold richly worked. From the centre of the roof hangs an enormous chandelier of massy silver, weighing 2940 pounds: it was made in England, and was a present from Morosoff, prime minister and favourite of Alexey Michaelovitch. The sacred utensils and episcopal vestments are extraordinarily rich, but the taste of the workmanship is in general rude, and by no means equal to the materials. Many of the paintings which cover the inside walls are of a colossal size: some are very ancient, and were executed so early as in the latter end of the 15th century. It contains, amongst the rest, a head of the Virgin, supposed to have been delineated by St Luke, and greatly celebrated in this country for its sanctity and the power of working miracles.

The place in the Khitai gorod, where the public archives are deposited, is a strong brick building, containing several vaulted apartments with iron floors. These archives, consisting of a numerous collection of state papers, were crowded into boxes and thrown aside like common lumber, until the empress Catharine ordered them to be revised and arranged. In conformity to this mandate, Mr Muller has disposed them in chronological order with such perfect regularity, that any single document may be inspected with little trouble.

The university of Moscow, all situated in the Khitai gorod, was founded, at the instance of Count Shuvalof, by the empress Elizabeth, for 600 students; who are clothed, boarded, and instructed, at the expense of the crown. Besides this institution, there are two gymnasias or seminaries for the education of youth, endowed also by Elizabeth; in which are taught, by twenty-three professors, divinity, classics, philosophy, the Greek, Latin, Russian, German, French, Italian, and Tartar languages; history, geography, mathematics, architecture, fortification, artillery, algebra, drawing and painting, music, fencing, dancing, reading and writing.

Moscow is the centre of the inland commerce of Russia, and particularly connects the trade between Europe and Siberia. The only navigation to this city is formed by the Moskva, which falling into the Occa near Columbia, communicates by means of that river with the Volga. But as the Moskva is only navigable in spring upon the melting of the snows, the principal merchandize is conveyed to and from Moscow upon sledges in winter. The whole of the retail trade is carried on in the Khitai gorod; where according to a custom common in Russia, as well as in most kingdoms of the East, all the shops are collected together in one spot. The place is like a kind of fair, consisting of many rows of low brick buildings; the intervals between them resembling alleys. These shops or booths occupy a considerable space; they do not, as with us, make part of the houses inhabited by the tradesmen, but are quite detached from their dwellings, which for the most part are at some distance in another quarter of the town. The tradesman comes to his shop in the morning, remains there all day, and returns home to his family, in the afternoon. Every trade has its separate department; and they who sell the same goods have booths adjoining to each other. Furs and skins form the most considerable article of commerce in Moscow; and the shops which vend those commodities occupy several streets.

Amongst the curiosities of Moscow, the market for the sale of houses is not the least remarkable. It is held in a large open space in one of the suburbs; and exhibits a great variety of ready-made houses, thickly strewed upon the ground. The purchaser who wants a dwelling, repairs to this spot, mentions the number of rooms he requires, examines the different timbers, which are regularly numbered, and bargains for that which suits him. The house is sometimes paid for on the spot, and taken away by the purchaser; or sometimes the vender contracts to transport and erect it upon the place where it is designed to stand. It may appear incredible to assert, that a dwelling may be thus bought, removed, raised and inhabited, within the space of a week; but we shall conceive it practicable by considering that these ready-made houses are in general merely collections of trunks of trees tenoned and mortised at each extremity into one another, so that nothing more is required than the labour of transporting and adjusting them. But this summary mode of building is not always peculiar to the meaner houses; as wooden structures of very large dimensions and handsome appearance are occasionally formed in Russia with an expedition almost inconceivable to the inhabitants of other countries. A remarkable instance of this dispatch was displayed the last time the empress came to Moscow. Her majesty proposed to reside in the mansion of Prince Galitzin, which is esteemed the completest edifice in this city; but as it was not sufficiently spacious for her reception, a temporary addition of wood, larger than the original house, and containing a magnificent suite of apartments, was begun and finished within the space of six weeks. This meteor-like fabric was so handsome and commodious, that the materials which were taken down at her majesty's instance, were to be re-constructed as a kind of imperial villa upon an eminence near the city. Mr Coxe mentions an admirable palace in this city for preventing riots, or for stopping the concourse of people in case of fires, which are very frequent and violent in those parts, where the houses are mostly of wood, and the streets are laid with timber. At the entrance of each street there is a chevaux-de-frize gate, one end whereof turns upon a pivot, and the other rolls upon a wheel;
MOS [ 446 ]

his strength as to lead to the final overthrow of his
power. Large sums were collected in Britain and
elsewhere in behalf of the suffering inhabitants; and,
according to late accounts, the city is rising rapidly
from its ruins. Moscow was evacuated by the French
on the 23rd October, after they had destroyed some
parts of the town which had escaped the fire. Their
attempts to blow up the Kremlin were prevented by
the sudden arrival of a large Russian force.

MOSELLE, a river of Germany, which rises in
the mountains of Vosges in Lorraine, and falls into
the Rhine at Coblenz.

MOSELLE is also the name of a department of France,
which includes part of the late province of Lorraine.
Its population in 1800 was 333,788 upon a surface of
3,325 square miles.

MOSES, the son of Amram and Jochebed, was
born in the year 1571 before Christ. Pharaoh
king of Egypt, perceiving that the Hebrews became a
formidable nation, issued forth an edict commanding
all the male children to be put to death. To avoid
this cruel edict, Jochebed, the mother of Moses, having
concealed her son for three months, at length made a
ark or basket of bulrushes, daubed it with pitch, hid
the child in it, and deposited him on the banks of the
Nile. Thermuthis, the king’s daughter, who happened
to be walking by the river’s side, perceived the
floating cradle, commanded it to be brought to her,
and struck with the beauty of the child, determined
to preserve his life. In three years afterwards the
princess adopted him for her own son, called him name
Moses, and caused him be diligently instructed in all
the learning of the Egyptians. But his father and
mother, to whom he was restored by a fortunate acci-
dent, were at still greater pains to teach him the his-
tory and religion of his fathers. Many things are
related by historians concerning the first period of
Moses’s life, which are not to be found in the Old
Testament. According to Josephus and Eusebius, he
was made war on the Ethiopians, and completely defeated
them. They add, that the city Saba, in which the
enemy had been forced to take refuge, was betrayed
into his hands by the king’s daughter, who became
deeply enamoured of him, when she beheld from the
top of the walls his valorous exploits at the head of
the Egyptian army. But as the truth of this expedi-
tion is more than doubtful, we shall therefore confine
ourselves to the narrative of sacred writ, which com-
ences at the fortieth year of Moses’s life. He then
left the court of Pharaoh, and went to visit his coun-
trymen the Hebrews, who groaned under the ill usage
and oppression of their unfeeling masters. Having
perceived an Egyptian smiting a Hebrew, he slew
the Egyptian, and buried him in the sand. But he
was obliged, in consequence of this murder, to fly into
the land of Midian, where he married Zipporah, daugh-
ter of the priest Jethro, by whom he had two sons,
Gershom and Eliezar. Here he lived 40 years; dur-
ing which time his employment was to tend the
flocks of his father-in-law. Having one day led his
flock towards Mount Horeb, God appeared to him
in the midst of a bush which burned with fire but was
not consumed, and commanded him to go and deliver
his brethren from their bondage. Moses at first re-
fused to go; but was at length prevailed on by two
maces
Moses races which the Almighty wrought for his conviction. Upon his return to Egypt, he, together with his brother Aaron, went to the court of Pharaoh, and told him that God commanded him to let the Hebrews go offer sacrifices in the desert of Arabia. But the impious monarch disregarded this command, and caused the labour of the Israelites to be doubled. The messengers of the Almighty again returned to the king, and wrought a miracle in his sight, that they might move his heart, and induce him to let the people depart. Aaron having cast down his miraculous rod, it was immediately converted into a serpent; but the same thing being performed by the magicians, the king’s heart was hardened more and more; and his obstinacy at last drew down the judgments of the Almighty on his kingdom, which was afflicted with ten dreadful plagues. The first was the changing of the waters of the Nile and of all the rivers into blood, so that the Egyptians died of thirst. In consequence of the second plague, the land was covered with innumerable swarms of frogs, which entered even into Pharaoh’s palace. By the third plague, the dust was converted into lice, which cruelly tormented both man and beast. The fourth plague was a multitude of destructive flies which spread throughout Egypt, and infested the whole country. The fifth was a sudden pestilence, which destroyed all the cattle of the Egyptians, without injuring those of the Israelites. The sixth produced numberless ulcers and fiery boils upon man and upon beast. The seventh was a dreadful storm of hail, accompanied with thunder and lightning, which destroyed every thing that was in the field, whether man or beast, and spared only the land of Goshen, where the children of Israel dwelt. By the eighth plague swarms of locusts were brought into the country, which devoured every green herb, the fruit of the trees and the produce of the harvest. By the ninth plague thick darkness covered all the land of Egypt, except the dwellings of the children of Israel. The tenth and last plague was the death of the firstborn in Egypt, who were all in one night cut off by the destroying angel, from the firstborn of the king to the firstborn of the slaves and of the cattle. This dreadful calamity moved the heart of the hardened Pharaoh, and he at length consented to allow the people of Israel to depart from his kingdom.

Profane authors who have spoken of Moses, seem to have been in part acquainted with these mighty wonders. That he performed miracles, must have been allowed by many, by whom he was considered as a famous magician; and he could scarcely appear in any other light to men who did not acknowledge him for the messenger of the Almighty. Both Diodorus and Herodotus mention the disturbed state to which Egypt was reduced by these terrible calamities. The Hebrews, amounting to the number of 650,000 men, without reckoning women and children, left Egypt on the 1st day of the month Nisan, which, in memory of this deliverance, was henceforth reckoned the first month of their year. Scarcely had they reached the shores of the Red sea when Pharaoh with a powerful army set out in pursuit of them. On this occasion Moses stretched forth his rod upon the sea; and the waters thereof being divided, remained suspended on both sides till the Hebrews passed through dry-footed. — The Egyptians determined to follow the same course; but God caused a violent wind to blow, which brought back the waters to their bed, and the whole army of Pharaoh perished in the waves.

After the miraculous passage of the Red sea, the army proceeded towards Mount Sinai, and arrived at Marah, where the waters were bitter; but Moses, by casting a tree into them, rendered them fit for drinking. Their tenth encampment was at Rephidim, where Moses drew water from the rock in Horeb, by smiting it with his rod. Here likewise Amalek attacked Israel. While Joshua fought against the Amalekites, Moses stood on the top of a hill, and lifted up his hands; in consequence of which the Israelites prevailed, and cut their enemies in pieces. They at length arrived at the foot of Mount Sinai on the third day of the ninth month after their departure from Egypt. Moses having ascended several times into the mount, received the law from the hand of God himself in the midst of thunders and lightnings, and concluded the famous covenant betwixt the Lord and the children of Israel. When he descended from Sinai, he found that the people had fallen into the idolatrous worship of the golden calf. The messenger of God, shocked at such ingratitude, broke in pieces the tables of the law which he carried in his hands, and put 23,000 of the transgressors to the sword. He afterwards ascended into the mountain, and there obtained new tables of stone on which the law was inscribed. When Moses descended, his face shone so that the Israelites dared not come nigh unto him, and he was obliged to cover it with a veil. The Israelites were here employed in constructing the tabernacle according to a pattern shown them by God. It was erected and consecrated at the foot of the Mount Sinai on the first day of the first month after their departure from Egypt; and it served the Israelites instead of a temple till the time of Solomon, who built a house for the God of his fathers after a model shown him by David.

Moses having dedicated the tabernacle, he consecrated Aaron and his sons to be its ministers, and appointed the Levites to its service. He likewise gave various commandments concerning the worship of God and the political government of the Jews. This was a theocracy in the full extent of the word. God himself governed them immediately by means of his servant Moses, whom he had chosen to be the interpreter of his will to the people; and he required all the honours belonging to their king to be paid unto himself. He dwelt in his tabernacle, which was situated in the middle of the camp, like a monarch in his palace. He gave answers to those who consulted him, and himself denounced punishment against the transgressors of his laws. This properly was the time of the theocracy, taken in its full extent; for God was not only considered as the divinity who was the object of their religious worship, but as the sovereign to whom the honours of supreme majesty were paid. The case was nearly the same under Joshua; who, being filled with the spirit of Moses, undertook nothing without consulting God. Every measure, both of the leader and of the people, was regulated by the direction of the Almighty, who rewarded their fidelity and obedience by a series of miracles, victories, and successes. After Moses had regulated every thing regarding the civil administration,
Moses [ 448 ]

Cudworth's Intellectual System, enriched with large annotations, discovered a profound acquaintance with ancient learning and philosophy. His illustrations of the Scriptures, his labours in defence of Christianity, and the light he cast upon religion and philosophy, appear in many volumes of sacred and profane literature; and the Ecclesiastical History, from the birth of Christ to the beginning of the 18th century, is unquestionably the best that is extant. This work, written in Latin, has been translated into English, and accompanied with notes and chronological tables by Archibald Maclaine, D. D. and from this translator's preface to the second edition, 1758, in 5 vols 8vo, this short account is taken.

MOSQUITO, or MOSQUITO COUNTRY, is situated in North America, between 85 and 98 degrees of west longitude, and between 13 and 15 degrees of north latitude; having the North sea on the north and east, Nicaragua on the south, and Honduras on the west; and indeed the Spaniards esteem it a part of the principality of Honduras, though they have no colonies in the Mosquito country. When the Spaniards first invaded this part of Mexico, they massacred the greatest part of the natives, which gave those that escaped into the inaccessible part of the country an insuperable aversion to them; and they have always appeared ready to join any Europeans that come upon their coasts against the Spaniards, and particularly the English, who frequently come hither; and the Mosquito men being excellent marksmen, the English employ them in striking the manati fish, &c. and many of the Mosquito Indians come to Jamaica, and sail with the English in their voyages.

These people are so situated between morasses and inaccessible mountains, and a coast full of rocks and shoals, that no attempts against them by the Spaniards, whom they mortally hate, could ever succeed. Nevertheless, they are a mild inoffensive people, of great morality and virtue, and will never trust a man who has once deceived them. They have so great a reverence towards the English, that they have spontaneously put themselves and their lands under the protection and dominion of the crown of England. This was first done when the duke of Albermarle was governor of Jamaica, and the king of the Mosquitoes received a commission from his grace, under the seal of that island; and since this time they have been steady in their alliance with the English. But in the year 1786, this country was ceded to Spain, and consequently became a Spanish province.

MOSQUE, a temple or place of religious worship among the Mahometans.

All mosques are square buildings, generally constructed of stone. Before the chief gate there is a square court paved with white marble; and low galleries round it, whose roof is supported by marble pillars. In these galleries the Turks wash themselves before they go into the mosque. In each mosque there is a great number of lamps; and between these hang many crystal rings, ostrich eggs, and other curiosities, which when the lamps are lighted, make a fine show. As it is not lawful to enter the mosque with stockings or shoes on, the pavements are covered with pieces of stuff sewed together, each being wide enough to hold a row of men kneeling, sitting, or prostrating. The women are
not allowed to enter the mosque, but stay in the porches without. About every mosque there are six high towers, called minarets, each of which has three little open galleries, one above another: these towers, as well as the mosques, are covered with lead, and adorned with gilding and other ornaments; and from thence, instead of a bell, the people are called to prayers by certain officers appointed for that purpose. Most of the mosques have a kind of hospital belonging to them, in which travellers of what religion soever, are entertained three days. Each mosque has also a place called tarbe, which is the burying-place of its founders; within which is a tomb six or seven feet long, covered with green velvet or satin; at the ends of which are two tapers, and round it several seats for those who read the Koran and pray for the souls of the deceased.

Moss or Mosses. See Musci, Botany Index.

Moss on Trees, in gardening. The growth of large quantities of moss on any kind of tree is a distemper of very bad consequence to its increase, and much damages the fruit of the trees of our orchards.

The present remedy is the scraping it off from the body and large branches by means of a kind of wooden knife that will not hurt the bark, or with a piece of rough hair cloth, which does very well after a soaking rain. But the most effectual cure is the taking away the cause. This is to be done by draining off all the superfluous moisture from about the roots of the trees, and may be greatly guarded against in the first planting of the trees, by not setting them too deep.

If trees stand too thick in a cold ground, they will always be covered with moss; and the best way to remedy the fault is to thin them. When the young branches of trees are covered with a long and shaggy moss, it will utterly ruin them; and there is no way to prevent it but to cut off the branches near the trunk, and even to take off the head of the tree if necessary; for it will sprout again; and if the cause be in the mean time removed by thinning the plantation, or draining the land and stirring the ground well, the young shoots will continue clear after this.

If the trees be covered with moss in consequence of the ground's being too dry, as this will happen from either extreme in the soil, then the proper remedy is the laying mud from the bottom of a pond or river, pretty thick about the root, opening the ground to some distance and depth to let it in; this will not only cool it, and prevent its giving growth to any great quantity of moss, but it will also prevent the other great mischief which fruit-trees are liable to in dry grounds, which is the falling off of the fruit too early.

The mosses which cover the trunks of trees, as they always are freshest and most vigorous on the side which points to the north, if only produced on that, serve to preserve the trunk of the tree from the severity of the north winds, and direct the traveller in his way, by always plainly pointing out that part of the compass.

Moss is also a name given to boggy ground in many parts of England, otherwise called a fen and bog.

In many of these grounds, as well in England and Ireland as in other parts of the world, there are found vast numbers of trees standing with their stumps erect, and their roots piercing the ground in a natural po-

VOL. XIV. Part II.

4

sition as when growing. Many of those trees are broken or cut off near the roots, and lie along, and this usually in a north-east direction. People who have been willing to account for this, have usually resolved it into the effect of the deluge in the days of Noah; but this is a very wild conjecture, and is proved false by many unanswerable arguments. The waters of this deluge might indeed have washed together a great number of trees, and buried them under loads of earth; but then they would have lain irregularly and at random; whereas they all lie lengthwise from south-west to north-east, and the roots all stand in their natural perpendicular posture, as close as the roots of trees in a forest.

Besides, these trees are not all in their natural state, but many of them have the evident marks of human workmanship upon them, some being cut down with an axe, some split, and the wedges still remaining in them; some burnt in different parts, and some bored through with holes. These things are also proved to be of a later date than the deluge, by other matters found among them, such as utensils of ancient people, and coins of the Roman emperors.

It appears from the whole that all the trees which we find in this fossil state, originally grew in the very places where we now find them, and have only been thrown down and buried there, not brought from elsewhere. It may appear indeed an objection to this opinion, that most of these fossil trees are of the fir kind; and that Caesar says expressly, that no fir grew in Britain in his time; but this is easily answered, by observing, that these trees, though of the fir kind, yet are not the species usually called the fir, but pitch-tree; and Caesar has no where said that pitch-trees did not grow in England. Norway and Sweden yet abound with these trees; and there are at this time whole forests of them in many parts of Scotland, and a large number of them wild upon a hill at Waret on in Staffordshire to this day.

In Hatfield marsh, where such vast numbers of the fossil trees are now found, there has evidently once been a whole forest of them growing. The last of these was found alive, and growing in that place within 70 years last past, and cut down for some common use.

It is also objected by some to the system of the fir growing where they are found fossil, that these countries are all bogs and moors, whereas these sorts of trees grow only in mountainous places. But this is founded on an error; for though in Norway and Sweden, and some other cold countries, the fir kinds all grow upon barren and dry rocky mountains, yet in warmer places they are found to thrive as well on wet plains. Such are found plentifully in Pomerania, Livonia, and Courland, &c. and in the west parts of New England there are vast numbers of fine stately trees of them in low grounds. The whole truth seems to be, that these trees love a sandy soil; and such as is found at the bottoms of all the mosses where these trees are found fossil. The roots of the fir kind are always found fixed in these; and those of oaks, where they are found fossil in this manner, are usually found fixed in clay; so that each kind of tree is always found rooted in the places where they stand in their proper soil; and there is no doubt to be made but that they ori-
When we have thus found that all the fossil trees we meet with once grew in the places where they are now buried, it is plain that in these places there were once noble forests, which have been destroyed at some time, and the question only remains how and by whom they were destroyed. This we have reason to believe, by the Roman coins found among them, was done by the people of that empire, and that at the time when they were established or establishing themselves here.

Their own historians tell us, that when their armies pursued the wild Britons, these people always sheltered themselves in the miry woods and low watery forests. Caesar expressly says this; and observes, that Cassibelenus and his Britons, after their defeat, passed the Thames, and fled into such low morasses and woods, that there was no pursuing them: and we find that the Silures secured themselves in the same manner when attacked by Ostorius and Agricola. The same thing is recorded of Venutius king of the Brigantes, who fled to secure himself into the boggy forests of the midland part of this kingdom: and Herodian expressly says, that in the time of the Romans pushing their conquests in these islands, it was the custom of the Britons to secure themselves in the thick forests which grew in their boggy and wet places, and when opportunity offered, to issue out thence and fall upon the Romans. The consequence of all this was the destroying all these forests; the Romans finding themselves so plagued with parties of the natives issuing out upon them at times from these forests, that they gave orders for the cutting down and destroying all the forests in Britain which grew on boggy and wet grounds. These orders were punctually executed; and to this it is owing that at this day we can hardly be brought to believe that such forests ever grew with us as are now found buried.

The Roman historians all agree, that when Suetonius Paulinus conquered Anglesea, he ordered all the woods to be cut down there, in the manner of the Roman generals in England: and Galen tells us, that the Romans, after their conquest in Britain, kept their soldiers constantly employed in cutting down forests, draining of marshes, and paving of bogs. Not only the Roman soldiers were employed in this manner, but all the native Britons made captives in the wars were obliged to assist in it: and Dion Cassius tells us, that the emperor Severus lost no less than 50,000 men in a few years time in cutting down the woods and draining the bogs of this island. It is not to be wondered at, that such numbers executed the immense destruction which we find in these buried forests. One of the greatest subterranean treasures of wood is that near Hatfield; and it is easy to prove, that these people, to whom this havoc is thus attributed, were upon the spot where these trees now lie buried. The common road of the Romans out of the south into the north, was formerly from Lindum (Lincoln), to Segelochum (Little Burrow upon Trent), and from thence to Danum (Doncaster), where they kept a standing garrison of Crispinian horse. A little off on the east, and north-east of their road, between the two last-named towns, lay the borders of the greatest forest, which swarmed with wild Britons, who were continually making their sallies out, and their retreats into it again, intercepting their provisions, taking and destroying their carriages, killing their allies and passengers, and disturbing their garrisons. This at length so exasperated the Romans, that they were determined to destroy it; and to do this safely and effectually, they marched against it with a great army, and encamped on a great moor not far from Finningly; this is evident from their fortifications yet remaining.

There is a small town in the neighbourhood called Osterfield; and as the termination field seems to have been given only in remembrance of battles fought near the towns whose names ended with it, it is not improbable that a battle was fought here between all the Britons who inhabited this forest and the Roman troops under Ostorius. The Romans slew many of the Britons, and drove the rest back into this forest, which at that time overspread all this low country. On this the conquerors taking advantage of a strong south-west wind, set fire to the pitch-trees, of which this forest was principally composed; and when the greater part of the trees were thus destroyed, the Roman soldiery and captive Britons cut down the remainder, except a few large ones which they left standing as remembrances of the destruction of the rest. These single trees, however, could not stand long against the wind, and these falling into the rivers which run through the country, interrupted their currents; and the water then overspreading the level country, made one great lake, and gave origin to the mosses or moory bogs, which were afterwards formed there, by the workings of the waters, the precipitation of earthy matter from them, and the putrefaction of rotten boughs and branches of trees, and the vast increase of water-moss and other such plants which grow in prodigious abundance in all these sorts of places. Thus were these burnt and fell trees buried under a new-formed spongy and watery earth, and afterwards found on the draining and digging through this earth again.

Hence it is not strange that Roman weapons and Roman coins are found among these buried trees; and hence it is that among the buried trees some are found burnt, some chopped and hewn; and hence it is that the bodies of the trees all lie by their proper roots, and with their tops lying north-east, that is, in that direction in which a south-west wind would have blown them down: hence also it is, that some of the trees are found with their roots lying flat, these being cut or burned down, but blown up by the roots afterwards when left single; and it is not wonderful, that such trees as these should have continued to grow even after their fall, and shoot up branches from their sides which might easily grow into high trees.

By this system it is also easily explained why the moor soil in the country is in some places two or three yards thicker than in others, or higher than it was formerly, since the growing up of peat-earth or bog-ground is well known, and the soil added by overfiltering of waters is not a little.

As the Romans were the destroyers of this great and noble forest, so they were probably also of the several other ancient forests; the ruins of which furnish us with the bog-wood of Staffordshire, Lincolnshire, Yorkshire, and other counties. But as the Romans were not much in Wales, in the Isle of Man, or...
Moss is Ireland, it is not to be supposed that forests cut down by these people gave origin to the fossil wood found there; but though they did not cut down these forests, others did; and the origin of the bog-wood is the same with them and with us. Holingshead informs us, that Edward I being not able to get at the Welsh because of their hiding themselves in boggy woods, gave orders at length that they should all be destroyed by fire and by the axe; and doubtless the roots and bodies of trees found in Pembrookshire under ground, are the remains of the execution of this order. The fossil wood in the bogs of the island of Man is doubtless of the same origin, though we have not any account exact of the time or occasion of the forests there being destroyed; but as to the fossil trees of the bogs of Ireland, we are expressly told that Henry II. when he conquered that country, ordered all the woods to be cut down that grew in the low parts of it, to secure his conquests, by cutting away the places of resort of rebels. For a fuller detail of the natural history of mosses, see Essays on this subject by the Rev. Mr Rennie of Kilsyth.

Moving—Moss. We have an account in the Philosophical Transactions of a moving moss near Churchtown in Lancashire, which greatly alarmed the neighbourhood as miraculous. The moss was observed to rise to a surprising height, and soon after sunk as much below the level, and moved slowly towards the south.

A very surprising instance of a moving moss is that of Solway in Scotland, which happened in the year 1771, after severe rains which had produced terrible inundations of the rivers in many places. For the better understanding of this event, we shall give the following description of the spot of ground where it happened. Along the side of the river Eak there is a vale, about a mile broad, less or more in different places. It is bounded on the south-east by the river Eak, and on the north-west by a steep bank 30 feet in height above the level of the vale. From the top of the bank the ground rises in an easy ascent for about a quarter of a mile, where it is terminated by the moss; which extends about two miles north and south, and about a mile and a half east and west, and is bounded on the north-west by the river Sark. It is probable that the solid ground from the top of the bank above the vale was continued in the same direction under the moss, before its eruption, for a considerable space; for the moss at the place where the eruption happened, was inclined towards the sloping ground. From the edge of the moss there was a gully or hollow, called by the country people the gap, and said to be 50 yards deep where it entered the vale; down which ran a small rill of water, which was often dry in summer, having no supply but what filtered from the moss. The eruption happened at the head of this gap, on Saturday November 16, 1771, about ten or eleven at night, when all the neighbouring rivers and brooks were prodigiously swelled by the rains. A large body of the moss was forced, partly by the great fall of rain, and partly by some springs below it, into a small beck or burn, which runs within a few yards of its border to the south east. By the united pressure of the water behind it, and of this beck, which was then very high, it was carried down a narrow glen between two banks about 300 feet high, into a wide and spacious plain, over part of which it spread with great rapidity. The moss continued for some time to send off considerable quantities; which being borne along by the torrent on the back of the first great body, kept it for many hours in perpetual motion, and drove it still farther on. This night at least 400 acres of fine arable land were covered with moss from 3 to 12 or 15 feet deep. Several houses were destroyed, a good deal of corn lost, &c. but all the inhabitants escaped. When the waters subsided, the moss also ceased to flow; but two pretty considerable streams continued to run from the heart of it, and carried off some pieces of mossy matter to the place where it burst. There they joined the beck already mentioned; which, with this addition, resumed its former channel; and, with a little assistance from the people of the neighbourhood, made its way to the Esk, through the midst of that great body of moss which obstructed its course. Thus, in a great measure drained, the new moss fell several feet, when the fair weather came in the end of November, and settled in a firmer and more solid body on the lands it had overrun. By this inundation about 800 acres of arable ground were overflowed before the moss stopped, and the habitations of 27 families destroyed. Tradition has preserved the memory of a similar inundation in Montcalm in Scotland. A moss there altered its course in one night, and covered a great extent of ground.

Moss Trepper, a rebellious sort of people in the north of England, who lived by robbery and rapine, not unlike the tories in Ireland, the bucaniers in Jamaica, or banditti of Italy. The counties of Northumberland and Cumberland were formerly charged with a yearly sum, and a command of men, to be appointed by justices of the peace, to apprehend and suppress them.

MOSTRA, in the Italian music, a mark at the end of a line or space, to show that the first note of the next line is in that place: and if this note be accompanied with a sharp or flat, it is proper to place these characters along with the mostra.

MOSUL, or MOUSUL. See MOUSUL.

MOTACILLA, the Wagtail and Warbler; a genus of birds of the order of passerines. See Ornithology Index.

MOTE, in law books, signifies court or convention; as ward mote, burghe mote, swain mote, &c.

Mote was also used for a fortress or castle; as mote de Winderour, &c.

Mote also denoted a standing water to keep fish in; and sometimes a large ditch encompassing a castle or dwelling house.

Mote-Bell, or Mot-bell, the bell so called, which was used by the English Saxons to call people together to the court. See Folkmote.

MOTH. See PHALENA, Entomology Index.

MOTHER, a term of relation, denoting a woman who hath born a child.

Mother-of-Pearl. See Mytilus, Conchology Index.

Motion is now generally considered as incapable of definition, being a simple idea or notion received by the senses. The ancients, however, thought differently. Some of them defined it to be a passage out of one state into another; which conveys no idea to him who
Motion.

who is ignorant of the nature of motion.—The Peripatetic definition has been mentioned elsewhere and shown to be wholly unintelligible, as well as their celebrated division of motion into four classes, belonging to the three categories, quality, quantity, and where; (see METAPHYSICS, N° 188, 189, 190). The Cartesians, too, among the moderns, pretend to define motion, by calling it a passage or removal of one part of matter, out of the neighbourhood of those parts to which it is immediately contiguous, into the neighbourhood of others. Descartes defines motion to be the successive passage of a body from place to place. Others say that it is the application of a body to different parts of infinite and immovable space; and a late writer of uncommon acuteness has given as a definition of motion—change of place.

We have elsewhere offered our opinion of every possible attempt to define motion: but as the author of the last quoted definition has endeavoured to obviate such objections as ours, candour requires that be heard for himself. "It is said (be observes) by some, that change implies motion, and therefore cannot be a part of its definition, being the very thing defined. To this I answer, We are speaking of the sensible idea of motion, as it appears to our sight; now changes do appear to our view, and to all our senses, which give us no idea of motion. Changes in heat or cold; in colour, flavour, smell, sound, hardness, softness, pain, pleasure; in these, and many other ideas, changes do not produce ideas like that produced by a ball rolling or a stone falling. We may perhaps ultimately trace them to motion, but to insensible motions; to motions which arise only in reflection, and constitute no part of the actual idea of change. We can therefore conceive of change, without conceiving at the same time of motion. Change is a generic idea, including many species; motion, as a sensible idea, is a species of that genus. Change is therefore a necessary part of the definition of motion; it marks the genus of the thing defined. Motion is a change; but as there are many species of change, which of those species is motion? The answer is, It is a change of place. This marks the species, and distinguishes it from change of colour, of temperament and figure."

This is the ablest defence of an attempt to define motion that we have ever seen; and at first view the definition itself appears to be perfect. Aristotle, the prince of definers, "considers a definition as a speech declaring what a thing is. Everything essential to the thing defined, and nothing more, must be contained in the definition. Now the essence of a thing consists of these two parts: first, what is common to it with other things of the same kind; and secondly, what distinguishes it from other things of the same kind. The first is called the genus of the thing; the second, its specific difference. The definition, therefore, consists of these two parts."

In obedience to this rule, the definition under consideration seems to consist of the genus, signified by the word change; and of the specific difference, denoted by the words of place. But does the speech change of place really declare what motion is? We cannot admit that it does; as, in our apprehension, a change of place is the effect of motion, and not motion itself. Suppose a lover of dialectic undertaking to define the stroke by which he saw his neighbour wounded with a bludgeon; would what should we think of his art were he to call it a contusion on the head? He might say that contusion is a general term, as contusions may be produced on the arms, on the legs, and on various parts of the body; and as there are many species of contusion, if he were asked which of those species was the stroke to be defined, he might answer, "a contusion on the head." Here would be apparently the genus and specific difference; the former denoted by contusion, and the latter by the words of the head. But would this be a definition of a stroke? No, surely; a contusion on the head may be the effect of a stroke; but it can no more be the stroke itself, than a blow can be a bludgeon, or a flesh wound the point of a sword. Equally evident it is, that a change of place cannot be motion; because every body must have been actually moved before we can discern, or even conceive, a change of its place.

The act of changing the place would perhaps come nearer to a definition of motion; but so far it would be from "a speech declaring what motion is," that we are confident a man who had never by any of his senses perceived a body in actual motion, would acquire no ideas whatever from the words "act of changing place." He might have experienced changes in heat, cold, smell, and sound; but he could not possibly combine the ideas of such changes with the signification of the word place, were he even capable of understanding that word, which to us appears to be more than doubtful. (See METAPHYSICS, N° 40, 41.)

The distinctions of motion into different kinds have been no less various, and no less insignificant, than the several definitions of it. The moderns who reject the Peripatetic division of motion into four classes, yet consider it themselves as absolute or relative. Thus we are told, that "absolute motion is the change of absolute place, and that its celerity must be measured by the quantity of absolute space which the moving body runs through in a given time." "Relative motion, on the other hand, is a mutation of the relative or vulgar place of the moving body, and has its celerity estimated by the quantity of relative space run through."

Now it is obvious, that this distinction conveys no ideas without a farther explanation of the terms by which it is expressed; but that explanation is impossible to be given. Thus, before we can understand what absolute motion is, we must understand what is meant by absolute place. But absolute place is a contradiction; for all place is relative, and consists in the positions of different bodies with regard to one another. Were a globe, in the regions of empty space to be put in motion by Almighty Power, and all the rest of the corporeal world to be soon afterwards annihilated, the motion would undoubtedly continue unchanged; and yet, according to this distinction, it would be at first relative, and afterwards absolute. That the beginning of such a motion would be perceptible, and the remainder of it imperceptible, is readily granted; but on this account to consider it as of two kinds, is as absurd as to suppose the motion of the minute hand of a clock as being affected by our looking at it.

Leaving therefore these unintelligible distinctions, we now come to consider a question still of a very abstruse nature, but much agitated among philosophers.
vii. What is the original source of motion in the creation: Is it general to matter? or are we to ascribe it to the immediate and continual agency of some immaterial being? The former has been strenuously argued by the Cartesians, and the latter by the Newtonians. The arguments of the former, founded upon the chimerical hypothesis of vortices and the original construction of matter, were evidently inconclusive; and the hypothesis of Sir Isaac Newton, who asserted that it was naturally incapable of motion, appeared more probable. To account for the quantity of motion in the universe, therefore, it became necessary to have recourse either to the Deity, or to some subordinate spiritual agent; and this became the more necessary, as the doctrine of an absolute vacuum in the celestial spaces, that is, throughout the incomparably greatest part of the creation, was one of the fundamental maxims of the system. As it was absolutely denied that matter existed in these spaces, and it was plain that the celestial bodies affected one another at immense distances, the powers of attraction and repulsion were naturally called in as the sources of motion by their impulse upon inert and sluggish matter. These being admitted, a speculation ensued concerning their nature. Spiritual, it was confessed; they were; but whether they were to be accounted the immediate action of the divine Spirit himself, or that of some subordinate and inferior spirit, was a matter of no little dispute. Sir Isaac Newton, towards the latter part of his life, began to relax somewhat of the rigidity of his former doctrine; and allowed that a very subtle medium, which he called ether, might be the cause of attraction and repulsion, and, thus of the whole phenomena of nature. Since his time the multitude of discoveries in electricity, the similarity of that fluid to fire and light, with the vast influence it has on every part of the creation with which we are acquainted, have rendered it very probable that the ether mentioned by Sir Isaac is no other than the element of fire, the most subtle and elastic of all bodies, which seems to pervade and expand itself throughout the whole universe. Electrical experiments show that this mighty agent is everywhere present, ready to break forth into action, if not restrained and governed with the greatest wisdom. Being always restless and in motion, it acts and enlivens the whole visible mass; is equally fitted to produce and to destroy; distinguishes the various stages of nature, and keeps up the perpetual round of generation and corruption, pregnant with forms which it constantly sends forth and resorbs. So quick in its motions, so subtle and penetrating in its nature, so extensive in its effects, it seems no other than the vegetable soul or vital spirit of the world.

"The animal spirit in man is the instrument both of sense and motion. To suppose sense in the corporeal world would be gross and unwarranted; but locomotive faculties are evident in all its parts. The Pythagoreans, Platonists, and Stoics, held the world to be an animal; though some of them have chosen to consider it as a vegetable. However, the phenomena do plainly show, that there is a spirit that moves, and a mind or providence that presides. This providence, Plutarch saith, was thought to be in regard to the world what the soul is in regard to man. The order and course of things, and the experiments we daily make, show that there is a mind which governs and acts upon this mundane system as the proper and real agent and cause; and that the inferior instrumental cause is pure ether, fire, or the substance of light, which is applied and determined by an infinite mind in the macrocosm or universe, with unlimited power, and according to stated rules, as it is in the microcosm with limited power and skill by the human mind. We have no proof either from experiment or reason of any other agent or efficient cause than the mind or spirit. When, therefore, we speak of corporeal agents or corporeal causes, this is to be understood in a different, subordinate, and improper sense; and such an agent we know light or elementary fire to be."

That this elementary fire, absorbed and fixed in all bodies, may be the cause of the universal principle of gravity, is made sufficiently evident by numerous experiments. Homberg having calcined in the focus of the fire of a burning glass some regulus of antimony, found that it had gained one-tenth in weight, though the regulus, during the whole time of the operation, sent up the plane of a thick smoke, and thereby lost a considerable part of its substance. It is vain to allege that any heterogeneous matter floating in the air, or that the air itself, may have been buried into the mass by the action of the fire, and that by this additional matter the weight was increased; for it is known experimentally, that if a quantity of metal be very hermetically secured within a vessel of glass to keep off the air and all foreign matter, and the vessel be placed for some time in a strong fire, it will exhibit the same effect. 1 I have seen the operation performed (says Mr Jones) on two ounces of pewter filings, hermetically sealed up in a Florence flask, which in two hours gained 55 grains of natural is nearly one seventh. Had it remained longer in the fire, it might probably have gained something more; as, in one of Mr Boyle's experiments, steel filings were found to have gained a fourth.

"Of accounting for these effects there are but two possible ways: 1. If the quantity of matter be the same, or, in the case of calcination, be somewhat less, after being exposed to the action of the fire, while the gravity of the whole is become greater; then does it follow, that gravity is not according to the quantity of matter; and of course is not one of its properties. 2. If there be an increase of the mass, it can be imputed to nothing but the matter of light, or fire, entangled in its passage through the substance, and so fixed in its pores, or combined with its solid parts, as to gravitate together with it. Yet it is certain, from the phenomena of light darting from the sun, that this elementary fire does not gravitate till it is fixed in metal, or some other solid substance. Here then we have a fluid which gravitates, if it gravitate at all, in some cases and not in others. So that which way soever the experiment be interpreted, we are forced to conclude that elementary or solar fire may be the cause of the law of gravitation."

That it is likewise in many cases the cause of repulsion, is known to every one who has seen it fuse metals, and convert water and mercury into elastic vapour. But there is a fact recorded by Mr Jones, which seems to evoince that the same fluid, which as it issues from the sun exhibits itself in the form of light and heat, is in other circumstances converted into a very fine air,
Motion or cold ether, which rushes very forcibly towards the body of that luminary. "As a sequel to what has been observed (says he) concerning the impregnation of solid substances with the particles of fire, give me leave to subjoin an experiment of M. de Stair. He tells us, that upon heating red lead in a glass, whence the air was exhausted by the rays of the sun collected in a burning glass, the vessel in which the said red lead was contained burst in pieces with a great noise. Now, as all explosions in general must be ascribed either to an admission of the air into a rarefied space, or to what is called the generation of it; and as air was not admitted upon this occasion, it must have been generated from the calx within the vessel; and certainly was so, because Dr Hales has made it appear that this substance, like crude tartar and many others, will yield a considerable quantity of air in distillation. What went into the metal therefore as fire, came out of it again as air; which in a manner forces upon us conclusions of inestimable value in natural philosophy, and such as may carry us very far into the most sublime part of it."

One of the conclusions which the ingenious author thinks thus forced upon us, is, that the motion of the planets round the sun, as well as round their own axes, is to be attributed to the continual agency of this fluid, under its two forms of elementary fire and pure air. As fire and light, we know that it rushes with inconceivable rapidity from the body of the sun, and penetrates every corporeal substance, exerting itself sometimes with such force as nothing with which we are acquainted is able to resist. If it be indeed a fact, that this elementary fire, or principle of light and heat, afterwards cools, and becomes pure air, there cannot be a doubt, but that under such a form it will return with great force, though surely in a somewhat different direction, towards the sun, forming a vortex, in which the planets are included, and by which they must of course be carried round the centre. Mr Jones does not suppose that the fire into which the principle of light and heat is converted, is of so gross a nature as our atmosphere. He rather considers it as cool ether, just as he represents light to be ether heated: but he maintains, that this ether, in its aëriform form, though not fit for human respiration, is a better panem of fire than the air which we breathe.

This theory is exceedingly plausible; and the author supports it by many experiments. He has not, indeed, convinced us that the solar light is converted or convertible into pure air; but he has, by just reasoning from undoubted facts, proved that the whole expansion of heaven, as far as comets wander, is filled not only with light, which is indeed obvious to the senses, but also with a fluid, which, whatever it may be called, supplies the place of the air in feeding the fire of these ignited bodies.

That the motion of the heavenly bodies should result from the perpetual agency of such a medium, appears to us a much more rational hypothesis, than that which makes them act upon each other at immense distances through empty space. But the hypothesis is by no means so complete a solution of the phenomena as some of its most admirers pretend to think it. This fluid, whether called ether, heat, light, or air, is still material; and the question returns upon him who shall imagine that it is sufficient to account for gravitation, repulsion, magnetism, and cohesion, &c. "What moves the fluid itself, and makes the parts of which it is composed cohere together?" However widely it may be extended, it is incapable of positive infinity; and therefore may be divided into parts separated from each other; so that it must be held together by a foreign force, as well as a ball of lead, or a piece of wax. As matter is not essentially active, the motion of this ether, under both its forms, must likewise be considered as an effect, for which we do not think that any propelling power in the body of the sun can be admitted as a sufficient cause. For how comes the sun to possess that power, and what makes the fluid return to the sun? We have no notion of power, in the proper sense of the word, but as intelligence and volition; and by the pious and excellent author of the Essay on the First Principles of Natural Philosophy, we are certain that the sun was never supposed to be intelligent.

Bishop Berkeley, who admits of light or ether as the instrumental cause of all corporeal motion, gets rid of this difficulty, by supposing, with the ancients, that this powerful agent is animated. "According to the Pythagoreans and Platonists (says his Lordship), there is a life infused throughout all things; the yv, yv, yv, yv, yv, yv, an intellectual and artificial fire, in inward principle, animal spirit, or natural life, producing and forming within, as art doth without; regulating, moderating, and reconciling the various motions, qualities, and parts of the mundane system. By virtue of this life, the great masses are held together in their ordinary courses, as well as the minutest particles governed in their natural motions, according to the several laws of attraction, gravity, electricity, magnetism, and the rest. It is this gives instincts, teaches the spider her web, and the bee her honey. This is that which directs the roots of plants to draw forth juices from the earth, and the leaves and cortical vessels to separate and attract such particles of air and elementary fire as suit their respective natures."

This life or animal spirit seems to be the same thing which Cudworth calls plastic nature, and which has been considered elsewhere. (See Metaphysics, No. 200, and Plastic Nature). We shall therefore dismiss it at present, with just admitting the truth of the bishop's position, "that if nature be supposed the life of the world, animated by one soul, compounded into one frame, and directed or governed in all its parts by one supreme and distinct intelligence, this system cannot be accused of atheism, though perhaps it may of mistake or impropriety."

A theory of motion somewhat similar to that of Berkeley, though in several respects different from it, was not many years ago stated with great cleance, and supported with much ingenuity, in An Essay on the Powers and Mechanism of Nature, intended to improve, and more firmly establish, the grand superstructure of the Newtonian system. Mr Young, the author of the essay, admits with most other philosophers of the present age, that body is composed of atoms which are inseparable to each other, and may be denominated solid. These atoms, however, he does not consider as primary and simple elements, incapable of resolution into principles;
He then proceeds to combat, which he does very successfully, the arguments by which the more rigid Newtonians endeavour to prove that a body in motion will continue to be moved by its own inertia, till stopped by some opposite force. Having done this, he establishes the contrary conclusion by the following syllogisms:

"I. Whatever requires an active force to stop its motion, is disposed to move.

   Every body in motion requires an active force to stop its motion.

   Therefore every body in motion is disposed to move.

"II. Whatever is disposed to motion is possessed of action.

   But a body in motion is disposed to continue in motion.

   Therefore a body in motion is possessed of action.

Thus it appears, that the middle part of any motion is action equally with the beginning.

"The last part of motion is its termination. It is admitted that all motion is terminated by an action contrary to the direction of the motion. It is admitted, too, that the moving body acts at the time its motion is destroyed. Thus the beginning and the end of any uniform motion are confessed to be actions; but all the intermediate continuation which connects the beginning with the end is denied to be action. What can be more unaccountable than this denial? Is it more consonant to reason and analogy, to ascribe to the whole continued motion one uninterrupted action? Such a conclusion true philosophy, we think, requires us to make.

"To move or act, is an attribute which cannot be conceived to exist without a substance. The action of a body in motion is indeed the attribute of the body, and the body relatively to its own motion is truly a substance, having the attribute or quality of motion. But the body being a name signifying a combination of certain ideas, which ideas are found to arise from action (see Plastic Nature), that action which is productive of those ideas whose combination we denominate body, is of the nature of an attribute so long as it is considered as constituted of action.—To this attribute we must necessarily assign its substance. The actions which constitute body must be actions of something, or there must be something which acts. When then is this active something, from whose agency we get the idea of body, or whose actions constitute body? Is it not sufficient that it is something active? A name might be surely given it, but a name would not render the idea more clear. Its description may be found in every sensation; it is colour to the eye, flavour to the palate, odour to the nose, sound to the ear, and feeling to the touch; for all our sensations are but so many ways in which this active something is manifested to us. A substratum of solidity philosophers have imagined to exist, and have in vain sought to find. Our active substance is the substratum so long sought for, and with so little success. We give it a quality by which it may be perceived; it acts. One modification of action produces matter, another generates motion. These modifications of action are modes of the active substance, whose presence is action: matter and motility, constitute...
MOTION constitute the whole of nature. THERE IS THEREFORE THROUGHOUT NATURE AN ACTIVE SUBSTANCE, THE CONSTITUENT ESSENCE OF MATTER, AND IMMEDIATE NATURAL AGENT IN ALL EFFECTS."

By an argument which we do not think very conclusive, our author determines this active substance to be unintelligent. "In our sensations individually, not discovering (says he) the traces, not seeing the characters of intelligence, but finding only action present and necessary, our inferences go no farther than our observations warrant us to do; and we conclude in all these things an action only, and that action unintelligent." Having given our opinion of real agency elsewhere (see Metaphysics, N° 118.), we shall not here stop to examine this reasoning. We may however ask, Whether all our sensations individually be not excited for a certain end? If they be, according to our author's mode of arguing in another place, the exciting agent should be an intelligent being. By this we are far from meaning to deny the reality of sensation which is destitute of intelligence. We are strongly inclined to think that there is such a cause, though our persuasion results not from this argument of our author's. In our opinion, he reasons better when he says, "that a subordinate agent constructed as the matter of creation, invested with perpetual laws, and producing agreeably to those laws all the forms of being, through the varieties of which inferior intelligences can, by progressive steps, arrive ultimately at the supreme contriver, is more agreeable to our ideas of dignity, and tends to impress us with more exalted sentiments, than viewing the Diety directly in all the individual impressions we receive, divided in the infinity of particular events, and unlawful, by his continual presence in operations to our view insignificant and mean."

This active substance, or secondary cause, our author concludes to be neither matter nor mind. "Matter (says he) is a being, as a whole quiescent and inactive, but constituted of active parts, which resist separation, or cohere, giving what is usually denominated solidity to the mass. Mind is a substance which thinks. A being which should answer to neither of these definitions, would be neither matter nor mind; but an immaterial, and, if I may so say, an immortal substance." Such is the active substance of Mr Young, which, considered as the cause of motion, seems not to differ greatly from the plastic nature, hydraulical principle, or vis generatix, of others. The manner in which it operates is indeed much more minutely detailed by our author than by any other philosopher, ancient or modern, with whose writings we have any acquaintance.

"Everything (he says) must be in its own nature either disposed to rest or motion; consequently the active substance must be considered as a being naturally either quiescent or motive. But it cannot be naturally quiescent; for then it could not be active, because activity, which is a tendency to motion, cannot originate in a tendency to rest. Therefore the active substance is by nature motive, that is, tending to motion. The active substance is not solid, and does not resist penetration. It is, therefore, incapable of impelling or of sustaining impulse. Whence it follows, that as it tends to move, and is incapable of having its motion impeded by impulse, it must actually and continually move: in other words, motion is essential to the active substance."

"In order that this substance may act, some other thing upon which it may produce a change is necessary; for whatever suffers an action, receives some change. The active substance, in acting on some other thing, must impart and unite itself thereto; for its action is communicating its activity. But it cannot communicate its activity without imparting its substance; because it is the substance alone which possesses activity, and the quality cannot be separated from the substance. Therefore the active substance acts by uniting itself with the substance on which it acts. The union of this substance with bodies, is not to be conceived of as a junction of small parts intimately blended together and attached at their surfaces; but as an entire diffusion and incorporation of one substance with another in perfect coalescence. As bodies are not naturally active, whenever they become so, as they always do in motion, it must be by the accession of some part of the active substance. The active substance being imparted to a body, penetrates the most solid or resisting parts, and does not reside in the pores without, and at the surfaces of the solid parts. For the activity is imparted to the body itself; and not to its pores, which are no parts of the body: therefore if the active substance remained within the pores, the case would not be present with its effect; but the case would be in one place and the effect in another, which is impossible."

"Bodies by their impulse on others lose their activity in proportion to the impulse. This is matter of observation. Bodies which suffer impulse acquire activity in proportion to the impulse. This also is matter of observation. In impulse, therefore, the active substance passes out of the impelling body into the body impelled. For since bodies in motion are active, and activity consists in the presence of the active substance, and by impulse bodies lose their activity, therefore they lose their active substance, and the loss is proportional to the impulse. Bodies impelled acquire activity; therefore acquire active substance, and the acquisition is proportional to the impulse. But the active substance lost by the impelling body ought to be concluded to be that found in the other; because there is no other receptacle than the impelled body to which the substance parted from can be traced, nor any other source than the active body whence that which is found can be derived. Therefore, in impulse, the active substance ought to be concluded to pass from the impelling body to the body impelled. The flowing of such a substance is a sufficient cause of the communication of activity, and no other rational cause can be assigned."

"The continued motion of a body depends not upon its inertia, but upon the continuance of the active substance within the body. The motion of a body is produced by the motion of the active substance in union with the body. It being evident, that since the active substance itself does always move, whatever it is united to will be moved along with it, if no obstacle prevent. In mere motion, the body moved the patient, and the active substance the agent. In impulse,
MOT [ 457 ] MOT

While the active substance is flowing out of the active body into the obstacle or impelled body, the active body will press or impel the obstacle. For while the active substance is yet within the body, although flowing through it, it does not cease to impart to the body its own nature, nor can the body cease to be active because not yet deprived of the active substance. Therefore during its passing out of the body, such portion of the active substance as is yet within, is urging and disposing the body to move, in like manner as if the active substance were continuing in the body; and the body being thus urged to move, but impeded from moving, presses or impels the obstacle.

"We see here (says our author) an obvious explanation of impulse; it consists in the flowing of the motive substance from a source into a receptacle;" and he thinks, that although the existence of such a substance had not been established on any previous grounds, the communication of motion by impulse does alone afford a sufficient proof of its reality.

He employs the agency of the same substance to account for many other apparent activities in bodies, such as those of fire, electricity, attraction, repulsion, electricity, &c. All these are apparent activities of the same active substance. He, says, to impart the active substance to bodies; and where activity is without any manifest origin, the active substance is derived from an invisible source.

Our limits will not permit us to attend him in his solution of all the apparent activities in bodies; but the orbicular motions of the planets have been accounted for in so many different ways by philosophers ancient and modern, and each account has been so little satisfactory to him who can think, and wishes to trace effects from adequate causes, that we consider it as our duty to furnish our readers with the account of this phenomenon which is given by Mr. Young.

"The question which has been so long agitated, "Whence is the origin of motion?" our author considers as implying an absurdity. "It supposes (says he) that rest was the primitive state of matter, and that motion was produced by a subsequent act. But this supposition must ever be rejected, as it is giving precedence to the inferior, and inverting the order of nature." The substance which he holds to be the basis of matter is essentially active; and its action is motion. This motion, however, in the original element, was power without direction, agency without order, activity to no end. To this power it was necessary that a Law should be superadded; that its agency should be guided to some regular purpose, and its motion conspire to the production of some uniform effects. Our author shows, or endeavours to show, by a process of reasoning which shall be examined elsewhere, that the primary atoms of matter are produced by the circular motion of the parts of this substance round a centre; and that a similar motion of a number of these atoms around another centre common to them all, produces what in common language is called a solid body; a cannon ball, for instance, the terrestrial globe, and the body of the sun, &c. In a word, he labours to prove, and with no small success, that a principle of union is implied in the revolving or circulating movements of the active substance.

"But we may also assume (he says) a priori, that a principle of union is a general law of nature; because we see in fact all the component parts of the universe are united systems, which successively combine into larger unions, and ultimately form one whole." Let us then suppose the sun with all his planets, primary and secondary, to be already formed for the purpose of making one system, and the orbits of all of them, as well as these great bodies themselves, to be pervaded by the active substance, which necessarily exists in a state of motion, and is the cause of the motion of every thing corporeal. If to this motion a principle of union be added, the effect of such a principle would be a determination of all the parts of the active substance, and of course all the bodies to which it is united, towards a common centre, which would be at rest, and void of any tendency in any direction. But this determination of all the parts of the system towards a common centre, tends to the destruction both of the motion of the active substance and of the system; for should all the parts continually approximate from a circumference towards a centre, the sun and planets would at last meet, and form one solid and quiescent universe to preserve existence, and consequently motion, is the first law of the active substance, as of all being; and it cannot be doubted, that to preserve distinct the several parts of the solar system, is the first law given to the substance actuating that system. The union of the system is a subsequent law.

"When the direct tendency of any inferior law is obviated by a higher law, the inferior law will operate indirectly in the manner the nearest to its direct tendency that the superior law will permit. If a body in motion be obliquely obstructed, it will move on in a direction oblique to its first motion. Now the law of union, which pervades the solar system, being continually obstructed by the law of self-preservation, the motion of the active substance, and of the bodies to which it is united, can be no other than a revolving motion about the common centre of approach, towards which all the parts have a determination. But when this revolution has actually taken place, it gives birth to a new tendency, which supersedes the operation of the law of self-preservation. It has been shown, that the law essential to the active substance, required to be governed by some law to give being to an orderly state of things. Now, there are motions simple and motions complex; the more simple is in all things first in order, and out of the more simple the more complex arises in order posterior. The most simple motion is rectilinear; therefore a rectilinear motion is to be considered as that which is the original and natural state of things, and consequently that to which all things tend. It will follow from hence, that when any portion of active substance in which the law of union operates, has in the manner above explained been compelled to assume a revolving motion, that is, a motion in some curve; a tendency to a rectilinear motion will continually exist in every part of the revolving portion, and in every point of the curve which it describes during its revolution. And this rectilinear tendency will be a tendency to recede from the centre in every
Motion, point of the revolving orb, and to proceed in a tangent to the orbit at each point. These two tendencies, if not originally equal, must necessarily in all cases arrive at an equality. For the tendency towards the centre, called the centrifugal tendency, that is, the force of motion, operating first, if we suppose the motion perpetual, continues to the centre, the tendency to recede from it, called the centripetal tendency, will have its proportion to the centrifugal continually increased as the orbit of revolution grows less, so as ultimately to equal the centrifugal tendency, and restrain the motion from its central course, at which point it will no longer seek the centre but revolve round it.

As our author holds that every atom of matter is formed by the motion of parts of the active substance, and every body formed by the motion of atoms; as he maintains, not only that the sun, moon, earth, planets, and stars, are penetrated by the same substance, but that each in the centre of a vortex of that substance, and that of those vortices some are included within others. "The subtle revulsing fluid, the centre of whose vortex, the earth occupies, not only surrounds but pervades the earth, and other vortices their earths, as their vortices; and the earth and planets are by its revolutions carried around on their own axes. The earth is an active mass, and all its component masses are necessarily so, collectively inactive; but the earth and all its parts have various collective and separate movements, imparted from the fluid, which surrounds, pervades, and constitutes it. Being immersed together with its proper surrounding sphere or vortex in the larger sphere or vortex of the sun, it is carried thereby in a larger orbit about the sun, at the same time that by the revolution of its proper sphere it rotates on its own axis."

Such is the most complete view which our limits will permit us to give of Mr. Young's theory of motion. To the philosopher who considers experiments as the only test of truth, and who, in all his inquiries employs his hands, more than his head, we are fully aware that it will appear in no better light than as "the useless fabric of a vision." Even to the intellectual philosopher, who is not frightened at the word metaphysics, we are afraid that such an active substance whose author contends for, will appear so inadequate to the production of the phenomena of gravitation and revolution as the material matter of Mr. Jones and his followers. Being void of intelligence, whether it be material, or immaterial, quiescent or motion, cannot be the subject of law, in the proper sense of the word. The laws of which Mr. Young speaks as necessary to regulate the motions of the active substance, must be mere forces, applied by some extrinsic and superior power. And since "motion, as it is essential to the active substance, is power without direction, agency without order, activity to no end; since it is of such a nature, that from its unguided operations there could result neither connection, order, nor harmony;" it follows that those extrinsic forces must be perpetually applied, because what is essential to any substance can never be destroyed or changed as long as the substance itself remains.

Forests producing order out of confusion, can be applied only by a being possessed of intelligence; and if the immediate and perpetual agency of an intelligent being be necessary to regulate the motions of the active substance, that substance itself may be thought superfluous, and its very existence be denied. Electricity multiplies cases obscure necessitates a role of philosophising which every man of science acknowledges to be just. And it will hardly be denied that the immediate and perpetual agency of an intelligent being upon Mr. Jones's ethereal fluid, or even upon the matter of solid bodies themselves, would be capable of producing every kind of motion without the intermixture of a substance which is neither mind or matter.

Such, we conceive, are the objections which our metaphysical readers may make to this theory. But of their force, however, will perhaps be removed by the ingenious manner in which our author analyses matter into an immaterial principle. But so much it remains, that the writers of this article is inclined to believe that no mechanical account can be given of the motions of the heavenly bodies, the growth of plants, and various other phenomena which are usually ascribed to attraction and repulsion. In the present age, philosophers in general are strangely averse from admitting, on any occasion, the agency of mind: yet as every effect must have a cause, it is surely not irrational to attribute such effects as mechanism cannot produce to the operation either of intelligence or instinct. To suppose the Deity the immediate agent in the great motions of the universe, has been deemed improper; and it must be confessed that very impious conclusions have been deduced from that principle. But then it is surely no impiety in supposing, with the excellent bishop of Cloyne, that the fluid which is known to pervade the solar system, and to operate with resistless force, may be animated by a powerful mind, which acts instinctively for ends of which itself knows nothing. For the existence of such a mind, no other evidence, indeed, can be brought than what is afforded by a very ancient and very general tradition, and by the impossibility of accounting for the phenomena upon principles of mere mechanism. Perhaps some of our more pious readers may be inclined to think that the Supreme Being has committed the immediate government of the various planetary systems to powerful intelligences, or angels, who, as his ministers, direct their motions with wisdom and foresight. Such an opinion is certainly not absurd in itself; and it seems to be countenanced by an ancient writer, who, though not known by the name of a philosopher, knew as much of the matter as any founder of the most celebrated school.

To object to either of these hypotheses, as has been sometimes done, that it represents the government of the world as a perpetual miracle, betrays the grossest ignorance; for we might as well call the movements of the bodies of men and brutes, which are certainly produced by minds, miraculous. We do not affirm that either hypothesis is certainly true; but they are both as probable and as satisfactory as the hypothesis which attributes agency to attraction and repulsion, to a subtle ether, or to a substance which is neither mind nor matter. Were the immediate agency of intellect to be admitted, there would be no room for any of those disputes which have been agitated among philosophers, about the increase or diminution of matter.
in reality, motion becomes continually less and less.—

For bodies which are either so perfectly hard or so
soft as to have no elastic power, will not rebound from
each other; their impenetrability will only stop their
motion. And if two such bodies equal to one an-
other be carried with equal but opposite motions, so
as to meet in a void space, by the laws of motion they
must stop in the very place of concourse, lose all their
motion, and be at rest for ever, unless they have an elas-
tic power to give them a new motion. If they have
elasticity enough to make them rebound with one-fourth,
one-half, or three-fourths, of the force they meet with,
they will lose three-fourths, one-half, or one-fourth, of
their motion. And this is confirmed by experiments:
for if two equal pendulums be let fall from equal heights,
so as to strike full upon each other; if those pendulums
be of lead or soft clay, they will lose all, or almost all,
their motion; and if they be of any elastic matter, they
will only retain so much motion as they receive from
their elastic power.

Motion, therefore, being thus, in the opinion of our
celebrated author, lost, or absolutely destroyed, it is ne-
necessary to find some cause by which it may be renewed.
Such renovation Sir Isaac attributes to active princi-
ples; for instance, "the cause of gravity, whereby the
planets and comets preserve their motions in their or-
bits, and all bodies acquire a great degree of motion
in falling; and the cause of fermentation, whereby the
heart and blood of animals preserve a perpetual warmth
and motion, the inner parts of the earth are kept per-
petually warmed; many bodies burn and shine, and
the sun himself burns and shines, and with his light
warms the earth and everything else."  

Elasticity is another cause of the renovation of mo-
tion mentioned by Sir Isaac.  "We find but little
motion in the world (say be), except what plainly flows
either from these active principles, or from the com-
mand of the willer."

With regard to the destruction or positive loss of No power
motion, however, we must observe, that notwithstanding
of motion, the authority of Sir Isaac Newton, it is altogether
impossible that any such thing can happen. All mov-
ing bodies which come under the cognizance of our
senses are merely passive, and acted upon by some-
thing which we call powers or fluids, and which are
to us totally invisible. Motion, therefore, cannot be
lost without a destruction or diminution of one of
these powers, which we have no reason to think can
ever happen. When two pendulums rush against each
other, the motion is the mere effect of the action of
gravity; and that action, which in this case is the
power, continues to be the same whether the pen-
dulum moves or moves not. Could motion, therefore,
be exhausted in this case, we must suppose, that by se-
parating two pendulums to the same distance from each
other, and then letting them come together for a great
number of times, they would at last meet with less
force than before. But there is certainly not the least
foundation for this supposition; and no rational person
will take it into his head, that supposing the whole
human race had employed themselves in nothing else
from the creation to the present day, but separating
pendulums and letting them stop each other's motion,
they would now come together with less force than
they did at first. Power, therefore, which is the cause

MOTION

of motion, is absolutely indestructible. Powers may
indeed counteract one another, or they may be made
to counteract themselves; but the moment that the
obstacle is removed, they show themselves in their pri-
tine vigour, without the least symptom of abatement or
decay.

Whether, therefore, we reckon the ultimate source
of motion to be spiritual or material, it is plain that it
must be to our conceptions infinite; neither will the
phenomena of nature allow us to give any other ex-
planation than we have done: for no power whatever
can lose more than its own quantity; and it seems ab-
tard to think that the Creator would create the world
in such a manner that it would ultimately become im-
moveable, and then have recourse to unknown prin-
ciples to remedy the supposed defect. On the prin-
inciple we have now just laid down, however, the mat-
ter becomes exceedingly plain and obvious. The Cre-
ator at first formed two opposite powers, the action
of which is varied according to the circumstances of the
bodies upon which they act; and these circumstances
are again varied by the action of the powers them-
selves in innumerable ways upon one another, and the
approach of one body to another, or their receding to
a greater distance. Where these powers happen to
oppose each other directly, the body on which they
act is at rest; when they act obliquely, it moves in
the diagonal; or if the force acting upon one side is
by any means lessened, the body certainly must move
towards that side, as is evident from the case of the
atmosphere, where the pressure of the air, when re-
moved from one side of a body, will make it move very
violently towards that side. If the body is removed
off the pressure in this manner, the motion would as-
sumed be perpetual. We must not imagine that the
motion is destroyed because it is counteracted; for it is im-
possible to destroy motion by any means but removing
the cause; counteracting the effect is only a tempo-
rary obstacle, and must cease whenever the obstacle is
removed. Nature, therefore, having in itself an in-
finite quantity of motion, produces greater or lesser
motions, according to the various action of the mov-
ing powers upon different bodies or upon one another,
without a possibility of the general stock being either
augmented or diminished, unless one of the moving
powers was to be withdrawn by the Creator; in which
case, the other would destroy the whole system in an
instant.

As to the nature of these great original
powers, we must confess ourselves totally ignorant;
and yet we perceive any data from which the nature
of them can be investigated. The elements of light,
air, &c. are the agents; but in what manner they act,
or what manner they received their action, can be
known only to the Creator.

Perpetual Motion, in Mechanics, a motion which is
supplied and renewed from itself, without the interven-
tion of any external cause; or it is an uninterrupted
communication of the same degree of motion from one
part of matter to another, in a circle or other curve re-
turning into itself, so that the same momentum still re-
turns undiminished upon the first mover.

The celebrated problem of a perpetual motion con-
ists in the inventing a machine, which has the prin-
ciple of its motion within itself. M. de la Hire has de-
monstrated the impossibility of any such machine, and
finds that it amounts to this, viz. to find a body which
is both heavier and lighter at the same time, or to find
a body which is heavier than itself.

Animal Motion, that which is performed by animals
at the command of the mind or will.

Though all the motions of animals, whether volun-
tary or involuntary, are performed by means of the
muscles and nerves, yet neither these nor the subtle
fluid which resides in them are to be accounted the
ultimate sources of animal motion. They depend enti-

ally upon the mind for those motions which are properly
to be accounted voluntary. All the involuntary motions,
such as those of the blood, the heart, muscles, organs
subservient to respiration and digestion, &c. are to be
classed with those of vegetables; for though no vege-
tables have them in such perfection as animals, there
are yet traces of them to be found evidently among ve-
gettes; and that so remarkable, that some have im-
gined the animal and vegetable kingdoms to approach
each other so nearly that they could scarce be distin-
guished by a philosophic eye. See MUSCLE.

Though the motions of animals, however, depend on
the action of the mind or of the will, external objects
seem originally to have the command of the mind itself;
for unless an animal perceive something, it will not be
inclined to act. By means of the ideas once received,
indeed, and retained in the memory, it acquires a self-
moving power, independent of any object present at the
time, which is not the case with vegetables; for how-
ever they may act from a present impulse, their motions
never appear to be derived from any source which may
not be accounted truly mechanical.

According to some, motion is the cause of sensation
itself; and indeed it seems very probable that the mo-
tions of that subtle fluid, called light or electricity, in
our bodies always accompany our sensations; but whet-
ner these be the cause, or only the medium, of sense,
cannot be discovered.

Though all animals are endowed with a power of vol-
tuntary motion, yet there is a very great variety in the
degrees of that power; to determine which no certain
rules can assign; neither can we, from the situa-
tion and manner of life of animals, derive any probable
reason why the motion of one should differ so very much
from that of another. This difference does not arise
from their size, their ferocity, their timidity, nor any
other property that we can imagine. The elephant,
though the strongest land animal, is by no means the
slowest in its motions; the horse is much swifter than
the bull, though there is not much difference in their
size; a greyhound is much swifter than a cat, though
the former be much larger, and though both live in the
same manner, viz. by hunting. Among insects the
same unaccountable diversity is observable. The loco-
and flea are both vermin, are both nearly of the same
size, and both feed on the bodies of animals; yet there
is no comparison between the swiftness of their motions:
while the bug, which is much larger than either, seems
to have a kind of medium swiftness between both.

This very remarkable circumstance seems not even
to depend on the range which animals are obliged to take
in order to procure food for themselves: the motion
of a snail is slower than that of an earth worm; while
that
that of many caterpillars is much quicker than either; though we can scarce determine which of the three has the greatest or the least extensive range for its food.

Of all animals the shell fish move the slowest, inasmuch that some have supposed them to be entirely destitute of locomotive powers; and muscles particularly are denied to have any faculty of this kind. Every one knows that these animals can open and shut their shells at pleasure; and it cannot escape observation, that in every muscle there is a fleshy protuberance of a much redder colour than the rest. This has been thought to be a tongue or proboscis, by which the animal takes in its food; but is in reality the instrument of its motion from place to place. This is a peculiar motion, by division into two lobes, which perform the office of feet. When the river muscle is inclined to remove from its station, it opens its shells, thrusts out this protuberance, and digs a furrow in the sand; and into this furrow, by the action of the same protuberance, the shell is made to fall in a vertical position. It is recovered out of this into the former horizontal one, by pushing back the sand with the same tentacula, lengthening the furrow, and thus the animal continues its journey by a continual turning topsy-turvy.—Marine muscles perform their motions in the same manner, and by similar instruments. In general they are firmly attached to rocks or small stones by threads about two inches long, which are spun from a glutinous substance in the protuberances already mentioned.

Other animals which inhabit bivalved shells, perform their motions by a kind of leg or foot; which, however, they can alter into almost any figure they please. By means of this leg they can not only sink into the mud, but also leap out of it at pleasure; but can even leap from the place where they are; and this can be done by the limpet, which people are apt to imagine one of the most sluggish animals in nature. — When this creature is about to make a spring, it sets its shell on edge, as if to diminish friction; then, stretching out the leg as far as possible, it makes it embrace a portion of the shell, and by a sudden movement, similar to that of a spring, let loose, it strikes the earth with its leg, and actually leaps to a considerable distance.

The spout, or razor-fish, is said to be incapable of moving forward horizontally on the surface; but it digs a hole sometimes two feet deep in the sand, in which it can ascend or descend at pleasure. The leg, by which it performs all its movements, is fleshy, cylindrical, and pretty long; and the animal can at pleasure make it assume the form of a ball. When lying on the surface of the sand, and about to sink into it, the leg is extended from the inferior end of the shell, and makes it resemble a shovel, sharp on each side, and terminating in a point. With this instrument the animal makes a hole in the sand; after which it advances the leg still farther into it, makes it assume the form of a hook, and with this, as a fulcrum, it oblige the shell to descend into the hole. This operation is continued until the whole shell be covered; and when the animal wishes to regain the surface, it makes the extremity of the leg to assume the form of a ball, and makes an effort to extend it. The ball, however, prevents any farther descent, and the reaction of the muscular effort raises up the whole shell, which operation is continued until it reaches the surface; and it is surprising with what facility these motions are accomplished by an animal seemingly so little qualified to move at all. Another particularity in this fish is, that though it lives among salt water, it abhors salt so much, that when a little is thrown into its hole it instantly leaves it. But it is still more remarkable, that if you once take hold of the spout-fish, and then allow it to retire into its hole, it cannot then be driven out by salt; though unless it be taken hold of by the hand, the application of salt will make it come to the surface as often as you please.

All other shell fish, even those apparently the most sluggish and destitute of any apparatus for motion, are found to be furnished with such instruments as enable them to perform all those movements for which they have any occasion. Thus the scallop, a well-known animal inhabiting a bivalved shell, can both swim upon the surface of water and move upon land. When it happens to be deserted by the tide, it opens its shell to the full extent, and shutting it again with a sudden jerk, the reaction of the ground gives such an impulse to the whole, that it sometimes springs five or six inches from the ground; and by a continued repetition of this action, it gradually tumbles forward until it regains the water. Its method of sailing is still more curious. Having attained the surface of the water by means unknown to us, it opens the shell, and puts one-half above water, the other with the body of the animal in it remaining below. Great numbers of them are thus frequently seen sailing in company with their shells sticking up above water when the weather is fine, and the wind acting upon them as sails; but on the least alarm they instantly shut their shells, and all sink to the bottom together.

The oyster has generally been supposed one of the most sluggish animals in nature, and totally incapable of voluntary motion; but from the researches of the Abbé Dicquemarre, this opinion seems to be erroneous. The oyster, like many other bivalved shell-fish, has a power of squirting water out from its body; and this power may easily be observed by putting some of them into a plate with as much sea water as will cover them. The water is ejected with so much force, as not only to repel the approach of ordinary enemies, but to move the whole animal backwards or sidewise, in a direction contrary to that in which the water was ejected. It has been also supposed, that oysters are destitute of sensation; but M. Dicquemarre has shown, that they not only possess sensation, but that they are capable of deriving knowledge from experience. When removed from such places as are entirely covered with the sea, when destitute of experience, they open their shells and die in a few days; but if they happen to escape this danger, and the water covers them again, they will not open their shells again, but keep them shut, as if warned by experience to avoid a danger similar to what they formerly underwent.

The motions of the sea-urchin are perhaps more curious and complicated than those of any other animal. It inhabits a beautiful multivalved shell, divided into triangular compartments, and covered with great numbers of prickers; from which last circumstance it receives the name of sea urchin or sea hedgehog. The triangles
Motion. Triangles are separated from one another by regular belts, and perforated by a great number of holes, from every one of which issues a fleshy horn similar to that of a snail, and capable of moving in a similar manner. The principal use of these horns seems to be to fix the animal to rocks or stones, though it likewise makes use of them in its progressive motion. By means of these horns and prickles, it is enabled to walk either on its back or its belly; but it most commonly makes use of those which are near the mouth. Occasionally it has a progressive motion by turning round like a wheel.

The animals called sea-nettles or medusae, though extremely slow in their motions, are nevertheless evidently capable of moving at pleasure from place to place. The variety of their figure is such, that it is difficult to assign them any determinate figure whatever. In general, however, they resemble a truncated cone, the base of which is applied to the rock to which they adhere. Their colours are various, whitish, brown, red or greenish: the mouth is very large; and when opened appears surrounded with filaments resembling the horns of snails, which being disposed in three rows around it, give the animal the appearance of a flower; and through every one of these the animal has the power of squirting the sea water. The structure of these animals is extremely singular; they consisting all of one organ, viz. a stomach. When searching for food, they extend their filaments, and quickly entangle any small animals that come within their reach. The prey is instantly swallowed, and the mouth shut close upon it like a purse; in which state it remains for many days before the nutritive parts are extracted. The animal, though scarcely an inch or an inch and a half in diameter, is nevertheless so dilatable, that it can swallow large whelks and muscles, the shells of which are thrown out by the mouth after the nutritive parts have been exhausted. Sometimes the shell is too large to be voided this way; in which case the body of the animal splits, and the shell is voided through the opening, which in a short time heals up again. The progressive motion of this creature is so slow, that it resembles that of the hour hand of a clock, and is performed by means of innumerable muscles placed on the outside of the body. All these are tubular, and filled with a fluid, which makes them project like prickles. On occasion it can likewise loosen the base of the cone from the rock, and inverting its body, move by means of the filaments already mentioned, which surround the mouth; but even the motion performed in this manner is almost as slow as the other.

Some animals are capable of moving backwards, apparently with the same facility that they do forwards, and that by means of the same instruments which move them forward. The common house fly exhibits an instance of this, and frequently employs this retrograde motion in its ordinary courses; though we cannot know the reason of its employing such an extraordinary method. Another remarkable instance is given by Mr. Smellie in the ramson-bee. This is one of the solitary species, and has its name from the mode of constructing its nest with mud or mortar. Externally this nest has no regular appearance, but at first sight is taken for a quantity of dirt adhering to the wall; though the internal part is furnished with cells in the same regular manner with the nests of other insects of the bee kind. When this bee leaves its nest, another frequently takes possession of it; in which case a battle never fails to ensue on the return of the real proprietor. The dispute is decided in the air; and each party endeavors to get above the other, as birds of prey are wont to do in order to give a downward blow. The undermost one, to avoid the stroke, instead of flying forward or laterally, always flies backward. The encounter is so violent, that when they strike, both parties fall to the ground.

Vegetable Motion. Though vegetables have not the power of moving from one place to another like animals, they are nevertheless capable of moving their different parts in such a manner as would lead us to suspect that they are actuated by a sort of instinct. Hence many have been induced to suppose, that the animal and vegetable kingdoms are in a manner indistinguishable from one another; and that the highest degree of vegetable life can hardly be known from the lowest degree of animal life. The essential and inexpressible distinction however between the two, is the faculty of sensation, and loco-motion in consequence of it. Were it not, indeed, for the manifestation of sense by moving from one place to another, we should not be able to tell whether vegetables were possessed of sensation or not; but whatever motions they may be possessed of, it is certain that no vegetable has the faculty of moving from one place to another. Some have endeavored to distinguish the two kingdoms by the digestion of food; alleging that plants have no proper organs, such as a stomach, &c. for taking in and digesting their aliment. But to this it has been replied, that the whole body of a vegetable is a stomach, and absorbs its food at every pore. This, however, seems not to be a sufficient answer. All animals take in their food at intervals, and there is not a single instance of one which eats perpetually. The food is also taken into the body of the animal, and application of the parts made by means of the internal organization of the viscus; but in vegetables, their whole bodies are immersed in their food, and absorb it by the surface, as animal bodies will sometimes absorb liquids when put into them. The roots of a tree indeed will change their direction when they meet with a stone, and will turn from barren into fertile ground; but this is evidently mere mechanism, without any proof of will or sensation; for the nourishment of the root comes not from the stone, but from the earth around it; and the increase in size is not owing to any expansion of the matter which the root already contains, but to the apposition of new matter; whence the increase in size must always take place in the direction from whence the nourishment proceeds. On this principle also we may explain the reason why the roots of a tree, after having arrived at the edge of a ditch, instead of shooting out into the air, will creep down the one side, along the bottom, and up the other.

In their other movements the vegetables discover nothing like sensation or design. They will indeed uniformly bend towards light, or towards water; but in the one case we must attribute the phenomenon to the action of the elements of light and air upon them; and in the latter, the property seems to be the same; with what in other cases we call attraction. Thus, if
The motions of the sensitive plant, and others of the same kind, have been considered as very wonderful; but it is doubtful if any of them are really more so than that of the vine just mentioned. None of these show any kind of propensity to move without an actual touch. A very slight one, indeed, marks the sensitive plant, but the whole branch, together with the leaves, bend down towards the earth.

These phenomena are by some ascribed to electricity. Even the motions of the *hedge-sparrow wing*, which at first sight seem so much more surprising than those of the sensitive plant, may, it is supposed, admit of explanation upon the same principle. The American plant called *dionaea muscipula*, or Venus's fly-trap, is another example of very wonderful mechanism in vegetables, though even this does not argue any degree of sensation in this plant more than in others. The leaves of the diones are jointed, and furnished with two rows of prickles. A number of small glands upon the surface secrete a sweet juice which entices flies to come and settle upon it; but the moment these insects touch the fatal spot, the leaves fold up, and squeeze them to death between the prickles. The leaves fold up in the same manner when the plant is touched with a straw or pin. The *drosera rotundifolia* and *longifolia*, round and long-leaved sundew, plants of our own country, not uncommon in boggy ground, possess a similar structure, and perform similar functions.

The folding up of the leaves of certain plants in the absence of the sun's light, called their *sleep*, affords another very curious instance of vegetable motion. Almost all vegetables, indeed, undergo such a remarkable change in the night, that it is difficult to know exactly how many kinds do really sleep. They fold up their leaves in many different ways; but all agree in disposing of them in such a manner as to afford the best protection to the young stems, flower buds or fruit. The leaves of the tamarind tree contract round the young fruit in order to protect it from nocturnal cold; and those of *senna*, *glycine*, and many other pinnatifidaceous plants, dispose of their leaves in the same manner. The leaves of the chickweed, *asarabae atriplicis*, &c. are disposed in opposite pairs: in the night time they rise perpendicular, and join so close at the top that the flowers are concealed by them. In like manner do the leaves protect the flowers of the fida or allium throughout, asthenia, solomon, and the Egyptian vetch. All these are erected during the night; but those of the white lupine, in time of sleep, hang down.

The flowers of plants also have motions peculiar to themselves. Many of them during the night are enclosed in their calyxes. Some, particularly those of the German mea, géraniaceae, striata, and common yellow grass, when asleep, bend towards the earth; and which means the monstrous effects of rain or dew are prevented. All these motions have been commonly ascribed to the sun's rays; and Mr. Smellie informs us that in some of the examples above mentioned the effects were evidently to be ascribed to heat: but plants kept in a hot-hose, where the temperature of the day and night are alike, contract their leaves, and sleep in the same manner as if they were exposed to the open air; "whence is appears (says he), that the sleep of plants is owing rather to a peculiar law, than to a quicker or slower motion of the juices." He suspects, therefore, that as the sleep of plants is not owing to the mere absence of heat, it may be occasioned by the want of light; and to ascertain this he proposes an experiment of throwing upon them a strong artificial light. "If notwithstanding this light (says he), the plants are not moved, but continue to sleep as usual, then it may be presumed that their organs, like those of animals, are not only irritable, but require the restoration of some invigorating influence which they have lost while awake, by the agitation of the air and rays of the sun's rays, by the act of growing, or by some other latent cause." On this, however, we must remark, that the throwing of artificial light upon plants cannot be attended with the same consequences as that of the light of the sun, unless the former were as strong as the latter, which is impossible; and even granting that we could procure an artificial light as strong as that of the sun, a difference might be occasioned by the different directions of the rays, those of the sun being very nearly parallel, while the rays of all artificial light diverge very greatly. If, therefore, we are to make an experiment of this kind, the rays should be rendered parallel by means of a brassing mirror. Here again we would be involved in a difficulty; for the rays of the sun proceed all in one direction, but as of necessity we must employ different mirrors in our experiment, the light must fall upon the plant in different directions, so that we could not reasonably expect the same result as when the plants are directly exposed to the rays of the sun.

The motion of plants, not being deducible from sensation, as in animals, must be ascribed to that property called irritability; and this property is possessed insensibly by the parts of animals in a greater degree than even by the most irritable vegetable. The muscular fibers will contract on the application of any stimulating substance, even after they are detached from the body to which they belonged. The heart of a frog will continue to beat when pricked with a pin for several hours after it is taken out of the body. The heart of a viper, or of a turtle, beats distinctly from 20 to 30 hours after the death of these animals: When the intestines of a dog, or any other quadruped, are suddenly cut into different portions, all of them crawl about like worms, and contract upon the slightest touch. The heart, intestines, and diaphragm, are the most irritable.

the greatest affinity with those of animals, are the course of the sap, the passage of the air in the trachae, the different positions which the flowers of certain plants take at certain hours of the day, &c. But if we attend to the manner in which all these motions in plants are performed, we shall find that they present a greater number of modifications than the analogous motions that take place in animals. The temperature of the atmosphere, its agitation, light, &c. have great influence on the motions of plants, by accelerating or retarding the course of their fluids; and, as they cannot change their place, these variations produce in them changes more obvious and more uniform than in animals.

Our author now proceeds to inform us, that some of the motions of plants are occasioned by the rarity of the juices in plants, and others by their abundance. Of the former kind are those by which the capsules of some plants suddenly burst with a spring, and throw their seeds to some distance. Of the other kind are the action of the stamens in the *pistillaria*, the infection of the peduncles of flowers, and of the pistils. Those motions (says he) which are particularly observed in the organs destined to the reproduction of the individual, not supposing circumstances that render them absolutely necessary, seem in some measure to be the effect of a particular combination: they are, however, merely mechanical; for they are always produced in the same way and in the same circumstances. Thus the rose of Jericho, and the dry fruit of several species of *mesembryanthemum*, do not open but when their vessels are full of water.

The sudden disengagement of fluids produces a kind of motion. To this cause we must attribute a great number of phenomena observable in the leaves of several plants, and which do not depend on irritability. The small glands in each leaf of the *diasema* are no sooner punctured by an insect, that it instantly folds up and seizes the animal: the puncture seems to operate a disengagement of the fluid which kept the leaf expanded by filling its vessels. This explanation is the more probable, that in the early state of the vegetation of this plant, when the small glands are hardly evolved, and when probably the juice does not run in sufficient abundance, the leaves are folded up exactly as they appear when punctured by an insect at a more advanced period. We observe a phenomenon similar to this in both species of the *drosera* (sun-dew), mentioned above. The mechanism here is very easily observable: the leaves are at first folded up; the juices are not yet propelled into the fine hairs with which they are covered; but after they are expanded, the presence of the fluid is manifest by a drop seen at the extremity of each hair; it is by absorbing this fluid that an insect empties the vessels of the leaf, which then folds up, and resumes its first state: the promptitude of the action is proportioned to the number of hairs touched by the insect. This motion in some degree resembles that which takes place in the limb of an animal kept in a state of flexion by a tumor in the joint; when the matter which obstructed the motion is discharged, the limb instantly resumes its former position. The phenomena that depend on the abundance of fluids are particularly evident in plants which grow in wet soils; the *drosera* and *diasema* are of this kind: and it is known
by the experiments of Mess. Du Fay and Du Hamel, that sensitive plants are particularly sensible when the
sun is obscured by clouds and the air warm and moist. The influence of external causes sometimes so modifies
the vital motions in plants, that we would be tempted to ascribe them to volition, like those that depend enti-
really on that faculty in animals. If we set a pole in the ground near a twining plant, it always lays hold of
the pole for support, in whatever place we put it. The same thing occurs in the tendrils of the vine; which always attach themselves to the support presented them, or whatever side it may be placed, provided they can reach it; but these motions are entirely vital: the
twining plants and the tendrils direct themselves to every quarter, and consequently cannot fail of meet-
ing with the bodies within their reach. These motions are performed as long as the parts continue to
grow; but when they cease to elongate, if they have not been able to reach any body on which they can fix,
they bend back upon themselves. This and other obser-
vations show how far the vital motions in plants may be modified by external causes, and how essentially
they differ from those that are the effect of volition in animals.

Some plants appear endowed with no sort of motion: some have leaves that can move in different di-
rections: their motions are generally modified by dif-
ferent causes; but none appear so eminently possessed
of this quality as the hedyarum gyrans of Linneus.—
No part of this plant shows any signs of irritability upon
application of stimulus: and the motion of its folioli ceases when the leaflets are agitated by the wind. —
When the sun is warm, the little leaves of the bed-
yarum are also inmovable; but when the weather is
warm and moist, or when it rains, they move very fre-
ely. This motion seems indispensably necessary to
the plant; for it begins as soon as the first leaves un-
fold, and continues even during the night; but in
time it grows weaker. In our stoves it is most con-
derable during the first year; in the second, it is not
very sensible: in its native place all the leaves have a
motion never observed here. The moving leaflets are
most agitated while the plants are in full flower, and
the process of fructification goes on. The oscillatory
motion is so natural to it, that it not only remains for
three or four days in the leaflets of a branch that has
cut off and put in water, but is even continued
though the branch be exposed to the air. The leaves
seem to perform the office of the heart in vegetables.
When a plant is stripped of its leaves, the progress of
vegetation is arrested; and such vegetables resemble
those animals which have a periodical sleep, induced by
a diminution of the action of the heart. Many plants
hardly show any signs of motion; many seem also whol-
ly cataleptic; which is rarely if ever found in animals.
The footstalks of the flowers of dracopechum, a Vir-
ginian plant, preserve themselves in whatever position
they are placed.

Muscular Motion. See Muscle.

MOTIVE, is sometimes applied to that faculty of
the human mind, by which we pursue good and avoid
evil. Thus Hobbes distinguishes the faculties of the
mind into two sorts, the cognitive and motive.

MOTOUALIS, a small nation of Syria, inhabiting
to the east of the country of the DRUSES, in the valley
Vol. XIV. Part II.

which separates their mountains from those of Damas-
cus; of which the following account is given by Vol-
ney in his Travels, vol. ii.

The characteristic distinction between them and the
other inhabitants of Syria (says our author) is, that
they, like the Persians, are of the sect of Ali, while
all the Turks follow that of Omar or Moaouia. This
distinction, occasioned by the schism which in the
36th year of the Hegira arose among the Arabs, res-
specting the successors of Mahomet, is the cause of an
irreconcilable hatred between the two parties. The
sectaries of Omar, who consider themselves as the only
orthodox, assume the title of Sonnites, which has that
signification, and term their adversaries Shites, that is
"sectaries of Ali." The word Motoulai has the same
meaning in the dialect of Syria. The followers of
Ali, dissatisfied with this name, substitute that of Adlia,
which means "assertors of justice," literally "Justi-
ciation:" a denomination which they have assumed
in consequence of a doctrinal point they advance in
opposition to the Sonnite faith. A small Arabic trea-
sise, entitled Theological Fragments concerning the
Sects and Religions of the World, has the following
passage:

"These sectaries who pretend that God acts only
on principles of justice, conformable to human reason,
are called Adlia or Justiciarians. God cannot (say
they) command an impracticable worship, nor ordain
impossible actions, nor enjoin men to perform what is
beyond their ability; but wherever he requires obedi-
ence, will bestow the power to obey. He removes the
cause of evil, he allows us to reason, and imposes only
what is easy, not what is difficult; he makes no man
responsible for the actions of another, nor punishes
him for that in which he has no part; he imputes not
as a crime what himself has created in man; nor does
he require him to avoid what destiny has decreed.—
This would be injustice and tyranny, of which God
is incapable, from the perfection of his being." To
this doctrine, which diametrically opposes the system
of the Sonnites, the Motoualis add certain ceremonies
which increase their mutual aversion. They curse
Omar and Moaouia as rebels and usurpers; and cele-
brate Ali and Hosain as saints and martyrs. They
begin their ablutions at the elbow, instead of the end
of the finger, as is customary with the Turks; they
think themselves defiled by the touch of strangers; and,
contrary to the general practice of the East, neither eat
nor drink out of a vessel which has been used by a per-
son not of their sect, nor will they even sit with such at
the same table.

These doctrines and customs, by separating the
Motoualis from their neighbours, have rendered them a
distinct society. It is said they have long existed as
a nation in this country, though their name has never
been mentioned by any European writer before the
18th century; it is not even to be found in the maps of
D’Anville: La Roque, who left their country not a
hundred years ago, gives them the name of Amo-
edics. Be this as it may, in the later times their wars,
robberies, successes, and various changes of fortune,
have rendered them of consequence in Syria. Till about
the middle of this century, they only possessed Balbec
their capital, and a few places in the valley, and Ant-
Lebanon, which seems to have been their original

3 N
At that period we found them under a like government with the Druzes, that is to say, under a number of Shaiks, with one principal chief of the family of Harfoush. After the year 1750 they established themselves among the heights of Bekaa, and got footing in Lebanon, where they obtained lands belonging to the Maronites, almost as far as Bsharrâi. They even intimidated them so much by their ravages, as to oblige the emir Yousef to attack them with open force and expel them; but on the other side, they advanced along the river even to the neighbourhood of Sour (Tyre). In this situation, Shaik Daher had the address, in 1760, to attack them to his party.—The pachas of Saïde and Damascus claimed tributes, which they had neglected paying; and complained of several robberies committed on their subjects by the Motoualis; they were desirous of chastising them; but this vengeance was neither certain nor easy. Daher interposed; and by becoming security for the tribute, and promising to prevent any depredations, acquired allies who were able, as it is said, to arm 10,000 horsemen, all complete and formidable troops. Shortly after they took possession of Sour, and made this village their principal sea port. In 1771 they were of great service to Ali Bey and Daher against the Ottomans. But Emir Yousef having in their absence armed the Druzes, ravaged their country. He was besieging the castle of Djezin, when the Motoualis, returning from Damascus, received intelligence of this invasion. At the relation of the barbarities committed by the Druzes, an advanced corps, of only 500 men, were so enraged, that they immediately rushed forward against the enemy, determined to perish in taking vengeance. But the surprise and confusion they occasioned, and the discord which reigned between the two factions of Mansour and Yousef, so much favoured this desperate attack, that the whole army, consisting of 25,000 men, was completely overthrown.

In the following year, the affairs of Daher taking a favourable turn, the zeal of the Motoualis cooled towards him; and they finally abandoned him in the catastrophe in which he lost his life. But they have suffered for their imprudence under the administration of the pacha who succeeded him. Since the year 1777, Djezzar, master of Acre and Saïde, has incessantly laboured to destroy them. His persecution forced them in 1784 to a reconciliation with the Druzes, and to enter into an alliance with the emir Youssef. Though reduced to less than 700 armed men, they did more in that campaign than 15,000 or 20,000 Druzes and Maronites assembled at Dair-el-Kamar. They alone took the strong fortress of Mar-Djezbai; and put to the sword 50 or 60 Epirots who defended it. But the misunderstanding which prevailed among the chiefs of the Druzes having rendered abortive all their operations, the Pacha has obtained possession of the whole valley, and the city of Balbec itself. At this period not more than 500 families of the Motoualis remained, who took refuge in Anti-Lebanon, and the Lebanon of the Maronites; and, driven as they now are from their native soil, it is probable they will be totally annihilated, and even their very name become extinct.

MOTTO, in armory, a short sentence or phrase, carried in a scroll, generally under, but sometimes over the arms; sometimes alluding to the bearing, sometimes to the name of the bearer, and sometimes containing whatever pleases the fancy of the deviser.

Moveable, in general, denotes any thing capable of being moved.

Moveable Feasts, are such as are not always held on the same day of the year or month; though they be on the same day of the week. See Feasts.

Thus, Easter is a moveable feast, being always held on the Sunday which falls upon or next after the first full moon following the 21st of March.

All the other moveable feasts follow Easter, i.e. they keep their distance from it; so that they are fixed with respect thereto.

Such are Septuagesima, Sexagesima, Ash Wednesday, Ascension Day, Pentecost, Trinity Sunday, &c., which see under their proper articles, Septuagesima, &c.

Moveable Subject, in Law, any thing that moves itself, or can be moved; in contradistinction to immovable or heritable subjects, as lands, houses, &c.

Movement, Motion, a term frequently used is the same sense with automaton.

The most usual movements for keeping time are watches and clocks: the first are such as show the parts of time, and are portable in the pocket; the second, such as publish it by sounds, and are fixed as furniture. See Horology.

Movement, in its popular use among us, signifies all the inner works of a watch, clock, or other engine, which move, and by that motion carry on the design of the instrument.

The movement of a clock or watch is the inside, or that part which measures the time, strikes, &c. exclusive of the frame, case, dial plate, &c.

The parts common to both of these movements are, the main-spring, with its appurtenances; lying in the spring box, and in the middle thereof lapping about the spring-arbor, to which one end of it is fastened. A-top of the spring-arbor is the endless screw and its wheely, but in spring-clocks, this is a ratchet-wheel with its click; that stops it. That which the main-spring draws, and round which the chain or string is wrapped, is called the fusi; this is ordinarily taper; in large works, going with weights, it is cylindrical, and called the barrel. The small teeth at the bottom of the fusi or barrel, which stop it in winding up, is called the ratchet; and that which stops it when wound up, and is for that end driven up by the spring, the gard-en. The wheels are various: the parts of a wheel are, the hoop or rim, the teeth, the cross and the collet or piece of brass soldered on the arbor or spindle wherein the wheel is riveted. The little wheels, playing in the teeth of the larger are called pinions; and their teeth, which are 4, 5, 6, 8, &c., are called lèves; the ends of the spindle are called pivots; and the guttered wheel, with iron spikes at bottom, wherein the line of ordinary clocks runs, the pulley. We need not say any thing of the hand, screws, wedges, stops, &c. See Wheel, Fusi, &c.

Perpetual Movement. See Perpetual Motion.

Moufet, Thomas, a celebrated English physician, was born at London, and practised medicine with great reputation. Towards the latter end of his
Moulds of moneyers are frames full of sand, wherein the plates of metal are cast that are to serve for the striking of species of gold and silver. See Coining.

A sort of concave moulds made of clay, having within them the figures and inscriptions of ancient Roman coins, are found in many parts of England, and supposed to have been used for the casting of money. Mr. Baker having been favoured with a sight of some of these moulds found in Shropshire, bearing the same types and inscriptions with some of the Roman coins, gave an account of them to the Royal Society. They were found in digging of sand, at a place called Rycote in Shropshire, about a mile from the great Walsingham street road. They are all of the size of the Roman denarius, and of little more than the thickness of our halfpenny. They are made of a smooth pot or brick clay, which seems to have been first well cleansed from dirt and sand, and well beaten or kneaded, to render it fit for taking a fair impression. There were a great many of them found together, and there are of them not unfrequently found in Yorkshire; but they do not seem to have been met with in any other kingdom, except that some have been said to be once found at Lyons. They have been sometimes found in great numbers joined together side by side, on one flat piece of clay, as if intended for the casting of a great number of coins at once; and both these, and all the others that have been found, seem to have been of the emperor Severus. They are sometimes found impressed on both sides, and some have the head of Severus on one side and some well known reverse of his on the other. They seem plainly to have been intended for the coinage of money, though it is not easy to say in what manner they can have been employed for that purpose, especially those which have impressions on both sides, unless it may be supposed that they coined two pieces at the same time by the help of three moulds, of which this was to be the middle one. If by disposing these into some sort of iron frame or case, as our letter-founders do the brass moulds for casting their types, the melted metal could be easily poured into them, it would certainly be a very easy method of coining, as such moulds require little time or expense to make, and therefore might be supplied with new ones as often as they happen to break.

These moulds seem to have been burnt or baked sufficiently to make them hard; but not so as to render them porous like our bricks, whereby they would have lost their smooth and even surface, which in these is plainly so close, that whatever metal should be formed in them would have no appearance like the sandholes by which counterfeit coins and metals are usually detected.

Moulds of founders of small works are like the frames of coiners: it is in these frames, which are likewise filled with sand, that their several works are fashioned; into which, when the two frames of which the mould is composed, are rejoined, the melted brass is poured.

Moulds of letter-founders are partly of steel and partly of wood. The wood, properly speaking, serves only to cover the real mould which is within, and to prevent

MOUG-DEN, or CHIN-TANG; a city of Chinese Tartary, and capital of the country of the Manchews or Eastern Tartars. These people have been at great pains to ornament it with several public edifices, and to provide it with magazines of arms and storehouses. They consider it as the principal place of their nation; and since China has been under their dominion, they have established the same tribunals here as at Peking, excepting that called Lit-pou: there tribunals are composed of Tartars only; their determination is final; and in all their acts they use the Tartar characters and language. The city is built on an eminence; a number of rivers add much to the fertility of the surrounding country. It may be considered as a double city, of which one is enclosed within the other: the interior contains the emperor's palace, hotels of the principal mandarins, sovereign courts, and the different tribunals; the exterior is inhabited by the common people, tradesmen, and for those who by their employments or professions are not obliged to lodge in the interior. The latter is almost a league in circumference; and the walls which enclose both are more than three leagues round: these walls were entirely rebuilt in 1637, and repaired several times under the reign of King-hi.

MOULD, or MOLD, in the mechanic arts, &c. a cavity artificially cut, with a design to give its form or impression to some softer matter applied therein. Moulds are implements of great use in sculpture, foundry, &c. The workmen employed in melting the mineral or metallic ore dug out of mines, have their several moulds to receive the melted metal as it comes out of the furnace; but these are different according to the diversity of metals and works. In gold mines, they have moulds for ingots; in silver mines, for bars; in copper and lead mines, for pigs or salmon; in tin mines, for pigs and ingots; and in iron mines, for sows, chimney backs, anvils, caldrons, pots, and other large utensils and merchandise of iron; which are here cast, as it were, at first hand.

Moulds of founders of large works, as statues, bells, guns, and other brazen works, are of wax, supported within-side by what we call a core, and covered with outside with a case or case. It is in the space which the wax took up, which is afterwards melted away to leave it free, that the liquid metal runs, and the work
MOULD. [468] MOULD.

Moulds prevent the workman, who holds it in his hand, from being incommoded by the heat of the melted metal. Only one letter or type can be formed at once in each mould. See Letter Foundery.

Moulds, in the manufacture of paper, are little frames composed of several brass or iron wires, fastened together by another wire still finer. Each mould is of the bigness of the sheet of paper to be made, and has a rim or ledge of wood to which the wires are fastened. These moulds are more usually called frames or forms. See Paper-Making.

Moulds, with furnace and crucible makers, are made of wood, of the same form with the crucibles; that is, in form of a truncated cone: they have handles of wood to hold and turn them with, when being covered with the earth. The workman has a mind to round or flatten his vessel.

Moulds for leaden bullets are little iron pieces, each of whose branches terminates in a hemispherical concave, which when shut from an entire sphere. In the lips or sides where the branches meet is a little jet or hole, through which the melted lead is conveyed.

Laboratory Moulds are made of wood, for filing and driving all sorts of rockets and cartridges, &c.

Glassiers Moulds. The glassiers have two kinds of moulds, both serving to cast their lead: in the one they cast the lead into long rods or canes fit to be drawn through the vice, and the grooves formed therein; this they sometimes call ingot-mould. In the other, they mould those little pieces of lead a line thick and two lines broad, fastened to the iron bars. These may be also cast in the vice.

Goldsmiths Moulds. The goldsmiths use the bones of the cuttle fish to make moulds for their small works; which they do by pressing the pattern between two bones, and leaving a jet or hole to convey the metal through, after the pattern has been taken out.

Mould, among masons, is a piece of hard wood or iron hollowed within side, answerable to the contours of the mouldings or cornices, &c. to be formed. This is otherwise called

Moulds, among plumbers, are the tables on which they cast sheets of lead. These they sometimes call simply tables. Besides which they have other real moulds, wherewith they cast pipes without soldering. See each described under Plumbery.

Moulds, among the glass grinders, are wooden frames, whereas they make the tubes wherewith they fit their perspectives, telescopes, and other optic machines. These moulds are cylinders, of a length and diameter according to the use they are to be applied to, but always thicker at one end than the other, to facilitate the sliding. The tubes made on these moulds are of two kinds; the one simply of pasteboard and paper; the other of thin leaves of wood joined to the pasteboard. To make these tubes to draw out, only the last or innermost is formed on the mould; each tube made afterwards serving as a mould to that which is to go over it, but without taking out the mould from the first. See Grinding.

Moulds used in basket-making are very simple, consisting ordinarily of a willow or osier turned or bent into an oval, circle, square, or other figure, according to the baskets, panniers, bampers, and other utensils intended. On these moulds they make, or more properly measure all their work; and accordingly they have moulds of all sizes, shapes, &c.

Mould, in ship-building, a thin flexible piece of timber, used by shipwrights as a pattern whereby to form the different curves of the timbers, and other compassing pieces in a ship's frame. There are two sorts of these, viz. the bend mould and hollow mould; the former of these determines the convexity of the timbers, and the latter their concavity on the outside, whereby they approach the heel, particularly towards the extremities of the vessel. The figure given to the timbers by this pattern is called their bending.

Moulds, among tallow chandlers, are of two kinds: the first for the common dipped candles, being the vessel wherein the melted tallow is disposed, and the wick dipped. This is of wood, of a triangular form, and supported on one of its angles: so that it has an opening of near a foot a-top; the other, used in the fabric of mould candles, is of brass, pewter, or tin.—Hence each candle has its several mould. See Candle.

Mould, among gold-beaters, a certain number of leaves of vellum or pieces of gut, cut square of a certain size, and laid over one another, between which they put the leaves of gold and silver which they beat on the marble with the hammer. See Gold Leaf.

They have four kinds of moulds; two whereof are of vellum and two of gut; the smallest of those of vellum consists of 40 or 50 leaves; the largest contains 100: for the others, each contains 500 leaves. The moulds have all their several cases, consisting of two pieces of parchment, serving to keep the leaves of the mould in their place, and prevent their being disorder ed in beating.

Mould, in Agriculture, a general name for the soil or earthy substance with which the dry land is generally covered, and in which all kinds of vegetables take root and grow. It is far from being an homogeneous substance; being composed of decayed animal and vegetable matters, along with calcareous, argillaceous, and siliceous earths, mixed together in various proportions, and with the different degrees of moisture, constituting every variety of Soil.

MOULINESS, is a white down or lanugo, which is produced on the surface of animal or vegetable matters in a state of putrefaction; and which viewed through a microscope appears like a kind of meadow, out of which arise herbs and flowers. See Mucous, Botany Index.

MOULDING, any thing cast in a mould, or that seems to have been so, though in reality it were cut with a chisel or the axe.

Mouldings, in Architecture, projections beyond the naked wall, column, wainscot, &c. the assemblage of which forms cornices, door cases, and other decorations of Architecture. See that article.

MOULINET is used in Mechanics, to signify a roller, which being crossed with two levers, is usually applied to cranes, capstans, and other sorts of engines of the like nature to draw ropes, heave up stones, &c.

MOULINET is also a kind of turnstile or wooden cross, which turns horizontally upon a stake fixed in the ground; usually placed in passages to keep set horses, and to oblige passengers to go and come by one. These moulins are often set near the outworks of
attraction of mountains. This is a late discovery, and a very considerable confirmation of Sir Isaac Newton's theory of universal gravity. According to the Newtonian system, an attractive power is not only exerted between those large masses of matter which constitute the sun and planets, but likewise between all comparatively smaller bodies, and even between the smallest particles of which they are composed. Agreeably to this hypothesis, a heavy body, which ought to gravitate or tend toward the centre of the earth, in a direction perpendicular to its surface, supposing the said surface to be perfectly even and spherical, ought likewise, though in a less degree, to be attracted and tend towards a mountain placed on the earth's surface; so that a plumb line, for instance, of a quadrant, hanging in the neighbourhood of such a mountain, ought to be drawn from a perpendicular situation, in consequence of the attractive power of the quantity of matter of which it is composed acting in a direction different from that exerted by the whole mass of matter in the earth, and with a proportionally inferior degree of force.

Though Sir Isaac Newton had long ago hinted at an experiment of this kind, and had remarked, that "a mountain of an hemispherical figure, three miles high and six broad, would not, by its attraction, draw the plumb line two minutes out of the perpendicular (E)" yet no attempt to ascertain this matter by actual experiment was made till about the year 1738; when the French academicians, particularly Messrs. Bouguer and Condamine, who were sent to Peru to measure a degree under the equator, attempted to discover the attractive power of Chimboraço, a mountain in the province of Quito. According to their observations, which were however made under circumstances by no means favourable to an accurate solution of so nice and difficult a problem, the mountain Chimboraço exerted an attraction equal to eight seconds. Though this experiment was not perhaps sufficient to prove satisfactorily even the reality of an attraction, much less the precise quantity of it; yet it does not appear that any steps had been since taken to repeat it.

Through the munificence of his Britannic majesty, the Royal Society were enabled to undertake the execution of this delicate and important experiment; the astronomer royal was chosen to conduct it. After various inquiries, the mountain Schellahien, situated nearly in the centre of Scotland, was pitched upon as the most proper for the purpose that could be found in this island. The observations were made by taking the meridian zenith distances of different fixed stars, near the zenith, by means of a zenith sector of ten feet radius; first on the south, and afterwards on the north side of the hill, the greatest length of which extended in an east and west direction.

It is evident, that if the mass of matter in the hill exerted any sensible attraction, it would cause the plumb-line of the sector, through which an observer viewed a star in the meridian, to deviate from its perpendicular situation, and would attract it contrariwise at the

(E) By a very easy calculation it is found that such a mountain would attract the plumb line 1° 18' from the perpendicular.
Mountains. The two stations, thereby doubling the effect. On the south side the plummet would be drawn to the northward by the attractive power of the hill placed to the northward of it: and on the north side, a contrary and equal deflection of the plummet line would take place in consequence of the attraction of the hill, now to the southward of it. The apparent zenith distances of the stars would be affected contrariwise; those being increased at the one station which were diminished at the other: and the correspondent quantities of the deflection of the plummet line would give the observer the sum of the contrary attractions of the hill, acting on the plummet at the two stations; half of which will of course indicate the attractive power of the hill.

The various operations requisite for this experiment lasted about four months; and from them it appears that the sum of the two contrary attractions of the mountain Schellalien, in the two temporary observations which were successively fixed half way up the hill (where the effect of its attraction would be greatest), was equal to \(11^\circ.6\) — From a rough computation, founded on the known law of gravitation, and on an assumption that the density of the hill is equal to the mean density of the earth, it appears that the attraction of the hill should amount to about the double of this quantity. From thence it was inferred that the density of the hill is only about half the mean density of the earth. It does not appear, however, that the mountain Schellalien has ever been a volcano, or is hollow; as it is extremely solid and dense, and seemingly composed of an entire rock.

The inferences drawn from these experiments may be reduced to the following:

1. It appears, that the mountain Schellalien exhibits a sensible attraction; therefore, from the rules of philosophizing, we are to conclude, that every mountain, and indeed every particle of the earth, is endowed with the same property, in proportion to its quantity of matter.

2. The law of the variation of this force, in the inverse ratio of the squares of the distances, as laid down by Sir Isaac Newton, is also confirmed by this experiment. For if the force of attraction of the hill had been only to that of the earth, as the matter in the hill to that of the earth, and had not been greatly increased by the near approach to its centre, the attraction thereof must have been wholly insensible. But now, by only supposing the mean density of the earth to be double to that of the hill, which seems very probable from other considerations, the attraction of the hill will be reconciled to the general law of the variation of attraction in the inverse duplicate ratio of the distances, as deduced by Sir Isaac Newton from the comparison of the motion of the heavenly bodies with the force of gravity at the surface of the earth; and the analogy of nature will be preserved.

3. We may now, therefore, be allowed to admit this law, and to acknowledge, that the mean density of the earth is at least double of that at the surface; and consequently that the density of the internal parts of the earth is much greater than near the surface. Hence also, the whole quantity of matter in the earth will be at least as great again, as if it had been all composed of matter of the same density with that at the surface, or will be about four or five times as great as if it were all composed of water. — This conclusion, Mr. Yermolaev in his Maskelyne, is totally contrary to the hypothesis of some naturalists, who suppose the earth to be only a great hollow shell of matter; supporting itself from the property of an arch, with an immense vacuum in the midst of it. But were that the case, the attraction of mountains, and even smaller inequalities in the earth's surface would be very great, contrary to experiment, and would affect the measures of the degrees of the meridian much more than we find they do; and the variation of gravity, in different latitudes, in going from the equator to the poles, as found by pendulums, would not be near so regular as it has been found by experiment to be.

4. As mountains are by these experiments found capable of producing sensible deflections of the plummet lines of astronomical instruments; it becomes a matter of great importance, in the mensuration of degrees in the meridian, either to choose places where the irregular attraction of the elevated parts may be small; or where, by their situation, they may compensate or counteract the effects of each other. — See MOUNTAINS, SUPPLEMENT.

For measuring the heights of mountains, see BAROMETER.

Burning Mountains. See Ætna, Hecla, Vesuvius; see also Volcano, Geology Index.

Marble Mountains. Of these there are great numbers in Egypt, from which, though immense quantities have been carried off for the multitude of great works erected by the ancient Egyptians; yet in the opinion of Mr Bruce, who passed by them in his journey to Abyssinia, there is still a sufficient supply to build Rome, Athens, Corinthus, Syracuse, Memphis, Alexandria, and half a dozen more of such cities.

The first mountain of this kind mentioned by Mr Bruce is one opposite to Terfowey, consisting partly of green marble, partly of granite, with a red blush upon a gray ground, and square oblong spots. Here he saw a monstrous obelisk of marble, nearly square, broken at the end, and nearly 30 feet long and 10 feet in the face. Throughout the plain there were scattered small pieces of jasper, with green, white, and red spots, called in Italy diaspro sanguineo; and all the mountains upon that side seemed to consist of the same materials. From Mr Bruce's description of these mountains, it would appear that they are composed of serpentine, and not of calcareous marble.

Written Mountain, Mountain of Inscriptions, or Jbel-al-Makatteh, a supposed mountain or chain of mountains, in the wilderness of Sinaï; on which, for a great extent of space, the marble of which the mountain consists is inscribed with innumerable characters, reaching from the ground sometimes to the height of 12 or 14 feet. These were mentioned by a Greek author in the third century, and some of them have been copied by Pococke and other late travellers; but, after all, there is still a very great uncertainty even of the existence of such mountain or mountains. The vast number of these inscriptions, the desert place in which they are found, and the length of time requisite for executing the task, have induced a notion by no means unnatural, that they are the work of the Israelites during their forty years wandering in the wilderness. Others are of opinion that they contain nothing of any importance,
M. Niebuhr, who visited this country during his travels in the east, made every attempt in his power, though without success, to obtain a sight of this celebrated mountain; they, however, directed him to an Arabian sheik, who had passed all his lifetime in travelling between Suez and Mount Sinai; but he knew no more of it than the former. Understanding, however, that a considerable reward would be given to any person who would conduct them thither, this Arab directed them to another; who pretended not only to know that mountain, but all others upon which there were any inscriptions throughout the desert. On inquiring particularly, however, our travellers found that he was not to be depended upon; so that they were obliged to have recourse to a guide among who by his conversation convinced them that he had seen mountains with inscriptions in unknown characters upon them. It does not appear, however, that this person was very capable, more than the rest, of leading them to the place they so much wished for; though he conducted them to some rocks upon which there were inscriptions in unknown characters. They are most numerous in a narrow pass between two mountains named Om-en-Ridisthein; and, says M. Niebuhr, "the pretended Jabel-el-Mokatteb may possibly be in its neighbourhood." Some of these inscriptions were copied by our author; but he does not look upon them to be of any consequence. They seem (says he) to have been executed at idle hours by travellers, who were satisfied with cutting the unpolished rock with any pointed instrument, adding to their names and the date of their journeys some rude figures, which bespeak the hand of a people but little skilled in the arts. When such inscriptions are executed with the design of transmitting to posterity the memory of such events as might afford instructive lessons, greater care is generally taken in the preparation of the stones, and the inscriptions are engraven with more regularity."

When M. Niebuhr arrived at last at the mountain to which the sheik had promised to conduct him, he did not find any inscriptions; but on climbing up to the top, he found out an Egyptian cemetery, the stones of which were covered with hieroglyphs. The tomb stones are from five to seven feet in length, some standing on end and others lying flat; and the more carefully they are examined (says he), the more certainly do they appear to be sepulchral stones, having epitaphs inscribed on them. In the middle of the stones is a building, of which only the walls now remain; and within it are likewise a great many of the sepulchral stones. At one end of the building seems to have been a small chamber, of which the roof still remains. It is supported upon square pillars; and these, as well as the walls of the chamber, are covered with hieroglyphic inscriptions. Through the whole building are various busts executed in the manner of the ancient Egyptians. The sepulchral stones and the busts are of hard and fine grained sand stone." M. Niebuhr is of opinion that this cemetery was not the work of the Egyptians themselves, but of some colony which came from Egypt, and had adopted the manners and customs of the people. He supposes that it might have been built by the Arabs, who had conquered Egypt under the shepherd kings, and adopted the Egyptian manners during their residence there. As it must have belonged to an opulent city, however, he owns that there is a great difficulty in accounting for the existence of such a city in the midst of a desert.

The translator of Volney's travels ascribes these inscriptions to the pilgrims who visit Mount Sinai. But to this, as well as to every other conjecture, there is this objection, that whether the inscriptions be well executed or not, whether they contain matters of importance or not, they ought to have been written in a language which somebody could understand; but from the copies that have been taken of them by Dr. Po coercé and others, it does not appear that they could be explained either by him or any other person.

When Dr. Clayton, bishop of Clapham, visited this part of the world about the year 1723, he expressed the greatest desire to have the matter concerning this written mountain or mountains ascertained, and even made an offer of 500l. sterling to any literary person who would undertake the journey and endeavour to decipher the inscriptions; but no such person has appeared, and the existence of the mountains is testified only by the superior of a convent at Cairo, who gave that mentioned in the beginning of this article. Until that part of the world, therefore, become more accessible to travellers, there is but little hope that we can come to any certainty in the matter. M. Niebuhr plainly, from his own accounts, had not influence enough with the Arabs to show him almost any thing, as they refused to conduct him ever to the summit of Mount Sinai.

**White Mountains.** See **New Hampshire.**

*Mountains of the Moon*, a chain of mountains in Africa, extending between Abyssinia and Monomotapa, and so called from their great height.

*Mountains of the Lion*, also in Africa, divide Nigritia from Guinea, and extend as far as Ethiopia. They were styled by the ancients *the mountains of God*, on account of their being greatly subject to thunder and lightning.

*Mountains of Forty Days*; a mountain of Judaea, situated in the plain of Jericho, to the north of that city. According to the abbe Maritil's description, the summit of it is covered neither with shrubs, turf, nor earth; it consists of a solid mass of white marble, the surface of which is become yellow by the injuries of the air. The path by which you ascend to it (says our author) fills one with terror, as it rises with a winding course between two abysses, which the eye dares scarcely behold. This path is at first pretty broad, but it at length becomes so confined, that one can with difficulty place both feet upon it at the same time. When we had ascended a little higher, we found an Arab stretched out on the path, who made us pay a certain toll for our passage. Here the traveller requires courage. One of the parapets of the path being broke, we clung to the part which remained until we had reached a small grotto, situated very commodiously, as it gave us an opportunity of recovering our breath. When we had rested ourselves a little, we pursued our course, which became still more dangerous. Suspected almost from the rock, and having before our eyes all the horror of the
MOUNTAIN, the precipice, we could advance only by dragging one
foot after the other; so that had the smallest fragments
given way under us, we should have been hurried to
the bottom of this frightful abyss.

"This mountain is one of the highest in the province,
and one of its most sacred places. It takes its name
from the rigorous fast which Christ observed here after
having triumphed over the vanities of the world and
the power of hell. In remembrance of this miracle, a
chapel was formerly constructed on the summit of
the mountain. It may be seen from the plain, but we
could not approach it, as the path was almost entirely
destroyed. It, however, may be accessible on the other
side of the mountain, which we did not visit. A
great many scattered grottos are seen here; in one of
which, according to Quaresimius, were deposited the
bodies of several anchorites, which are still entire.
I have heard the same thing asserted in the country, but
I could never meet with any person who had seen them.
Here we enjoyed the most beautiful prospect imaginable.
This part of the mountain of Forty Days overlooks
the mountains of Arabia, the country of Gilead,
the country of the Ammonites, the plains of Moab, the
plain of Jericho, the river Jordan, and the whole extent of
the Dead sea. It was here that the devil said to the
Son of God, 'All these kingdoms will I give thee,
if thou wilt fall down and worship me.'

MOURNING, a particular dress or habit worn to
signify grief on some melancholy occasion, particularly
the death of friends or of great public characters.—
The modes of mourning are various in various coun-
tries; as also are the colours that obtain for that end.
In Europe, the ordinary colour for mourning is black;
China, it is white; in Turkey, blue or violet; in
Egypt, yellow; in Ethiopia, brown. White obtained
formerly in Castile on the death of their princes.
Herrera observes, that the last time it was used was in 1498,
at the death of Prince John. Each people pretend to
have their reasons for the particular colour of their
mourning; white is supposed to denote purity; yellow,
that death is the end of human hopes, in regard that
leaves when they fall, and flowers when they fade, be-
come yellow: brown denotes the earth, whither the
dead return; black, the privation of life, as being the
privation of light: blue expresses the happiness which
it is hoped the deceased does enjoy; and purple or vi-
olen, sorrow on the one side, and hope on the other, as
being a mixture of black and blue.

MOURNING, among the ancients, was expressed va-
rious ways.

Amongst the Jews, on the death of their relations
or intimate friends, grief or mourning was signified
by weeping, tearing their clothes, smiting their breasts,
or tearing them with their nails, pulling or cutting
off their hair and beard, walking softly, i.e., barefoot,
lying upon the ground, fasting, or eating upon the
ground. They kept themselves close shut up in their
houses, covered their faces, and abstained from all
work, even reading the law, and saying their usual
prayers. They neither dressed themselves, nor made
the beds, nor shaved themselves, nor cut their nails,
nor went into the bath, nor saluted any body: so that
squalor seems to have been an indication of sorrow,
and dirtiness of distress. The time of mourning a-
among the Jews was generally seven days: though this
was lengthened or shortened according to circumstan-
ces; but 30 days were thought sufficient upon the se-
verest occasions. The different periods of the time of
mourning required different degrees of grief, and dif-
ferent tokens of it.

The Greeks, on the death of friends, showed their
sorrow by excluding themselves from all gaiety,
entertainments, games, public solemnities, the enjoyment
of wine, and the delights of music. They sat in gloomy
and solitary places, stripped themselves of all exter-
nal ornaments, put on a coarse black stuff by way of
mourning, tore their hair, shaved their heads, ruled
themselves in the dust and mire, sprinkled ashes on their
heads, smote their breasts with their palms, tore their
faces, and frequently cried out with a lamentable voice
and despairing tone, reiterating the interjection 4, 4, 4, 4;
hence funeral lamentations were called Aฆyai. If they
appeared in public during the time of mourning, they
had a veil thrown over their faces and heads. During
the funeral procession, certain persons called Σταυρὸς
ἐκεχριστός, marched before, and sung melancholy strains
called ὕμνοι, ἀλωνίασμα, ἀλωνία, and Λύπη. These vocal
mourners sung thrice during the procession round the
pilar and round the grave. Flutes were also used to
heighten the solemnity. At the funerals of soldiers,
their fellow soldiers who attended, as a testimony of
their affection, held their shields, their spears, and the
rest of their armour, inverted.

The tokens of private grief among the Romans were
the same as those already observed as customary among
the Greeks. Black or dark brown were the colours of
the mourning habits worn by the men; they were also
common to the women. The mourning of the emperors
at first was black. In the time of Augustus, the women
wore white veils, and the rest of their dress black. From
the time of Domitian they wore nothing but white ha-
bits, without any ornaments of gold, jewels, or pearls.
The men let their hair and beards grow, and wore no
wreaths of flowers on their heads while the days of
mourning continued. The longest time of mourning
was ten months: this was Numa's establishment, and
took in his whole year. For a widow to marry during
this time was infamous. Mourning was not used for
children who died under three years of age. From this
time to ten they mourned as many months as the child
was years old. A remarkable victory, or other happy
event, occasioned the shortening of the time of mour-
ning: The birth of a child, or the attainment of any
remarkable honour in the family, certain feasts in ho-
our of the gods, or the consecration of a temple, had
the same effect. After the battle of Canne, the com-
monwealth decreed that mourning should not be worn
for more than 30 days, that the loss might be forgotten
as soon as possible. When public magistrates died, or
persons of great note, also when any remarkable cal-
munity happened, all public meetings were interrump-
ted, the schools of exercise, baths, shops, temples, and
all places of concourse were shut up, and the whole city
put on a face of sorrow; the senators laid aside the in-
clavus, and the consuls sat in a lower seat than ordinary.
This was the custom of Athens also, and was observed
upon the death of Socrates not long after he had been
sentenced to death by the judges; for he was seen to be
weeping, and distress.

Preface, or mourning women, (by the Greeks called
Σπαραγόμενοι Εὐχαριστο), went about the streets: this was cus-

MOUSSOLE, the name of an East Indian tree, with white tubular flowers, which fall off every day in great plenty. They are of a sweet agreeable smell, and the Gentoos are very fond of wearing them, stringing and bunching them about their necks and arms. The fruit is a pale red cherry, of the shape and size of our white heart cherry, but the footstalk is not quite so long. This fruit has a stone in it, containing a bitter oily kernel. The Indians rub with this oil any part stung by a scorpion or bitten by a centipede, which it soon cures. The crows are very fond of the fruit.

MOUSUL, or Mousul, a large city of Turkey in Asia, and capital of a beglerbegate, stands on the west bank of the Tigris, in the latitude, according to Mr Ives's observation, of 36° 30' north. It is surrounded with stone walls, but has many of its streets lying waste. Tavernier speaks of it as a ruined place, with only two blind markets and a sorry castle; yet, he says, that it is much frequented by merchants, and that its bazaar commands 30,000 men. There is a bridge of boats over the Tigris; and the city is a thoroughfare from Persia to Syria, which makes it a place of trade, and which is more augmented by a constant traffic from this place to Bagdad. The country on this side the river is sandy and barren; but on the opposite side it is exceedingly fruitful, yielding good crops of corn and fruit in abundance. Mr Ives says it was the best built city he had seen in Turkey; but had nothing in it to attract the notice of a European. It was besieged for near six months by Nadir Shah without success. Breaches were frequently made in the walls, and assaults continued for three days successively; but the assailants were constantly repulsed, and the breaches made in the day time repaired during the night. The besieged had unanimously resolved to die rather than to submit. The Turks declared, that should the place be forced to surrender, they were determined to put to death all their wives and daughters first, that they might not fall into the vile hands of the abhorred Persians. The place was therefore defended with uncommon bravery; even the women and children exerted themselves with the greatest alacrity. The Christians behaved in such a manner as to gain the esteem and admiration of the other inhabitants; and some of their churches being demolished, they were afterwards repaired at the expense of government.

In this city there are a great many mosques, the largest and most stately of which is ornamented on the top with green tiles. At the doors of these houses there are usually inscriptions in gilt letters, declaring the awfulness of the building, as being the house of God. One of them has a minaret which bends like those of Bagdad. Some of the most bigotted Turks say, that Mahomet saluted this minaret as he passed; on which it bent its head in reverence to the prophet, and even after continued in that situation. The manufacture of this city is musolen (muslin), which is made very strong and pretty fine. In the year 1757, this city and the country adjacent were visited by a dreadful famine, owing to the preceding hard winter, and innumerable multitudes of locusts, by which the fruits of the earth were destroyed. When Mr Ives was there in 1758, the country was comparatively depopulated. Almost all the brute creation had been destroyed for the subsistence of man. During the famine, the people had eaten dogs, and every kind of animal which is held in abhorrence at any other time, not sparing even their own children; and the dead bodies lay in the streets for want of people to bury them. Their fruit trees were also destroyed by the frost; so that when our author was there scarcely any fruit could be had. The neighbouring mountains afford silver mines; and they would yield much quicksilver if the Turks had either the skill or inclination to work them to advantage. Lanza says, that some time ago an Englishman who travelled through this country got two or three bottles of it, which he presented to the basha as a specimen of what might be done in that way: but no farther attempt was made. Here also are some lead mines, which supply as much of that metal as furnishes them with bullets and some necessary utensils.

MOU-TAN or Peony Shrub of China: also called hooa-chung, or "the king of flowers," and pei-chink, "an hundred ounces of gold," in allusion to the excessive price given formerly by some of the virtuosi for certain species of this plant. The mou-tan seems to claim pre-eminence, not only on account of the splendour and number of its flowers, and of the sweet odour which they diffuse around, but also on account of the multitude of leaves which compose them, and of the beautiful golden spots with which they are interspersed. This plant, which is of a shrubby nature, shoots forth a number of branches, which form a top almost as large as those of the finest orange trees.

MOUTH, in Anatomy, a part of the face, consisting of the lips, the gums, the inside of the cheeks, the palate, the salivary glands, the os hyoides, the uvula, and the tonsils; which see under the article Anatomy.

Mr Derham observes, that the mouth in the several species of animals is nicely adapted to the uses of such a part, and well sized and shaped for the formation of speech, the gathering and receiving of food, the catching of prey, &c. In some creatures it is wide and large, in others little and narrow; in some it is formed with a deep incisure into the head, for the better catching and holding of prey, and more easy commination of hard, large, and troublesome food; and in others with a shorter incisure, for the gathering and holding of herbageous food. In birds it is neatly shaped for piercing the air; hard and horny, to supply the want of teeth; hooked, in the rapacious kind, to catch and hold their prey; long and slender in those that have their food to gorge for in moistish places; and broad and long in those that search for it in the mud. Nor is the mouth less remarkable in insects; in some it is forcipated, to catch, hold, and tear the prey; in others aculeated, to pierce and wound animals, and suck their blood; in others, strongly rigid, with jaws and teeth, to gnaw and scrape.
MUF

MUFFLE. out their food, carry burdens, perforate the earth, nay the hardest wood, and even stones themselves, for houses and nests for their young. MOUHEE, one of the Sandwich islands, discovered by Captain Cook, is 162 miles in circumference. A low isthmus divides it into two circular peninsulas, of which the eastern is double the size of the western. The mountains in both rise to a great height, and may be seen at the distance of more than 30 leagues. The northern shores, like those of Owlyhee, afford no soundings, and the country presents the same appearance of verdure and fertility. The number of inhabitants is computed at about 65,000. W. Long. 175. 56. N. Lat. 20. 53.

MOXA, or MUGWORT of China, is a soft lanuginous substance, prepared in Japan from the young leaves of a species of Artemisia, by beating them together when thoroughly dried, and rubbing them between the hands till only the fine fibres are left. The down on the leaves of mullein, cotton, hemp, &c. answers the same purpose.

In the Eastern countries it is used by burning it on the skin: a little cone of the moxa is laid upon the part, previously moistened, and set on fire at the top; it burns down with a temperate glowing heat, and produces a dark coloured spot, the exucleration of which is promoted by applying a little garlic; the ulcer is left to discharge, or is soon healed, according to the intention in using the moxa.

MOYRA. See MOIRA.

MUCILAGE, in Pharmacy, is in general any viscid or glutinous liquor.

Mucilage also imports the liquor which principally serves to moisten the ligaments and cartilages of the articulations, and is supplied by the mucilaginous glands.

MUCOR, in Botany, a genus of the order of fungi, belonging to the cryptogamia class of plants. See BOTANY INDEX.

MUCUS, a mucilaginous liquor secreted by certain glands, and serving to lubricate many of the internal cavities of the body. In its natural state it is generally limpid and colourless; but, from certain causes, assumes a thick consistence and a whitish colour like pus. For the distinguishing characters between pus and mucus, see CHEMISTRY, p. 2769.

MUCK, or RUNNING A MUCK, is a practice that has prevailed time immemorial in Batavia. To run a muck, in the original sense of the word, is to get intoxicated with opium, and then rush into the street with a drawn weapon, and kill any one that comes in the way, till the party is himself either killed or taken prisoner. If the officer take one of these Amocks or Mohawks (as they have been called by an easy corruption) alive, he has a considerable reward; and the unhappy wretch is always broken alive on the wheel: but such is the fury of their desperation, that three out of four are necessarily destroyed in attempting to secure them.

MUD-IGWANA. See MURANA, Ichthyology Index.

MUFFLE, in Chemistry, a vessel employed in some metallurgic operations. In figure it represents an oblong arch or vault, the hinder part of which is closed by a semicircular plane, and the lower part or floor of which is a rectangular plane. It is a little over that is placed horizontally in assaying and enamelling furnaces, so that its open side corresponds with the door of the fire-place of the furnace. Under this arched over small cupels or crucibles are placed; and the substances contained are thus exposed to intense heat without contact of fuel, smoke, or ashes.

MUFTI, the chief of the ecclesiastical order, or primate of the Mussulman religion. The authority of the mufti is very great in the Ottoman empire; for even the sultan himself, if he would preserve any appearance of religion, cannot, without hearing his opinion, put any person to death, or so much as inflict any corporal punishment. In all actions, especially criminal ones, his opinion is required, by giving him writing in which the case is stated under legued names; which he subscribes with the words, He shall, or shall not, be punished. Such outward honour is paid to the mufti, that the grand signior himself rises up to him, and advances seven steps to meet him when he comes into his presence. He alone has the honour of kissing the sultan's left shoulder, whilst the prime vizier kisses only the hem of his garment. When the grand signior addresses any writing to the mufti, he gives him the following title: To the Most Esteemed, the wisest of the wise, instructed in all knowledge, the most excellent of excellent, abstaining from things unlawful, the spring of virtue and of true science, heir of the prophetic doctrines, rescuer of the problems of faith, revealer of the orthodox articles, key of the treasures of truth, the light to the doubtful allegories, strengthened with the grace of the supreme Legislator of mankind, may the Most High God perpetuate thy virtues! The election of the mufti is solely in the grand signior, who presents him with a vest of rich sables, &c. If he is convicted of treason or any great crime, he is put into a mortar kept for that purpose in the Seven Towers at Constantinople, and wounded to death.

MUGGLETIONS, a religious sect which arose in England about the year 1657; so denominated from their leader Lodowick Muggleton, a journeyman tailor, who, with his associate Reeves, set up for great prophets, pretending, as it is said, to have an absolute power of saving and damning whom they pleased; and giving out that they were the two last witnesses of God that should appear before the end of the world.

MUGIL, the Mullet, a genus of fishes belonging to the order of abdonimales. See Ichthyology Index.

MUGWORT, a species of Artemisia; which see, Botany Index.

MUID, a large measure in use among the French, for things dry. The muid is no real vessel used as a measure, but an estimation of several other measures; as the septime, minot, bussel, &c.

MUID, is also one of the nine casks, or regular vessels used in France, to put wine and other liquors in. The muid of wine is divided into two demi-muids, four quarter-muids, and eight half-quarter muids, containing 36 septrs.

MULATTO, a name given in the Indies to those who are begotten by a negro man on an Indian or white woman, or by an Indian or white man on a negro woman.

MULBERRY. See MORUS, Botany Index.

MULBERRY-OYSTER, a name given by the people of Devonshire, and some other parts of England, to a
M U L

sort of cyder rendered very palatable by an admixture of mulberry juice in the making; they choose for this purpose the ripest and blackest mulberries, and press out their juice, and mixing it with a full bodied cyder at the time of the grinding and pressing, give just so much of it as adds a perceptible flavour. It is very worthy the attention of people who live in other countries, where strong and good cyder is made, that this renders it a sort of wine much more agreeable than any other English liquor, and might be brought into general use, to the great advantage of the dealer. The colour of this liquor resembles that of the brightest red wine, and the flavour of the mulberry never goes off. Phil. Trans. No. 133.

MULCT, a fine of money laid upon a man who has committed some fault or misdemeanour.

MULE, a mongrel kind of quadruped, usually generated between an ass and a mare, and sometimes between a horse and a she ass; but the signification of the word is commonly extended to every kind of animal produced by a mixture of two different species. See Mammalia Index.

Mules, among gardeners, denote a sort of vegetable monsters produced by putting the farina fecundans of one species of plant into the pistil or utricle of another. The carnation and sweet-william being somewhat alike in their parts, particularly their flowers, the farina of the one will impregnate the other, and the seed so enlivened will produce a plant differing from either. An instance of this we first had in Mr Fairchild’s garden at Hoxton; where a plant is seen neither sweet-william nor carnation, but resembling both equally; this was raised from the seed of a carnation that had been impregnated by the farina of the sweet-william. These coupleings being not unlike those of the mare with the ass, which produce the mule, the same name is given them; and they are, like the others, incapable of multiplying their species.

This furnishes a hint for altering the property and taste of any fruit, by impregnating one tree with the farina of another of the same class; e. g., a codlin with a pear-main, which will occasion the codlin so impregnated to last a longer time than usual, and to be of a sharper taste.

MULHAUSEN, an imperial and Hansatic town of Germany, in Upper Saxon, and in Thuringia, under the protection of the elector of Saxon; seated in a fertile country, on the river Unstruth, 1 1/2 miles northeast of Eisenach, and 45 east by south of Cassel. E. Long. 10. 49. N. Lat. 51. 13.

MULHAUSEN, a considerable town in Alsace, formerly capital of a republic in alliance with the Swiss. It is populous, and well built, seated in a pleasant fertile country, on an island formed by the river Ill, 1 1/2 miles north-west of Bischwiller. It was united to France in 1552, and belongs to the department of the Upper Rhine. E. Long. 7. 24. N. Lat. 47. 48.

MULLER, in Law, signifies the lawful issue born in wedlock, though begotten before. The muller is preferred to an older brother born out of matrimony; as for instance, if a man has a son by a woman before marriage, which issue is a bastard, and afterwards marries the mother of the bastard, and they have another son, this second son is muller and lawful, and shall be heir of the father; but the other can be heir to no person*. By the civil law, where a man has issue by a woman, if after that he marries her, the issue is mulier.

MULL, one of the Western islands of Scotland, about 25 miles long, and as much in breadth. It is in general rocky and barren, not producing a sufficient quantity of corn for the inhabitants; but a great number of cattle are annually exported, which with the fishings and a considerable quantity of kelp are the only articles of commerce. It is deeply indented with bays and creeks, forming in several parts good natural harbours. There are no villages except Tobermorey, near the northern point of the island, where a fishing station has been fixed. The island was originally part of the dominions of the Lords of the Isles; but in after times it became a part of the possessions of the ancient family of Macleane, who still retain a considerable part. The duke of Argyll is also a considerable proprietor. The ruins of several ancient castles are seen on this island. The population of Mull, in 1795, amounted to about 4000 persons.

Mull of Cantyre. See Cantyre.

Mull of Galloway. See Galloway.

MULLEIN. See Verbascum, Botany Index.

MULLER, or Regiomontanus, John, a celebrated astronomer of the 15th century, was born at Koningshoven in Franconia in 1436, and acquired great reputation by publishing an abridgement of Ptolemy’s Almagest, which had been begun by Furback. He went to Rome to perfect himself in the Greek tongue, and to see the Cardinal Bassarion; but finding some faults in the Latin translation of George de Trebizond, that translator’s son assassinated him in a second journey he made to Rome in 1476, where Pope Sixtus IV. had provided for him the archbishopric of Hamilton, and had sent for him to reform the calendar. Others say that he died of the plague.

Muller, or Mullor, denotes a stone flat and even at bottom, but round a-top; used for grinding of matters on a marble.—The apothecaries use mullers to prepare many of their testaceous powders; and painters for their colours, either dry or in oil.

Muller is an instrument used by the glass-grinders, being a piece of wood, to one end whereof is cemented the glass to be ground, whether convex in a basin, or concave in a sphere or bowl.—The muller is ordinarily about six inches long, turned round: the cement used is composed of ashes and pitch. See Grinding.

MULLERAS, a town of Germany, in the circle of Upper Saxon, and marquisate of Brandenburg, seated 38 miles south of Berlin, upon a canal which joins the Oder and the Spree. This canal is 1 1/2 miles in length, 10 yards in breadth, and seven feet in depth. It was eight years in making; and since that time the cities of Hamburg and Breslaw have carried on great trade by water. E. Long. 14. 50. N. Lat. 52. 21.

MULLET. See Mugil, Ichthyology Index.

Mullet, or Mollet, in Heraldry, a bearing in form of the ravel of a spurr, which it originally represented.

MULLINGAR, the county town of Westmeath, and province of Leinster, in Ireland, 38 miles from Dublin.
M U M [ 476 ] M U M

Mullingar

Dublin. N. Lat. 53° 30'. W. Long. 7° 50'. Within a few miles of it are the ruins of the church, and also those of a castle. It is situated on the river Fyly. It holds a great wool fair, and is a place of good trade. In 1227, the priory of St Mary, formerly known by the name of The House of God of Mullingar, was founded here by Ralph de Petyt bishop of Meath, for regular canons of the order of St Augustin. A Dominican friary was also founded here in 1337 by the family of Nugent; some ruins of which still remain. In 1622, the friars of Multifarnham began to erect a house there for friars of the order of St Francis, but it was never completed.

MULLUS, the Surmullet, a genus of fishes belonging to the order of thoracii. See Ichthyology Index.

MULTIPLE, in Arithmetic, a number which comprehends some other several times; thus 6 is a multiple of 2, and 12 is a multiple of 6, 4, and 3; comprehending the first twice, the second thrice, &c.

ACTION of MULTIPLEPOINDING, in Scots Law. See Law, No cxxxiii. 24.

MULTIPLICAND, in Arithmetic, the number to be multiplied by another. See Arithmetic.

MULTIPLICATION, in general, the act of increasing the number of any thing.

MULTIPLICATION, in Arithmetic, is a rule by which any given number may be speedily increased, according to any proposed number of times. See Arithmetic.

MULTIPLICATION, in Algebra. See Algebra.

MULTIPLICATOR, or Multiplier, in Arithmetic, the number by which any other is multiplied, or the number of times it is supposed to be taken.

MULTIPLICATUS FLOS, a luxuriant flower, whose petals are multiplied so as to exclude a part or the whole of the stamina.

MULTIPLYING GLASS, in Optics, a glass where-with objects appear increased in number. See Optics.

MULTURE in Scots Law, a certain stipulated quantity of meal given as payment to the proprietor or tacksman of a mill for grinding the corn: and all corn ground on farms thirled to the mill is obliged to pay multure whether the corn be ground at that mill or elsewhere.

MULVIA, a river of Barbary in Africa, which rises in the mountains of Atlas, and divides the empire of Morocco from that of Algiers, and then falls into the Mediterranean, to the westward of Marsalgiver.

MUM, a kind of malt liquor much drunk in Germany, and chiefly brought from Brunswick, which is the place of most note for making it. The process of brewing mum, as recorded in the townhouse of that city, is as follows: Take 63 gallons of water that has been boiled till one third part is consumed, and brew it with seven bushels of wheaten malt, one bushel of oat meal, and one bushel of ground beans. When it is turned, the hogshad must not be filled too full at first: as soon as it begins to work, put into it three pounds of the inner kind of fir, one pound of the tops of fir and beech, three handfuls of carduus benedixtus, a handful or two of the flower of rosa solis: add burnet, betony, marjoram, avens, pennyroyal, and wild thyme, of each a handful or a half; of elder flowers, two handfuls or more of seeds of cardamom bruised, 30 ounces; barberries bruised, one ounce: when the liquor has worked a while, put the herbs and seeds into the vessel; and, after they are added, let it work over as little as possible; then fill it up: lastly, when it is stopped, put into the hogshad ten new-laid eggs unbroken; stop it up close, and use it at two years end. The English brewers, instead of the inner kind of fir, use cardamom, ginger, and sassafras; and also add clecampane, madder, and red sanders.

MUMMIES, L. a Roman consul sent against the Achaean, whom he conquers in B.C. 147. He destroyed Corinth, Thebes, and Chalcis, by order of the senate, and obtained the surname of Achaeus from his victories. He did not enrich himself with the spoils of the enemy, but returned home without any increase of fortune. He was so little acquainted with the value of the paintings and works of the most celebrated artists of Greece which were found in the plunder of Corinth, that he said to those who conveyed them to Rome, that if they lost or injured them, they should make others in their stead.

MUMMY, a body embalmed or dried, in the manner used by the ancient Egyptians; or the composition with which it is embalmed. There are two kinds of bodies denominated mummies. The first are only carcases dried by the heat of the sun, and by that means kept from putrefaction: these are frequently found in the sands of Libya. Some imagine, that these are the bodies of deceased people buried there on purpose to keep them entire without embalming; others think they are the carcasses of travellers who have been overwhelmed by the clouds of sand raised by the hurricanes frequent in those deserts. The second kind of mumories are bodies taken out of the catacombs near Cairo, in which the Egyptians deposited their dead after embalming. See Embalming.

We have two different substances preserved for medicinal use under the name of mummy, though both in some degree of the same origin. The one is the dried and preserved flesh of human bodies, embalmed with myrrh and spices; the other is the liquor running from such mumories, when newly prepared, or when affected by great heat or damps. The latter is sometimes in a liquid, sometimes of a solid form, as it is preserved in vials well stopped, or suffered to dry and harden in the air. The first kind of mummy is brought to us in large pieces, of a lax and friable texture, light and spongy, of a blackish brown colour, and often damp and clammy on the surface: it is of a strong but disagreeable smell. The second kind of mummy, in its liquid state, is a thick, opaque, and viscous fluid, of a blackish colour, but not disagreeable smell. In its indurated state, it is a dry solid substance, of a fine shining black colour, and close texture, easily broken, and of a good smell; very inflammable, and yielding a scent of myrrh and aromatic ingredients while burning. This, if we cannot be content without medicines from our own bodies, ought to be the mummy used in the shops; but it is very scarce and dear; while the other is so cheap, that it will always be most in use.

All these kinds of mumories are brought from Egypt. But we are not to imagine, that any body breaks up the real Egyptian mumories, to sell them in pieces.
MUN [477]

MUN

pieces to the druggists, as they make a much better market of them in Europe whole, when they can contrive to get them. What our druggists are supplied with, is the flesh of executed criminals, or of any other bodies the Jews can get, who fill them with the common bitumen, so plentiful in that part of the world; and adding a little aloes, and two or three other cheap ingredients, send them to be baked in an oven, till the juices are exhausted, and the embalming matter has penetrated so thoroughly that the flesh will keep and bear transporting into Europe. Mummy has been esteemed resolvent and balsamic: but whatever virtues have been attributed to it, seem to be such as depend more upon the ingredients used in preparing the flesh than in the flesh itself; and it would surely be better to give those ingredients without so shocking an addition.

There are found in Poland a kind of natural mummies, or human bodies preserved without the assistance of art. These lie in considerable numbers in some of the vast caverns in that country. They are dried with the flesh and skin shrunk up almost close to the bones, and are of a blackish colour. In the wars which several ages ago laid waste that country, it was common for parties of the weaker side to retire into these caves, where their enemies, if they found them out, suffocated them by burning straw, &c. at the mouth of the cavern, and then left the bodies; which, being out of the way of injuries from common accidents, have lain there ever since.

Mummy, among gardeners, a kind of wax used in grafting and planting the roots of trees, made in the following manner: Take one pound of black pitch, and a quart of a pound of turpentine; put them together into an earthen pot, and set them on fire in the open air, holding something in your hand to cover and quench the mixture in time, which is to be alternately lighted and quenched till all the nitrous and volatile parts be evaporated. To this a little common wax is to be added; and the composition is then to be set by for use.

MUMPS. See Medicine Index.

MUNDA, an ancient town of Spain, in the kingdom of Granada, seated on the declivity of a hill, at the bottom of which runs a river. W. Long. 4° 13'. N. Lat. 48° 15'.

This city was anciently famous for a victory gained by Caesar over the two sons of Pompey, who had collected an army in Spain after the defeat of their father at Pharsalia. See (History) of Rome.

The Pompeys posted their army advantageously on a rising ground, whereof one side was defended by the city of Munda, and the other by a small river which watered the plain, and by a marsh: so that the enemy could not attack them but in front. Caesar likewise drew up his troops with great art, and having advanced a little way from his camp, ordered them to halt, expecting the enemy would abandon their advantageous post, and come to meet him. But as they did not stir, Caesar made as if he intended to fortify himself in that post; which induced the young general, who looked upon this as a sign of fear, to advance into the plain, and attack the enemy before they could secure themselves with any works. Pompey's army was by far the most numerous: for it consisted of 13 legions, 6000 horse, and an incredible number of auxiliaries, among whom were all the forces of Bocchus king of Mauritania, commanded by his two sons, both youths of great valour and bravery. Caesar had 80 cohorts, three legions, to wit, the third, the fifth, and the tenth, and a body of 8000 horse. As the enemy drew near, Caesar betrayed a great deal of uneasiness and concern, as if he were doubtful of the success, knowing he was to engage men no way inferior in valour and experience to his own, and commanded by officers who had on many occasions given signal proofs of their bravery and conduct. Cneius, the elder of the two brothers, was generally looked upon as an able commander; and Labienus, who had revolted, esteemed scarce inferior to himself.

However, the dictator, desirous to put an end to the civil war, either by his own death, or that of his rivals, gave the signal for the battle, and fell upon the enemy with his usual vigour and resolution. At the first onset, which was dreadful, the auxiliaries on both sides betook themselves to flight, leaving the Romans to decide their quarrel by themselves. Then the legionaries engaged with a fury hardly to be expressed; Caesar's men being encouraged by the hopes of putting an end to all their labours by this battle; and those of Pompey exerting themselves out of necessity and despair, since most of them expected no quarter, as having been formerly pardoned. Never was victory more obstinately disputed. Caesar's men, who had been always used to conquer, found themselves so vigorously charged by the enemy's legionaries, that they began to give ground; and though they did not turn their backs, yet it was manifest that shame alone kept them in their posts. All authors agree, that Caesar had never been in so great danger; and he himself, when he came back to his camp, told his friends, that he had often fought for victory, but this was the first time he had ever fought for life. Thinking himself abandoned by fortune, which had hitherto favoured him, he had some thoughts of stabbing himself with his own sword, and by a voluntary death preventing the disgrace of a defeat: but returning soon to himself, and concluding it would be more to his reputation to fall by the enemy's hand at the head of his troops, than, in a fit of despair, by his own, he dismounted from his horse, and snatching a buckler from one of his legionaries, he threw himself like a man in despair into the midst of the enemy, crying out to his men, Are you not ashamed to deliver yourself into the hands of boys? At these words, the soldiers of the tenth legion, animated by the example of their general, fell upon the enemy with fresh vigour, and made a dreadful havoc of them. But in spite of their utmost efforts, Pompey's men still kept their ground, and, though greatly fatigued, returned to the charge with equal vigour. Then the Cisareans began to despair of victory; and the dictator, running through the ranks of his disheartened legionaries, had much ado to keep them together. The battle had already lasted from the rising to the setting of the sun, without any considerable advantage on either side.

At length a mere accident decided the dispute in favour of the dictator. Bogud, a petty king of Mauritania, had joined Caesar soon after his arrival in Spain, with some squadrons of Numidian horse; but in the very
very beginning of the battle, being terrified at the shouting of the soldiers, intermingled with groans, and the clashing of their arms, he had abandoned his post, and retired with the auxiliaries under his command to a rising ground at a small distance from the enemy's camp. There he continued the whole day an idle spectator of the battle that was fought in the plain. But towards the evening, partly out of shame and partly out of compassion for his friend Caesar, he resolved to fall upon Pompey's camp; and accordingly flew thither with all the forces he had with him. Labienus, apprised of his design, hastened after him to the defence of the camp; which Caesar observing, cried to his legions, "Courage, fellow soldiers! the victory at length is ours; Labienus flies." This artifice had the desired effect: Caesar's men, believing that Labienus was truly fled, made a last effort, and charged the wing he commanded so briskly, that after a most obstinate dispute they put them to flight.

Though the enemy's left wing was thus entirely defeated, the right wing, where the elder Pompey commanded, still kept their ground for some time. Pompey dismounting from his horse, fought on foot like a private man in the first line, till most of his legionsaries being killed, he was forced to save himself by flight from falling into the enemy's hands. Part of his troops fled back to their camp, and part took shelter in the city of Munda. The camp was immediately attacked, and taken sword in hand; and as for the city, Caesar, without loss of time, drew a line of circumvallation round it. This victory was gained on the 16th of the kalends of April, i.e. according to our way of counting, on the 17th day of March, when the Dionysian festival, or the Liberalia, were celebrated at Rome; the very day, as Plutarch observes, in which Pompey the Great, four years before, had set out for the war. In this action Pompey lost 30,000 men; among whom were the famous Labienus, Attius Varinius, and some Roman knights. Seventeen officers of distinction were taken, and all the enemy's eagles and ensigns, together with Pompey's fasces, which he had assumed as governor of Spain. On Caesar's side, only 2000 men were killed and 500 wounded.

MUNDIC, or MARCASITE, an old name for pyrites of copper or iron. See Ores of Copper and Iron, MINERALOGY INDEX.

MUNDINGEES, the name of a people who live on the sides of the river Gambia in Africa, and who are of a jet black colour, strong, and well made. They have a priest sent over every year from one of the Cape de Verd islands to christen and marry.

MUNDUS PATENS, the open world, in Roman antiquity, a solemnly performed in a small temple, of a round form like the world, dedicated to DIS and the rest of the infernal gods. This temple was opened but three times in the year, viz. the 24th of August, the 4th of October, and the 7th of November. During these days, the Romans believed hell was open; on these days therefore the never offered battle, listed soldiers, put to sea, or married.

MUNICH, a town of Germany, capital of the duchy, now the kingdom, of Bavaria. It stands on the Iser, 70 miles south of Ratisbon and 214 west of Vienna, being one of the most pleasant and populous cities of Germany for its bigness. The number of the inhabitants in 1781 was 48,000. Having been Munic, built at first on a spot of ground belonging to a cone Munich, i.e. Munic's town, and a monk for its arms. The elector's palace here is a very grand structure, consisting of several courts, furnished and adorned in the most magnificent manner, with tapestry, gilding, sculpture, statues, and paintings. It contains an amazing collection of jewels, antiques, and curiosities. The great hall is 118 feet long and 52 broad; and the staircase leading to it, from top to bottom of marble and gold. In the hall of antiques are 334 busts and statues of jasper and porphyry, brass and marble. In this palace is a library, containing a vast collection of books, and many valuable manuscripts, in most languages ancient and modern; and a chamber of rarities, among which is the picture of a brave or assassin, who is said to have committed 345 murders with his own hand, and to have been accomplice in, or privy to, 400 more. The treasury in the chapel contains also a vast number of pictures, precious stones, medals, vessels of gold and silver, &c. Among other curiosities, here is a cherry stone with 140 heads distinctly engraved upon it. The gardens of the palace are also very fine, and it is said a secret passage leads from it to all the churches and convents in the town. There is a great number of other fine buildings in this city, public and private, particularly the riding house, town house, opera room, the Jesuits college, the large edifice for tournaments, the churches, convents, fountains, &c. Its manufactures are those of silk, particularly velvet, woolen cloths, and tapestry; and it has two annual fairs, at which great quantities of salt, wine, &c. are sold. The streets are broad and regular; and most of the houses well built, and painted on the outside. The market place is extremely beautiful. Not far from Munich are four other palaces, with fine gardens, belonging to the elector, viz. those of St. Heinrich, Neunmenhagen, Dachau, and Tumberg. The first and last are about three leagues from the capital; the second about half a league; and the third about two leagues. It was unsuccessfully attacked by the French in 1796. See BAVARIA, SUPPLEMENT.

MUNICH, Count d', was the favourite of the czarina Anna, and was concerned in all the events of her reign. Being appointed general of her armies, he gained great advantages over the Crim Tartars, beat the Turks, A. D. 1739, in an engagement near Choczin, and took that city together with Jassy the capital of Moldavia. He was afterwards prime minister to the czar Iwan VI. but in a short time after he was accused of employing the power which his office conferred on him to gratify his own ambition and private resentment. The empress Elizabeth brought him to trial, and he was condemned to lose his life, A. D. 1742. This sentence was mitigated to banishment into Siberia, whither many of the victims of his power had been exiled. He was recalled by Peter III. A. D. 1762, and declared field marshal. Upon the death of this prince, the empress Catharine II. appointed him director general of the ports of the Baltic. He died on the 8th of October 1767, at the age of 84.

MUNICIPAL, in the Roman civil law, an epiteth which signifies invested with the rights and privileges of Roman citizens. See MUNICIPIUM, MUNICIPAL.
MUNICIPAL, among us, is applied to the laws that obtain in any particular city or province. And those are called municipal officers who are elected to defend the interests of cities, to maintain their rights and privileges, and to preserve order and harmony among the citizens; such as mayors, sheriffs, consuls, &c.

MUNICIPES, an appellation given by the Romans to the inhabitants of the municipia or municipal cities. See MUNICIPIUM.

MUNICIPIUM, in Roman antiquity, a corporation borough, or enfranchised city or town, where the inhabitants enjoyed their own laws and customs, and at the same time were honoured with the privileges of Roman citizens; but then this privilege generally reached no further than the base title. Some, indeed, by particular merit, obtained the liberty of votes, which occasioned that distinction of municipium sine suffragio, and municipium cum suffragio. The inhabitants of the municipium sine suffragio were called barely Romani, but those of the municipium cum suffragio were called civis Romani.

The difference between proper citizens of Rome and the inhabitants of the municipia may be thus expressed. The proper citizens of Rome were, 1. Registered in the census; 2. Had the right of suffrage and of bearing honours; 3. Were assessed in the poll-tax; 4. Served in the legions; 5. Used the Roman laws and religion; 6. Were called Quirites and populus Romanus. Whereas the municipies enjoyed the three first of these privileges, but were denied the three last.

MUNITION, the provisions with which a place is furnished in order for defence; or that which follows a camp for its subsistence.

MUNITION Ships, are those that have stores on board in order to supply a fleet of men of war at sea. In an engagement, all the munition ships and victuallers attending the fleet take their station in the rear of all the rest; they are not to engage in the fight, but to attend to such directions as are sent to them by the admiral.

MUNSTER, in Latin Monomachia, and in Irish Moan, the most southerly province of Ireland; bounded on the north by Leinster and Connaught, and on the east, west, and south, by the ocean. It contains the counties of Cork, Clare, Kerry, Limerick, Tipperary, and Waterford; and 3,289,932 Irish plantation acres, 740 parishes, 63 baronies, and 26 boroughs. It is about 225 miles long and 120 broad; and its principal town is Cork. Its ancient name was Munhase; and in latter ages it was divided into Desmond or South Munster, Ormond or East Munster, and Thomond or North Munster. It lies between 51° 15' and 53° 30' N. Lat. and 7° 10' and 10° 40' W. Long.

MUNSTER, a bishopric of Germany in the circle of Westphalia, and territories of Prussia; bounded on the north by Embden and Oldenburg, on the south by the county of Mark and duchy of Westphalia, on the west by the county of Bentheim and the United Provinces, and on the east by the bishoprics of Osnabrug and Paderborn together with the county of Ravensberg. It is the largest of all the Westphalian bishoprics, being in length about 80 miles, and in breadth from 20 to 60, and contains 350,000 inhabitants. It is divided into 13 bailiwicks: and though in general but a barren country, has some fruitful plains, with woods, and quarries of stone. The inhabitants, excepting a few of the nobility and gentry, are all Roman Catholics; though Lutheranism had once a considerable footing here. The bishop, who was generally also elector of Cologne, has a revenue of about 70,000 pounds, and can maintain 8000 men. By an unjust custom, unknown in the rest of the empire, he is heir to all strangers who die in the country without children. In the main he is rated at 20 foot and 118 horse; or 832 florins monthly in lieu of them. His chapter consists of six canons, who are all noble.

MUNSTER, a city of Germany, capital of a bishopric of the same name, and of all Westphalia, stands at the confluence of the river As with the Ems, in E. Long. 7° 49' N. Lat. 52° 0'. It is of a circular form, large, and had strong fortifications which have been thrown down. The citadel, called the Brille, has been converted into a residence for the bishop. The dean and chapter now elect the bishop; but till the beginning of the 13th century he was nominated by the emperor. This city has been rendered famous by three remarkable transactions. 1. By the peace concluded here in 1648, which put an end to the war of 30 years; occasioned by the persecuting spirit of bigotted Papists, who chose rather to plunge their country into all the calamities of war than allow liberty of conscience to the Protestants. By this peace, however, they consented, much against their inclinations, to grant them a toleration. 2. By the disorders and disturbances occasioned here in 1553, by a parcel of enthusiasts, headed by a taylor, called John of Leyden from the place of his birth, who turned out the magistrates, and took possession of the city, where they perpetrated the most horrid villanies and cruelties. 3. For the noble, though unsuccessful efforts it made in defence of its liberties against the tyranny and oppression of the above-mentioned turbulent and bloody-minded bishop, Bernard van Galen. In this city are a great number of convents and other religious houses, many of them stately piles, and surrounded with beautiful gardens.

MUNYCHA, or Munichus Portus, in Ancient Geography, a village and port of Athens, nearer to the city, fortified in the same manner as the Piraeus, to the east of which it lay, or between it and the promontory Sunium, at the mouth of the Ilistus. Strabo says it was an eminence in form of a peninsula, at the foot of which stood three harbours, anciently encompassed with a wall, taking within its extent the Piraeus and other harbours full of docks, with the temple of Diana Munychia; taking its name from Munichus, the founder of the temple.

MUNYCHA, an anniversary solemnity observed at Athens, in honour of Diana, on the 16th of the month Munychion. Cakes were offered on the occasion, called araphers.

MUNYCHION, the tenth month of the Athenian year, containing 29 days, and answering to the latter part of our March and the beginning of April. It was so called from the festival Munychia, which was observed in this month. See MONTH and MUNYCHA.

MUPHITI. See MUFTI.

MURÉNA, or Eel; a genus of fishes, belonging to the order of apodes. See Ichthyology INDEX.
MURAL, something belonging to a wall, which the Latins called murus.

MURAL CROWN, among the ancient Romans. See CROWN.

MURAL ARCH, is a wall, or walled arch, placed exactly in the plane of the meridian, i.e., upon the meridian line, for the fixing of a large quadrant, sextant, or other instrument, to observe the meridian altitudes, &c. of the heavenly bodies.

Tycho Brahe was the first who used a mural arch in his observations; after him Hevelius, Mr Flamstead, De la Hire, &c. used the same means. See ASTRONOMY.

MURANUM, in Ancient Geography, a town on the confines of Lucania. Now Murano; a citadel in Calabria Citra, at the springs of the Sybaris, midway between the Sinus Tarentinus to the east, and the Tuscan Sea to the west. Supposed to have risen from the ruins of Syphaxum, a town of the Bruttii mentioned by Livy.

MUHATORI, Lewis Anthony, a learned and celebrated Italian writer, born at Vignoles, in the territory of Bologna, in 1672. He early discovered an extreme fondness for the learned languages and sciences; and this was seconded by an excellent education. After having completed his first studies, he embraced the state of an ecclesiastic; and applied himself to polite literature, philosophy, theology, civil law, antiquities, and other sciences; by which means he became in a manner universally learned. He was scarcely 22 years of age when he was made librarian of the Ambrosian library at Milan. It 1700 the duke of Modena, his sovereign, recalled him, and made him his librarian, and keeper of the archives of his duchy. Muratori discharged this double employment during the rest of his life, and had no other benefit than the provostship of Santa Maria del Pomposa. The principal of his works are,—1. Anecdota, or a collection of pieces taken from the Ambrosian library, 2 vols 4to, with learned notes and dissertations. 2. A treatise on the perfection of the Italian poetry, 2 vols 4to. 3. Anecdota Graeca, 3 vols 4to. 4. A genealogical history of the house of Modena, 2 vols folio. 5. An excellent collection of the writers of the Italian history, 27 vols folio, with learned notes. 6. Another collection, under the title of Antiquitates Italicae. 7. A collection of ancient inscriptions, under the title of Novus Theaurus, 6 vols folio. 8. The annals of Italy, 12 vols 4to, in Italian, &c. 9. Letters, dissertations, Italian poems, &c.

MURCIA, the Pagan goddess of idleness. The name is taken from murcus or murcidus, an obsolete word, signifying a dull, slothful, or lazy person. The statues of this goddess were always covered with dust and moss, to express her idleness and negligence. She had a temple at Rome, at the foot of the Aventine mount.

MURCIA, a kingdom in Spain, bounded on the north by New Castile, on the east by the kingdom of Valencia, on the west by Andalusia and Granada, and on the south by the Mediterranean sea. It is about 62 miles in length, and 58 in breadth; and its principal river is the Segura. The soil is dry, because it seldom rains, and therefore it produces little corn or wine; but there is plenty of oranges, citrons, lemons, olives, almonds, mulberries, rice, pulse, and sugar. It has also a great deal of silk. It was taken from the Moors in 1265. The air is very healthful.

MURCIA, a large, handsome, and populous town of Spain, capital of a kingdom of the same name. It is a bishop's see, and contains six parishes. The cathedral is a most superb edifice, with the stairs of the steeple so contrived that a man may ride up to the top, either on horseback or in a coach. It is situated in a pleasant plain, which abounds in fine gardens about the city, and in which are the best fruits in Spain. It is seated on the river Segura, in W. Long. 8. 36. N. Lat. 37. 48.

MURDER, or Murther, the act of killing another with violence and injustice. The word comes from the Saxon mort, "death," which some will have to signify a violent death; whence the barbarous Latin murdrum and modrwm.

Among the number of popular errors, is the notion which has obtained, that the dead body would bleed in the presence or upon the touch of the murderer.

The crime of murder is punished with death in almost all nations.

MURDER, or Murther, in Law, is thus defined, or rather described, by Sir Edward Coke: "When a person, of sound memory and discretion, unlawfully killeth any reasonable creature in being, and under the king's peace, with malice aforethought, either express or implied." The best way of examining the nature of this crime will be by considering the several branches of this definition.

1. It must be committed by a person of sound memory and discretion: for lunatics or infants are incapable of committing any crime; unless in such cases where they show a consciousness of doing wrong, and of course a discretion or discernment between good and evil.

2. Next, it happens when a person of such sound discretion unlawfully killeth. The unlawfulness arises from the killing without warrant or excuse: and there must also be an actual killing to constitute murder; for a bare assault, with intent to kill, is only a great misdemeanor, though formerly it was held to be murder.

The killing may be by poisoning, striking, starving, drowning, and a thousand other forms of death, by which human nature may be overcome. Of these the most detestable of all is poison; because it can of all others be the least prevented, either by manhood or forethought. And therefore, by the stat. 22 Hen. VIII. c. 9. it was made treason, and a more grievous and lingering kind of death was inflicted on it than the common law allowed; namely, bailing to death: but this act did not live long, being repealed by 1 Edw. VI. c. 12. There was also, by the ancient common law, one species of killing held to be murder, which may be dubious at this day, as there hath not been an instance wherein it hath been held to be murder for many ages past, viz. bearing false witness against another, with an express premeditated design to take away his life, so his innocent person be condemned and executed. The Gothic laws punished in this case both the judge, the witnesses, and the prosecutor; and, among the Romans, the lex Cornelia de sicariis, punished the false witnesses with death, as being guilty of a species of assassination, and there is no doubt but this is equally murder in foro conscientiae.
sign is evidenced by external circumstances discovering that inward intention; as lying in wait, antecedent menaces, former grudges, and concerted schemes to do him some bodily harm. This takes in the case of deliberate duelling, where both parties meet avowedly with an intent to murder; thinking it their duty, as gentlemen, and claiming it as their right, to wanton with their own lives and those of their fellow creatures; without any warrant or authority from any power either divine or human, but in direct contradiction to the laws of both God and man; and therefore the law has justly fixed the crime and punishment of murder on them, and on their seconds also. Yet it requires such a degree of passive valour to combat the dread of even undeserved contempt, arising from the false notions of honour too generally received in Europe, that the strongest prohibitions and penalties of the law will never be entirely effectual to eradicate this unhappy custom, till a method be found out of compelling the original aggressor to make some other satisfaction to the affronted party, which the world shall esteem equally reputable as that which is now given at the hazard of the life and fortune, as well of the person insulted, as of him who has given the insult. Also, if even upon a sudden provocation one beats another, in a cruel and unusual manner, so that he dies, though he did not intend his death, yet he is guilty of murder by express malice; i.e. by an express evil design, the genuine sense of malitia: As when a park-keeper tied a boy that was stealing wood to a horse’s tail, and dragged him along the park: when a master corrected his servant with an iron bar, and a schoolmaster stamped on his scholar’s belly, so that each of the sufferers died: these were justly held to be murders, because the correction being excessive, and such as could not proceed but from a bad heart, it was equivalent to a deliberate act of slaughter. Neither shall he be guilty of a less crime who kills another in consequence of such a wilful act as shows him to be an enemy to all mankind in general; as going deliberately, and with an intent to do mischief, upon a horse used to strike, or coolly discharging a gun among a multitude of people. So if a man resolves to kill the next man he meets, and does kill him, it is murder, although he knew him not; for this is universal malice. And if two or more come together to do an unlawful act against the king’s peace, of which the probable consequence might be bloodshed; as to beat a man, to commit a riot, or to rob a park, and one of them kills a man; it is murder in them all, because of the unlawful act, the malitia praecontigua, or evil intended beforehand.

Also in many cases where no malice is expressed, the law will imply it: as, where a man wilfully poisons another, in such a deliberate act the law presumes malice, though no particular enmity can be proved. And if a man kills another suddenly, without any, or without a considerable provocation, the law implies malice; for no person, unless of an abandoned heart, would be guilty of such an act upon a slight or no apparent cause. Nor all, by words or gestures only, is a sufficient provocation, so as excuse or extenuate such acts of violence as manifestly endanger the life of another. But if the person so provoked had unfortunately killed the other, by beating him in such a manner as showed
**Murder.**

only an intent to chastise and not to kill him, the law so far considers the provocation of contumacious behaviour, as to adjudge it only manslaughter, and not murder. In like manner, if one kills an officer of justice, either civil or criminal, in the execution of his duty, or any of his assistants endeavouring to conserve the peace, or any private person endeavouring to suppress an affray or apprehend a felon, knowing his authority or the intention with which he interposes, the law will imply malice, and the killer shall be guilty of murder. And if one intends to do another felony, and undesignedly kills a man, this is also murder. Thus if one shoots at A, and misses him, but kills B, this is murder; because of the previous felonious intent, which the law transfers from one to the other. The same is the case, where one lays poison for A, and B, against whom the prisoner had no malicious intent, takes it, and it kills him, this is likewise murder. So also, if one give a woman with child a medicine to procure abortion, and it operates so violently as to kill the woman, this is murder in the person who gave it. It was endless to go through all the cases of homicide, which have been adjudged, either expressly or impliedly, malicious: these therefore may suffice as a specimen; and we may take it for a general rule, that all homicide is malicious, and of course amounts to murder, unless where justified by the command or permission of the law; excused on a principle of accident or self-preservation; or alleviated into manslaughter, by being either the involuntary consequence of some act, not strictly lawful, or (if voluntary) occasioned by some sudden and sufficiently violent provocation. And all these circumstances of justification, excuse, or alleviation, it is incumbent upon the prisoner to make out, to the satisfaction of the court and jury, the latter of whom are to decide whether the circumstances alleged are proved to have actually existed; the former, how far they extend to take away or mitigate the guilt. For all homicide is presumed to be malicious, until the contrary appears upon evidence.

The punishment of murder, and that of manslaughter, were formerly one and the same; both having the benefit of clergy; so that none but unlearned persons, who least knew the guilt of it, were put to death for this enormous crime. But now, by several statutes, the benefit of clergy is taken away from murderers through malice propense, their abettors, procurers, and coallowers. In atrocious cases it was frequently usual for the court to direct the murderer, after execution, to be hung upon a gibbet in chains near the place where the fact was committed; but this was no part of the legal judgment; and the like is still sometimes practised in the case of notorious thieves. This, being quite contrary to the express command of the Mosaic law, seems to have been borrowed from the civil law; which, besides the terror of the example, gives also another reason for this practice, viz. that it is a comfortable sight to the relations and friends of the deceased.

But now, in England, it is enacted by statute 25 Geo. II. c. 37 that the judges, before whom any persons found guilty of wilful murder, shall pronounce sentence immediately after conviction, unless he sees cause to postpone it; and shall in passing sentence direct him to be executed on the next day but one (unless the same shall be Sunday, and then on the Monday following), and that his body shall be delivered to the surgeons to be dissected and anatomized; and that the judge may direct his body to be afterwards hung in chains, but in no wise to be buried without dissection. And, during the short but awful interval between sentence and execution, the prisoner shall be kept alone, and sustained with only bread and water. But a power is allowed to the judge, upon good and sufficient cause, to reprieve the execution, and relax the other restraints of this act. See further, _Parricide_, and _Petit treason._

**MURDERERS, or Murdering Pieces, in a ship, are small pieces of ordnance, either of brass or iron, which have chambers put in at their breeches. They are used at the bulk-heads of the fore-castle, half-deck, or steerage, in order to clear the deck, on the ship's being boarded by an enemy.**

**MURENA.** See _Murena, Ichthyology Index._

**MURENGERS,** two officers of great antiquity in the city of Chester, annually chosen out of the aldermen, to see the walls kept in repair, and to receive a certain toll for that purpose.

**MUREX,** a genus of animals belonging to the order of vermes testaceae. See _Conchology Index._

**Murex,** a caltrap or iron instrument, with sharp points projecting in every direction, used by the Romans as a defence against the enemy's horse; so called, probably from some resemblance to the spines on the shell of the murex.

**Murgi, or Murgis, in Ancient Geography, the last town of Batica, next the Tarraconensis; the site of Ptolemy. Now Mussara, a port-town of Granada, on the Mediterranean. W. Long. 1° 50'. N. Lat. 37° 6'.**

**Muria, the Latin name of common salt. See Soda, Murate of, Chemistry Index.**

**Muriatic Acid.** See _Chemistry Index._ This acid, according to the views of Sir H. Davy, is composed of chlorine (the oxyuric acid of all chemists formerly, and of some still) and hydrogen.

**Murina, or Murines, a delicious sweet wine, medicated with spices, and the usual drink of the ladies of antiquity.**

**Murrain, or Garble, a contagious disease among cattle. See _Farriry Index._**

**Murray, or Moray, the name of a district in the north of Scotland, which, in a former division of the kingdom, was denominatud a province. This district includes the counties of Banff, Elgin and Nairn. The county of Elgin, the middle division of this district, is still known by the name of Morayshire.**

**Murrhine, Murrhinus, Murenes, in antiquity, an appellation given to a delicate sort of ware brought from the east, whereof cups and vases were made, which added not a little to the splendour of the Roman banquets. Critics are divided concerning the matter of the pocula or vase murrhina, murrina, or muresa. Some will have them to have been of our porcelain or china ware. The generality held them to have been made of some precious kind of stone, which was found chief, as Pliny tells us, in Parthia, but more especially in Germania. Arrian tells us, that there was a great quantity of them made at Diospolis in Egypt. This he calls another sort of murrhina work; and it is evident, from all accounts, that the murrhina of Diospolis was a sort...**
MUS [ 483 ]

MUS

MUSCA, the FLY; a genus of insects belonging to the order of diptera. See ENTOMOLOGY INDEX.

MUSCA, a name given to such persons among the Romans as officiously thrust themselves into the company of their superiors and those who despised them, by finding means of getting admittance to entertainments without invitation, and without a welcome: So that musca were the same as parasites, who were frequently by the Greeks termed Mousai. See PARASITE.

MUSCADINE, a rich wine, of the growth of Provence, Languedoc, Cività, etc. — The word is supposed to be derived from musck; the wine being supposed to have a little of the smell of that perfume; others from musca, "a fly," because the flies are extremely fond of its grapes; as the Latinas had their vinum apiumum, so called ab opibus, from the bees which fed on it.

The process for making muscadine at Frontignac, is the following: The muscadine grapes are allowed to be half dried on the vine; and as soon as they are gathered, they are trode and pressed, and the liquor is turned, without letting it stand to ferment in the fat; the lee which remains is supposed to produce the peculiar flavour of this wine.

MUSCHENBROECK, Peter de, a very distinguished natural philosopher and mathematician, was born
MUSCULUS, a military machine, made use of by the Romans to cover and protect the soldiers while they approached and undermined the walls of besieged places, or filled the ditches. It seems to have resembled the testudo in form, but was smaller in size. See **Testudo**.

**MUSEA,** were Grecian festivals in honour of the Muses, celebrated with games every fifth year, particularly by the Thespian. The Macedonians also observed a festival of the same name in honour of Jupiter and the Muses, which lasted for nine days, and was celebrated with stage-plays, songs, and poetical compositions.

**MUSES,** certain fabulous deities among the Pagans, supposed to preside over the arts and sciences: for this reason it is usual for the poets, at the beginning of a poem, to invoke these goddesses to their aid.

The Muses were originally only singers and musicians in the service of Osiris, or the great Egyptian Bacchus, under the instruction and guidance of his son Orus; but in succeeding times they were called the **daughters of Jupiter and Mnemosyne or Memory.**

These are the only pagan divinities whose worship has been continued through all succeeding changes in the religion and sentiments of mankind. Professors of every liberal art in all the countries of Europe still revere them; particularly the poets, who seldom undertake the slightest work without invoking their aid.

Sir Isaac Newton tells us, that the singing women of Osiris were celebrated in Thrace by the name of the **Muses;** and that the daughters of Pierus, a Thracian, imitating them, were celebrated by the same name.

Diodorus Siculus informs us, that Alcman of Messene, a lyric poet who flourished in the 27th Olympiad, 670 years B.C. makes them the daughters of Uranus and Terra. It has been asserted by some ancient writers, that at first they were only three in number: but Homer, Hesiod, and other profound mythologists, admit of nine (A).

In his hymn to Apollo, Homer says,

---By turns the nine delight to sing.

And Hesiod, in his Theogony, names them all.——They are said severally to preside over some art or science, as music, poetry, dancing, astronomy. By some they are called virgins, because the virtues of education appear unalterable: they are called muses from a Greek word which signifies to explain mysteries, because they have taught things the most curious and important to know, and which are above the comprehension of vulgar minds. Each of their names is said to include some particular allegory; Clio, for instance, has been thus called, because those who are praised in verse acquire immortal fame; Euterpe, on account of the pleasure accruing to those who hear learned poetry; Thalia, implies for ever flourishing; Melpomene, that her melody insinuates itself into the inmost recesses of the soul; Terpsichore marks the pleasure which those receive who are versed in the liberal arts; Erato seems to indicate, that the learned command the esteem and friendship of all mankind; Polyhymnia, that many poets are become immortal by the number of hymns which they have addressed to the gods; Urania, that those whom she instructs elevate their contemplations and celebrity to the heavens and the stars; and lastly, the exquisite voice of Calliope has acquired her that appellation, as the mistress and guardian of eloquence and rhetoric.

An epigram of Callimachus gives the attributes of the Muses in as many lines.

*Calliope the deeds of heroes sings;
Great Clio sweeps to history the strings;
Euterpe teaches mimes their silent show;
Melpomene presides o'er scenes of wo;
Terpsichore the flute's soft pow'r displays;
And Erato gives hymns the gods to raise;
Polyhymnia's skill inspires melodious strains;
Urania wise, the starry course explains;
And gay Thalia's glass points out where folly reigns.*

This epigram does not, however, exactly correspond with the ideas of other poets, or of the ancient painters, in characterizing the attributes of the Muses. The ancients had numberless ingenious and fanciful ideas concerning the muses, which we have not room to recite. ——It seems (says the abbé Barthelemy) as if the first poets, enchanted with the beauties of nature, occasionally were led to invoke the nymphs of the woods, hills, and fountains; and that yielding to the prevailing taste, for allegory, they gave them names relative to the science...
MUSEUM

Science might be supposed to have over the productions of the mind. At first three Muses only were admitted, Melete, Mneme, and Aëre: that is to say, the meditation or reflection necessary to study; memory, which records illustrious deeds; and song, which accompanies their recital. In proportion as improvement was made in the art of verification, its characters and effects were personified, the number of the Muses increased, and the names they now received referred to the charms of poetry, its celestial origin, the beauty of its language; the pleasure and pietuity it inspires, the song and dance which add to it new charms, and the glory with which it is crowned. Afterwards were associated with them the Graces, whose employment it is to embellish poetry, and Love who is so frequently its object. These ideas took birth in a barbarous country, in Thrace, where Orpheus, Linus, and their disciples, suddenly appeared in the midst of ignorance. The Muses were honoured there on the Pician mount; and extending their dominion, successively took their stations on Pindus, Parnassus, Helicon, and all those solitary places where the painters of nature, surrounded by the most pleasing images, experience the divine glow of inspiration."

Pythagoras, and afterwards Plato, make the Muses the soul of the planets in our system; from whence the imaginary music of the spheres.

MUSEUM, a name which originally signified a part of the palace of Alexandria, which took up at least one-fourth of the city. This quarter was called the museum, on account of its being set apart for the Muses and the study of the sciences. Here were lodged and entertained the men of learning; who were divided into many companies or colleges, according to the sciences of which they were the professors; and to each of these houses or colleges was allotted a handsome revenue. The foundation of this establishment is attributed to Ptolemy Philadelphus, who here placed his library. Hence the word museum is now applied to any place set apart as a repository for things that have an immediate relation to the arts.

The museum at Oxford, called the Ashmolean museum, is a noble pile of building, erected at the expense of the university, at the west end of the theatre, at which side it has a magnificent portal, sustained by pillars of the Corinthian order. The front, which is to the street, extends about 60 feet, where there is this inscription over the entrance in gilt characters, Museum Ashmoleanum, schola naturalis historiae, officina chymica. It was begun in 1679, and finished in 1683, when a valuable collection of curiosities was presented to the university by Elias Ashmole, Esq, which were the same day reposed there: several accessions have been since made to the museum; among which are hieroglyphics, and other Egyptian antiquities, an entire mummy, Roman antiquities, altars, medals, lamps, &c. and a variety of natural curiosities.

For an account of the British museum, see LONDON, No 146.

MUSHROOM. See Fungi, Botany Index.

To try the quality of mushrooms:—Take an onion, and strip the outer skin, and boil it with your mushrooms: if the onion become blue or black, there are certainly dangerous ones amongst them; if it remain white, they are good.

MUSIC;

The art of combining sounds in a manner agreeable to the ear. This combination may be either simultaneous or successive: in the first case, it constitutes harmony; in the last, melody. But though the same sounds, or intervals of sound, which give pleasure when heard in succession, will not always produce the same effect in harmony; yet the principles which constitute the simpler and more perfect kinds of harmony, are almost, if not entirely, the same with those of melody. By perfect harmony, we do not here mean that plenitude, those complex modifications of harmonic sound, which are admired in practice; but that harmony which is called perfect by theorists and artists; that harmony which results from the coalescence of simultaneous sounds produced by vibrations in the proportions of thirds, fifths, and octaves, or their duplicates.

The principles upon which these various combinations of sound are founded, and by which they are regulated, constitute a science, which is not only extensive but profound, when we would investigate the principles from whence these happy modifications of sound result, and by which they are determined; or when we would explore the sensations, whether mental or corporeal, with which they affect us. The ancient definitions of music are not proportioned in their extent to our present ideas of that art; but M. Rousseau be-Definition. trays a temerity highly inconsistent with the philosophical character, when from thence he infers, that their ideas were vague and undetermined. Every soul susceptible of refinement and delicacy in taste or sentiment, must be conscious that there is a music in action as well as in sound; and that the ideas of beauty and decorum, of harmony and symmetry, are, if we may use the expression, equally constituent of visible as of audible music. Those illustrious minds, whose comprehensive prospects in every science where taste and propriety prevail, took in nature at a single glance, would behold with contempt and ridicule those narrow and microscopic views of which alone their successors in philosophy have discovered themselves capacious. With these definitions, however, we are less concerned, as they bear no proportion to the ideas which are now entertained of music. Nor can we follow M. Rousseau, from whatever venerable sources his authority may be derived, in adopting his Egyptian etymology for the word music. The established derivation from Musa could only be questioned by a paradoxical genius. That music had been practised in Egypt before it was known as an art in Greece, is indeed a fact which cannot be questioned; but it does not thence follow that the Greeks had borrowed the name as well as the art
from Egypt. If the art of music be so natural to man that vocal melody is practised wherever articulate sounds are used, there can be little reason for deducing the idea of music from the whistling of winds through the reeds that grew on the river Nile. And indeed, when we reflect with how easy a transition we may pass from the accents of speaking to diastonic sounds; when we observe how early children adapt the language of their amusements to measure and melody, however rude; when we consider how early and universally these practices take place—there is no avoiding the conclusion, that the idea of music is consonant to man, and implied in the original principles of his constitution. We have already said, that the principles on which it is founded, and the rules by which it is conducted, constitute a science. The same maxims when applied to practice form an art: hence its first and most capital division is into speculative and practical music.

Speculative music is, if we may be permitted to use the expression, the knowledge of the nature and use of those materials which compose it, or, in other words, of all the different relations between the high and low, between the harsh and the sweet, between the swift and the slow, between the strong and the weak, of which sounds are susceptible: relations which, comprehending all the possible combinations of music and sounds, seem likewise to comprehend all the causes of the impressions which their succession can make upon the ear and upon the soul.

Practical music is the art of applying and reducing to practice those principles which result from the theory of agreeable sounds, whether simultaneous or successive; or, in other words, to conduct and arrange sounds according to the proportions resulting from consonance, from duration and succession, in such a manner as to produce upon the ear the effect which the composer intends. This is the art which we call composition. With respect to the actual production of sounds by voices or instruments, which is called execution, this department is merely mechanical and operative: which, only presupposing the powers of sounding the intervals true, of exactly proportioning their degrees of duration, of elevating or depressing sounds according to those gradations which are prescribed by the tone, and to the value required by the time, demands no other knowledge but a familiar acquaintance with the characters used in music, and a habit of expressing them with promptitude and facility.

Speculative music is likewise divided into two departments; viz. the knowledge of the proportions of sounds or their intervals, and that of their relative durations; that is to say, of measure and of time.

The first is what among the ancients seems to have been called harmonical music. It shows in what the nature of air or melody consists; and discovers what is consonant or discordant, agreeable or disagreeable, in the modulation. It discovers, in a word, the effects which sounds produce on the ear by their nature, by their force, and by their intervals; which is equally applicable to their consonance and their successions.

The second has been called rhythmic, because it treats of sounds with regard to their time and quantity. It contains the explication of their continuance, of their proportions, of their measures, whether long or short, quick or slow, of the different modes of time and the parts into which they are divided, that to these the succession of sounds may be conformed.

Practical music is likewise divided into two departments, which correspond to the two preceding.

That which answers to harmonical music, and which the ancients called melopoeia, teaches the rules for combining and varying the intervals, whether consonant or dissonant, in an agreeable and harmonious manner.

The second, which answers to the rhythmical music, and which they called rythmopoeia, contains the rules for applying the different modes of time, for understanding the feet by which verses were scanned, and the diversities of measure; in a word, for the practice of the rhythms.

Music is at present divided more simply into melody and harmony; for, since the introduction of harmony, the proportion between the length and shortness of sounds, or even that between the distance of returning cadences, are of less consequence amongst us. For it often happens in modern languages, that the verses assume their measures from the musical air, and almost entirely lose the small share of proportion and quantity which in themselves they possess.

By melody the successions of sound are regulated in such a manner as to produce pleasing airs. See MELODY.

Harmony consists in uniting to each of the sounds, in a regular succession, two or more different sounds, which simultaneously striking the ear soothe it by their concurrence. See HARMONY.

Music, according to Rousseau, may be, and perhaps likewise ought to be, divided into the physical and the imitative. The first is limited to the mere mechanism of sounds, and reaches no farther than the external senses, without carrying its impressions to the heart, and can produce nothing but corporeal sensations more or less agreeable. Such is the music of songs, of hymns, of all the airs which only consist in combinations of melodious sounds, and in general all music which is merely harmonious.

It may, however, be questioned, whether every sound, even to the most simple, is not either by nature or by confirmed and associated imitation, imitative. If we may trust our own feelings, there is no such thing in nature as music which gives mechanical pleasure alone. For if so, it must give such pleasure as we receive from tastes, from odours, or from other grateful titillations; but we absolutely deny that there are any musical sensations or pleasures in the smallest degree analogous to these. Let any piece of music be resolved into its elementary parts and their proportions, it will then easily appear from this analysis, that sense is no more than the vehicle of such perceptions, and that mind alone can be susceptible of them. It may indeed happen, from the number of the performers and the complication of the harmony, that meaning and sentiment may be lost in the multiplicity of sounds; but this, though it may be harmony, loses the name of music.

The second department of this division, by lively and accentuated inflections, and by sounds which may be said to speak, expresses all the passions, paints every possible picture, reflects every object, subjects the whole of nature to its skillful imitations, and impresses even on the heart and soul of man sentiments proper to affect them in the most sensible manner. This, conti-
M U S I C.

not only as a symbol of that universal order and symmetry which prevails through the whole frame of material and intelligent nature, but as productive of the most momentous effects both in moral and political life. Plato and Aristotle, who disagreed almost in every other maxim of politics, are unanimous in their approbation of music, as an efficacious instrument in the formation of the public character and in conducting the state; and it was the general opinion, that whilst the gymnastic exercises rendered the constitution robust and hardy, music humanised the character, and softened those habits of roughness and ferocity by which men might otherwise have degenerated into savages. The gradations by which voices were exerted and tuned, by which the invention of one instrument succeeded to another, or by which the principles of music were collected and methodised in such a manner as to give it the form of an art and the dignity of a science, are topics so fruitful of conjecture and so void of certainty, that we must leave them to employ minds more speculative and inventions more prolific than ours, or transfer them to the History of music as a more proper place for such disquisitions. For the amusement of the curious, Rousseau in his Musical Dictionary, Plates C and N, has transcribed some fragments of Grecian, Persian, American, Chinese, and Swiss music, with which performers may entertain themselves at leisure. When they have tried the pieces, it is imagined they will be less sanguinely fond than that author of ascribing the power of music to its affinity with the national accents where it is composed. This may doubtless have its influence; but there are other causes more permanent and less arbitrary to which it owes its most powerful and universal charms.

The music now most generally celebrated and practiced is that of the Italians, or their successful imitators. The English, from the invasion of the Saxons, to that more late though lucid era in which they imbibed the art and copied the manner of the Italians, had a music which neither pleased the soul nor charmed the ear. The primitive music of the French deservers no higher panegyric. Of all the barbarous nations, the Scots and Irish seem to have possessed the most affecting original music. The first consists of a melody characterised by tenderness: It melts the soul to a pleasing pensive languor. The other is the native expression of grief and melancholy. Tassoni informs us, that in his time a prince from Scotland had imported into Italy a lamentable kind of music from his own country; and that he himself had composed pieces in the same spirit. From this expressive though laconic description, we learn that the character of our national music was even then established; yet so gross is our ignorance and credulity, that we ascribe the best and most impromptu airs which are extant among us to David Rizzo; as if an Italian lutenist who had lived so short a time in Scotland, could, at once, as it were by inspiration, have imbibed a spirit and composed in a manner so different from his own. It is yet more surprising that Geminiiani should have entertained and published the same prejudice, upon the miserable authority of popular tradition alone; for the fact is authenticated by no better credentials. The primitive music of the Scots may be divided into the *narrative*, the *pastoral*, and the *festive*. The first consists either
either in marches, which were played before the chief-tains, in imitation of the battles which they fought, or in lamentations for the catastrophes of war and the extinction of families. These wild effusions of natural melody preserve several of the rules prescribed for composition. The strains, though rude and untutored, are frequently terrible or mournful in a very high degree. The port or march is sometimes in common, sometimes in treble time; regular in its measures, and exact in the distance between its returning cadences; most frequently, though not always, loud and brisk. The pi-broch, or imitation of battles, is wild and abrupt in its transitions from interval to interval and from key to key; various and desultory in its movements; frequently irregular in the return of its cadences; and in short, through the whole, seems inspired with such fury and enthusiasm, that the hearer is irresistibly infected with all the rage of precipitate courage, notwithstanding the rudeness of the accents by which it is kindled. To this the pastoral forms a striking contrast. Its accents are plaintive, yet soothing; its harmony generally flat; its modulations natural and agreeable; its rhythmus simple and regular; its returning cadences at equal distance; its transitions from one concinnous interval to another, at least for the most part; its movements slow, and may be either in common or treble time. It scarcely admits of any other harmony than that of a simple bass. A greater number of parts would cover the air, and destroy the melody. To this we shall add what has been said upon the same subject by Dr. Franklin. Writing to Lord K———, he proceeds thus:

"Give me leave, on this occasion, to extend a little the sense of your position, 'That melody and harmony are separately agreeable, and in union delightful;' and to give as my opinion, that the reason why the Scotch tunes have lived so long, and will probably live for ever (if they escape being stifled in modern affected ornament), is merely this, that they are really compositions of melody and harmony united, or rather that their melody is harmony. I mean, the simple tunes sung by a single voice. As this will appear paradoxical, I must explain my meaning. In common acceptation, indeed, only an agreeable succession of sounds is called melody; and only the coexistence of agreeable sounds harmony. But since the memory is capable of retaining for some moments a perfect idea of the pitch of a past sound, so as to compare it with the pitch of a succeeding sound, and judge truly of their agreement or disagreement, there may and does arise from thence a sense of harmony between the present and past sounds, equally pleasing with that between two present sounds. Now the construction of the old Scotch tunes is this, that almost every succeeding emphatical note is a third, a fifth, an octave, or in short some note that is in concord with the preceding note. Thirds are chiefly used, which are very pleasing concords. I use the word emphatical, to distinguish those notes which have a stress laid on them in singing the tune, from the lighter connecting notes that serve merely, like grammar-articles in common speech, to tack the whole together.

"That we have a most perfect idea of a sound just past, I might appeal to all acquainted with music, who know how easy it is to repeat a sound in the same pitch with one just heard. In tuning an instrument, a good ear can as easily determine that two strings are in unison by sounding them separately, as by sounding them together; their disagreement is also as easily, I believe I may say more easily and better distinguished when sounded separately; for when sounded together, though you know by the beating that one is higher than the other, you cannot tell which it is. I have ascribed to memory the ability of comparing the pitch of a present tone with that of one past. But if there should be, as possibly there may be, something in the ear similar to what we find in the eye, that ability would not be entirely owing to memory. Possibly the vibrations given to the auditory nerves by a particular sound may actually continue for some time after the cause of these vibrations is past, and the agreement or disagreement of a subsequent sound become by comparison with them more discernible. For the impression made on the visual nerves by a luminous object will continue for 20 or 30 seconds."

After some experiments to prove the permanency of visible impressions, he continues thus:

"Farther, when we consider by whom these ancient tunes were composed, and how they were first performed, we shall see that such harmonical succession of sounds was natural, and even necessary in their construction. They were composed by the minstrels of those days, to be played-on the harp accompanied by the voice. The harp was strung with wire, which gives a sound of long continuance; and had no constancy like that of the modern harpsichord, by which the sound of the preceding note can be stopped the moment a succeeding note begins. To avoid actual discord, it was therefore necessary that the succeeding emphatic note should be a chord with the preceding, as their sounds must exist at the same time. Hence arose that beauty in those tunes that has so long pleased, and will please for ever, though we scarce know why. That they were originally composed for the harp, and of the most simple kind, I mean a harp without any half notes but those in the natural scale, and with no more than two octaves of strings, from C to C, I conjecture from another circumstance; which is, that not one of these tunes really ancient, has a single artificial half-note in it; and that in tunes where it is most convenient for the voice to use the middle notes of the harp, and place the key in F, there the B, which if used should be a B flat, is always omitted, by passing over it with a third. The connoisseurs in modern music will say I have no taste; but I cannot help adding, that I believe our ancestors in having a good song, distinctly articulated, sung to one of those tunes, and accompanied by the harp, felt more real pleasure than is communicated by the generalty of modern operas, exclusive of that arising from the scenery and dancing. Most tunes of late composition, not having this natural harmony united with their melody, have recourse to the artificial harmony of a bass, and other accompanying parts. This support, in my opinion, the old tunes do not need, and are rather confused than aided by it. Whoever has heard James Oswald play them on his violin, will be less inclined to dispute this with me. I have more than once seen tears of pleasure in the eyes of his auditors: and yet I think, even his playing those tunes would..."
MUSIC

would please more if he gave them less modern ornament."

As these observations are for the most part true, and
always ingenious, we need no other apology for quoy-
ing them at length. It is only proper to remark, that
the transition in Scots music by consonant intervals,
does not seem, as Dr Franklin imagines, to arise from
the nature of the instruments upon which they played.
It is more than probable, that the ancient British harp
was not strong with wire, but with the same materials
as the Welsh harps at present. These strings have not
the same permanency of tone as metal; so that the
sound of a preceding emphatic note must have expired
before the subsequent accented note could be intro-
duced. Besides, they who are acquainted with the
manoeuvre of the Irish harp, know well that there is a
method of discontinuing sounds as less easy and effect-
tual than upon the harpsichord. When the performer
finds it proper to interrupt a note, he has no more to do
but return his finger gently upon the string immedi-
ately struck, which effectually stops its vibration.

That species of Scots music which we have distinc-
ted by the name of festive seems now limited to reels
and country-dances. These may be in common or treble
time. They most frequently consist of two
strains: each of these contains eight or twelve bars.
They are truly rhythmical; but the mirth with which
they excite seems rather to be inspired by the vivacity of
the movement, than either by the force or variety of the
melody. They possess a manœuvre and expression pecu-
liar to themselves, which it is impossible to describe,
and which can only be exhibited by good performers.

Having thus far pursued the general idea of music,
we shall, after the history, give a more particular detail
of the science.

HISTORY OF MUSIC.

MUSIC is capable of so infinite a variety, so greatly
does the most simple differ from the most complex, and
so multiplied are the degrees between these two ex-
tremes, that in no age could the incidents respecting
that fascinating art have been few or uninteresting.

But, that accounts of these incidents should have been
handed down to us, scanty and imperfect, is no matter
of surprise, when we recollect that the history of music
is the history only of sounds, of which writing is a very
inadequate medium; and that men would long employ
themselves in the pleasing exercise of cultivating music
before they possessed either the ability or the inclination
to record their exertions.

No accurate traces, therefore, of the actual state of
music, in the earlier ages of the world, can be discern-
ed. Our ideas on the subject have no foundation fir-
mer than conjecture and analogy.

It is probable, that among all barbarous nations
some degree of similarity is discernible in the style of
their music. Neither will much difference appear dur-
ing the first dawnings of civilization. But in the
more advanced periods of society, when the powers
of the human mind are permitted without obstacle to
erect their native activity and tendency to invention,
and are at the same time affected by the infinite variety
of circumstances and situations which before had no ex-
istence, and which in one case accelerate, and in an-
other retard; then that similarity, once so distinguishable,
gives place to the endless diversity of which the subject
is capable.

The practice of music being universal in all ages and
all nations, it would be absurd to attribute the invention
of the art to any one man. It must have suffered a reg-
ular progression, through infancy, childhood, and
youth, before it could arrive at maturity. The first
attempts must have been rude and artless. Perhaps the
first flute was a reed of the lake.

No nation has been able to produce proofs of anti-
quity so indisputable as the Egyptians. It would be
vain, therefore, to attempt tracing music higher than the
history of Egypt.

By comparing the accounts of Diodorus Siculus
Vol. XIV. Part II. 4

and of Plato, there is reason to suppose, that in very
ancient times the study of music in Egypt was con-
strained to the priesthood, who used it only on religious
and solemn occasions; that, as well as sculpture, it
was circumscribed by law; that it was esteemed sa-
cred, and forbidden to be employed on light or com-
mon occasions; and that innovation in it was prohib-
ited: But what the style or relative excellence of
this very ancient music was, there are no traces by
which we can form an accurate judgment. After the
reigns of the Pharaohs, the Egyptians fell by turns
under the dominion of the Ethiopians, the Persians,
the Greeks, and the Romans. By such revolutions,
the manners and amusements of the people, as well as
their form of government, must have been changed.
In the age of the Ptolemies, the musical games and
tests instituted by those monarchs were of Greek
origin, and the musicians who performed were chiefly
Greek.

The most ancient monuments of human art and in-
dustry, at present extant at Rome, are the obelisks
brought thither from Egypt, two of which are said to
have been erected by Sesostris at Heliopolis, about 400
years before the siege of Troy. These were by the or-
der of Augustus brought to Rome after the conquest
of Egypt. One of them, called 
ugita rotta, or the
broken pillar, which during the sacking of the city in
1527 was thrown down and broken, still lies in the
Campus Martius. On it is seen the figure of a mus-

cal instrument of two strings, and with a neck. It re-
tains much the calascone still used in the kingdom
of Naples.

This curious relic of antiquity is mentioned, be-
cause it affords better evidence than, on the subject
of ancient music, is usually to be met with, that the
Egyptians, at so very early a period of their history,
had advanced to a considerable degree of excellence
in the cultivation of the arts. By means of its neck,
this instrument was capable, with only two strings,
of producing a great number of notes. These two
strings, if tuned fourths to each other, would furnish
that series of sounds called by the ancients 
epstachon, which
MUSIC.

which consists of a conjunct tetrachord as B, C, D, E; E, F, G, A; if tuned fifths, they would produce an octave, or two disjunct tetrachords. The calascione is tuned in this last manner. The annals of no nation other than Egypt, for many ages after the period of the obelisk at Heliopolis, exhibit the vestige of any contrivance to shorten strings during performance by a neck or finger-board. Father Montfaucon observes, that after examining 300 ancient lyres, harps, and citharas, he could discover no such thing.

Egypt indeed seems to have been the source of human intelligence, and the favourite residence of genius and invention. From that celebrated country did the Greeks derive their knowledge of the first elements of those arts and sciences in which they afterwards so eminently excelled. From Greece again did the Romans borrow their attainments in the same pursuits. And from the records of those different nations the moderns have been enabled to accomplish so wonderful an improvement in literature.

The Hermis of the Egyptians, surnamed Trimegistus, or thrice illustrious, who, was, according to Sir Isaac Newton, the secretary of Osiris, is celebrated as the inventor of music. It has already been observed, that no one person ought strictly to be called the inventor of an art which seems to be natural to, and coeval with, the human species; but the Egyptian Mercury is without doubt entitled to the praise of having made striking improvements in music, as well as of having advanced in various respects the civilization of the people, whose government was chiefly committed to his charge. The account given by Apollonius of the manner in which he accidentally invented the lyre, is at once entertaining and probable. "The Nile (says Apollonius), after having overflowed the whole country of Egypt, when it returned within its natural bounds, left on the shore a great number of dead animals of various kinds, and among the rest a tortoise; the flesh of which being dried and wasted by the sun, nothing remained within the shell but nerves and cartilages, and these being braised and contracted by the drying heat became sonorous. Mercury walking along the banks of the Nile, happened to strike his foot against this shell; and was so pleased with the sound produced, that the idea of a lyre started into his imagination. He constructed the instrument in the form of a tortoise, and strung it with the dried sinews of dead animals."

How beautiful to conceive the energetic powers of the human mind in the early ages of the world, exploring the yet undiscovered capabilities of nature, and directed to the inexhaustible store by the finger of God in the form of accident!

The monaulus, or single flute, called by the Egyptians photinx, was probably one of the most ancient instruments used either by them or any other nation. From various remains of ancient sculpture, it appears to have been shaped like a bull's horn, and was at first, it may be supposed, no other than the horn itself—Before the invention of flutes, as no other instrument except those of percussion were known, music must have been little more than metrical. When the art of refining and lengthening sounds was first discovered, the power of music over mankind, from the agreeable surprise occasioned by soft and extended notes, was probably irresistible. At a time when all the rest of the world was involved in savage ignorance, the Egyptians were possessed of musical instruments capable of much variety and expression.—Of this the astonishing remains of the city Thebes still subsisting afford ample evidence. In a letter from Mr Bruce, ingrossed in Dr Burney's history of Music, there is given a particular description of the Theban harp, an instrument of extensive compass, and exquisite elegance of form. It was hung with a drawing taken from the ruins of an ancient sepulchre at Thebes, supposed by Mr Bruce to be that of the father of Sesostris. On the subject of this harp, Mr Bruce makes the following striking observation. It overturns all the accounts of the earliest state of ancient music and instruments in Egypt, and is altogether, in its form, ornaments, and compass, an incontestable proof, stronger than a thousand Greek quotations, that geometry, drawing, mechanics, and music were at the greatest perfection when this harp was made; and that what we think in Egypt was the invention of arts was only the beginning of the era of their restoration."

Indeed, when the beauty and powers of this harp, along with the very great antiquity of the painting which represents it, are considered, such an opinion as that which Mr Bruce hints at, does not seem to be void of probability.

It cannot be doubted that during the reigns of the Ptolemies, who were voluptuous princes, music must have been much cultivated and encouraged. The father of Cleopatra, who was the last of that race of kings, derived his title of auletes, or flute-player, from his excessive attachment to the flute. Like Nero, he is said to have arrayed himself in the dress of a tibicen, and to have exhibited his performance in the public musical contests. Some authors, particularly Mr. M. Marcellinus and M. Pan, refuse to the Egyptians, at any period of their history, any musical genius, or any excellence in the art; but the arguments used to support this opinion seem to be inconclusive, and the evidences of the opposite decision appear to be incontestable.

The sacred Scriptures afford almost the only materials from which any knowledge of Hebrew music can be drawn. In the rapid sketch, therefore, of ancient music which we mean to exhibit, a very few observations are all which can properly be given to that department of our subject.

Moses, who led the Israelites out of Egypt, was educated by Pharaoh's daughter in all the literature and elegant arts cultivated in that country. It is probable, therefore, that the taste and style of Egyptian music would be infused in some degree into that of the Hebrews. Music appears to have been interwoven through the whole tissue of religious ceremony in Palestine. The priesthood seem to have been musicians hereditary and by office. The prophets appear to have accompanied their inspired effusions with music; and every prophet, like the present improvisatori of Italy, seems to have been accompanied by a musical instrument.

Music, vocal and instrumental, constituted a great part of the funeral ceremonies of the Jews. The pomp and expense used on these occasions advanced by degrees to an excessive extent. The number of instrumental players in the processions amounted sometimes to several hundred,
hundreds, and the attendance of the guests continued
plus, frequently for 30 days. The Hebrew language abounds with consonants,
and has so few vowels, that in the original alphabet
they had no characters. It must, therefore, have been
harsh and unfavourable to music. Their instruments
of music were chiefly those of percussion; so that,
both on account of the language and the instruments,
and the music must have been coarse and noisy. The vast
numbers of performers too, whom it was the taste of
the Hebrews to collect together, could with such a lan-
guage and such instruments produce nothing but clam-
our and jargon. According to Josephus, there were
200,000 musicians at the dedication of Solomon's
temple. Such are the circumstances from which only
an idea of Hebrew music can be formed; for the Jews,
neither ancient nor modern, have ever had any char-
ters peculiar to music; and the melodies used in their
religious ceremonies have at all times been entirely tra-
ditional.

Cadmus, with the Phoenician colony which he led
into Greece, imported at the same time various arts
into that country. By the assistance of his Phoenician
artificers, that chief discovered gold in Thrace and copper
at Thebes. At Thebes that metal is still term-
ed cadmia. Of these materials, and of iron, they
formed to themselves armour and instruments of war.
These they struck against each other during their
dances at sacrifices, by which they first obtained the
idea of music. Such is the account given of the ori-
gin of that species of music in Greece produced by
instruments of percussion. The invention of wind
instruments in Greece is attributed to Minerva; and to
the Greek Mercury is assigned, by the poets and
historians of that country, the honour of many discov-
eries probably due to the Egyptian Hermes, particu-
larly the invention of stringed instruments. The lyre
of the Egyptian Mercury had only three strings; that
of the Grecian seven: the last was perhaps no more
than an improvement on the other. When the Greeks
deified a prince or hero of their own country, they
usually assigned him an Egyptian name, and with the
name bestowed on their new divinity all the actions,
attributes, and rites of the original.

The Grecian lyre, although said to have been in-
vented by Mercury, was cultivated principally by
Apollo, who first played upon it with method, and
accompanied it with the voice. The celebrated con-
test between him and Marsyas is mentioned by various
authors; in which, by enjoining the voice with his
lyre (a combination never before attempted), his music
was declared superior to the flute of Marsyas. The
progress of the lyre, according to Diodorus Siculus,
is the following: "The muses added to the Grecian
lyre the string called meos; Linus that of lichanos;
and Orpheus and Thamyris those strings which are
named hypate and parhypate." It has been already
mentioned, that the lyre invented by the Egyptian
Mercury had but three strings. By putting these cir-
cumstances together, we may perhaps acquire some
knowledge of the progress of music, or at least of the
extension of its scale in the highest antiquity. Mese,
in the Greek music, is the fourth sound of the second
tetradchord of the great system, and first tetradchord
invented by the ancients, answering to our A, on the
fifth line in the base. If this sound then was added to
the former three, it proves that the most ancient
tetradchord was that from E in the base to A; and that
the three original strings in the Mercarian and Apollon-
ian lyre were tuned E, F, G, which the Greeks call
hypate meos, parhypate meos, and meos diatonos:
The addition, therefore, of mese to these, completed
the first and most ancient tetradchord E, F, G, A.
The string lichanos again being added to these, and an-
twering to our D on the third line in the base, extended
the compass downwards, and gave the ancient lyre a regu-
lar series of five sounds. The two strings hypate and
parhypate, corresponding with our B and C in the base,
completed the heptachord or seven sounds b, c, d, e, f,
g, a; a compass which received no addition till after
the days of Pindar.

It might perhaps be expected, that in a history of
Greek music something ought to be said concerning
the muses, Apollo, Bacchus, and the other gods and
demi-gods, who in the mythology of that country ap-
pear to have promoted and improved the art. But
such a discussion would be too diffuse, and involve too
much foreign matter for the plan we have chosen to
adopt. We cannot avoid, however, making a few
observations on the poems of Homer, in so far as con-
ected with our subject. It has been imagined, with
much appearance of probability, that the occupation
of the first poets and musicians of Greece resembled
that of the Celtic and German bards and the scalds
musicians of Iceland and Scandinavia. They sang their poems
in the streets of the cities and in the palaces of princes.
They were treated with high respect, and regarded as
inspired persons. Such was the employment of Ho-
er. His poems, so justly celebrated, exhibit the
most authentic picture that can be found in the annals
of antiquity, although perhaps somewhat highly col-
oured, of the times of which he wrote and in which
he lived. Music is always named throughout the Iliad
and Odyssey with rapture; but as in these poems no
mention is made of instrumental music unaccompanied
with poetry and singing, a considerable share no doubt
of the poet's praises is to be attributed to the poetry.
The instruments most frequently named are the lyre,
the flute, and the syrinx. The trumpet appears not
to have been known at the siege of Troy, although
it had come to be in use in the days of Homer him-
self. From the time of Homer till that of Sappho,
there is almost a total blank in literature. Only a few
fragments remain of the works of those poets and mu-
icians whose names are preserved as having flourished
between those periods (A). During the century which
elapsed between the days of Sappho and those of Ana-
creon, no literary productions are preserved entire.

(A) Hesiod lived so near to Homer, that it has been disputed which of them is the most ancient. It is now,
we believe, universally admitted, that the palm of antiquity is due to Homer; but we consider them as having
both flourished in the same era.

Q 2 From
From Anacreon to Pindar there is another chasm of
near a century. Subsequent to this time, the works
still extant of the three great tragic poets, Aeschylus,
Sophocles, and Euripides, together with those of Plato,
Aristotle, Aristoxenus, Euclid, Theocritus, Callimachus,
Polybius, and many others, produced all within a
space less than 300 years, distinguish this illustrious
and uncommon period as that in which the whole
powers of genius seem to have been exerted to illumine
and instruct mankind in future ages. Then it
was that eloquence, poetry, music, architecture, history,
painting, sculpture, like the spontaneous blossoms of na-
ture, flourished without the appearance of labour or of
arts.

The poets, as well epic as lyric and elegiac, were all
likewise musicians; so strictly connected were music and
poetry for many ages. It would afford amusement to
collect the biographical anecdotes of these favourites of
genius, and to assign to each the respective improvements
made by him in music and poetry; but our limits do
not admit of so extensive a dissertation; for which,
therefore, reference must be made to the editors and
commentators of these authors, and to the voluminous
histories of music lately published.

The invention of notation and musical characters
marked a distinguished era in the progress of music.
There are a diversity of accounts respecting the person
to whom the honour of that invention is due; but the
evidences seem to preponderate in favour of Terpander,
a celebrated poet and musician, to whose genius music
is much indebted. He flourished about the 27th Olym-
piad, or 677 years before Christ.

Before that valuable discovery, music being entirely
traditional, must have depended much on the memory
and taste of the performer.

There is an incident mentioned in the accounts
handed down to us of the Olympic games, which may
serve in some degree to mark the character of music
at the time in which it happened. Lucian relates that
a young flute-player named Harmonides, at his first
public appearance in these games, began a solo with so
violent a blast, on purpose to surprise and elevate the
audience, that he breathed his last breath into his flute,
and died on the spot. When to this anecdote, won-
terful to us, and almost incredible, is added that cir-
cumstance, that the trumpet-players at these public
exhibitions expressed an excess of joy when they found
their exertions had neither rent their cheeks nor burst
their blood-vessels, some idea may be formed of the
noisy and vociferous style of music which then pleased;
and from such facts only can any opinion be obtained
of the actual state of ancient music.

In whatever manner the flute was played on, there
is no doubt, it was long in Greece an instrument of
high favour, and that the flute-players were held
in much estimation. The flute used by Lysanias, a
celebrated Theban musician, cost at Corinth three ta-
lets, or 381l. 5s. If, says Xenophon, a bad flute-
player would pass for a good one, he must, like the
great flute-players, expend large sums on rich furniture,
and appear in public with a great retinue of servants.

The ancients, it appears, were not less extravagant
in gratifying the ministers of their pleasures than our
selves. Ammonius, a harper, was paid an Attic talent
or 331 l. 15s. per day for his performance (b).

It is proper to add, that the celebrated musicians of
Greece who performed in public were of both sexes;
and that the beautiful Lamia, who was taken captive
by Demetrius, in the sea engagement in which he van-
quished Polycnem Soter, and who herself captivated her
conqueror, was a public performer, as well as were
many other celebrated female spirits, who are recorded
by ancient authors in terms of admiration, and of whom
we had our limits here admit of biography, we would treat
with pleasure. The philosophers of Greece, whose
courageous minds grasped every other object of human in-
elligence, were not inattentive to the theory of music, or
the philosophy of sound. This department of science
became the source of various sects, and of much diversity
of opinion. — The founders of the most distinguished
sects were Pythagoras and Aristoxenus.

Like every other people, the Romans, from their
first origin as a nation, were possessed of a species of
music which might be distinguished as their own. It
appears to have been rude and coarse, and probably
was a variation of the music in use among the Etrus-
cans and other tribes around them in Italy; but as
soon as they began to open a communication with
Greece, from that country, with their arts and philo-
sophy, they borrowed also their music and musical in-
tstruments. No account, therefore, of Roman music
is to be expected that would not be a repetition of
what has been said on the subject of the music of
Greece.

The excessive vanity of Nero with respect to music,
displayed in his public conserations for superiority with
the most celebrated professors of the art in Greece
and Rome, is known to every one conversant in the
history of Rome. The solicitude with which that
detestable tyrant attended to his voice is curious, and
will throw some light on the practices of singers in
ancient times. He was in use to lie on his back, with
a thin plate of lead on his stomach. He took frequent
emetics and cathartics, abstained from all kinds of
fruits and such meats as were held to be prejudicial
to singing. Apprehensive of injuring his voice, he lay
teight desisted from haranguing the soldiery and the
senate; and after his return from Greece established
an officer (Phonascus) to regulate his tones in speak-
ing.

Most nations have consented in introducing music
into their religious ceremonies. That art was early
admitted into the rites of the Egyptians and Hebrews;
and that it constituted a considerable part of the Cer-
cian and Roman religious service, appears from the
writings of many ancient authors. The same pleasing
art soon obtained an introduction into the Christian
church, as the Acts of the Apostles discover in many
passages. There remain no specimens of the music
employed in the worship of the primitive Christians;
but probably it was at first the same with that used
in the Pagan rites of the Greeks and Romans. The
practice

(b) Roscius gained 500 sestertia, or 403 l. 9s. 2d. sterling.
MUSIC.

practice of chanting the psalms was introduced into the western churches by St Ambrose, about 350 years after Christ. In the year 500, the method of chanting was improved by St Gregory the Great. The Ambrosian chant contained four modes. In the Gregorian number was doubled. So early as the age of Constantine the Great, prior to either of the periods last mentioned, when the Christian religion first obtained the countenance of power, instrumental music came to be introduced into the service of the church. In England, according to Bishop Stillingsfleet, music was employed in the church service, first by St Augustine, and afterwards much improved by St Dunstan, who was himself an eminent musician, and who is said to have first furnished the English churches and convents with the organ. The organ, the most majestic of all instruments, seems to have been an improvement of the hydraulic or water organ of the Greeks.—The first organ seen in France was sent from Constantinople in 757, as a present to King Pepin from the emperor Constantine Copronymus VI. In Italy, Germany, and England, that instrument became frequent during the 10th century.

During the dark ages no work of genius or taste in any department of science seems to have been produced in any part of Europe; and except in Italy, where the cultivation of music was rather more the object of attention, that art was neglected equally with all others. There has always been observed a correspondence in every country between the progress of music and the cultivation of other arts and sciences. In the middle ages, therefore, when the most fertile provinces of Europe were occupied by the Goths, Huns, Vandals, and other barbarous tribes, whose language was as harsh as their manners were savage, little perfection and no improvement of music is to be looked for. Literature, arts, and refinements, were encouraged more early at the courts of the Roman pontiffs than in any other country; and owing to that circumstance it is, that the scale, the counterpoint, the best melodies, the dramas religious and secular, the chief graces and elegancies of modern music, have derived their origin from Italy. In modern times, Italy has been to the rest of Europe what ancient Greece was to Rome. The Italians have sided the civilization of their conquerors, and enlightened the minds of those whose superior prowess had enslaved them.

Having mentioned counterpoint, it would be improper not to make one or two observations on an invention which is supposed to have been the source of great innovation in the practice of music. Counterpoint, or music in parts, seems to be an invention purely modern. The term harmony meant in the language of antiquity what is now understood by melody. Guido, a monk of Arezzo in Tuscany, is, in the general opinion, supposed to have entertained the first idea of counterpoint about the year 1025: an art which, since his time, has experienced gradual and in perceptible improvements, far exceeding the powers or comprehension of any one individual. The term counterpoint, or contra punctum, denotes its own etymology and import. Musical notation was at one time performed by small points; and the present mode is only an improvement of that practice. Counterpoint, therefore, denotes the notation of harmony or music in parts, by points opposite to each other. The improvements of this important acquisition to the art of music kept pace at first with those of the organ; an instrument admirably adapted to harmony: And both the one and the other were till the 13th century employed chiefly in sacred music. It was at this period that sacred music began to be cultivated.

Before the invention of characters for time, music in parts must have consisted entirely of simple counterpoint, or note against note, as is still practised in psalmody. But the happy discovery of a time-table extended infinitely the powers of combined sounds. The ancients had no other resource to denote time and movement in music except two characters (— —), equivalent to a long and a short syllable. But time is of such importance in music, that it can impart meaning and energy to the repetition of the same sound. Without it variety of tones has no effect with respect to gravity and acuteness. The invention of the time-table is attributed by almost all the writers of the on music of the last and present century to John de l'art de la table, who flourished about the year 1330. But in a manuscript of John de l'Art de la table, bequested to the Vatican library by the Queen of Sweden, that honour seems to be yielded to Magister Franco, who appears to have been alive as late as 1083. John de Darmus, however, who has some cause to believe was an Englishman, though not the inventor of the art de table, did certainly by his numerous writings greatly improve it. His tract on the Art of Counterpoint is the most clear and useful essay on the subject of which these times can boast.

In the 11th century, during the first crusade, Europe began to emerge from the barbarous stupidity and ignorance which had long overwhelmed it. While its inhabitants were exercising in Asia every species of rapine and pious cruelty, art, ingenuity, and reason, insensibly civilized and softened their minds. Then it was that the poets and songsters, known by the name of Troubadours, who first appeared in Provence, instituted a new profession; which obtained the patronage of the count of Poitou, and many other princes and barons, who had themselves cultivated music and poetry with success. At the courts of their munificent patrons the troubadours were treated with respect. The ladies, whose charms they celebrated, gave them the most generous and flattering reception. The success of some inspired others with hopes, and excited exertions in the exercise of their art; impelling them towards perfection with a rapidity which the united force alone of emulation and emulation could occasion. These founders of modern verisimilitude, constructing their songs on plans of their own, classical authority, either through ignorance or design, was entirely disregarded. It does not appear, however, during the cultivation and favour of Provençal literature, that any one troubadour so far outstripped the rest as to become a model of imitation. The progress of taste must ever be impeded by the ignorance and cupidity of those who cultivate an art without science or principles.

During almost two centuries after the arrangement of
of the scale attributed to Guido, and the invention of the time-table ascribed to Franco, no remains of secular music can be discovered, except those of the troubadours or Provençal poets. In the simple tunes of these bards no time is marked, and but little variety of notation appears: It is not difficult, however, to discover in them the germs of the future melodies, as well as the poetry of France and Italy. Had the poetry and music of the troubadours been treated of in an agreeable manner by the writers who have chosen that subject, it would have been discovered to be worthy of attention; the poetry, as interesting to literature; the melody to which it was sung, as curious to the musical historian.

Almost every species of Italian poetry is derived from the Provençals. Air, the most captivating part of secular vocal music, seems to have had the same origin. The most ancient strains that have been spared by time, are such as were set to the songs of the troubadours. The Provençal language began to be in favour with poets about the end of the 15th century. In the 13th became the general vehicle, not only of poetry, but of prose, to all who were ignorant of Latin. And these were not the laity only. At this period violins, or performers on the vielle or viol, juglers, or flute-players, musara or players on other instruments, and comics or comedians, abounded all over Europe. This swarm of poet-musicians, who were formerly comprehended in France under the general title of jongleurs, travelled from province to province, singing their verses at the courts of princes. They were rewarded with clothes, horses, arms, and money. Jongleurs or musicians were employed often to sing the verses of troubadours, who themselves happened to be deficient in voice or ignorant of music. The term troubadour, therefore, implies poetry as well as music. The jongleurs, menetriers, strollers, or minstrels, were frequently musicians, without any pretensions to poetry. These last have been common at all times; but the troubadour or bard has distinguished a particular profession, either in ancient or modern times, only during the early dawning of literature.

In the 13th century the songs were on various subjects; moral, merry, amorous: and at that time melody seems to have been little more than plain song or chanting. The notes were pure, and written on four lines only like those of the Roman church in the cliff C, and without any marks for time. The movement and embellishments of the air depended on the abilities of the singer. Since that time, by the cultivation of the voice modern music has been much extended, for it was not till towards the end of St Lewis's reign that the fifth line began to be added to the stave. The singer always accompanied himself with an instrument in unison.

As the lyre is the favourite instrument in Grecian poetry, so the harp held the same place in the estimation of the poets who flourished in the period of which we at present speak. A poet of the 14th century, Machaut, wrote a poem on the subject of the harp alone; in which he assigns to each of its 25 strings an allegorical name; calling one liberality, another wealth, &c.

The instrument which frequently accompanied, and indeed disputed the pre-eminence with the harp, was the violin. Till the 16th century this instrument was furnished with frets; after that period it was reduced to four strings: and still under the denomination of violin holds the first place among the treble instruments. The violin was played with a bow, and differed entirely from the vielle, the tones of which were produced by the friction of a wheel: The wheel performed the part of a bow.

British harpers were famous long before the conquest. The bounty of William of Normandy to his joculator or bard is recorded in the Doomsday book. The harp seems to have been the favourite instrument in Britain for many ages, under the British, Saxons, Danish, and Norman kings. The fiddle, however, is mentioned so early as 1200 in the legendary life of St Christopher. The ancient privileges of the minstrel at the fairs of Chester are well known in the history of England.

The extirpation of the bards of Wales by Edward I. is likewise too familiar an incident to be particularly mentioned here. His persecuting spirit, however, seems to have been limited to that principality; for we learn, that at the ceremony of knightling his son, a multitude of minstrels attended.

In 1315, during the reign of Edward II., such extensive privileges were claimed by the minstrels, and so many dissolute persons assumed that character, that it became necessary to restrain them by express laws.

The father of our genuine poetry, who in the 14th century enlarged our vocabulary, polished our numbers, and with acquisitions from France and Italy augmented our store of knowledge (Chaucer), entitles one of his poems The History of St Cecilia; and the celebrated patroness of music must no doubt be mentioned in a history of the art. Neither in Chaucer, however, nor in any of the histories or legendary accounts of this saint, does any thing appear to authorize the religious veneration paid to her by the rostaries of music; nor is it easy to discover whence it has arisen.

As an incident relative to the period of which we speak, it may be mentioned, that, according to Spelman, the appellation of Doctor was not among the degrees granted to graduates in England sooner than the reign of King John, about 1207; although, in the early 15th century, Wood's history of Oxford, that degree is said to have been conferred, even in music, in the reign of Henry II. It is known that the title was created on the continent in the 12th century; and as, during the middle ages, music was always ranked among the seven liberal arts, it is likely that the degree was extended to it.

After the invention of printing, an art which has tended to disseminate knowledge with wonderful rapidity among mankind, music, and particularly counterpoint, became an object of high importance. The names of the most eminent composers who flourished in England, from that time to the Reformation, were Fairfax, William of Newark, Shrewsbury, Tegs, Banister, Tudor, Taverner, Tye, Johnson, Parsons; to whom may be added John Marbeck, who set the whole English cathedral service to music.

Before this period Scottish music had advanced to a high degree of perfection. James I. was a great music composer of airs to his own verses; and may be considered
MUSIC.

flourished in the 16th century, were, Francesco Ga- Emi-
nerius, or Gafforio of Lode, Pietro Aaron of Flo-
rence, Lodovico Fogliano, Giov. Spaturo, Giov. Ma-
ria da Terentio Lanfranco, Stefano Uanneo, Anton-
16th cent.
Francisco Done, Luigi Dentice, Nicolò Vicentino,
and Giuseppe Zarlino, the most general, voluminous,
and celebrated theorist of that period, Vincentio Gall-
lei, a Florentine nobleman, and father of the great Ga-
leio Galilei, Maria Artuse of Bologna, Orsese Te-
grini, Pietro Pontio, and Lodovico Zacconi.

The principal Roman authors were: Giovanni An-
muccia, Giovanni Pierluigi da Palestrina, justly cele-
brated, Ruggiero Giovannelli, Luca Marenzio, who-
brought to perfection madrigals, the most cheerful-
species of secular music.

Of the Venetians, Adrian Willaert is allowed to be-
at the head.

At the head of the Neapolitans is deservedly placed
Rocco Rodio.

At Naples, too, the illustrious dilettante, Don Carlo
Gesualdo prince of Venosa, is highly celebrated. He
seems, however, to have owed much of his fame to his
high rank.

Lombardy might also furnish an ample list of eminent
musicians during the 16th century, of whom, however,
our limits will not admit of a particular enumeration:
—
The chief of them were, Constantino Porta, Gastoldi,
Bischi, Cima, Vocchi, and Monteverde.

At Bologna, besides Artusi already mentioned, An-
drea Bota of the same city appears to have been an
admirable contrapunctist.

Francisco Cerutia, a celebrated organist and com-
poser, and Alessandro Striggio, a lutenist and vol-
uminous composer, were the most eminent Florentines.

The inhabitants of the extensive empire of Germany
have long made music a part of general education.—
y.

They hold the place, next to Italy, among the most
successful cultivators of the art. During the 16th cen-
tury, the most eminent composers of music and writ-
ers on the subject were, Geo. Reischius, Michael Ros-
wick, Andreas Oenithorpharion, Paul Hofhaimer,
Luspeinus, Henry Lori or Lorit, Faber, Fink, Hos-
man, and many others whom it would be tedious to
mention; and for a particular account of whose treat-
s and compositions we must refer to more volumi-
nous histories of music.

In France, during the 16th century, no art except
in France: the art of war made much progress in improve-
ment.—
Ronsard, Baif, Goudinel, Claude le Jeune, Caurey,
and Maudit, are the chief French musicians of that
period.

In Spain, music was early received into the circle of Spai-
science in the universities. The musical professorship
at Salamanca was founded and endowed by Alfonso the
Wise, king of Castile.

One of the most celebrated of the Spanish musicians
was Francisco Salinas, who had been blind from his in-
fo-

D. Cristoforo Morales, and Tomaio Lodovico da
Vittorio, deserve likewise to be mentioned; and to
mention them is all we can attempt; the purpose of
which is, to excite more minute inquiry by those who
may choose to investigate the subject particularly.

The Netherlands, likewise, during the period of which, The
we have been speaking, produced eminent composers; theirlands.
of whom we may mention Verletot, Gembert, Arkadelt, Berchem, Richefort or Ricciardot, Crequilon Le Cock or Le Coq, Canis, Jacob Clemens Nea Papa, Pierre Manchicourt, Baston, Kari, Rore, Orlando di Lasso, and his sons Ferdinand and Rodolph.

In the 17th century, the musical writers and composers who acquired fame in England were, Dr Nathaniel Giles, Thomas Tomkins, and his son of the same name; Elway Bevin, Orlando Gibbons, Dr William Child, Adrian Batten, Martin Pierson, William Lawes, Henry Lawes, Dr John Wilson, John Hilton, John Playford, Captain Henry Cook, Pelham Humphrey, John Blow, William Turner, Dr Christopher Gibbons, Benjamin Rogers, and Henry Purcell. Of these, Orlando Gibbons, Pelham Humphrey, and Henry Purcell, far excelled the rest.

About the end of the reign of James I. a music-lecture or professorship was founded in the university of Oxford by Dr William Hyckin.

In the reign of Charles I. a charter was granted to the musicians of Westminster, incorporating them, as the king's musicians, into a body politic, with powers to prosecute and fine all who, except themselves, should "attempt to make any benefit or advantage of music in England or Wales;" powers which in the subsequent reign were put in execution.

About the end of the reign of Charles II. a passion seems to have been excited in England for the violin, and for pieces expressly composed for it, in the Italian manner (a). Prior to 1650, there was little other music except masses and madrigals, the two principal divisions of sacred and secular music; but from that time to the present, dramatic music becomes the chief object of attention. The music of the church and of the chamber continued indeed to be cultivated in Italy with diligence, and in a learned and elaborate style, till near the middle of the century; yet a revolution in favour of melody and expression was preparing, even in sacred music, by the success of dramatic composition, consisting of recitation and melodies for a single voice. Such melodies began now to be preferred to music of many parts; in which canons, fugues, and full harmony, had been the productions which chiefly employed the master's study and the hearer's attention.

So late as the beginning of the 18th century, according to Riccoboni, the performers in the operas of Germany, particularly at Hamburg, "were all tradesmen or handicrafts. Your shoemaker (says he) was often the first performer on the stage; and you might have bought fruit and sweetmeats of the same girls, whom the night before you had seen in the characters of Armida or Semiramis. But, however, the German opera arose to a most respectable situation, and even during the 17th century many eminent composers flourished in that country." The list of great musicians which France produced during the early part of the same century is not so numerous. Music seems to have been but little cultivated in that country, till the operas of Lulli, under the powerful patronage of Louis XIV. excited public attention.

The favourite singing-master and composer of France, about the middle of the 17th century, was Michael Lambert. John Baptist Lulli, soon after this time, rose from the rank of a menial servant to fame, opulence, and nobility, by his skill in musical compositions. The celebrated singer Le Bochois was taught singing and acting by Lulli.

La Maupin the successor of Le Bochois, as no-Corine, account of her extraordinary character and romantic adventures, deserves to be mentioned. She eloped from her husband with a fencing-master, of whom she learned the small sword. She became an excellent fencer. At Marseilles she entertained a strange attachment to a young lady, who was seized with a whimsical fancy in return, on account of which the latter was confined in a convent. La Maupin obtained admission into the same convent as a novice. She set fire to the building, and in the confusion carried off her favourite. At Paris when she appeared on the stage in 1695, Dumesni a singer having anticipated her, she put on men's clothes, and insisted on his drawing his sword and fighting her. When he refused, she caimed him, and took from him his watch and snuff-box as trophies of her victory. At a ball given by Monsieur brother of Louis XIV, she again put on men's clothes; and having behaved imprudently to a lady, three of the lady's friends, supposing La Maupin to be a man, called her out. She killed them all; and returning coolly to the ball, told the story to Monsieur, who obtained her pardon. She became afterwards mistress to the elector of Bavaria. This prince quitting her for the countess of Arco, sent her by the count, husband of that lady, a purse of 40,000 livres. She threw it at the count's head, telling him, it was a recompense worthy of such meanness as he displayed. At last, seized with a fit of devotion, she recalled her husband, and spent the remainder of her life in piety. She died in 1707 at the age only of 34.

The English musician whom we last mentioned was the celebrated Purcell. After his time the chief composers for the church were Clarke, Dr Holdes, Dr Creyghton, Tucker, Aldrich, Golwin, Welden, Dr Crofts, Dr Greene, Boyce, and Nares; to whom may be added John Stanley, who attained high proficiency in music, although from two years old totally deprived of sight.

The annals of modern music have hitherto furnished no event so important to the progress of the art as the invention of recitative or dramatic melody; a style of music which resembles the manner of the ancient rhapsodists.

The Orfeo of Peri was the first attempt at musical drama. It was afterwards perfected by Metastasio and others. No musical dramas similar to those afterwards known

(a) The most celebrated violin players of Italy, from the 16th century to the present time, have been Farina, M. Angelo Rossi, Bassani the violin-master of Corelli, the admirable Angelico Corelli himself, Torelli, Alberti, Albenevi, Tesserini, Vivaldi, Geminianni, one of the most distinguished of Corelli's scholars, Tartini, Veracini, Barbella, Locatelli, Ferrari, Martinuti, Boccherini, and Giardini. 
known by the names of opera and oratorio, had existence in Italy before the beginning of the 17th century. It was about the 1600, or a little before that time, that castrati were first employed for singing in Italy.

There seem to have been no singing castrati in ancient times, unless the galli or archigalli, priests of Cybele, were such. Castration has, however, at all times been practised in eastern countries, for the purpose of furnishing to tyrannic jealousy guards of female chastity; but never, so far as modern writers on the subject have discovered, merely to preserve the voice, till about the end of the 16th century.

At Rome, the first public theatre opened for the exhibition of musical dramas, in modern times, was il Torre de Nona, where in 1671 Giassone was performed. In 1679, the opera of Trois Amores, set by the famous organist Bernardo Pasquini, was represented at Nola Solo de Signori Copernica; a theatre which still subsists. In the year 1680, L’Onesta negl’Amore was exhibited; the first dramatic composition of the elegant, profound, and original Alessandro Scarlatti.

The inhabitants of Venice have cultivated and encouraged the musical drama with more zeal and diligence than the rest of Italy, during the end of the last and beginning of the present century; yet the opera was not established in Venice before the year 1637. In that year the first regular drama was performed. It was Andromeda.

In 1680 the opera of Berenice was exhibited at Padua with such astonishing splendour as to merit notice. There were choruses of 100 virgins, 100 soldiers, 100 horsemen in iron armours, 40 cornets of horse, 6 trumpeters on horseback, 6 drummers, 6 enpieces, 4 sackbutts, 6 great flutes, 6 minstrels playing on Turkish instruments, 6 others on octave flutes, 6 pages, 3 sergeants, 6 cymbalists. There were 12 huntsmen, 12 grooms, 6 coachmen for the triumph; 6 others for the procession; 2 lions led by two Turks, 2 elephants by two others, Berenice’s triumphal char drawn by 4 horses, 6 other cars with prisoners and spoils drawn by 12 horses, 6 coaches. Among the scenes and representations in the first act were, a vast plain with two triumphal arches, another plain with pavilions and tents, and a forest for the chase. In set third, the royal dressing room completely furnished, stables with 100 live horses, postico adorned with tapestry, and a stupendous palace in perspective. At the end of the first act were representations of every kind of chase, wild boar, stag, deer, bears. At the end of the third act, an enormous globe, descending as from the sky, divided itself into other globes suspended in the air, and ornamented with emblematical figures of time, fame, honour, &c.

Early in the last century, machinery and decoration usurped the importance due to poetry and music in such exhibitions.

Few instances occur of musical dramas at Naples till the beginning of the present century. Before the time of the elder Scarlatti, it seems as if Naples had been less fertile in great contrapuntists, and less diligent in the cultivation of dramatic music, than any other state of Italy. Since that time all the rest of Europe has been furnished with composers and performers from that city.

Vol. XIV. Part II.

The word opera seems to have been familiar to French

English poets from the beginning of the last century, and Eng-

lish recitative, a recent innovation even in Italy, is mentioned by Ben Johnson so early as 1647. From this time it was used in masques, occasionally in plays, and in cantatas, before a regular drama wholly set to music was attempted. By the united abilities of Qui-

nault and Lulli, the opera in France had risen to high favour. This circumstance afforded encouragement to several attempts at dramatic music in England by Sir William D'Avenant and others, before the music, language, or performers of Italy were employed on our stage. Pieces, styled dramatic operas, preceded the Italian opera on the stage of England. These were written in English, and exhibited with a profuse decoration of scenery and habits, and with the best singers and dancers that could be procured. Psyche and Circe are entertainments of this kind: The Tempest and Macbeth were acted with the same accompaniments.

During the 17th century, whatever attempts were made in musical drama, the language sung was always English. About the end of that century, however, Italian singing began to be encouraged, and vocal as well as instrumental musicians from that country began to appear in London.

The first musical drama, performed wholly after the Italian manner in recitative for the dialogue or narrative parts, and measured melody for the airs, was Arsinoë Queen of Cyprua, translated from an Italian opera of the same name, written by Stanzani of Bologna. The English version of this opera was set to music by Thomas Clayton, one of the royal band, in the reign of William and Mary. The singers were all English, Messrs Hughes, Leveredge, and Cook; Mrs Tofts, Mrs Cross, and Mrs Lyndsey. The translation of Arsinoë, and the music to which it is set, are execrable; yet such is the charm of novelty, that this miserable performance, deserving neither the name of a drama by its poetry, nor of an opera by its music, sustained 24 representations, and the second year 11.

Operas, notwithstanding their deficiencies in poetry, music and performance (no foreign composer or eminent singer having yet arrived), became so formidable to our actors at the theatres, that it appears from the Daily Courant, 14th January 1707, a subscription was opened “for the encouragement of the comedians acting in the Haymarket, and to enable them to keep the diversion of plays under a separate interest from operas.”

Mr Addison's opera of Rosamond appeared about this time; but the music set by Clayton is so contemptible, that the merit of the poetry, however great, could not of itself long support the piece. The choice of so mean a composer as Clayton, and Mr Addison's partiality to his abilities, betray a want of musical taste in that elegant author.

The first truly great singer who appeared on the stage of Britain was Cavalier Nicolo Grimaldi, commonly known by the name of Nirolini. He was a Neapolitan; and though a beautiful singer indeed, was still more eminent as an actor. In the Tatler, No 115, the elegance and propriety of his action are Spectator, particularly described. Recently before his appearance, Valentini Urbanus, and a female singer called The Baranci.
Music.

Faustina Bordoni, wife of the celebrated Saxon composer Hasse, invented a new kind of singing, by running divisions, with a neatness and velocity which astonished all who heard her. By taking her breath imperceptibly, she had the art of sustaining a note apparently longer than any other singer. Her beats and trills were strong and rapid; her intonation perfect. Her professional perfections were enhanced by a beautiful face, fine symmetry of figure, and a countenance and gesture on the stage which indicated an entire intelligence and possession of the several parts allotted to her.

These two angelic performers excited so signal the attention of the public, that a party spirit between the abettors of the one and of the other was formed, as violent and as inveterate almost as any of those that had ever occurred relative to matters either theological or political: yet so distinct were their styles of singing, so different their talents, that the praise of the one was no reproach to the other.

In less than seven years, the whole 50,000 l. subscribed by the Royal Academy, besides the produce of admission to non-subscribers, was expended, and the governor and directors of the society relinquished the idea of continuing their engagements; consequently, at the close of the season 1727, the whole band of singers dispersed. The next year we find Senesino, Faustina, Balde, Cuzzoni, Niccolini, Farinelli, and Bosche, at Venice.

Handel, however, at his own risk, after a suspension of about a twelvemonth, determined to recommence the Opera; and accordingly engaged a band of performers entirely new. These were Signor Bernachi, Signora Merighi, Signora Strada, Signor Anibale Pio Fabri, his wife, Signora Bertoldi, and John Godfrid Reimschneider.

The sacred musical drama, or oratorio, was invented early in the 17th century. Every nation in Europe seems first to have had recourse to religious subjects for dramatic exhibitions. The oratorios had been common in Italy during the last century. They had never been publicly introduced in England, till Handel, stimulated by the rivalry of other adventurers, exhibited in 1732 his oratorios of Esther, and of Acis and Galatea, the last of which he had composed twelve years before for the duke of Chando’s chapel at Cannons. The most formidable opposition which Handel met with in his conduct of the Italian opera was a new theatre for exhibiting these operas, opened by subscription in Lincoln’s-inn Fields, under the conduct of Nicola Porpora, a respectable composer. A difference having occurred between Handel and Senesino; Senesino had for some time deserted the Haymarket, where Handel managed, and was now engaged at the rival theatre of Lincoln’s-inn Fields. To supply the place of Senesino, Handel brought over Giovanoni Carestini, a singer of the most extensive powers. His voice was at first a powerful and clear soprano: Afterwards it changed into the fullest, finest, deepest counter-tenor that has perhaps ever been heard. Carestini’s person was tall, beautiful, and majestic. He rendered everything he sung interesting by energy, taste, and judicious embellishment. In the execution of difficult divisions from the chest, his manner was articulate and admirable. It was the opinion of Hasse, as well as other eminent professors,
that whoever had not heard Carestini, was unacquainted with the most perfect style of singing. The opera under the direction of Porpora was removed to the Haymarket, which Handel had left. Handel occupied the theatre of Lincoln's-inn Fields; but his rivals were unable to maintain the same advantage of attraction by the accession of Carlo Broschi detto Farinelli to their part, who at this time arrived. This renowned singer seems to have transcended the limit of all anterior vocal excellence. No vocal performer of the present century has been so unanimously allowed to possess an uncommon power, sweetness, extent, and agility of voice, as Farinelli. Nicolini, Senesino, and Carestini, gratified the eye as much by the dignity, grace, and propriety of their action and deportment, as the ear, by the judicious use of a few notes within the limits of a small compass of voice; but Farinelli, without the assistance of significant gestures or graceful attitudes, enchanted and astonished his hearers, by the force, extent, and mellifluous tones of the mere organ, when he had nothing to execute, articulate, or express. Though during the time of singing he was as motionless as a statue, his voice was so active that no intervals were too close, too wide, or too rapid, for his execution.

Handel having lost a great part of his fortune by the opera, was under the necessity of trying the public gratuity in a benefit, which was not disgraced by the event. The theatre, for the honour of the nation, was so crowded, that he is said to have cleared 800l.

After a fruitless attempt by Heidegger, the coadjutor of Handel in the conduct of the opera, and pattentee of the King's Theatre in Haymarket, to procure a subscription for continuing it, it was found necessary to give up the undertaking.

It was about this time that the statue of Handel was erected in Vauxhall, at the expense of Mr Tyers, proprietor of those gardens.

The next year (1739) Handel carried on oratorios at the Haymarket, as the opera there was suspended. The Earl of Middlesex now undertook the troublesome office of impresario of the Italian opera. He engaged the King's theatre, with a band of singers from the continent almost entirely new. Calluppi was his composer. Handel, almost ruined, retired at this time to Ireland, where he remained a considerable time. In 1744 he again attempted oratorios at the King's theatre, which was then, and till 1746, unoccupied by the opera, on account of the rebellion.

The arrival of Giardini in London this year forms a memorable era in the history of instrumental music of England. His powers on the violin were unequaled. The same year Dr Crozat, then manager of the opera, eloped, leaving the performers, and innumerable trades people, his creditors. This incident put an end to operas of all kinds for some time.

This year a comic opera, called Il Filosofo di Campagna, composed by Calluppi, was exhibited, which surpassed in musical merit all the comic operas performed in England till the Bionda Fignola. Signora Paganini acquired such fame by the airs allotted to her in that piece, that the crowds at her benefit were beyond example. Caps were lost, gowns torn in pieces, and ladies in full dress, without servants or carriages, were obliged to walk home, amidst the merriment of the spectators on the streets.

At this period the arrival of Giovanni Manzoli marked 1764 and a splendid era in the annals of musical drama, by conferring on serious opera a degree of importance to which it had seldom yet attained since its establishment in England. Manzoli's voice was the most powerful and voluminous soprano that had been heard since the time of Farinelli: His manner of singing was grand, and full of taste and dignity.

At this time Tenducci, who had been in England, some time before, and was now returned much improved, performed in the station of second man to Manzoli.

Gaetano Guadagni made a great figure at this time. He had been in this country early in life (1748), as a serious man in a burletta troop of singers. His voice was then a full and well-toned counter tenor; but he sung wildly and carelessly. The excellence of his voice, however, attracted the notice of Handel, who assigned him the parts in his oratorios, the Messiah and Samson, which had been originally composed for Mrs Cibber. He quitted London for the first time about 1753. The highest expectations of his abilities were raised by his fame before his second arrival, at the time of which we treat. As an actor he seems to have had no equal on any stage in Europe. His figure was uncommonly elegant and noble; his countenance replete with beauty, intelligence, and dignity; his attitudes were full of grace and propriety. Those who remembered his voice when formerly in England were now disappointed: It was comparatively thin and feeble: He had now changed it to a soprano, and extended its compass from six or seven notes to fourteen or fifteen. The music he sung was the most simple imaginable; a few notes with frequent pauses, and opportunities of being librated from the composer and the band, were all he required. In these effusions, seemingly extemporaneous, he displayed the native power of melody unaided by harmony or even by unisonous accompaniment: The pleasure he communicated proceeded principally from the artful manner of diminishing the tones of his voice, like the dying notes of the Æolian harp. Most other singers affect a swell, or messa de voce; but Guadagni, after beginning a note with force, attenuated it so delicately that it possessed all the effect of extreme distance. During the season 1770 and 1771, Tenducci was the immediate successor of Guadagni. This performer, who appeared in England first only as a singer of the second or third class, was during his residence in Scotland and Ireland so much improved as to be well received as first man, not only on the stage of London, but in all the great theatres of Italy.

It was during this period that dancing seemed first to gain the ascendant over music by the superior talents of Mademoiselle Heinzel, whose grace and execution were so perfect as to eclipse all other excellence.

In the first opera performed this season (Lucre Vero) 1773, appeared Miss Cecilia Davies, known in Italy by the Miss Da- name of L'ingleisea. Miss Davies had the honour of being the first English woman who had ever been thought worthy of singing on any stage in Italy. She even performed with eclat the principal female characters on many of the great theatres of that country. 3 R 2

Gabrielli
Gabrielli only on the Continent was said to surpass her. Her voice, though not of great volume, was clear and perfectly in tune; her shake was open and distinct, without the sluggishness of the French cadence. The flexibility of her throat rendered her execution equal to the most rapid divisions.

Next season introduced Venanzio Ravygui, a beautiful and animated young man; a composer as well as a singer. His voice was sweet, clear, flexible; in compass more than two octaves.

The season 1775 and 1776 was rendered memorable by the arrival of the celebrated Caterina Gabrielli, styled early in life La Cucchetina, being the daughter of a cardinal's cook at Rome. She had, however, in her countenance and deportment no indications of low birth. Her manner and appearance depicted dignity and grace. So great was her reputation before her arrival in England for singing and for caprice, that the public, expecting perhaps in both too much, were unwilling to allow her due praise for her performance, and were apt to ascribe every thing she did to pride and insolence. Her voice, though exquisite, was not very powerful. Her chief excellence having been the neatness and rapidity of her execution, the surprise of the public must have been much diminished on hearing her after Miss Davies, who sung many of the same songs in the same style, and with a neatness so nearly equal, that common hearers could distinguish no difference. The discriminating critic, however, might have discovered a superior sweetness in the natural tone of Gabrielli's voice, an elegance in the finishing of her musical periods or passages, an accent and precision in her divisions, superior not only to Miss Davies, but to every other singer of her time. In slow movements her pathetic powers, like those in general of performers most renowned for agility, were not exquisitely touching.

About the time of which we have been treating, the proprietors of the Pantheon ventured to engage Agujari at the enormous salary of 100l. per night, for singing two songs only: Lucrezia Agujari was a truly wonderful performer. The lower part of her voice was full, round, and of excellent quality; its compass amazing. She had two octaves of fair natural voice, from A on the fifth line in the base to A on the sixth line in the treble, and beyond that in alt she had in early youth more than another octave. She has been heard to ascend to B b in altissimo. Her shake was open and perfect: her intonation true; her execution marked and rapid; the style of her singing, in the natural compass of her voice, grand and majestic.

In 1776 arrived Anna Pozzi, as successor to Gabrielli. She possessed a voice clear, sweet, and powerful; but her inexperience, both as an actress and as a singer, produced a contrast very unfavourable to her when compared with so celebrated a performer as Gabrielli. After that time, however, Pozzi, with more study and knowledge, became one of the best and most admired female singers in Italy.

After the departure of Agujari for the second and last time, the managers of the Pantheon engaged Georgi as her successor. Her voice was exquisitely fine, but totally uncultivated. She was thereafter employed as the first woman in the organs of the principal cities of Italy.
MUSIC

benefit of the Musical Fund. The members and guardians of that fund are now incorporated under the title of Royal Society of Musicians. See HAENDEL.

This year Pacchierotti and his friend Bertoni left England. About the same time our country was deprived of the eminent composer Sacchini, and Girdini the greatest performer on the violin now in Europe.

As a compensation for these losses, this memorable year is distinguished by the arrival of Madame Mara, whose performance in the commemoration of Handel in Westminster Abbey inspired an audience of 5000 of the first people of the kingdom, not only with pleasure but with ecstasy and rapture.

In 1736 arrived Giovanni Rubinielli. His voice was a true and full contralto from C in the middle of the scale to the octave above. His style was grand; his execution neat and distinct; his taste and embellishments new, select, and masterly.

In 1788 a new dance, composed by the celebrated M. Noverre, called Cupid and Psyche, was exhibited along with the opera La Locandiera, which produced an effect so uncommon as to deserve notice. So great was the pleasure it afforded to the spectators, that Noverre was unanimously brought on the stage and crowned with laurel by the principal performers. This, though common in France, was a new mark of approbation in England.

This year arrived Signor Luigi Marchesi, a singer whose talents have been the subject of praise and admiration on every great theatre of Europe. Marchesi's style of singing was not only elegant and refined in an uncommon degree, but often grand and full of dignity, particularly in his recitative and occasional low notes. His variety of embellishment and facility of running extempore divisions were wonderful. Many of his graces were elegant and of his own invention.

The three greatest Italian singers of these times were certainly Pacchierotti, Rubinielli, and Marchesi. In discriminating the several excellencies of these great performers, a very respectable judge, Dr Burney, has particularly praised the sweet and touching voice of Pacchierotti; his fine shade, his exquisite taste, his great fancy, and his divine expression in pathetic songs: Of Rubinielli's voice, the fullness, sonority, and masterly, the accuracy of his intonations, his judicious graces: Of Marchesi's voice, the elegance and flexibility, his grandeur in recitative, and his boundless fancy and embellishments.—Having mentioned Dr Burney, we are in justice bound to acknowledge the aid we have derived from his history; a work which we greatly prefer to every other modern production on the subject.

During the latter part of the 18th century many eminent composers flourished on the continent; such as Jomelli, the family of the Bachs, Gluck, Haydn, and many others, whose different styles and excellencies would well deserve to be particularized, would our limits permit. With the same regard to brevity, we can do no more than just mention the late king of Prussia, the late elector of Bavaria, and Prince Lobkowitz, as eminent dilettanti of modern times.

Besides the opera singers whom we have mentioned, our theatres and public gardens have exhibited singers of considerable merit. In 1730 Miss Rafter, afterwards the celebrated Mrs Clive, first appeared on the stage at Drury-lane as a singer. The same year introduced Miss Cecilia Young, afterwards the wife of Dr Arne. Her style of singing was infinitely superior to that of any other English woman of her time.

Our favourite musicians at this time were, Dubourg, Favart, and Clegg, Clarke, and Festing, on the violin; Kyte, on the hautboy; Jack Festing on the German flute; Baston on the common flute; Kartan on the bassoon; Valentine Snow on the trumpet; and on the organ, Roseingrave, Green, Robinson, Maganna, and James, and the blind Stanley, who seems to have been preferred. The favourite playhouse singer was Salway; and at concerts Mountier of Chichester.

As composers for our national theatre, Pepusch and Galliard seem to have been unrivalled till 1738; when two competitors appeared, who were long in possession of the public favour: We allude to John Frederick Lampe and Thomas Augustus Arne.

In 1736 Mrs Cibber, who had cultivated every hearer of sensibility by her native sweetness of voice and powers of expression as a singer, made her first attempt as a tragic actress. The same year Beard became a favourite singer at Covent-garden. At this time Miss Young, afterwards Mrs Arne, and her two sisters Isabella and Esther, were the favourite English female singers.

In 1738 was instituted the fund for the support of Fund for decayed musicians and their families.

It was in 1747 that Mr Tyers, proprietor of Vauxhall gardens, first added vocal music to the other entertainments of that place. A short time before Vauxhall had become a place of public amusement.

In 1749 arrived Giardini, whose great taste, hand, and style in playing on the violin, procured him universal admiration. A few years after his arrival he formed a morning academy or concert at his house, composed chiefly of his scholars.

About this time San Martini and Charles Avison were eminent composers.

Of near 150 musical pieces brought on our national theatres within 40 years, 38 of them at least were set by Arne. The style of this composer, if not in any particular, but very well suited the taste of the age; however, would perhaps appear to be neither Italian nor English; but an agreeable mixture of both and of Scotch eccentricity.

The late earl of Kelly, who died some years ago, the earl of Lonsdale, and the late earl of Dartmouth, all describe particular notice, as possessed of a very eminent degree of musical science, far superior to other dilettanti, and perhaps not inferior to any professor of his time. There was no part of theoretical or practical music in which he was not thoroughly versed: He possessed a strength of hand on the violin, and a genius for composition, with which few professors are gifted.

Charles Frederick Abel was an admirable musician: Abel. His playing on the violin da gamba was in every particular complete and perfect. He had a hand which no difficulties could embarrass; a taste the most refined and delicate; a judgment so correct and certain as never to permit a single note to escape him without meaning. His compositions were easy and elegantly simple. In writing and playing an adagio he was superior to all praise; the most pleasing yet learned modulation, the richest harmony, the most elegant and polished melody, were all expressed with the most exquisite feeling, taste, and science. His manner of playing
playing an adagio soon became the model of imitation for all our young performers on bowed instruments. Bartholomew Cervetto, Cramer, and Crozal, were in this respect to be ranked as of his school. All lovers of music must have lamented that Abel in youth had not attached himself to an instrument more worthy of his genius, taste, and learning, than the viol da gamba, that remnant of the old chest of viols which during the 17th century was a necessary appendage of a nobleman’s or gentleman’s family throughout Europe, previous to the admission of violins, tenors, and basses, in private houses or public concerts. Since the death of the late elector of Bavaria, who was next to Abel the best performer on the viol da gamba in Europe, the instrument seems quite laid aside. It was used longer in Germany than elsewhere; but the place of gambist seems now as much suppressed in the chapels of German princes as that of lutist. The celebrated performer on the violin, Lolli, came to England in 1785. Such was his caprice, that he was seldom heard; and so eccentric was his style and composition, that by many he was regarded as a madman. He was, however, during his lucid intervals a very great and expressive performer in the serious style.

Mrs Billington. After distinguishing herself in childhood as a neat and expressive performer on the piano-forte, appeared all at once in 1786 as a sweet and captivating singer. In emulation of Mara and other great bravura singers, she at first too frequently attempted passages of difficulty; afterward, however, so greatly was she improved, that no song seemed too high or too rapid for her execution. Now, at the distance of 20 years, she retains her high reputation. The natural tone of her voice is so exquisitely sweet, her knowledge of music so considerable, her shake so sweet, her choices and embellishments so various, her expressions so grateful, that envy only or apathy could bear her without delight.

The present composers, and performers of the first class, are so well known to the lovers of the art, that it would be needless and improper to mention them particularly.

The catch-club and the concert of ancient music.

Madame Grassini. The Catch-club at the Thatched House, instituted in 1762 by the earl of Eglington, the duke of Queensberry, and others; and the concert of ancient music, suggested by the earl of Sandwich in 1776, have had a beneficial effect in improving the art.

Two female performers have lately appeared of distinguished eminence.

Madame Grassini had exhibited her vocal powers in Paris with extraordinary applause, and arrived in London in 1805, where she excited uncommon admiration. She appeared in Zaira, where the display of her powers not only pleased, but she astonished, when it was considered that the compass of her voice did not exceed eight or ten notes.

The year following Madame Catalani divided the public attention with Grassini.—This eminent performer is a native of Sinigaglia in Italy, where her father was a singer of the comic order.

She was educated in a convent. The virtuous im-
PRELIMINARY DISCOURSE.

MUSIC may be considered, either as an art, which has for its object one of the greatest pleasures of which our senses (d) are susceptible; or as a science, by which that art is reduced to principles. This is the double view in which we mean to treat of music in this work.

It has been the case with music as with all the other arts invented by man; some facts were at first discovered by accident; soon afterwards reflection and observation investigated others; and from these facts, properly disposed and united, philosophers were not slow in forming a body of science, which afterwards increased by degrees.

The first theories of music were perhaps as ancient as the earliest age which we know to have been distinguished by philosophy, even as the age of Pythagoras; nor does history leave us any room to doubt, that from the period when that philosopher taught, the ancients cultivated music, both as an art and as a science, with great assiduity. But there remains to us much uncertainty concerning the degree of perfection to which they brought it. Almost every question which has been proposed with respect to the music of the ancients has divided the learned; and probably may still continue to divide them, for want of monuments sufficient in their number, and incontestable in their nature, from whence we might be enabled to exhibit testimonies and discoveries instead of suppositions and conjectures. In the preceding history we have stated a few facts respecting the nature of ancient music, and the inventors of the several musical instruments; but it was to be wished, that in order to elucidate, as much as possible, a point so momentous in the history of the sciences, some person of learning, equally skilled in the Greek language and in music, should exert himself to unite and discuss in the same work the most probable opinions of the learned, upon a subject so difficult and curious. This philosophical history of in literature of our times.

In the mean time, till an author can be found sufficiently instructed in the arts and in history to undertake such a labour with success, we shall content ourselves with considering the present state of music, and limit our endeavours to the explication of those accidents which have accrued to the theory of music in these latter times.

There are two departments in music, melody * and harmony †. Melody is the art of arranging several sounds in succession one to another in a manner agreeable to the ear; harmony is the art of pleasing that organ by the union of several sounds which are heard at one and the same time. Melody has been known and felt through all ages: perhaps the same cannot be affirmed of harmony (x); we know not whether the ancients made any use of it or not, nor at what period it began to be practised.

Not but that the ancients certainly employed in their music

---

(c) To deliver the elementary principles of music, theoretical and practical, in a manner which may prove at once entertaining and instructive, without protracting this article much beyond the limits prescribed in our plan, appears to us no easy task. We therefore hesitated for some time whether to try our own strength, or to follow some eminent author on the same subject. Of these the last seemed preferable. Amongst these authors, none appeared to us to have written any thing so fit for our purpose as M. d'Alembert, whose treatise on music is the most methodical, perspicuous, concise, and elegant dissertation on that subject with which we are acquainted. As it was unknown to most English readers before a former edition of this work, it ought to have all the merit of an original. We have given a translation of it; and in the notes, we have added, from the works of succeeding authors, and from our own observations, such explanations as appeared necessary, to adapt the work to the present day.

(d) In this passage, and in the definitions of melody and harmony, our author seems to have adopted the vulgar error, that the pleasures of music terminate in corporeal sense. He would have pronounced it absurd to assert the same thing of painting. Yet if the former be no more than a mere pleasure of corporeal sense, the latter must likewise be ranked in the same predicament. We acknowledge that corporeal sense is the vehicle of sound; but it is plain from our immediate feelings, that the results of sound arranged according to the principles of melody, or combined and disposed according to the laws of harmony, are the objects of a reflex or internal sense.

For a more satisfactory discussion of this matter, the reader may consult that elegant and judicious treatise on Musical Expression by Mr Avison. In the mean time it may be necessary to add, that, in order to shun the appearance of affectation, we shall use the ordinary terms by which musical sensations, or the mediums by which they are conveyed, are generally denominated.

(x) Though no certainty can be obtained what the ancients understood of harmony, nor in what manner and in what period they practised it; yet it is not without probability, that, both in speculation and practice, they were in possession of what we denominate counterpoint. Without supposing this, there are some passages in the Greek authors which can admit of no satisfactory interpretation. See the Origin and Progress of Language, vol ii.

Besides,
music. Those chords which were most perfect and simple; such as the octave, the fifth, and the third; but it seems doubtful whether they knew any of the other consonances or not, or even whether in practice they could deduce the same advantages from the simple chords which were known to them, that have afterwards accrued from experience and combinations.

If that harmony which we now practice owes its origin to the experience and reflection of the moderns, there is the highest probability that the first essays of this art, as of all the others, were feeble and the progress of its efforts almost imperceptible: and that, in the course of time, improving by small gradations the successive labours of several geniuses have elevated it to that degree of perfection in which at present we find it.

The origin of arts often accidental, and their progress gradual.

The first inventor of harmony escapes our investigation, from the same causes which leave us ignorant of those who first invented each particular science; because the original inventors could only advance one step, a succeeding discoverer afterwards made a more sensible improvement, and the first imperfect essays in every kind were lost in the more extensive and striking views to which they led. Thus the arts which we now enjoy, are for the most part far from being due to any particular man, or to any nation exclusively: they are produced by the united and successive endeavours of mankind; they are the results of such continued and united reflections, as have been formed by all men at all periods and in all nations.

It might, however, be wished, that after having ascertained, with as much accuracy as possible, the state of ancient music by the small number of Greek authors which remain to us, the same application were immediately directed to investigate the first incontestable traces of harmony which appear in the succeeding ages, and to pursue those traces from period to period. The products of these researches would doubtless be very imperfect, because the books and monuments of the middle ages are by far too few to enlighten that gloomy and barbarous era; yet these discoveries would still be precious to a philosopher, who delights to observe the human mind in the gradual evolution of its powers, and the progress of its attainments.

Delineations of the laws of harmony recent and imperfect.

The first compositions upon the laws of harmony which we know, are of no higher antiquity than two ages prior to our own; and they were followed by many others. But some of these essays was capable of satisfying the mind concerning the principles of harmony: they confined themselves almost entirely to the single occupation of collecting rules, without endeavouring to account for them; neither had their analogies one with another, nor their common source, been perceived; a blind and unenlightened experience was the only compass by which the artist could direct and regulate his course.

Besides, we can discover some vestiges of harmony, however rude and imperfect, in the history of the Gothic ages, and amongst the most barbarous people. This they could not have derived from more cultivated countries, because it appears to be incorporated with their national music. The most rational account, therefore, which can be given, seems to be, that it was conveyed in a mechanical or traditional manner through the Roman provinces from a more remote period of antiquity.

(2) See M. Rameau's letter upon this subject, Merc. de Mai, 1752.

M. Rameau was the first who began to transfigure light and order through this chaos. In the different tones produced by the same sure sonorous body, he found the most probable original harmony, and the cause of that pleasure which we receive from it. His principle was unfolded, and showed how the different phenomena of music were produced by it: he reduced all the consonances to a small number of simple and fundamental chords, of which the others are only combinations of various arrangements. He has, in short, been able to discover, and render sensible to others, the mutual dependence between melody and harmony.

Though these different topics may be contained in the writings of this celebrated artist, and in these writings may be understood by philosophers who are likewise adepts in the art of music; still, however, such musicians as were not philosophers, and such philosophers as were not musicians, have long desired to see these objects brought more within the reach of their capacity. Such is the intention of the present treatise, in which we claim no other merit than that of having developed, elucidated, and perhaps in some respects improved, the ideas of another (2).

The first edition of this essay, published in 1754, having been favourably received, we have endeavoured to render this more perfect. The detail which is meant to be given of my labour, will present the reader with a general idea of the principle of M. Rameau, of the consequences deduced from it, of the manner in which I have disposed this principle and its consequences; in short, of what is still wanting, and might be advantageous to the theory of this delightful art; of what still remains for the learned to contribute towards the perfection of this theory; of the rocks and quicksands which they ought to avoid in this research, and which could serve no other purpose than to retard their progress.

Every sonorous body, besides its principal sound, likewise exhibits to the ear the 12th and 17th major of that sound. This multiplicity of different yet concordant sounds, known for a considerable time, constitutes the basis of the whole theory of M. Rameau, and the foundation upon which he builds the whole superstructure of a musical system. In those our elements may be seen, how from this experiment one may deduce, by an easy operation of reason, the chief points of melody and harmony; the perfect chorde, as well as major as minor; the two t tetrachords employed in ancient music; the formation of our diatonic scale; the different values of which the same sound may have in that scale, according to the turn which is given to the base; the alterations which we observe in that scale, and the reason why they are totally imperceptible to the ear; the rules peculiar to the mode of major; the difficulty in the intonation of forming three tones in succession; the reason why two perfect chords are prescribed;
MUSIC.

Music in immediate succession in the diatonic order, the origin of the minor mode, its subordination to the major mode major, and its variations; the use of discord; the causes of such effects as are produced by different kinds of music, whether diatonic, chromatic, or enharmonic; the principles and laws of temperament.

In this discourse we can only point out these different objects, the subsequent essay being designed to explain them with the minuteness and precision which they require.

One end which we have proposed in this treatise, was not only to elucidate, but to simplify the discoveries of M. Rameau. For instance, besides the fundamental experimental mention made above, that celebrated musician, to facilitate the explanation of certain phenomena, had recourse to another experiment; that which shows that a sonorous body struck and put in vibration, forces its 12th and 17th major in descending to divide themselves and produce a tremendous sound. The chief use which M. Rameau made of this second experiment was to investigate the origin of the minor mode, and to account for some other rules established in harmony; but we have found means to deduce from the first experiment alone the formation of the minor mode, and, besides, to disengage that formation from all questions foreign to it.

In some other points also; (as, the origin of the chord of the sub-dominant, and the resolution of the seventh in certain cases) it is imagined that we have simplified, and perhaps in some measure extended the principles of the celebrated artist.

We have likewise banished every consideration of geometrical, arithmetical, and harmonic proportions and progressions, which have been sought in the mixture and proportion of tones produced by a sonorous body; persuaded as we are, that M. Rameau was under no necessity of paying the least regard to these proportions, which we believe to be not only useless, but even, if we may venture to say so, fallacious when applied to the theory of music. In short, though the relations produced by the octave, the fifth, and the third, &c. were quite different from what they are; though in these chords we should neither remark any progression nor any law; though they should be incommensurable one with another; the protracted tone of the sonorous body, and the multiplied sounds which result from it, are a sufficient foundation for the whole harmonic system.

But though this work is intended to explain the theory of music, and to reduce it to a system more complete and more luminous than has hitherto been done, we ought to caution our readers against misapprehension either of the nature of our subject or of the purpose of our endeavours.

We must not here look for that striking evidence which is peculiar to geometrical discoveries alone, and which can be so rarely obtained in these mixed disquisitions, where natural philosophy is likewise concerned. Into the theory of musical phenomena there must always enter a particular kind of metaphysics, which these phenomena implicitly take for granted, and which brings along with it its natural obscurity. In this subject, therefore, it would be in vain to expect what is called demonstration: it is much to have reduced the principal facts to a consistent and connected system; to have deduced them from one simple experiment; and to have established upon this foundation the most common and essential rules of the musical art. But if the intimate and unalterable conviction which can only be produced by the strongest evidence is not here to be required, we must also doubt whether a clearer elucidation of our subject be possible.

After this declaration, it will not excite surprise, that amongst the facts deduced from our fundamental experiment, some should immediately appear to depend upon that experiment, and others to result from it in a way more remote and less direct. In disquisitions of natural philosophy, where we are scarcely allowed to use any other arguments than those which arise from analogy or congruity, it is natural that the analogy should be sometimes more and sometimes less sensible; and we will venture to pronounce that mind very unphilosophical, which cannot recognise and distinguish this gradation and the different circumstances on which it proceeds. It is not even surprising, that, in a subject where analogy alone can take place, this conductress should desert us all at once in our attempts to account for certain phenomena. This likewise happens in the subject which we now treat; nor do we conceal the fact, however mortifying, that there are certain points (though their number be but small) which appear still in some degree unaccountable from our principle. Such, for instance, is the procedure of the diatonic scale of the minor mode in descending, the formation of the chord commonly termed the sixth redundant or superfluous, and some other facts of less importance, for which as yet we can scarcely offer any satisfactory account except from experience alone.

Thus, though the greatest number of the phenomena of music appear to be deducible in a simple and easy manner from the protracted tone of sonorous bodies, it ought not perhaps with too much temerity to be affirmed as yet that this mixed and protracted tone is demonstratively the only original principle of harmony. But in the mean time it would not be less unjust to reject this principle, because certain phenomena appear to be deduced from it with less success than others.

It is only necessary to conclude from this, either that future scrutinies means may be found for reducing counted for these phenomena to this principle; or that harmony all the phenomena has perhaps some other unknown principle, more general than that which results from the protracted and compounded tone of sonorous bodies, and of which this other is only a branch; or, lastly, that we ought not perhaps to attempt the reduction of the whole science of music to one and the same principle; which, however, is the natural effect of an impatience so frequent even among philosophers themselves, which induces them to take a part for the whole, and to judge of objects in their full extent by the greatest number of their appearances.

In those sciences which are called physico-mathematical (and amongst this number perhaps the science of sounds may be placed), there are some phenomena which depend only upon one single principle and one single experiment: there are others which necessarily suppose a greater number both of experiments and principles, whose combination is indispensable in forming an exact and complete system; and music perhaps is in this last case. It is for this reason, that whilst

VOL. XIV. Part II. 38 we
we bestow on M. Rameau all due praise, we should not at the same time neglect to stimulate the learned in their endeavours to carry them still to higher degrees of perfection, by adding, if it is possible, such improvements as may be wanting to consummate the science.

Whatever the result of their efforts may be, the reputation of this intelligent artist has nothing to fear: he will still have the advantage of being the first who rendered music a science worthy of philosophical attention: of having made the practice of it more simple and easy; and of having taught musicians to employ in this subject the light of reason and analogy.

We would the more willingly persuade those who are skilled in theory and eminent in practice to extend and improve the views of him who before them pursued and pointed out the career, because many amongst them have already made laudable attempts, and have even been in some measure successful in diffusing new light through the theory of this enchanting art. It was with this view that the celebrated Tartini has presented us in 1754 with a treatise of harmony, founded on a principle different from that of M. Rameau. This principle is the result of a most beautiful experiment (c). If at once two different sounds are produced from two instruments of the same kind, these two sounds generate a third different from both the others. We have inserted in the Encyclopædia, under the article Fundamental, a detail of this experiment according to M. Martin; and we owe to the public an information, of which in composing this article we were ignorant: M. Romeu, a member of the Royal Society of Science at Montpellier, had presented to that society in the very year 1733, before the work of M. Tartini had appeared, a memorial printed the same year, and where may be found the same experiment displayed at full length. In relating this fact, which it was necessary for us to do, it is by no means our intention to detract in any degree from the reputation of M. Tartini; we are persuaded that he owes this discovery to his own researches alone: but we think ourselves obliged in honour to give public testimony in favour of him who was the first in exhibiting this discovery.

But whatever be the case, it is in this experiment that M. Tartini attempts to find the origin of harmony: his book, however, is written in a manner so obscure, that it is impossible for us to form any judgment of it; and we are told that others distinguished for their knowledge of the science are of the same opinion. It were to be wished that the author would engage some man of letters, equally practised in music and skilled in the art of writing, to unfold these ideas which

(c) Had the utility of the preliminary discourse in which we are now engaged been less important and obvious than it really is, we should have not given ourselves the trouble of translating, or our readers that of perusing it. But it must be evident to every one, that the cautions here given, and the advice offered, are no less applicable to students than to authors. The first question here decided is, Whether pure mathematics can be successfully applied to the theory of music? The author is justly of a contrary opinion. It may certainly be doubted with great justice, whether the solid contents of sonorous bodies, and their degrees of cohesion or elasticity, can be ascertained with sufficient accuracy to render them the subjects of musical speculation, and to determine their effects with such precision as may render the conclusions deduced from them geometrically true. It is admitted, that sound is a secondary quality of matter, and that secondary qualities have no obvious connexion which we can trace with the sensations produced by them. Experience, therefore, and not speculation, is the grand criterion of musical phenomena. For the effects of geometry in illustrating the theory of music (if any will still be so credulous as to pay them much attention), the English reader may consult Smith's Harmonics, Malcolm's Dissertation on Music, and Pleyel's Treatise on the same subject inserted in a former edition of this work. Our next treatise of the famous discovery made by Signor Tartini, of which the reader may accept the following copious account.

If two sounds be produced at the same time properly tuned and with due force, from their conjunction a third sound is generated, so much more distinctly to be perceived by delicate ears as the relation between the generating sounds is more simple; yet from this rule we must except the unison and octave. From the fifth is produced a sound unison with its lowest generator; from the fourth, one which is an octave lower than the highest of its generators; from the third major, one which is an octave lower than its lowest; and from the sixth minor (whose highest note forms an octave with the lowest in the third formerly mentioned) will be produced a sound lower by a double octave than the highest of the lesser sixth; from the third minor, one which is double the distance of a greater third from its lowest; but from the sixth major (whose highest note makes an octave to the lowest in the third minor) will be produced a sound only lower by double the quantity of a greater third than the highest; from the second major, a sound lower by a double octave than the lowest; from a second minor, a sound lower by triple the quantity of a third major than the highest; from the interval of a diatonic or greater semitone, a sound lower by a triple octave than the highest; from that of a minor or chromatic semitone, a sound lower by the quantity of a fifth four times multiplied than the lowest, &c. &c. But that these musical phenomena may be tried by experiments proper to ascertain them, two hautboys tuned with scrupulous exactness must be procured, whilst the musicians are placed at the distance of some pace from the other, and the hearers in the middle. The violin will likewise give the same chords, but they will be less distinctly perceived, and the experiment more fallacious, because the vibrations of other strings may be supposed to enter into it.

If our English reader should be curious to examine these experiments and the deductions made from them in the theory of music, he will find them clearly explained and illustrated in a treatise called Principles and Power of Harmony, printed at London in the year 1771.
MUSIC.

If philosophical musicians ought not to lose their

time in searching for mechanical explications of the

phenomena in music, explications which will always be

vague and unsatisfactory; much less is it their

province to exhaust their powers in vain attempts to

calculate conclusions above their sphere into a region still more remote from

the prospect of their faculties, and to lose themselves in a labyrinth of metaphysical speculations upon

the causes of that pleasure which we feel from harmony.

In vain would they accumulate hypothesis on hypothesis, to find a reason why some chords should please

us more than others. The futility of these suppositious accounts must be obvious to everyone who has

the least penetration. Let us judge of the rest by the most probable which has till now been invented for

that purpose. Some ascribe the different degrees of pleasure which we feel from chords, to the more or

less frequent coincidence of vibrations; others to the accident with which these vibrations have assumed themselves as they are more or less simple. But why should this coincidence of vibrations, that is to say, their simultaneous impulse on the same organs of sensation, and the accident of beginning frequently at the same time, prove so great a source of pleasure? Upon what is this gratuitous supposition founded? And though it should be granted, would it not follow, that the same chord should successively and rapidly affect us with contrary sensations, since the vibrations are alternately coincident and discrepant? On the other hand, how should the ear be so sensible to the simplicity of relations, whilst for the most part these relations are entirely unknown to him whose organs are notwithstanding sensibly affected with the charms of agreeable music? We may conceive without difficulty how the eye judges of relations; but how does the ear form similar judgments? Besides, why should certain chords which are extremely pleasing in themselves, such as the fifth, lose almost nothing of the pleasure which they give us, when they are altered, and of consequence when the simplicity of their relations are destroyed; whilst other chords, which are likewise extremely agreeable, such as the third, become harsh almost by the smallest alteration? Nay, whilst the most perfect and the most agreeable of all chords, the octave, cannot suffer the most inconsiderable change? Let us in sincerity confess our ignorance concerning the genuine causes of these effects (h). The meta-

(h) We have as great an aversion as our author to the explication of musical phenomena from mechanical

principles; yet we fear the following observations, deduced from irresistible and universal experience, evidently

show that the latter necessarily depend on the former. It is, for instance, universally allowed, that dissonances

grate, and concords please a musical ear: It is likewise no less unanimously agreed, that in proportion as a

chord is perfect, the pleasure is increased; now the perfection of a chord consists in the regularity and frequen-
cy of coincident oscillations between two sonorous bodies impelled to vibrate: thus the third is a chord less perfect than the fifth, and the fifth than the octave. Of all these consonances, therefore, the octave is most pleasing to the ear; the fifth next; and the third is

incident, and of consequence a perpetual pulsation or jarring is recognised between the protracted sounds, which

exceedingly hurts the ear; but in proportion as the vibrations coincide, those pulsations are superseded, and a

kindred formed betwixt the two continued sounds, which delights even the corporeal sense: that relation, therefore, without recognizing the aptitudes which produce it, must be the obvious cause of the pleasure which

chords give to the ear. What we mean by coincident vibrations is, that while one sonorous body performs

a given number of vibrations, another performs a different number in the same time: so that the vibrations of

the quickest must sometimes be simultaneous with those of the slowest, as will plainly appear from the

following
MUSIC.

Elements.

Physical conjectures concerning the acoustic organs are probably in the same predicament with those which are formed concerning the organs of vision, if one may speak so, in which philosophers have even till now made such inconsiderable progress, and in all likelihood will not be surpassed by their successors.

Since the theory of music, even to those who confine themselves within its limits, implies questions from which every wise musician will abstain; with much greater reason should they avoid idle excursions beyond the boundaries of that theory, and endeavours to investigate between music and the other sciences chimerical relations which have no foundation in nature. The singular opinions advanced upon this subject by some even of the most celebrated musicians, deserve not to be rescued from oblivion, nor refuted; and ought only to be regarded as a new proof how far men of genius may err, when they engage in subjects of which they are ignorant.

The rules which we have attempted to establish concerning the track to be followed in the theory of the musical art, may suffice to show our readers the end which we have proposed, and which we have endeavoured to attain in this Work. We have here (we repeat it), nothing to do with the mechanical principles of protracted and harmonic tones produced by sonorous bodies; principles which have hitherto been and perhaps may yet be long explored in vain: we have less to do with the metaphysical causes of the sensations impressed on the mind by harmony; causes which are still less discovered, and which, according to all appearances, will remain latent in perpetual obscurity. We are alone concerned to show how the principal laws of harmony may be deduced from one single experiment; for which, if we may speak so, preceding artists have not been under the necessity of groping in the dark.

With an intention to render this work as generally useful as possible, we have endeavoured to adapt it to the capacity even of those who are absolutely un instructed in music. To accomplish this design, it appeared necessary to pursue the following plan.

To begin with a short introduction, in which are defined the technical terms most frequently used in this art; such as chord, harmony, key, third, fifth, octave, &c.

Afterwards to enter into the theory of harmony, which is explained according to M. Rameau, with all possible perspicuity. This is the subject of the First Part; which, as well as the introduction, presupposes no other knowledge of music than that of the names of the notes, C, D, E, F, G, A, B, which all the world knows (1).

The theory of harmony requires some arithmetical calculations, necessary for comparing sounds one with another. These calculations are short, simple, and may be comprehended by every one; they demand no operation but what is explained, and which every school-boy may perform. Yet, that even the trouble of this may be spared to such as are not disposed to take it, these calculations are not inserted in the text, but in the notes, which the reader may omit, if he can take for granted the propositions contained in the text which will be found proved in the notes.

These calculations we have not endeavoured to multiply; we could even have wished to suppress them, if it had been possible: so much did it appear to us to be apprehended that our readers might be misled upon this subject, and might either believe, or suspect us of believing,

following deduction: Between the extremes of a third, the vibrations of the highest are as 5 to 4 of the lowest; those of the fifth as 3 to 2; those of the octave as 2 to 1. Thus it is obvious, that in proportion to the frequent coincidence of periodical vibrations, the compound sensation is more agreeable to the ear. Now, to inquire why that organ should be rather pleased with these than with the pulsation and tremulous motion of encountering vibrations which can never coalesce, would be to ask why the touch is rather pleased with polished than rough surfaces; or why the eye is rather pleased with the waving line of Hogarth than with sharp angles and abrupt or irregular prominences? No alteration of which any chord is susceptible will but the ear unless it should violate or destroy the regular and periodical coincidence of vibrations. When alterations can be made without this disagreeable effect, they form a pleasing diversity; but still this fact corroborates our argument, that in proportion as any chord is perfect, it is impamet of the smallest alteration; for this reason, even in temperament, the octave endures no alteration at all, and the fifth as little as possible.

(1.) In our former editions, the French syllabic names of the notes ut, re, mi, fa, sol, la, si, were retained, as being thought to convey the idea of the relative sounds more distinctly than the seven letters used in Britain. It is no doubt true, that by constantly using the syllables, and considering each as representing one certain sound in the scale, a singer will in time associate the idea of each sound with its proper syllable, so that he will habitually give ut the sound of the first or fundamental note, re that of a second, mi of a third, &c. but this requires a long time, and much application: and is, besides, useless in modulation or changes of the key, and in all instrumental music. Teachers of sol-faing as it is called, or singing by the syllables, in Britain, have long discarded, (if they ever used), the syllables ut, re, and si: and the prevalent, and we think, the sounder opinion is now, that a scholar will, by attending to the sounds themselves rather than to their names, soon learn their distinct characters and relations to the key, and to each other, and be able of course to assign to each its proper degree in the scale which he employs for the time, by whatever name the note respectively be called, may be generally known. See Holden's Essay towards a Rational System of Music, Part I. chap. i. § 32, 33.

We have therefore, in our present edition, preferred to the French syllables the British nomenclature by the letters C, D, E, F, G, A, B, as being more simple, more familiar to British musicians, and equally applicable to instrumental as to vocal music.
believing, all this arithmetic necessary to form an artist.

Calculations may indeed facilitate the understanding of certain points in the theory, as of the relations between the different notes in the gamut and of the temperament; but the calculations necessary for treating of these points are so simple, and of so little importance, that nothing can require a less ostentatious display. Let us not imitate those musicians, who believing themselves geometers, or those geometers who, believing themselves musicians, fill their writings with figures upon figures; imagining, perhaps, that this apparatus is necessary to the art. The propensity of adorning their works with a false air of science, can only impose upon ignorance, and render their treatises more obscure and less instructive.

This abuse of geometry in music may be condemned with so much more reason, that in this subject the foundations of those calculations are in some manner hypothetical, and can never arise to a degree of certainty above hypothesis. The relation of the octave as 1 to 2, that of the fifth as 2 to 3, that of the third major as 4 to 5, &c. are not perhaps the genuine relations established in nature; but only relations which approach them, and such an experience can discover. For are the results of experience anything more but mere approaches to truth?

It is not always so, and sometimes this approximation is sufficient, though they should not be exactly agreeable to truth, for giving a satisfactory account of those phenomena which depend on the relations of sound; as in the difference between the notes in the gamut, of the alterations necessary in the fifth and third, of the different manner in which instruments are tuned, and other facts of the same kind. If the relations of the octave, of the fifth and of the third, are not exactly such as we have supposed them, at least no experiments can prove that they are not so; and since these relations are signified by a simple expression, since they are besides sufficient for all the purposes of theory, it would be useless, and contrary to sound philosophy, to invent other relations in order to form the basis of any system of music less easy and simple than that which we have delineated in this treatise.

The second part contains the most essential rules of composition*, or in other words the practice of harmony. These rules are founded on the principles laid down in the first part; yet those who wish to understand no more than is necessary for practice, without exploring the reasons why such practical rules are necessary, may limit the objects of their study to the introduction and the second part. They who have read the first part, will find at every rule contained in the second, a reference to that passage in the first where the reasons for establishing that rule are given.

That we may not present at once too great a number of objects and precepts, we have transferred to the notes in the second part several rules and observations which are less frequently put in practice, which perhaps it may be proper to omit till the treatise is read a second time, when the reader is well acquainted with the essential and fundamental rules explained in it.

This second part presupposes, no more than the first, any habit of singing, nor even any knowledge of music; it only requires that one should know, not even the intonation, but merely the position of the notes in the clef $F$ on the fourth line, and that of $G$ upon the second; and even this knowledge may be acquired from the work itself; for in the beginning of the second part we explain the position of the clefs and of the notes. Nothing is necessary but to render it a little familiar, and any difficulty in it will disappear.

It would be wrong to expect here all the rules of composition, and especially those which direct the rules of composition of music in several parts, and which, being less severe and indispensable, may be chiefly acquired by practice, by studying the most approved models, in an early age, by the assistance of a proper master, but above all by the cultivation of the ear and of the taste. This treatise is properly nothing else, if the expression may be allowed, but the rudiments of music, intended for explaining to beginners the fundamental principles, not the practical detail of composition. Those who wish to enter more deeply into this detail, will either find it in M. Rameau's treatise of harmony, or in the code of music which he published more lately ($x$), or lastly in the explanation of the theory and practice of music by M. Bethizy ($t$); this last book appears to us clear and methodical ($m$).

Is it necessary to add, that in order to compose the music in a proper taste, it is by no means enough to essential have familiarized with much application the principles of musical composition explained in this treatise? Here can only be learned the mechanism of the art; it is the province of nature alone to accomplish the rest. Without her assistance, it is no more possible to compose agreeable music by having read these elements, than to write verses in a proper manner with the Dictionary of Richelet. In one word, it is the elements of music alone, and not the principles of genius, that the reader may expect to find in this treatise.

DEFINITIONS.

1. Melody is a series of sounds which succeed one to another in a manner agreeable to the ear.

2. A Chord is a combination of several sounds heard together; and Harmony is properly a series of chords in harmony, of which the succession pleases the ear. A single chord.

---

(x) From my general recommendation of this code, I except the reflections on the principle of sound which are at the end, and which I should not advise any one to read.

(t) Printed at Paris by Lambert in the year 1774.

(m) In addition to the works mentioned in the text, we recommend to our readers, Holdén's Essay, Glasgow 1770, Edin. 1805; Kollmann's Essay on Musical Harmony, 1796; his Essay on Musical Composition, fol. 1799; Shield's Introduction, 1800; and Dr Calcutt's Musical Grammar, 1806.
MUSIC.

Elements.

To distinguish the first from the second C, we have originally marked the last with a small letter (n).

5. In general, the interval between two sounds is proportionally greater, as one of these sounds is higher or lower with relation to the other: but it is necessary to observe, that two sounds may be equally high, or low, though unequal in their force. The string of a violin touched with a bow produces always a sound equally high, whether strongly or faintly struck; the sound will only have a greater or lesser degree of strength. It is the same with vocal modulation; let any one form a sound by gradually swelling the voice, the sound may be perceived to increase in force, whilst it continues always equally low or equally high.

6. We must likewise observe concerning the scale, that the intervals between C and D, between D and E, between F and G, between G and A, between A and B, are equal, or at least nearly equal; and that the intervals between E and F, and between B and C, are likewise equal among themselves, but consist almost only of half the former. This fact is known and recognised by every one: the reason for it shall be given in the sequel; in the mean time every one may ascertain its reality by the assistance of an experiment (c).

7. It

(n) We shall afterwards find that three different series of the seven letters are used, which we have distinguished by capitals, small Roman, and Italic characters. When the notes represented by small Roman characters occur in this treatise we shall, merely to distinguish them from the typography of the text, place them in inverted commas, thus 'C', 'D', &c.

(o) This experiment may be easily tried. Let any one sing the scale C, D, E, F, G, A, B 'c', it will be immediately observed without difficulty, that the last four notes of the octave G, A, B, 'c', are quite similar to the first C, D, E, F; inasmuch, that if, after having sung this scale, one would choose to repeat it, beginning with C in the same tone which was occupied by G in the former scale, the note D of the last scale would have the same sound with the note A in the first, the E with the B, and the F with the 'c'.

Whence it follows, that the interval between C and D, is the same as between G and A; between D and F, as between A and B, and E and F, as between B and 'c'.

From D to E, from F to G, there is the same interval as from C to D. To be convinced of this, we need only sing the scale once more; then sing it again, beginning with C, in this last scale, in the same tone which was given to D in the first; and it will be perceived, that the D in the second scale will have the same sound, at least as far as the ear can discover, with the E in the former scale; whence it follows, that the difference between D and E is, at least as far as the ear can perceive, equal to that between C and D. It will also be found, that the interval between F and G is, so far as our sense can determine, the same with that between C and D.

This experiment may perhaps be tried with some difficulty by those who are not inured to form the notes and change the key; but such may very easily perform it by the assistance of a harpsichord, by means of which the performer will be saved the trouble of retaining the sounds in one intonation whilst he performs another. In touching upon this harpsichord the keys G, A, B, 'f', and in performing with the voice at the same time C, D, E, F, in such a manner that the same sound may be given to C in the voice with that of the key G in the harpsichord, it will be found that D in the vocal intonation shall be the same with A upon the harpsichord, &c.

It will be found likewise by the same harpsichord, that if one should sing the scale beginning with C in the same tone with E on the instrument, the D, which ought to have followed C, will be higher by an extremely perceptible degree than the F which follows E; thus it may be concluded, that the interval between E and F is less than between C and D; and if one would rise from F to another sound which is at the same distance from F, as F from E, he would find, in the same manner, that the interval from E to this new sound is almost the same as that between C and D.

The interval then from E to F is nearly half of that between C and D.

Since then, in the scale thus divided, 'G, A, B, 'c', the first division is perfectly like the last; and since the intervals between C and D, between D and E, and between F and G, are equal; it follows, that the intervals between G and A, and between A and B, are likewise equal to every one of the three intervals between C and D, between D and E, and between F and G; and that the intervals between E and F and between B and 'c' are also equal, but that they only constitute one half of the others.
Elements.

MUSIC

7. It is for this reason that they have called the interval from E to F, and from B to C, a semitone; whereas those between C and D, D and E, F and G, G and A, and A and B, are tones.

The tone is likewise called a second major *, and the semitone a second minor 1.

8. To descend or rise diatonically, is to descend or rise from one sound to another by the interval of a tone or of a semitone, or in general by seconds, whether major or minor; as from D to C, or from C to D, from F to E, or from E to F.

II. The terms by which the different Intervals of the Scale are denominated.

9. An interval composed of a tone and a semitone, as from E to G, from A to C, or from D to F, is called a third minor.

0. An interval composed of two full tones, as from C to E, and from F to A, or from G to B, is called a third major.

Fourth, what.

An interval composed of two tones and a semitone, as from C to F, or from G to C, is called a fourth.

Tritone, what.

An interval consisting of three full tones, as from F to B, is called a tritone or fourth redundant.

Fifth, what.

An interval consisting of three tones and a semitone, as from C to G, from F to C, from D to A, or from E to B, &c. is called a fifth.

Sixth minor, what.

An interval composed of three tones and two semitones, as from E to C, is called a sixth minor.

Sixth major, what.

An interval composed of four tones and a semitone, as from C to A, is called a sixth major.

Seventh minor, what.

An interval consisting of four tones and two semitones, as from C to D, is called a seventh minor.

Seventh major, what.

An interval composed of five tones and a semitone, as from C to B, is called a seventh major.

And in short, an interval consisting of five tones and two semitones, as from C to 'c' is called an octave.

Several of the intervals now mentioned, are distinguished by other names, as may be seen in the beginning of the second part; but those now given are the most common, and the only terms which our present purpose demands.

10. Two sounds equally high, or equally low, however unequal in their force, are said to be in unison one with the other.

11. If two sounds form between them any interval, whatever it be, we say, that the highest when ascending is in that interval with relation to the lowest; and when descending, we pronounce the lowest in the same interval with relation to the highest. Thus in the third minor, E, G, where E is the lowest and G the highest sound, G is a third minor from E ascending, and E is a third minor from G in descending.

12. In the same manner, if, speaking of two sonorous bodies, we should say, that the one is a fifth above the other in ascending; this infers that the sound given by the one is at the distance of a fifth ascending from the sound given by the other.

III. Of Intervals greater than the Octave.

13. If, after having sung the scale C, D, E, F, G, Fig. 2, A, B, C, one would carry this scale still farther in ascent, it would be discovered without difficulty that a new scale would be formed, 'c, d, e, f,' &c. entirely similar to the former, and of which the sounds will be an octave ascending, each to its correspondent note in the former scale; thus 'd', the second note of the second scale, will be an octave in ascent to the D of the first scale; in the same manner 'e' shall be the octave to E, &c. and so of the rest.

14. As there are nine notes from the first C to the Ninth, second 'd', the interval between these two sounds is called the ninth, and this ninth is composed of six full tones and two semitones. For the same reason, the interval from C to 'f' is called an eleventh, and the interval between C and 'g' a twelfth, &c.

It is plain that the ninth is the octave of the second, and twelfth the eleventh of the fourth, and the twelfth of the fifth, &c.

The octave above the octave of any sound is called a double octave *; the octave of the double octave is called a triple octave, and so of the rest.

The double octave is likewise called a fifteenth: and for the same reason the double octave of the third is called a seventeenth, the double octave of the fifth a nineteenth, &c. (p).
M U S I C.

V. What is meant by Sharp and Flats.

15. It is plain that one may imagine the five tones which enter into the scale, as divided each into two semitones; thus one may advance from C to D, forming in his progress an intermediate sound, which shall be higher by a semitone than C, and lower in the same degree than D. A sound in the scale is called sharp, when it is raised by a semitone; and it is marked with this character %: thus C % signifies C sharp, that is to say, C raised by a semitone above its pitch in the natural scale. A sound in the scale depressed by a semitone is called flat, and is marked thus, ♭: thus A ♭ signifies A flat, or A depressed by a semitone.

V. What is meant by Consonances and Dissonances.

16. A chord composed of sounds whose union or coalescence pleases the ear is called consonance; and the sounds which form this chord are said to be consonant one with relation to the other. The reason of this denomination is that a chord is found more perfect, as the sounds which form it coalesce more closely among themselves.

17. The octave of a sound is the most perfect of consonances of which that sound is susceptible; then the fifth, afterwards the third, &c. This is a fact founded on experiment.

18. A number of sounds simultaneously produced whose union is displeasing to the ear is called a dissonance, and the sounds which form it are said to be dissonant one with relation to the other. The second, the tritone, and the seventh of a sound are dissonants with relation to it. Thus the sounds C D, C B, or F B, &c. simultaneously heard, form a dissonance. See Dissonance. The reason which renders dissonance disagreeable, is, that the sounds which compose it, seem by no means coalescent to the ear, and are heard each of them by itself as distinct sounds, though produced at the same time.

PART I. THEORY OF HARMONY.

CHAP. 1. Preliminary and Fundamental Experiments.

EXPERIMENT I.

19. WHEN a sonorous body is struck till it gives a sound, the ear, besides the principal sound and its octave, perceives two other sounds very high, of which one is the twelfth above the principal sound, that is to say, the octave to the fifth of that sound; and the other is the seventeenth major above the same sound, that is, the double octave of its third major.

20. This experiment is peculiarly sensible upon the thick strings of the violoncello, of which the sound being extremely low, gives to an ear, though not very much practised, an opportunity of distinguishing with sufficient ease and clearness the twelfth and seventeenth now in question (a).

(a) Since the octave above the sound 1 is 2, the octave below the same sound shall be \( \frac{1}{2} \); that is to say, that the string which produces this octave shall have performed half its vibration, whilst the string which produces the sound 1 shall have completed one. To obtain therefore the octave above any sound, the operator must multiply the quantity which expresses the sound by 2; and to obtain the octave below, he must on the contrary divide the same quantity by 2.

It is for that reason that if any sound whatever, for instance C, is denominated

- Its octave above will be -
- Its double octave above -
- Its triple octave above -
- In the same manner its octave below will be -
- Its double octave below -
- Its triple octave below -
- And so of the rest.
- Its twelfth above -
- Its twelfth below -
- Its 17th major above -
- Its 17th major below -
- The fifth then above the sound 1 being the octave beneath the twelfth, shall be, as we have immediately observed.
21. The principal sound is called the generator; and the two other sounds which it produces, and with which it is accompanied, are, inclusive of its octave, called its harmonics.

**EXPERIMENT II.**

There is no person insensible of the resemblance which subsists between any sound and its octave, whether above or below. These two sounds, when heard together, almost entirely coalesce in the organ of sensation. We may besides be convinced (by two facts which are extremely simple) of the facility with which one of these sounds may be taken for the other.

Let it be supposed that any person has an inclination to sing a tune, and having at first begun this air

Vol. XIV. Part II.

served, $\frac{1}{2}$; which signifies that this string performs $\frac{1}{2}$ vibrations; that is to say, one vibration and a half during a single vibration of the string which gives the sound.

To obtain the fourth above the sound, we must take the twelfth below that sound, and the double octave above that twelfth. In effect, the twelfth below C, for instance, is F, of which the double octave $\frac{4}{3}$ is the fourth above C. Since then the twelfth below 1 is $\frac{1}{2}$, it follows that the double octave above this twelfth, that is to say, the fourth from the sound in ascending, will be $\frac{4}{3}$ multiplied by 4, or $\frac{3}{4}$.

In short, the third major being nothing else but the double octave beneath the seventeenth, it follows, that the third major above the sound 1 will be $\frac{3}{4}$ divided by 4, or in other words $\frac{1}{2}$.

The third major of a sound, for instance the third major E, from the sound C, and its fifth G, form between them a third minor E, G; now E is $\frac{1}{2}$, and G $\frac{1}{4}$, by what has been already demonstrated: from whence it follows, that the third minor, or the interval between E and G, shall be expressed by the relation of the fraction $\frac{1}{2}$ to the fraction $\frac{1}{4}$.

To determine this relation, it is necessary to remark, that $\frac{1}{2}$ are the same thing with $\frac{1}{4}$, and that $\frac{1}{4}$ are the same thing with $\frac{1}{2}$; so that $\frac{1}{2}$ shall be to $\frac{1}{4}$ in the same relation as $\frac{1}{4}$ to $\frac{1}{2}$; that is to say, in the same relation as 10 to 12, or as 5 to 6. If, then, two sounds form between themselves a third minor, and that the first is represented by 5, the second shall be expressed by 6; or, what is the same thing, if the first is represented by 1, the second shall be expressed by $\frac{1}{2}$.

Thus the third minor, an harmonic sound which is even found in the protracted and coalescent tones of a sonorous body between the sound E and G, an harmonic of the principal sound, may be expressed by the fraction $\frac{1}{2}$.

_N.B._ One may see by this example, that in order to compare two sounds one with another which are expressed by fractions, it is necessary first to multiply the numerator of the fraction which expresses the first by the denominator of the fraction which expresses the second, which will give a primary number; as here the numerator 5 of the fraction $\frac{1}{2}$, multiplied by 2 of the fraction $\frac{1}{4}$, has given 10. Afterwards may be multiplied the numerator of the second fraction by the denominator of the first, which will give a secondary number, as here 12 is the product of 4 multiplied by 3; and the relation between these two numbers (which in the preceding example are 10 and 12), will express the relation between these sounds, or, what is the same thing, the interval which there is between the one and the other; in such a manner, that the farther the relation between these sounds departs from unity, the greater the interval will be.

Such is the manner in which we may compare two sounds one with another whose numerical value is known.

We shall now show the manner how the numerical expression of a sound may be obtained, when the relation which it ought to have with another sound is known whose numerical expression is given.

Let us suppose, for example, that the third major of the fifth $\frac{1}{2}$ is sought. That third major ought to be, by what has been shown above, the $\frac{1}{4}$ of the fifth; for the third major of any sound whatever is the $\frac{1}{4}$ of that sound. We must then look for a fraction which expresses the $\frac{1}{4}$ of $\frac{1}{4}$; which is done by multiplying the numerators and denominators of both fractions one by the other, from whence results the new fraction $\frac{1}{2}$. It will likewise be found that the fifth of the fifth is $\frac{1}{2}$, because the fifth of the fifth is the $\frac{1}{2}$ of $\frac{1}{4}$.

Thus far we have only treated of fifths, fourths, thirds major and minor, in ascending; now it is extremely easy to find by the same rules the fifths, fourths, thirds major and minor in descending. For suppose C equal to 1, we have seen that its fifth, its fourth, its third, its major and minor in ascending, are $\frac{1}{2}$, $\frac{1}{4}$, $\frac{1}{8}$, $\frac{1}{16}$. To find its fifth, its fourth, its third, its major and minor in descending, nothing more is necessary than to reverse these fractions, which will give $\frac{1}{2}$, $\frac{1}{4}$, $\frac{1}{8}$, $\frac{1}{16}$.

(Q*) It is not then imagined that we change the value of a sound in multiplying or dividing it by 2, by 4, or by 8, &c. the number which expresses these sounds, since by these operations we do nothing but take the simple double, or triple octave, &c. of the sound in question, and that a sound coalesces with its octave.
MUSIC.

Part I.

Theory of Harmony.

CHAP. II. The Origin of the Modes Major and Minor; or, the most natural Modulation, and the most perfect Harmony.

To render our ideas still more precise and permanent, we shall call the tone produced by the sonorous body C: it is evident, by the first experiment, that this sound is always attended by its 12th and 17th major; that is to say, with the octave of G, and the double octave of E.

This octave of G then, and this double octave of E, produce the most perfect chord which can be joined with C, since that chord is the work and choice of nature (n).

For the same reason, the modulation formed by C with the octave of G, and the double octave of E, sung one after the other, would likewise be the most simple and natural of all modulations which do not descend or ascend directly in the diatonic order, if our voices had sufficient compass to form intervals so great without difficulty: but the ease and freedom with which we can substitute its octave to any sound, when it is more convenient for the voice, afford us the means of representing this modulation.

It is on this account that, after having sung the tone C, we naturally modulate the third E, and the fifth G; instead of the double octave of E, and the octave of G; from whence we form, by joining the octave of the sound G, this modulation, C, E, G, 'c', which in effect is the simplest and easiest of them all; and which likewise has its origin even in the protracted and compounded tones produced by a sonorous body.

The modulation C, E, G, 'c', in which the chord C, E, is a third major, constitutes that kind of harmony or melody which we call the mode major; from whence it follows, that this mode results from the immediate operation of nature.

In the modulation C, E, G, of which we have now been treating, the sounds E and G are so proportioned one to the other, that the principal sound C (art. 19.) causes both of them to resound; but the second tone E does not cause G to resound, which only forms the interval of a third minor.

29. Let us then imagine, that, instead of this sound E, one should substitute between the sounds C and G, another note which (as well as the sound C) has the sound C which we explore ought to be such, by art. 19. that it may have for its 17th major G, or one of the octaves of G; of consequence the sound which we seek ought to be a 17th major below G, or, what is the same thing, a third major below the same G. Now the sound E, being a third minor beneath G, and the third major being (art. 9.) greater by a semitone than the third minor, it follows, that the sound of which we are in search shall be a semitone beneath the natural E, and of consequence E.'

30. This new arrangement, C, E, G, in which the sounds C and E have both the power of causing G to resound, though C does not cause E to resound, is not indeed equally perfect with the first arrangement C, E, G; because in this the two sounds E and G are both the one and the other generated by the principal sound C; whereas, in the other, the sound E is not generated by the sound C; but this arrangement C, E, G, is likewise dictated by nature (art. 19.), though less immediately than the former; and accordingly experience evinces that the ear accommodates itself almost as well to the latter as to the former.

31. In this modulation or chord C, E, G, C, it is evident that the third from C to E is minor; and such is the origin of that mode which we call the mode minor (s).

32. The most perfect chords then are, 1. All chords related one to another, as C, E, G, 'c', consisting of any sound, of its third major, of its fifth, and of its octave. 2. All chords related one to another, as C, E, G, 'c', consisting of any sound, of its third minor.

(n) The chord formed with the twelfth and seventeenth major united with the principal sound, being exactly conformed to that which is produced by nature, is likewise for that reason the most agreeable of all; especially when the composer can proportion the voices and instruments together in a proper manner to give this chord its full effect. M. Rameau has executed this with the greatest success in the opera of Pygmalion, page 34, where Pygmalion sings with the chorus L'amour triomphé, &c.: in this passage of the chorus, the two parts of the vocal and instrumental basses give the principal sound and its octave; the first part above, or treble, and that of the counter-tenor, produce the seventeenth major, and its octave, in descending; and the second part, or tenor above, gives the twelfth.

(s) The origin which we have here given of the mode minor, is the most simple and natural that can possibly be given. M. Rameau deduces it, more artificially, from the following experiment:—If you put in vibration a musical string HI, and if there are at the same time contiguous to this two other strings KN, RW, of which the first shall be a twelfth, and the second a seventeenth major below the string HI, the strings KN, RW will vibrate without being struck as soon as the string HI shall give a sound, and divide themselves by a kind of modulation, the first into three, the last into five equal parts; in such a manner, that, in the vibration of the string KN, you may easily distinguish two points at rest LM, and in the tremulous motion of the string RW, four quiescent points S, T, U, V, all placed at equal distances from each other, and dividing the strings into three or five equal parts. In this experiment, says M. Rameau, if we represent by the note C the tone of the string HI, the two other strings will represent the sounds F and A; and from hence M. Rameau deduces the modulation F, A, c, and of consequence the mode minor. The origin which we have assigned to the minor mode, appears more direct and more simple, because it presupposes no other experiment than that of art. 19. and because also the fundamental sound C is still retained in both the modes, without being obliged, as M. Rameau found himself, to change it into F.
MUSIC.

33. Since the sound C causes the sound G to be heard, and itself is heard in the sound E, which sounds F and G are its two twelfths, we may imagine a modulation composed of that sound C and its two twelfths, or, which is the same thing (art. 22.) of its two fifths, F and G, the one below, the other above; which gives the modulation or series of fifths F, C, G, which we call the fundamental bass of C by fifths.

We shall find in the sequel (Chap. XVIII.), that there may be some fundamental bass by thirds, deduced from the two seventeenth, of which the one is an attendant of the principal sound, and of which the other includes that sound. But we must advance step by step, and satisfy ourselves as to consider immediately the fundamental bass by fifths.

34. Thus, from the sound C, one may make a transition indifferently to the sound G, or to the sound F.

35. One may, for the same reason, continue this kind of fifths in ascending, and in descending, from C, in this manner:

E♭, B♭, F, C, G, D, A, &c.

And from this series of fifths one may pass to any sound which immediately precedes or follows it.

36. But it is not allowed in the same manner to pass from one sound to another which is not immediately contiguous to it; for instance, from C to D, or from D to C: for this very simple reason, that the sound D is not contained in the sound C, nor the sound C in that of D; and thus these sounds have not any alliance the one with the other, which may authorize the transition from one to the other.

37. And as these sounds C and D, by the first experiment, naturally bring along with them the perfect chords consisting of greater intervals C, E, C, F, and D, F♭, A, d; hence may be deduced this rule. That two perfect chords, especially if they are major (T), cannot succeed one another diatonically in a fundamental bass; we mean, that in a fundamental bass two sounds cannot be diatonically placed in succession, each of which, with its harmonics, forms a perfect chord, especially if this perfect chord be major in both.

CHAP. IV. Of Modes in General.

38. A mode, in music, is, the order of sounds prescribed, as well in harmony as melody, by the series of fifths. Thus the three sounds, F, C, G, and the harmonies of each of these three sounds, that is to say, their thirds major and their fifths, compose all the major modes which are proper to C.

39. The series of fifths then, or the fundamental bass Mode, F, C, G, of which C holds the middle space, may be regarded as representing the mode of C. One may likewise take the series of fifths, or fundamental bass, of fifths, C, G, D, as representing the mode of F in the same manner B♭, F, C, will represent the mode of F.

Thus the mode of G, or rather the fundamental bass of that mode, has two sounds in common with the fundamental bass of the mode of C. It is the same with the fundamental bass of the mode F.

40. The mode of C (F, C, G) is called the principal mode with respect to the modes of these two fifths, which mode, and are called its two adjuncts.

41. It is then, in some measure, indifferent to the ear whether a transition be made to the one or to the other of these adjuncts, since each of them has equally Modes two sounds in common with the principal mode. Yet the one which is heard amongst the harmonics of C, and of consequence sounds are implied and signified by C; whereas C does not common cause F to be heard, though C is included in the same sound F. It is hence that the ear, affected by the mode of C, is a little more prepossessed for the mode of G than for that of F. Nothing likewise is more frequent, nor more natural, than to pass from the mode of C to that of G.

42. It is for this reason, as well as to distinguish the two fifths one from the other, that we call G the sub-major fifth above the generator the dominant sound, and the minor fifth F, below the generator, the subdominant.

43. As in the series of fifths, we may indifferently pass from one sound to that which is contiguous: so Transition having passed from the mode of C to that of G, one may from thence proceed to the mode of D. And on the other hand, having passed from the mode of C to managed. that of F we may then pass to the mode of B♭. But it is necessary, however, to observe, that the ear, which has been immediately affected with the principal mode, feels always a strong propensity to return to it. Thus the further the mode to which we make a transition is removed from the principal mode, the less time we ought to dwell upon it; or rather, to speak in the terms of the art, the less ought the phrase (v) of that mode to be protracted.

CHAP. V. Of the Formation of the Diatonic Scale as used by the Greeks.

44. From this rule, that two sounds which are contiguous may be placed in immediate succession in the series of fifths, F, C, G, it follows, that one may form
Musici.

In the modulation $B_e, d, e, f, g, a'$, the sounds $d'$ and $f'$ form between themselves a third minor, which is not so perfectly true as that between $e'$ and $g'$ (v).

Nevertheless, this alteration in the third minor between $d'$ and $f'$ gives the ear no pain, because that $d'$ and that $f'$ which do not form between themselves a true third minor, form, each in particular, consonances perfectly just with the sounds in the fundamental bass which correspond with them: for $d'$ in the scale is the true fifth of $C$, which answers to it in the fundamental bass; and $f'$ in the scale is the true octave of $F$, which answers to it in the same bass.

47. If, therefore, these sounds in the scale form consonances perfectly true with the notes which correspond to them in the fundamental bass, the ear gives itself little trouble to investigate the alterations which there may be in the intervals, which these sounds in the scale form between themselves. This is a new proof that the fundamental bass is the genuine guide of the ear, and the true origin of the diatonic scale.

48. Moreover, this diatonic scale includes only seven sounds, and goes no higher than $b'$, which would be the octave of the first: a new singularity, for which a reason may be given by the principles above established.

The use of the word phrase when transferred from language to that art, we have thought proper to insert the definition of Rousseau.

A phrase, according to him, is in melody a series of modulations, or in harmony a succession of chords, which form without interruption a sense more or less complete, and which terminates in a repose by a cadence more or less perfect.

(x) Nothing is easier than to find in this scale the value or proportions of each sound with relation to the sound $C$, which we call $1$; for the two sounds $C$ and $F$ in the bass are $\frac{3}{2}$ and $\frac{4}{3}$; from whence it follows,

1. That $e'$ in the scale is the octave of $C$ in the bass; that is to say, $2$.
2. That $b'$ is the third major of $G$; that is to say $\frac{5}{4}$ of $1$ (note $a$), and of consequence $\frac{5}{4}$.
3. That $d'$ is the fifth of $G$; that is to say $\frac{5}{4}$ of $1$, and of consequence $\frac{5}{4}$.
4. That $e'$ is the third major of the octave of $C$, and of consequence the double of $\frac{3}{2}$; that is to say, $\frac{5}{2}$.
5. That $f'$ is the double octave of $F$ of the bass, and consequently $\frac{7}{4}$.
6. That $g'$ of the scale is the octave of $G$, and consequently $3$.
7. That $a'$ in the scale is the third major of $f'$ of the scale; that is to say, $\frac{5}{4}$ of $\frac{3}{2}$, or $\frac{15}{8}$.

Hence then will result the following table, in which each sound has its numerical value above or below it.

<table>
<thead>
<tr>
<th>Diatonic Scale</th>
<th>$B_e, d, e, f, g, a'$</th>
</tr>
</thead>
</table>

And if, for the convenience of calculation, we choose to call the sound $C$ of the scale $1$; in this case we have only to divide each of the numbers by $2$, which represent the diatonic scale, and we shall have

$\frac{1}{2}, \frac{3}{2}, \frac{4}{3}, \frac{5}{4}, \frac{6}{5}, \frac{7}{6}, \frac{8}{7}, a, a$. 

(y) In order to compare $d'$ with $f'$, we need only compare $\frac{3}{2}$ with $\frac{4}{3}$; the relation between these fractions will be, (note $c$) that of $9$ times $3$ to $8$ times $4$: that is to say, of $27$ to $32$: the third minor, then, from $d'$ to $f'$, is not true; because the proportion of $27$ to $32$ is not the same with that of $5$ to $6$; these two proportions being between themselves as $27$ times $6$ is to $32$ times $5$, that is to say, as $162$ to $160$, or as the halves of these two numbers, that is to say, as $81$ to $80$.

M. Rameau, when he published, in 1726, his New theoretical and practical System of Music, had not as yet found the true reason of the alteration in the consonance which is between $d'$ and $f'$, and of the little attention which the ear pays to it. For he pretends, in the work now quoted, that there are two thirds minor, one in the proportion of $5$ to $6$, the other in the proportion of $27$ to $32$. But the opinion which he has afterwards adopted, seems much preferable. In reality, the genuine third minor, is that which is produced by nature between $e'$ and $g'$, in the continued tone of those sonorous bodies of which $e'$ and $g'$ are the two harmonics: and that third minor, which is in the proportion of $5$ to $6$, is likewise that which takes place in the minor mode, and not that third minor which is false and different, being in the proportion of $27$ to $32$.

In reality, in order that the sound 'f' may succeed immediately in the scale to the sound 'a', it is necessary that the note 'g', which is the only one from whence 'b' as a harmonic may be deduced, should immediately succeed to the sound 'f', in the fundamental bass, which is the only one from whence 'a' can be harmonically deduced. Now, the diatonic succession from F to G cannot be admitted in the fundamental bass, according to what we have remarked (art. 36). The sounds 'a' and 'b', then, cannot immediately succeed one another in the scale: we shall see in the sequel why this is not the case in the series 'c', 'd', 'e', 'f', 'g', 'a', 'b', 'c', which begins upon C; whereas the scale in question here begins upon B.

50. The Greeks, likewise, to form an entire octave, added below the first B the note A, which they distinguished and separated from the rest of the scale, which, for that reason they called protanomaleone, that is to say, a string or note subadded to the scale, and put before B to form the entire octave.

51. The diatonic scale B, 'c', 'd', 'e', 'f', 'g', 'a', is composed of two tetrachords, that is to say, of two diatonic scales, each consisting of four sounds, B, 'c', 'd', 'e', and 'f', 'g', 'a'. These two tetrachords are exactly similar; for from 'c' to 'd' there is the same interval as from B to 'c', from 'd' to 'e' the same as from 'c' to 'd', from 'f' to 'g' the same as from 'a' to 'e', and so on. This is the reason why the Greeks distinguished these two tetrachords; yet they joined them by the note 'a' which is common to both, and which gave them the name of conjunctive tetrachords.

52. Moreover, the intervals between any two sounds, taken in each tetrachord in particular, are precisely true: thus, in the first tetrachord, the intervals of C 'e', and B 'd', are thirds, the one major and the other minor, exactly true, as well as the fourth B 'e' (AA); it is the same thing with the tetrachord 'e', 'f', 'g', 'a', since this tetrachord is exactly like the former.

53. From thence it follows, that every consonance is absolutely perfect in each tetrachord taken by itself; but that there is some alteration in passing from one tetrachord to the other. This is a new reason for distinguishing the scale into these two tetrachords.

54. It may be ascertained by calculation, that in the tetrachord B, 'c', 'd', 'e', the interval, or the tone from 'd' to 'e', is a little less than the interval or tone from 'c' to 'd' (bb). In the same manner, in the second tetrachord 'e', 'f', 'g', 'a', which is, as we have proved, perfectly similar to the first, the note from 'g' to 'a' is a little less than the note from 'f' to 'g'. It is for this reason that they distinguish two kinds of tones: the greater tone * from 'c' to 'd', from 'f' to 'g', &c. and the lesser † from 'd' to 'e', from 'g' to 'a', &c.

55. We have just shown in the preceding chapter how the scale of the Greeks is formed, B, 'c', 'd', 'e', 'f', 'g', 'a', by means of a fundamental bass composed of three sounds only, E, C, G; but to form the scale 'c', 'd', 'e', 'f', 'g', 'a', 'b', 'c', which we use at present, we must necessarily add to the fundamental bass the note D, and form, with these four sounds F, C, G, D, the following fundamental bass:

\[ C, G, C, F, C, G, D, G, C; \]

from whence we deduce the modulation or scale

\[ c, d, e, f, g, a, b, c. \]

In effect (cc), 'c' in the scale belongs to the harmony of C which corresponds with it in the bass; 'd', which is the second note in the gamut, is included in the harmony of G; the second note of the bass; 'e' the third note of the gamut, is a natural harmonic of C, which is the third sound in the bass, &c.

56. Hence...
56. Hence it follows, that the diatonic scale of the Greeks is, at least in some respects, more simple than ours; since the scale of the Greeks (chap. v.) may be formed alone from the mode proper to $C$; whereas ours is originally and primitively formed, not only from the mode of $C$ ($F$, $C$, $G$), but likewise from the mode of $G$ ($C$, $G$, $D$).

It will likewise appear, that this last scale consists of two parts; of which the one, $c$, $d$, $e$, $f$, $g$, $c$, is in the mode of $G$; and the other, $g$, $a$, $b'$, $c$, in that of $C$.

57. For this reason the note $g'$ is twice repeated in immediate succession in this scale; once as the fifth of $C$, which corresponds with it in the fundamental bass; and again as the octave of $G$, which immediately follows $G$ in the same bass. These two consecutive $g'$s are otherwise in perfect unison. For this reason we sing only one of them when we modulate the scale $c$, $d$, $e$, $f$, $g$, $a$, $b'$, $c$; but this does not prevent us from employing a pause or repeat, expressed or understood, after the sound $g'$. There is no person who does not perceive this whilst he himself sings the scale.

58. The scale of the moderns, then, may be considered as consisting of two tetrachords, disjunctive indeed, but perfectly similar one to the other, $c$, $d$, $e$, $f$, and $g$, $a$, $b$, $c'$, one in the mode of $C$, the other in that of $G$. We shall see in the sequel, by what artifice one may cause the scale $c$, $d$, $e$, $f$, $g$, $a$, $b$, $c$ to be regarded as belonging to the mode of $G$ alone. For this purpose it is necessary to make some changes in the fundamental bass, which we have already assigned: but this shall be explained at large in chap. xiii.

59. The introduction of the mode proper to $G$ in the fundamental bass has this happy effect, that the notes $f$, $g$, $a$, $b'$ may immediately succeed each other in ascending the scale, which cannot take place (art. 48.) in the diatonic series of the Greeks, because that series is formed from the mode of $C$ alone. Whence it follows:

<table>
<thead>
<tr>
<th>tone</th>
<th>for $d$ being represented by</th>
<th>its fifth will be expressed by</th>
<th>so that the scale will be numerically signified thus</th>
</tr>
</thead>
<tbody>
<tr>
<td>$c$</td>
<td>$d$, $e$, $f$, $g$, $a$, $b'$, $c$</td>
<td>$g'$, $a'$, $b''$, $c''$</td>
<td>$2$</td>
</tr>
</tbody>
</table>

Where you may see, that the note $a'$ of this scale is different from that in the scale of the Greeks; and that the $a'$ in the modern series stands in proportion to that of the Greeks as $18$ to $1$, that is to say, as $81$ to $80$; these two $a'$s then will likewise differ by a comma.

56) In the scale of the Greeks, the note $a'$ being a third from $f'$, there is an altered fifth between $a'$ and $d'$; but in ours, $a'$ being a fifth to $d'$, produces two altered thirds, $f'$ and $a'$; and likewise a fifth altered, $a'$ as we shall see in the following chapter. Thus there are in our scale two intervals more than in the scale of the Greeks which suffer alteration.

56) But here it may be with some colour objected: The scale of the Greeks, it may be said, has a fundamental bass more simple than ours; and, besides, in it there are fewer chords which will not be found exactly true: why then, notwithstanding this, does ours appear more easy to be sung than that of the Greeks? The Greek scale begins with a semitone, whereas the intonation prompted by nature seems to impel us to rise by a full tone at once. This objection may be thus answered. The scale of the Greeks is indeed better disposed than ours for the simplicity of the bass, but the arrangement of ours is more suitable to natural intonation. Our scale commences by the fundamental sound $c$, and it is in reality from that sound that we ought to begin; it is from this that all the others naturally arise, and upon this that they depend; and, if we speak so, in this they are included: on the contrary, neither the scale of the Greeks, nor its fundamental bass, commences with $C$; but it is from this that we must depart, in order to regulate our intonation, whether in rising or descending; since, in ascending from $c'$, the intonation, even of the Greek scale, gives the series $c$, $d$, $e$, $f$, $g$, $a'$; and so true it is that the fundamental sound $C$ is here the genuine guide of the ear, that if, before we modulate the sound $c'$, we...
MUSIC.

CHAP. VII. Of Temperament.

64. The alterations which we have observed in the intervals between particular sounds of the diatonic scale, naturally lead us to speak of temperament. To give a clear idea of this, and to render the necessity of it palpable, let us suppose that we have before us an instrument with keys, a harpsichord, for instance, consisting of several octaves or scales, of which each includes its twelve semitones.

Let us choose in that harpsichord one of the strings which will sound the note C, and let us tune the string G to a perfect fifth with C in ascending; let us afterwards tune to a perfect fifth with this G the 'd' which is above it; we shall evidently perceive that this 'd' will be in the scale above that from which we set out: but it is also evident that this 'd' must have in the scale a D which corresponds with it, and which must be tuned a true octave below 'd'; and between 'd' and G there should be the interval of a fifth; so that the D in the first scale will be a true fourth below the G of the same scale. We may afterwards tune the note A of the first scale to a just fifth with this last D; then the note 'e' in the highest scale to a true fifth with this new A; and in consequence the E in the first scale to a true fourth beneath this same A: Having finished this operation, it will be found that the last E, thus tuned, will by no means form a just third major from the sound C (FF): that is to say, that it is impossible for E to constitute at the same time the third major of C and the true fifth of A; or, what is the same thing, the true fourth of A in descending.

65. If, after having successively and alternately tuned the strings C, G, 'd', A, E, in perfect fifths and fourths one from the other, we continue to tune successively by true fifths and fourths the strings E, B, F#, C#, G#, 'd*', E*, B*; we shall find, that, though B*, being a semitone higher than the natural note, should be equivalent to 'e' natural, it will by no means form a just octave to the first C in the scale, but be considerably higher (GG); yet this B* upon the harpsichord ought not

should attempt to rise to it by that note in the scale which is most immediately contiguous, we cannot reach it but by the note B, and by the semitone from B to 'c'. Now to make a transition from B to 'c', by this semitone, the ear must be necessity be predisposed for that modulation, and consequently preoccupied with the mode of C: if this were not the case, we should naturally rise from B to 'c', and by this operation pass into another mode.

(FF) The A considered as the fifth of D is \( \frac{5}{4} \); and the fourth beneath this A will constitute \( \frac{4}{5} \) of \( \frac{5}{4} \), that is to say, \( \frac{2}{5} \) of \( \frac{5}{4} \); then shall be the value of E, considered as a true fourth from A in descending: now E, considered as the third major of the sound C, is \( \frac{5}{4} \) or \( \frac{25}{16} \); these two E's then are between themselves in the proportion of 8t to 8q; thus it is impossible that E should be at the same time a perfect third major from C, and a true fourth beneath B.

(GG) In effect, if you thus alternately tune the fifth above and the fourth below, in the same octave, you may here see what will be the process of your operation.

C, G, a fifth; D a fourth; A a fifth; E a fourth; B a fifth; F# a fourth; C# a fifth; G# a fourth; 'd#' a fifth; A# a major fourth; 'e#' or 'f#' a fifth; B# a fourth: now it will be found, by a very easy computation, that the first C being represented by 1, G shall be \( \frac{4}{5} \), D \( \frac{3}{4} \), A \( \frac{5}{4} \), E \( \frac{2}{3} \), &c. and so of the rest till you arrive at B#, which will be found \( \frac{3}{4} \). This fraction is evidently greater than the number 2, which expresses the perfect octave c to its correspondent C: and the octave below B# would be one half of the same fraction, that is to say \( \frac{1}{2} \); which is evidently greater than C represented by unity. This last fraction \( \frac{3}{4} \) is composed of two numbers: the numerator of the fraction is nothing else but the number 3 multiplied 11 times in succession by itself, and the denominator is the number 2 multiplied 18 times in succession by itself. Now it is evident, that this fraction which expresses the value of B#, is not equal to the unity which expresses the value of the sound C, though upon the harpsichord, B and C are identical. This fraction rises above unity by \( \frac{3}{4} \), that is, by about \( \frac{3}{4} \); and this difference was called the comma of Pythagoras. It is palpable that this comma is much more considerable than that that we have already mentioned (note B), and which is \( \frac{3}{5} \).

We have already proved that the series of fifths produces a 'c' different from B#, the series of thirds major gives another still more different. For, let us suppose this series of thirds, C, E, G#, B#, we shall have E equal to \( \frac{4}{3} \), G# to \( \frac{5}{4} \), and B to \( \frac{3}{2} \), whose octave below is \( \frac{5}{4} \); from whence it appears, that this last B is less than unity (that is to say than C), by \( \frac{3}{4} \) or by \( \frac{3}{8} \), or near it: A new comma, much greater than the preceding, and which the Greeks have called apotome major.

It may be observed, that this B#, deduced from the series of thirds, is to the B# deduced from the series of fifths, as \( \frac{3}{4} \) is \( \frac{4}{5} \): that is to say, in multiplying by \( \frac{5}{4} \) and \( \frac{4}{5} \), we shall get \( \frac{3}{4} \) and \( \frac{4}{5} \), which are very considerably different one from the other, and even sufficiently different to make the ear sensible of it; because the difference consists almost of a minor semitone, whose value, as will afterwards be seen (art. 130.), is \( \frac{3}{8} \).

Moreover, if, after having found the G# equal to \( \frac{5}{4} \), we then tune by fifths and by fourths, G#, 'd', A, C, B#, as we have done with respect to the first series of fifths, we find that the B# must be \( \frac{5}{4} \); its difference, then, from unity, or, in other words, from C, is \( \frac{3}{4} \), that is to say, about \( \frac{3}{8} \); a comma still less than any of the preceding, and which the Greeks have called apotome minor.
not to be different from the octave above C; for every B⁰ and every 'c' is the same sound, since the octave or the scale only consists of seventeen semitones.

66. From thence it necessarily follows, 1. That it is impossible that all the octaves and all the fifths should be just at the same time, particularly in instruments which have keys, where no intervals less than a semitone are admitted. 2. That, of consequence, if the fifths are justly tuned, some alteration must be made in the octaves; now the sympathy or sound which subsists between any note and its octave, does not permit us to make such an alteration: this perfect coalescence of sound is the cause why the octave should serve as limits to the other intervals, and that all the notes which rise above or fall below the ordinary scale, are no more than replications, i.e., repetitions, of all that have gone before them.

For this reason, if the octave were altered, there could be no longer any fixed point either in harmony or melody. It is then absolutely necessary to tune the 'c' or B⁰ in a just octave with the first; from whence it follows, that, in the progression of fifths, or, what is the same thing, in the alternate series of fifths and fourths, C, G, D, A, E, B, F⁰, C⁰, G⁰, 'd'⁰, A⁰, 'c'⁰, B⁰, it is necessary that all the fifths should be altered, or at least some of them. Now, since there is no reason why one should rather be altered than another, it follows, that we ought to alter them all equally. By these means, as the alteration is made to influence all the fifths, it will be in each of them almost imperceptible; and thus the fifth, which, after the octave, is the most perfect of all consonances, and which Rameau, we are under the necessity of altering, must only be altered in the least degree possible.

67. It is true, that the thirds will be a little harsh; but as the interval of sounds which constitutes the third, produces a less perfect coalescence than that of the fifth, it is necessary, says M. Rameau, to sacrifice the justice of that chord to the perfection of the fifth; for the more perfect a chord is in its own nature, the more displeasing to the ear is any alteration which can be made in it. In the octave the least alteration is unsupportable.

68. This change in the intervals of instruments by little which have, or even which have not, keys, is that which we call temperament.

69. It results then from all that we have now said, that the theory of temperament may be reduced to this question. The alternate succession of fifths and fourths having been given, (art. 66.), in which B⁰ or C is not the true octave of the first C; it is proposed to alter all the fifths equally, in such a manner that the two C's may be in a perfect octave the one to the other.

70. For a solution of this question, we must begin with tuning the two C's in a perfect octave the one to the other; in consequence of which, we will render all the semitones which compose the octave as equal as possible. By this means (HH) the alteration made in each
MUSIC.

formed; then you may continue always in the same manner; till in this process you arrive at the last fifth from E ♯ to B ♯, which should of themselves be in tune; that is to say, they ought to be in such a state, that B ♯, the highest note of the two which compose the fifth, may be identical with the sound C, with which you began, or at least the octave of that sound perfectly just: it will be necessary then to try if this C, or its octave, forms a just fifth with the last sound E ♯ or F, which has been already tuned. If this be the case, we may be certain that the harpsichord is properly tuned. But if this last fifth be not true, in this case it will be too sharp, and it is an indication that the other fifths have been too much diminished, or at least some of them; or it will be too flat, and consequently discover that they have not been sufficiently diminished. We must then begin and proceed as formerly, till we find the last fifth in tune of itself, and without our immediate interposition (11).

(11) We have only to acknowledge, with M. Rameau, that this temperament is far remote from that which is now in practice: it may here be seen in what this last temperament consists as applied to the organ or harpsichord. They begin with C in the middle of the keys, and they flatten the four first fifths G, D, A, E, till they form a true third major from E to C; afterwards, setting out from this E, they tune the fifths B, F ♯, C ♯, G ♯, but flattening them still less than the former, so that G ♯ may almost form a true third major with E. When they have arrived at G ♯, they stop; they resume the first C, and tune to it the fifth F in descending, then the fifth B ♯, &c. and they heighten a little all the fifths till they have arrived at A ♯, which ought to be the same with the G ♯ already tuned.

If, in the temperament commonly practised, some thirds are found to be less altered than in that prescribed by M. Rameau, in return, the fifths in the first temperament are much more false, and many thirds are likewise so; insomuch, that upon a harpsichord tuned according to the temperament in common use, there are five or six modes which the ear cannot endure, and in which it is impossible to execute any thing. On the contrary, in the temperament suggested by M. Rameau, all the modes are equally perfect; which is a new argument in its favour, since the temperament is peculiarly necessary in passing from one mode to another, without shocking the ear; for instance, from the mode of C to that of G, from the mode of G to that of D, &c. It is true, that this uniformity of modulation will to the greatest number of musicians appear a defect: for they imagine, that, by tuning the semitones of the scale unequal, they give each of the modes a peculiar character; so that, according to them, the scale of C:

C, D, E, F, G, A, B, C,

is not perfectly similar to the gammut or diatonic scale of the mode of E,

E, F ♯, G ♯, A ♯, B, C ♯, D ♯, &c.,

which in their judgment, renders the modes of C and E proper for different manners of expression. But after all that we have said in this treatise on the formation of diatonic intervals, every one should be convinced, that, according to the intention of nature, the diatonic scale ought to be perfectly the same in all its modes: The contrary opinion, says M. Rameau, is a mere prejudice of musicians. The character of an air arises chiefly from the intermixture of the modes; from the greater or lesser degrees of vivacity in the movement; from the tones, more or less grave, or more or less acute, which are assigned to the generator of the mode; and from the chords more or less beautiful, as they are more or less deep, more or less flat, more or less sharp, which are found in it.

In short, the last advantage of this temperament is, that it will be found conformed with, or at least very little different from that which is practised upon instruments without keys; as the bass-viol, the violins, in which true fifths and fourths are preferred to thirds and sixths tuned with equal accuracy; a temperament which appears incompatible with that commonly used in tuning the harpsichord.

Yet M. Rameau, in his New System of Music, printed in 1726, adopted the ordinary temperament. In that work, (as may be seen chap. xxiv.), he pretends that the alteration of the fifths is much more supportable than that of the thirds major; and that this last interval can hardly suffer a greater alteration than the octave, which, as we know, cannot suffer the slightest alteration. He says, that if three strings are tuned, one by an octave, the other by a fifth, and the next by a third major to a fourth string, and if a sound be produced from the last, the strings tuned by a fifth will vibrate, though a little less true than it ought to have been; but that the octave and the third major, if altered in the least degree, will not vibrate: and he adds, that the temperament which is now practised, is founded upon that principle. M. Rameau goes still farther; and as, in the ordinary temperament,
MUSIC.

Chap. VIII. Of Repose or Cadences (XX).

73. In a fundamental bass whose procedure is by fifths, there always is, or always may be, a repose, or imperfect crisis, in which the mind acquiesces in its transition from one sound to another: but a repose may be more or less distinctly signified, and of consequence more or less perfect. If one should rise by fifths; if, for instance, we pass from C to G; it is the generator which passes to one of these fifths, and this fifth was already pre-existent in its generator: but the generator exists no longer in this fifth; and the ear, as this generator is the principle of all harmony and of all melody, feels a desire to return to it. Thus the transition from a sound to its fifth in ascent, is termed an imperfect repose, or imperfect cadence; but the transition from any sound to its fifth in descent, is denominated a perfect cadence, or an absolute repose: it is the departing which returns to its generator, and as it were recovers its existence once more in that generator itself, with which when sounding it resounds (chap. i.).

74. Amongst absolute reposes, there are some, if perfect we may be allowed the expression, more absolute, that is to say, more perfect, than others. Thus in the fundamental bass

which forms, as we have seen, the diatonic scale of the moderns, there is an absolute repose from D to G; and from G to C; yet this last absolute repose is more perfect than the preceding, because the ear, prepossessed with the mode of C by the multiplied impression of the sound C which it has already heard thrice before, feels a desire to return to the generator C; and it accordingly does so by the absolute repose G C.

75. We may still add, that what is commonly called cadence in melody, ought not to be confounded with what we name cadence in harmony.

temperament, there is a necessity for altering the last thirds major, and to make them a little more sharp, that they may naturally return to the octave of the principal sound, he pretends that this alteration is tolerable, not only because it is almost insensible, but because it is found in modulations not much in use, unless the composer should choose it on purpose to render the expression stronger. "For it is proper to remark (says he), that we receive different impressions from the intervals in proportion to their different alterations: for instance, the third major, which naturally elevates us to joy, in proportion as we feel it, heightens our feelings even to a kind of fury, when it is tuned too sharp; and the third minor, which naturally inspires us with tenderness and serenity, depresses us to melancholy when it is too flat." All this is very different from what this celebrated musician afterwards exhibited in his Generation Harmonique, and in the performances which followed it. From this we can only conclude, that the reasons which, after him, we have urged for the new temperament, must without doubt have appeared to him very strong, because in his mind they had superseded those which he had formerly adopted in favour of the ordinary temperament.

We do not pretend to give any decision for either the one or the other of these methods of temperament, each of which appears to us to have its particular advantages. We shall only remark, that the choice of the one or the other must be left absolutely to the taste and inclination of the reader; without, however, admitting the choice to have any influence upon the principles of the system of music, which we have followed even till this period, and which must always subsist, whatever temperament we adopt.

(MK) That the reader may have a clear idea of the term before he enters upon the subject of this chapter, it may be necessary to caution him against a mistake into which he may be too easily led by the ordinary significations of the word repose. In music, therefore, it is far from being synonymous with the word rest. It is, on the contrary, the termination of a musical phrase which ends in a cadence more or less emphatic, as the sentiment implied in the phrase is more or less complete. Thus a repose in music answers the same purpose as punctuation in language. See Repose, in Rousseau's Musical Dictionary.
Part I.

MUSIC

Theory of Harmony.

In the first case, the word only signifies an agreeable and rapid alternation between two contiguous sounds, called likewise a trill or shake; in the second, it signifies a repose or close. It is however true, that this shake implies, or at least frequently enough, passages, a repose, either present or impending, in the fundamental bass (121).

76. Since there is a repose in passing from one sound to another in the fundamental bass, there is also a repose in passing from one note to another in the diatonic scale, which is formed from it, and which this bass represents: and as the absolute repose G C is of all others the most perfect in the fundamental bass, the repose from B to c, which answers to it in the scale, and which is likewise terminated by the generator, is for that reason the most perfect of all others in the diatonic scale ascending.

77. It is then a law dictated by nature itself that if you would ascend diatonically to the generator of a mode, you may only do this by means of the third major, from the fifth of that very generator. This third step, which with the generator forms a semitone, has for that reason been called the sensible note or leading note, as introducing the generator, and preparing us for the most perfect repose.

We have already proved, that the fundamental bass is the principle of melody. We shall besides make it appear in the sequel, that the effect of a repose in melody arises solely from the fundamental bass.

CHAP. IX. Of the Minor Mode and its Diatonic Series.

The diatonic series of the minor mode ascended by different examples.

78. In the second chapter, we have explained (art. 20, 30, 31, and 32.) by what means, and upon what principle, the minor chord C, 5, G, c, may be formed, which is the characteristic chord of the minor mode. Now what we have there said, taking C for the principal and fundamental sound, we might likewise have said of any other note in the scale, assumed in the same manner as the principal and fundamental sound: but as in the minor chord, C, E, G, c, there succeeds as E flat which is not found in the ordinary diatonic scale, we shall immediately substitute, for greater ease and convenience, another chord, which is likewise minor and exactly similar to the former, of which all the notes are found in the scale.

79. The scale affords us three chords of this kind, viz. D, F, A, 'd'; A, c, e, a'; and E, G, B, 'c'. Among these three we shall choose A, 'c, e, a'; because this chord, without including any sharp or flat, has two sounds in common with the major chord C, E, G, 'c': and besides, one of these two sounds is the very same 'c': so that this chord appears to have the most simple, relation with the chord C, E, G, 'c'. Concerning this we need only add, that this preference of the chord A, 'c, e, a', to every other minor chord, is by no means in itself necessary for what we have to say in this chapter upon the diatonic scale of the minor mode. We might in the same manner have chosen any other minor chord; and it is Harmony, only, as we have said, for greater ease and convenience that we fix upon this.

80. In every mode, whether major or minor, the tonic or principal sound which implies the perfect chord, whether major or minor, is called the tonic note or key; thus.

\[ C \]

is the key in its proper mode, A in the mode of A. See Prinzel &c. Having laid down this principle, we have shown how the three sounds, F, C, G, which constitute (art. 38.) the mode of C, of which the first, F, and the last, G, are the two fifths of C, one descending, the other rising, produce the scale, B, 'c, d, e, f'.

81. We have seen that the three sounds, F, C, G, make up the elementary scale, and form the diatonic bass, G, C, F, C, F; let us in the same manner take the three sounds D, A, E, which constitute the mode of A, for the same reason that the sounds F, C, G, constitute the mode of C; and of them let us form this fundamental bass, perfectly like the preceding E, A, F, A, D, A, D; let us afterwards place See fig. 7, below each of these sounds one of their harmonics, as we have done (chap. v.), for the first scale of the major mode; with this difference, that we must suppose D, and A as implying their thirds minor in the fundamental bass to characterize the minor mode; and we shall have the diatonic scale of that mode.

\[ G, A, B, 'c, d, e, f' \]

82. The G, which corresponds with E in the fundamental bass, forms a third major with that E, though the mode be minor; for the same reason that a third from the fifth of the fundamental sound ought to be major (art. 77.) when the third rises to the fundamental sound A.

83. It is true, that, in causing E to imply its third See Imply minor G, one might also rise to A by a diatonic progrss. But that manner of rising to A would be less perfect than the preceding; for this reason (art. 76.), that the absolute repose or perfect cadence E, A, in the fundamental bass, ought to be represented in the most perfect manner in the two notes of the diatonic scale which answer to it, especially when one of these two notes is A, the key itself upon which the repose is made. From whence it follows, that the preceding note G ought rather to be sharp than natural; because G, being included in E (art. 19.), much more perfectly represents the note E in the bass, than the natural G could do, which is not included in E.

84. We may remark this first difference between the scale

\[ G, A, B, 'c, d, e, f' \]

and the scale which corresponds with it in the major mode

\[ B, 'c, d, e, f, g, a' \]

that from 'c' to 'f' which are the two last notes of the former scale, there is only a semitone; whereas from 'g' to 'a', which are the two last sounds of the latter series, there is the interval of a complete tone; but this not the only discrimination which may be found between the scales of the two modes.

32.

(121) M. Rousseau, in his letter on French music, has called this alternate undulation of different sounds a trill, from the Italian word trillo, which signifies the same thing; and some French musicians already appear to have adopted this expression.

MUSIC

Part I

Theory of Harmony.

Investigation of these differences and their reasons.

To investigate these differences, and to discover the reason for which they happen, we shall begin by forming a diatonic scale of the minor mode, similar to the second scale of the major mode,

\[ c, d, e, f, g, a, b', c. \]

That last series, as we have seen, was formed by means of the fundamental bass \( F \), \( C \), \( G \), \( D \), disposed in this manner,

Let us take in the same manner the fundamental bass \( D, A, E, B, B, A \), and arrange it in the following order,

\[ A, E, A, D, A, E, B, E, A. \]

See fig. 8.

and it will produce the scale immediately subjoined,

\[ A, B, c', d, e, f, g, a, \]

in which \( c' \) forms a third minor with \( A \), which in the fundamental bass corresponds with \( c \), which denominates the minor mode; and, on the contrary, \( g \) forms a third major with \( E \) in the fundamental bass, because \( g \) rises towards \( a \) (art. 82. 83.).

86. We see besides an \( f \) which does not occur in the former,

\[ G, A, B, c', d, e, f', \]

where \( f' \) is natural. It is because, in the first scale, \( f' \) is a third minor from \( D \) in the bass; and in the second, \( f' \) is the fifth from \( B \) in the bass (MM).

Difference between the two scales of the minor mode greater than those of the major.

87. Thus the two scales of the minor mode are still in this respect more different one from the other than the two scales of the major mode; for we do not remark this difference of a semitone between the two scales of the major mode. We have only observed (art. 63.) some difference in the value of \( A \) as it stands in each of these scales, but this amounts to much less than a semitone.

88. From thence it may be seen why \( f' \) and \( g' \) are sharp in the minor mode, besides the \( g' \) is only natural in the first scale \( G, A, B, c', d, e, f' \), because this \( f' \) cannot rise to \( g' \) (art. 48.).

89. It is not the same case in descending. For \( E \), the fifth of the generator, ought not to imply the third descending major \( g \); but in the case when that \( E \) descends to the generator \( A \) to form a perfect repose (art. 77. and 83.); and in this case the third major \( g \) rises to the generator \( a \); but the fundamental bass \( A, E, B, G \), natural, provided \( g \) does not rise again to \( a \).

Exposition of the descending scale in the minor mode from a fundamental bass difficult.

90. It is much more difficult to explain how the \( f' \) which ought to follow this \( g' \) in descending, is natural and not sharp; for the fundamental bass \( A, E, B, G, A, D, A, E, A \), produces in descending,

\[ g, f, e, c, d, e, b, A \]

And it is plain that the \( f' \) cannot be otherwise than sharply, since \( f' \) is the fifth of the note \( B \) of the fundamental bass. Experience, however, evinces that the \( f' \) is natural in descending in the diatonic scale of the major mode of \( A \), especially when the preceding \( g' \) is natural: and it must be acknowledged, that here the fundamental bass appears defective.

M. Rameau has attempted the following solution of this difficulty. In the diatonic scale of the minor mode, \( g' \) in descending, \( (a, g, f, e, d, c', b, A, A) \) \( g' \) may be regarded simply as a note of passage, merely added to give more sweetness to the modulation, and as a diatonic graduation, by which we may descend to \( f' \) natural. This is easily perceived, according to M. Rameau, by the fundamental bass,

\[ A, D, A, D, A, E, A, \]

which produces

\[ a, f, e, d, c', B, A \]

which may be regarded, as he says, as the real scale of the minor mode in descending; to which is added that \( g' \) natural between \( a \) and \( f' \) to preserve the diatonic order.

This appears the only possible answer to the difficulty above proposed: but we know not whether it will fully satisfy the reader; whether he will not see with regret, that the fundamental bass does not produce, to speak properly, the diatonic scale of the minor mode in descent, when at the same time this same bass so happily produces the diatonic scale of that identical mode in ascending, and the diatonic scale of the major mode whether in rising or descending (MM).

Chap. X. Of Relative Modes.

91. Two modes of such a nature that we can pass from the one to the other, are called relative modes. Thus the major mode of \( C \) is relative to the major mode of \( F \) and to that of \( G \). It has also been seen how many intimate connexions there are between the major mode of \( C \), and the minor mode of \( A \). For, the perfect chords, one major, \( C, E, G, c' \), the other minor, \( A, c, e, a \), which characterise each of these two kinds of modulation or harmony, have two sounds in common, \( c' \) and \( c' \). 2. The scale of the minor mode of \( A \) in descent, absolutely contains the same sounds with the scale of the major mode of \( C \).

Hence the transition is so natural and easy from the major mode of \( C \) to the minor mode of \( A \), or from the minor mode of \( A \) to the major mode of \( C \), as experience proves.

92. In the minor mode of \( E \), the minor perfect chord \( E, G, B, c' \), which characterises it, has likewise two sounds, \( E, G \), in common with the perfect chord major \( C, E, G, c' \), which characterises the major mode of (MM).

Besides, without appealing to the proof of the fundamental bass, \( f' \) obviously presents itself as the sixth note of this scale; because the seventh note being necessarily \( g' \) (art. 77.) if the sixth were not \( f' \), that would be an interval of three semitones between the sixth and the seventh, consequently the scale would not be diatonic (art. 8.).

(NN) When \( g' \) is said to be natural in descending the diatonic scale of the minor mode of \( A \), it is only meant that this \( g' \) is not necessarily sharp in descending as it is in rising: for it may be sharp, as may be proved by numberless examples, of which all musical compositions are full. It is true, that, when \( g' \) is found sharp in descending to the minor mode of \( A \), we are not sure that the mode is minor till the \( f' \) or \( c' \) natural is found; both of which impress a peculiar character on the minor mode, viz. \( c' \) natural, in rising and in descending, and the \( f' \) natural in descending.
MUSIC.

Of C. But the minor mode of E is not so closely related nor allied to the major mode of C as the minor mode of A; because the diatonic scale of the minor mode of E in descent, has not, like the series of the minor mode of A, all these sounds in common with the scale of C. In reality, this scale is 'c, d, e', B, A, G, F, E, where there occurs an 'f' sharp which is not in the scale of C. Though the minor mode of E is thus less relative to the major mode of C than that of A; yet the artist does not hesitate sometimes to pass immediately from the one to the other.

When we pass from one mode to another by the interval of a third, whether in descending or ascending, as from C to G, or from G to C, or from E to C, the major mode becomes minor, or the minor mode becomes major.

There is still another minor mode, into which an immediate transition may be made in issuing from the major mode of C. It is the minor mode of C itself in which the perfect minor chord C, E', G, 'c', has two sounds, C and G, in common with the perfect major chord C, E, G, 'c'. Nor is there anything more common than a transition from the major mode of C to the minor mode, or from the minor to the major (OO).

CHAP. XI. Of Dissonance.

We have already observed, that the mode of C (F, C, G,) has two sounds in common with the mode of G (C, G, D,); and two sounds in common with the mode of F (B, F, C). Consequently, this procedure of the scale G may belong to the mode of C, or to the mode of G, as the procedure of the scale F, C, or F, E, may belong to the mode of C or the mode of F. When one therefore passes from C to F or F to G in a fundamental base, he is still ignorant what mode he is in. It would be, however, advantageous to know it, and to be able by some means to distinguish the generator from its fifths.

This advantage may be obtained by uniting at the same time the sounds G and F in the same harmony, that is to say, by joining to the harmony G, B, 'd' of the fifth G, the other fifth F in this manner, G, B, 'd', F; this 'f' which is added, forms a dissonance with G (art. 18.). Hence the chord G, B, 'd', F, is called a dissonant chord, or a chord of the seventh. It serves to distinguish the fifth G from the generator C, which always implies, without mixture or alteration, the perfect chord C, E, G, 'c' resulting from nature itself (art. 32.). By this we may see, that when we pass from C to G, one passes at the same time from C to F, because 'f' is found to be comprehended in the chord of G; and the mode of C by these means plainly appears to be determined, because there is none but that mode to which the sounds F and G at once belong.

Let us now see what may be added to the harmony F, A, C of the fifth F below the generator, to distinguish this harmony from that of the generator continued. It seems probable at first, that we should add to it the other fifth G, so that the generator C, in passing to F, may at the same time pass to G, and that by this the mode should be determined: but this introduction of G, in the chord F, A, C, would produce two seconds in succession, F, G, G, A, that is to say, two dissonances whose union would prove extremely harsh to the ear; an inconvenience to be avoided. For if, to distinguish the mode, we should alter the harmony of the fifth F in the fundamental base, it must only be altered in the least degree possible.

For this reason, instead of G, we shall take its chord of fifth 'd', the sound that approaches it the nearest, and the great sixth, which we shall have, instead of the fifth F, the chord F, A, 'c', 'd', which is called a chord of the great sixth.

One may here remark the analogy there is observed between the harmony of the fifth G and that of the fifth F.

The fifth G, in rising above the generator, gives the subject a chord entirely consisting of thirds ascending from G, of dissonance, C, B, 'd', F; now the fifth F being below the generator continued C in descending, we shall find, as we go lower by thirds from 'd' towards E, the same sounds 'c', A, F, D, which form the chord F, A, 'c', 'd', given to the fifth F.

It appears besides, that the alteration of the harmony in the two fifths consists only in the third minor: D, F, which was reciprocally added to the harmony of these two fifths.

CHAP. XII. Of the Double Use or Employment of Dissonance.

It is evident by the resemblance of sounds to account of their octaves, that the chord F, A, 'c', 'd', is in effect the double so the same as the chord D, F, A, 'c', taken inversely employed; that the inverse of the chord C, A, F, D, has been found (art. 98.) in descending by thirds, from the generator.

The...

(00) There are likewise other minor modes, into which we may pass in our egress from the mode major of C; as that of F minor, in which the perfect minor chord F, A, 'c', includes the sound 'c', and whose scale in ascent, F, G, A, B, 'c', includes only the two sounds A, B, which do not occur in the scale of C. This transition, however, is not frequent.

The minor mode of D has only in its scale ascending D, E, F, G, A, B, 'c', 'd', one 'c' sharp which is not found in the scale of C. For this reason a transition may likewise be made, without grating the ear, from the mode of C major to the mode of D minor; but this passage is less immediate than the former, because the chords C, E, G, 'c', and D, F, A, 'd', not having a single sound in common, one cannot (art. 37.) pass immediately from the one to the other.

(FP) M. Ramonc, in several passages of his works (for instance, in p. 110, 111, 112, and 113, of the Generation Harmonique), appears to consider the chord D, F, A, C, as the primary chord and generator of the chord E, A, 'c', 'd', which is that chord reversed; in other passages (particularly in p. 116. of the same performance), he seems to consider that these chords as nothing else but the reverse of the second. It would seem that this...
MUSIC.

Part I.

101. The chord D, F, A, 'c', is a chord of the seventh like the chord G, B, 'd', f; with this only difference, that the latter in the third G, B, is major: whereas in the former, the third D, F, is minor. If the F were sharp, the chord D, F#, A, 'c', would be a genuine chord of the dominant, like the chord G, B, D, F; and as the dominant G may descend to C in the fundamental bass, the dominant D implying or carrying with it the third major F# might in the same manner descend to G.

102. Now if the F# should be changed into F natural, D, the fundamental tone of this chord D, F, A, 'c', might still descend to G; for the change from F# to F natural will have no other effect, than to preserve the impression of the mode of C, instead of that of the mode of G, which the F# would have here introduced. The note D will, however, preserve its character as a dominant, on account of the mode of C, which forms a seventh. Thus in the chord of which we treat (D, F, A, 'c'), D may be considered as an imperfect dominant: we call it imperfect, because it carries with it the third minor F, instead of the third major F#. It is for this reason that in the sequel we shall call it simply the dominant, to distinguish it from the dominant G, which shall be named the tonic dominant †.

103. Thus the sounds F and G, which cannot succeed each other (art. 36.) in a diatonic bass, when they only carry with them the perfect chords F A C, G B 'd', may succeed one another, if 'd' be added to the harmony of the first, and 'F' to the harmony of the second; and if the first chord be inverted, that is to say, if the two chords take this form, D, F, A, C, G, B, 'd', 'a'.

104. Besides, when the chord A, 'c', d', being allowed to succeed the perfect chord C, E, G, 'c', it follows for the same reasons, that the chord C, E, G, 'c' may be succeeded by D, F, A, 'c', which is not contradictory to what we have above said (art. 37.), that the sounds C and D cannot succeed one another in the fundamental bass: for in the passage quoted, we had supposed that both C and D carried with them a perfect chord major; whereas, in the present case, D carries the third minor E, and likewise the sound 'c', by which the chord D E F a 'c' is connected with that which precedes it C E G 'c'; and in which the sound 'c' is found. Besides, this chord, D E F a 'c', is properly nothing else but the chord F A 'c' inverted, and if we may speak so, disguised.

105. This manner of presenting the chord of the subdominant under two different forms, and of employing it under these two different forms has been called by M. Rameau its double office or employment. This is one of the most important varieties in harmony, and we shall see in the following chapter the advantage which results from it.

We may add, that as this double employment is a kind of license, it ought not to be practiced without some precaution. We have lately seen that the chord D, F, A, 'c', considered as the inverse of F A 'c', may succeed to C E G 'c', but this liberty is not reciprocal: at though the chord F A 'c', 'd', may be followed by the chord C E G 'c', we have no right to conclude from thence that the chord D F A 'c', considered as the inverse of F A 'c', 'd', may be followed by the chord C E G 'c'. For this reason the shall be given in chap. xvi.

Chap. XIII. Concerning the Use of this Double Employment, and its Rules.

106. We have shown (chap. xvi.) how the diatonic, or scale, or ordinary gammut, may be formed from the fundamental bass F, C, G, D, by twice repeating the note G in that series; so that this gammut is primitive composed of two similar tetrachords, one in the mode of C, the other in that of G. Now it is possible, impartial by means of this double employment, to preserve the impression of the mode of C through the whole extent of the scale, without twice repeating the note C, or even without supposing this repetition. For this effect we form the following fundamental bass,

C, G, C, F, C, D, G, C:

in which C is understood to carry with it the perfect chord C E G 'c'; G, the chord G B 'd', f; F, the chord F A 'c', 'd'; and D, the chord D F A 'c'. It is plain from what has been said in the preceding chapter, that in the case that C may ascend to D in the fundamental bass, and C descend to G, and that the impression of the mode of C is preserved by the 'd' natural, which forms the third minor 'd', f', instead of the third major which D ought naturally to imply.

107. This fundamental bass will, as it is evident, the ordinary diatonic scale,

'c', d, e, f, g, a, b', c

which of consequence will be in the mode of C alone, and if one should choose to have the second tetrachord in the mode of G, it will be necessary to substitute 'f#' instead of 'f', in the harmony of D (eq).

108. Thus the generator C may be followed accord

数字的这一行

The great artist, has neither expressed himself upon this subject, with so much uniformity nor with so much precision as is required. We think that there is some foundation for considering the chord F, A, 'c', d', as primitive: 1. Because in this chord, the fundamental and principal note is the subdominant F, which ought in effect to be the fundamental and principal sound in the chord of the sub-dominant. 2. Because that without having recourse, with M. Rameau, to harmonic and arithmetical progressions, of which the consideration appears to be quite foreign to the question, we have found a probable and even a satisfactory reason for adding the note 'd' to the harmony of the fifth F (art. 96. and 97.). The origin thus assigned for the chord of the sub-dominant appears to us the most natural, though M. Rameau does not appear to have felt its full value; for scarcely has it been slightly intimated by him.

It is obvious that this fundamental bass C, G, C, F, C, D, G, C, which formed the ascending scale 'c', d, e, f, g, a, b', c, cannot by inverting it, and taking it inversely in this manner, C, G, D, C, F, C, G, C, form the diatonic scale c, b, a, g, f, e, d, c, in descent. In reality, from the chord G, B, 'd', f, we cannot pass to the chord D, F, A, 'c', nor from thence to C, E, G, 'c'. For this reason, in order to have the fundamental bas
Part I.

**Music**

119. In the minor mode of A, the tonic dominant E ought always to imply its third major E G, when this dominant E descends to the generator A (art. 83.); and the chord of this dominant shall be E G B, entirely similar to G B d.

With respect to the sub-dominant D, it will immediately imply the third minor F, to denominate the minor mode; and we may add B above its chord D F A, in this manner D F A B, a chord similar to that of F A C d; and as we have deduced from the chord F A e d that of D F A c, we may in the same manner deduce from the chord D F A B a new chord of the seventh B d f a, which will exhibit the double employment of dissonances in the minor mode.

110. One may employ this chord B d f a, to preserve the impression of the mode of A in the diatonic scale of the minor mode, and to prevent the necessity of twice repeating the sound E; but in this case, the F must be removed sharp, and the chord changed to B d f a, the fifth of B being e f g, as we have seen above.

This chord is then the inverse of D F A B, the sub-dominant of the third minor mode, which ought not to surprise us; for in the minor mode of A, the second tetrachord E F G A is exactly the same as it would be in the major mode of A: Now, in the major mode of A the sub-dominant D ought to imply the third major F.

111. Hence the minor mode is susceptible of a much greater number of varieties than the major: the major mode is found in nature alone; whereas the minor is in some measure the product of art. But, in return, the major mode has received from nature, to which it owes its immediate formation, a force and energy which the minor cannot boast.

**Chap. XIV. Of the different Kinds of Chords of the Seventh.**

112. The dissonance added to the chord of the dominant and of the sub-dominant, though in some measure suggested by nature (chap. xi.), is nevertheless a work of art; but as it produces great beauties in harmony by the variety which it introduces into it, let us discover whether, in consequence of this first advance, theory of art may not be carried farther.

113. We have already three different kinds of chords of the seventh, viz.

1. The chord G B d f, composed of a third major followed by two thirds minor.

2. The chord D F A c, or B d f a, a third major between two minors.

3. The chord B d f a, two thirds minor followed by a major.

114. There are still two other kinds of chords of the seventh which are employed in harmony; one is composed of a third minor between two thirds major, C E G B, or F A c e; the other is wholly composed of thirds minor G E B d f. These two chords, which at first appear as if they ought not to enter into harmony if we rigorously keep to the preceding rules, are nevertheless frequently practised with success in the fundamental bass. The reason is this:

115. According to what has been said above, if we change a seventh to the chord C E G, to make it a dominant of C, one can add nothing but B b; and in this case C E G B b would be the chord of the tonic dominant in the mode of F, as G B d f is the chord of the tonic dominant in the mode of C; but if we would preserve the impression of the mode of C in the harmony, we change this B b into B natural, and the chord C E G B becomes C E G B. It is the same case with the chord F A c e, which is nothing else but the chord F A c e b; in which one may substitute for e b, e natural, to preserve the impression of the mode of C, or that of F.

Besides, in such chords as C E G B, F A c e, the sounds B and e, though they form a dissonance with C in the first case, and with F in the second, are nevertheless supportable to the ear, because these sounds B and e (art. 19.) are already contained and understood, the first in the note E of the chord C E G B, as likewise in the note G of the same chord; the second in the note A of the chord F A c e, as likewise in the note e of the same chord.

All together then seem to allow the artist to introduce the note B and e into these two chords (h). 116. With respect to the chord of the seventh G B d f, wholly composed of thirds minor, it may be re-considered as formed from the union of the two chords of the seventh which we have explained.

*h* Whichever of these two basses we shall choose, it is obvious that neither the one nor the other shall be wholly in the mode of C, but in the mode of C and in that of G. Whence it follows, that the double employment which gives to the scale a fundamental bass all in the same mode when ascending, cannot do the same in descending; and that the fundamental bass of the scale in descending will be necessarily in two different modes.

**(h)** On the contrary, a chord such as C E G B, in which E would be flat, could not be admitted in harmony, because in this chord the B is not included and understood in E. It is the same case with several other chords, such as B D F A, B D F A, &c. It is true, that in the last of these chords, A is included in F, but it is not contained in D; and this D likewise forms with F and with A a double dissonance, which, joined with the dissonance B F, would necessarily render this chord not very pleasing to the ear; we shall yet, however, see in the second part, that this chord is sometimes used.
Chap. XV. Of the Progression of Harmony.

125. In every series of harmony the progress of each successive harmony should be considered as dependent on the preceding harmony, and every harmony should have its proper connection with the harmony immediately preceding it. Thus, in the diatonic scale, the chord D F A C, which is the sub-dominant of the major mode, is followed by the chord E G C E, which is the dominant of the major mode. The chord E G C E, therefore, should be considered as dependent on the chord D F A C, and the chord D F A C as dependent on the chord E G C E.

126. Now in the chord of the tonic dominant, the note C, which is the sub-dominant of the major mode, is followed by the note E, which is the dominant of the major mode. The note E, therefore, should be considered as dependent on the note C, and the note C as dependent on the note E. In this manner, the progress of each successive harmony should be considered as dependent on the preceding harmony, and every harmony should have its proper connection with the harmony immediately preceding it.

127. In general, dissonance being the production of harmony (chap. xvi.), especially in each chord, and are not of the transitory dominant nor sub-dominant, the only means in which dissonance is to be avoided is by the introduction of other harmonies, such as the sub-dominant or dominant. In this manner, the progress of each successive harmony should be considered as dependent on the preceding harmony, and every harmony should have its proper connection with the harmony immediately preceding it.
Part I.

Music. Theory of Harmony. Let us take, for instance, the chord C B 'd' f' followed by the chord C E G 'c'; the part which formed the dissonance 'f' ought to descend to 'c' rather than rise to 'g', though both the sounds E and G are found in the subsequent chord C E G 'c'; because it is more natural and more conformable to the connexion which ought to be found in every part of the music, that G should be found in the same part where C has already been sounded, whilst the other part was sounding 'f', as may be here seen (Parts First and Fourth).

First part, - - - - - - - - 'f' 'c'
Second, - - - - - - - - 'd' 'f' 'c'
Third, - - - - - - - - B 'f'
Fourth, - - - - - - - - G G
Fundamental bass, - - - - - - - - G G

Consequences of the former rule. And the same consequence.

127. So, in the chord of the simple dominant DFA 'c', followed by G B 'd' f', the dissonance 'c' ought rather to descend than to rise to 'd'.

128. And, for the same reason, in the chord of the sub-dominant F A 'c'd', the dissonance 'd' ought to rise to 'c' of the following chord C E G 'c', rather than descend to 'c'; whence may be deduced the following rules.

But is deduced from the former propositions.

129. 1°. In every chord of the dominant, whether tonic or oblique, the note which constitutes the seventh, that is to say, the dissonance, ought diatonically to descend upon one of the notes which form a consonance in the subsequent chord.

2°. In every chord of the sub-dominant, the dissonance ought to rise diatonically upon the third of the subsequent chord.

Dissonance resolved, etc. See Resolution.

A dissonance which descends or rises diatonically according to these two rules, is called a dissonance resolved.

From these rules it is a necessary result, that the chord of the seventh DFA 'c', though it should even be considered as the inverse of FA 'c'd', cannot be succeeded by the chord C E G 'c', since there is not in this last chord the note B, upon which the dissonance 'c' of the chord DFA 'c' can descend.

One may besides find another reason for this rule, in examining the nature of the double employment of dissonances. In effect, in order to pass from DFA 'c', to C E G 'c', it is necessary that DFA 'c' should in this case be understood as the inverse of FA 'c'd'. Now the chord DFA 'c' can only be conceived as the inverse of FA 'c'd', when this chord DFA 'c' precedes or immediately follows the C E G 'c'; in every other case the chord DFA 'c' is a primitive chord, formed from the perfect minor chord DFA, to which the dissonance 'c' was added, to take from D the character of a tonic. Thus the chord DFA 'c', could not be followed by the chord C E G 'c', but after having been preceded by the same chord. Now, in this case, the double employment would be entirely a futile expedient, without producing any agreeable effect: because, instead of this succession of chords, C E G 'c', DFA 'c', C E G 'c', it would be much more easy and natural to substitute this other, which furnishes this natural succession C E G 'c', FA 'c'd', C E G 'c'. The proper use of the double employment is, that, by means of inverting the chord of the sub-dominant, it may be able to pass from that chord thus inverted to any other chord except that of the tonic, to which it naturally leads.

Chap. XVII. Of the Broken or Interrupted Cadence.

131. In a fundamental bass which moves by fifths, The test of there is always, as we have formerly observed (chap. viii.), a repose more or less perfect from one sound to another; and of consequence there must likewise be a repose more or less perfect from one sound to another in the diatonic scale, which results from that bass.

It may be demonstrated by a very simple experiment, that the cause of a repose in melody is solely in the fundamental bass expressed or understood. Let any person sing these three notes 'c d g', performing on the 'd' a shake, which is commonly called a cadence; the modulation will appear to him to be finished after the second 'c', in such a manner that the ear will neither expect or wish any thing to follow. The case will be the same if we accompany this modulation with its natural fundamental bass C G C: but if, instead of this bass, we should give it the following, C G A: in this case the modulation 'c d c' would not appear to be finished, and the ear would still expect and desire something more. This experiment may easily be made.

132. This passage GA, when the dominant G diatonically ascends upon the note A instead of descending theches, by a fifth upon the generator C, as it ought naturally to do, is called a broken cadence; because the perfect cadence GC, which the ear expected after the dominant G, is, if we may speak so, broken and suspended by the transition from G to A.

133. Hence it follows, that if the modulation 'c d c' appeared finished when we supposed no bass to it at all, it is because its natural fundamental bass CGC is implied; for the ear desires something to follow this modulation, as soon as it is reduced to the necessity of hearing another bass.

134. The broken cadence may be considered as having its origin in the double employment of dissonances; broken since this cadence, like the double employment, only the double consists in a diatonic procedure of the bass ascending employment (chap. xii.). In effect, nothing hinders us to descend from the chord GB 'd' f' to the chord CEGA by consonances, inverting the tonic C into a sub-dominant, that is to say, by passing all at once from the mode of C to the mode of G: now to descend from GB 'd' f' to CEGA is the same thing as to rise from the chord GB 'd' f' to the chord A 'c e g', in changing the chord of the sub-dominant CEGA for the imperfect chord of the dominant, according to the laws of the double employment.

135. In this kind of cadence, the dissonance of the Manner of first chord is resolved by descending diatonically upon the fifth of the subsequent chord. For instance, in the broken cadence G B 'd' f', A 'c e g', the dissonance 'f' is resolved by descending diatonically upon the fifth 'c'.

136. There is another kind of cadence, called an Interrupted interrupted cadence, where the dominant descends by a fifth to another dominant, instead of descending by a base fifth upon the tonic, as in this succession of the base:}

3 X
G B 'd' f'
M U S I C.

Part I.

141. The minor semitone is hit by young practitioners in intonation with more difficulty than the semitone major. For which this reason may be assigned: The semitone major which is found in the diatonic scale, as from E to F, results from a fundamental bass by fifths CF, that is to say, by a succession which is most natural, and for this reason the easiest to the ear. On the contrary, the minor semitone arises from a succession by thirds, which is still less natural than the former. Hence, that scholars may truly hit the minor semitone, the following artifice is employed. Let us suppose, for instance, that they intend to rise from G to G♯; they rise at first from G to A, then descend from A to G♯ by the interval of a semitone major: for this G sharp, which is a semitone major below A, proves a semitone minor above G. [See the notes (TT) and (UV).]

142. Every procedure of the fundamental bass by thirds, whether major or minor, rising or descending, gives the minor semitone. This we have already seen from the succession of thirds in ascending. The series of thirds minor in descending, C A, gives, C ♯ C (YY); and the series of thirds major in descending, C ♯ B ♯, gives C, C ♯ (ZZ). The minor semitone constitutes the species, called chromatic; and with the species which moves by semitones and diatonic intervals, resulting from the succession of fifths (chap. v. and vi.), it comprehends the whole of melody.

CHAP. XIX. Of the Enharmonic Species.

144. The two extremes, or highest and lowest notes, C G♯, of the fundamental bass by thirds major CEG, give this modulation 'c♯ B ♯ #; and these two sounds 'c♯ B ♯, differ between themselves by a small interval which is called the dièse, or enharmonic fourth of a tone (XX), being which

(TT) In reality, C being supposed 1, as we have always supposed it, E is 4 and G♯ is 5; then shall be to G as 4 to 1; that is to say, as 25 times 2 to 3 times 16: the proportion then of G♯ to G is as 25 to 24, an interval much less than that of 16 to 15, which constitutes the semitone from 'c to B, or from F to E (note Z).

(UV) A minor joined to a major semitone will form a minor tone; that is to say, if one rises, for instance, from E to F, by the interval of a semitone major, and afterwards from F to F♯ by the interval of a minor semitone, the interval from E to F♯ will be a minor tone. For let us suppose E to be 1, F will be , and F♯ will be of ; that is to say, 25 times 16 divided by 24 times 15, or ; E then is to F♯ as one is to , the interval which constitutes the minor tone (note BB).

With respect to the tone major, it cannot be exactly formed by two semitones; for, 1. Two major semitones in immediate succession would produce more than a tone major. In effect, by multiplied by gives , which is greater than 1, the interval which constitutes (note BB) the major tone. 2. A semitone minor and a semitone major would give less than a major tone, since they amount only to a true minor. 3. And, d fortiori, two minor semitones would still give less.

(XX) In effect, Eb being , G♯ will be of ; that is to say, (note Q) of ; now G being 1; G♯ then shall be to G as 4 to 1; that is to say, as 25 times 2 to 3 times 16: the proportion then of G♯ to G is as 25 to 24, an interval much less than that of 16 to 15, which constitutes the semitone from 'c to B, or from F to E (note Z).

(Y) A being , C♯ is of ; that is to say, , and C is : the proportion then between C and C♯ is that of 1 to 1, or of 24 to 25.

(ZZ) Ab being the third minor below C, will be (note Q), Cb then, is of ; that is to say, . The proportion, then, between C and Cb, is as 25 to 24.

(3 A) G♯ being and B♯ being of , we shall have B♯ equal (note Q) to , and its octave below shall be ; an interval less than unity by about or . It is plain then, from this fraction, that the B♯ in question must be considerably lower than C.
MUSIC.

This interval has been called the fourth of a tone, and this denomination is founded on reason. In effect, we may distinguish in music four kinds of quarter tones.

1. The fourth of a tone major: now, a tone major being $\frac{3}{2}$, and its difference from unity being $\frac{1}{2}$, the difference of this quarter tone from unity will be almost the fourth of $\frac{1}{2}$; that is to say, $\frac{1}{4}$.

2. The fourth of a tone minor; and as a tone minor, which is $\frac{5}{4}$, differs from unity by $\frac{1}{4}$, the fourth of a minor tone will differ from unity about $\frac{1}{4}$.

3. One half of a semitone major; and as this semitone differs from unity by $\frac{1}{4}$, one half of it will differ from unity about $\frac{1}{8}$.

4. Finally, one half of a semitone minor, which differs from unity by $\frac{1}{8}$: its half then will be $\frac{1}{16}$.

The interval, then, which forms the enharmonic fourth of a tone, as it does not differ from unity but by $\frac{1}{16}$, may justly be called the fourth of a tone, since it is less different from unity than the largest interval of a quarter tone, and the most nearly equal.

We shall add, that since the enharmonic fourth of a tone is the difference between a semitone major, and a semitone minor; and since the tone minor is formed (note uv) of two semitones, one major and the other minor; it follows, that two semitones major in succession form an interval larger than that of a tone by the enharmonic fourth of a tone; and that two minor semitones in succession form an interval less than a tone by the same fourth of a tone.

(3 a) That is to say, that if you rise from E to F, for instance, by the interval of a semitone major, and afterwards, returning to E, you should rise by the interval of a semitone minor to another sound which is not in the scale, and which I shall mark thus, F + , the two sounds F + and F will form the enharmonic fourth of a tone: for E being 1, F will be $\frac{5}{4}$; and F + $\frac{5}{4}$: the proportion then between F + and F is that of $\frac{5}{4}$ to $\frac{5}{4}$ (note q); that is to say, as 15 times 15 to 16 times 15; or otherwise, as 25 times 5 to 16 times 8, or as 125 to 125. Now this proportion is the same as that found, in the beginning of the preceding note, to express the enharmonic fourth of a tone.

(3 b) As this method for obtaining or supplying enharmonic gradations cannot be practised on every occasion when the composer or practitioner would wish to find them, especially upon instruments where the scale is fixed and invariable, except by a total alteration of their economy, and re-tuning the strings, Dr Smith in his Harmonics has proposed an expedient for redressing or qualifying this defect, by the addition of a greater number of keys or strings, which may divide the tone or semitone into as many appreciable or sensible intervals as may be necessary. For this, as for the other advantageous improvements which he proposes in the structure of instruments, we cannot with too much warmth recommend the perusal of his learned and ingenious book to such of our readers as aspire to the character of genuine adepts in the theory of music.
MUSIC.

Part I.

Chap. XX. Of the Diatonic Enharmonic Species.

147. If we form a fundamental bass, which rises alternately by fifths and thirds, as F, C, G, B, this bass will give the following modulation: "F, E, C, B, G#"; in which the semitones from "F" to "E", and from "E" to "C#", are equal and major (3 D).

This species of modulation or of harmony, in which all the semitones are major, is called the enharmonic diatonic species. The major semitones peculiar to this species give it the name of diatonic, because major semitones belong to the diatonic species; and the tones which are greater than major by the excess of a fourth, resulting from a succession of major semitones, give it the name of enharmonic (note 3 A).

Chap. XXI. Of the Chromatic Enharmonic Species.

148. If we pass alternately from a third minor in descending to a third major in rising, as C, F, A, C#, C, F, we shall form this modulation: "C#, F, A, C, F", in which all the semitones are minor (3 E).

This species is called the chromatic enharmonic species: the minor semitones peculiar to this kind give it the name of chromatic, because minor semitones belong to the chromatic species; and the semitones which are lesser by the diminution of a fourth resulting from a succession of minor semitones, give it the name of enharmonic (note 3 F).

149. These new species confirm what we have all along said, that the whole effects of harmony and melody reside in the fundamental bass.

150. The diatonic species is the most agreeable, because this fundamental bass which produces it is formed from a succession of fifths alone, which is the most natural of all others.

151. The chromatic being formed from a succession of thirds, is the most natural after the preceding.

152. Finally, the enharmonic is the least agreeable of all, because the fundamental bass which gives it is not immediately indicated by nature. The fourth of them is a tone which constitutes this species, and which is its own, self-inharmonic to the ear, neither produces nor can produce its effect, but in proportion as imagination suggests the fundamental bass from whence it results; a bass whose procedure is not agreeable to nature, since it is formed of two sounds which are not contiguous to the other in the series of thirds (art. 144).

Chap. XXII. Showing that Melody is the Offspring of Harmony.

153. All that we have hitherto said, as it seems to me, is more than sufficient to convince us, that melody has its original principle in harmony; and that it is a part of harmony, expressed or understood, that we ought to learn for the effects of melody.

154. If this should still appear doubtful, nothing more is necessary than to pay due attention to the first experiment (art. 19), where it may be seen that the principal sound is always the lowest, and that the sharper sounds which it generates are with relation to it what the triple of an air is to its bass.

155. Yet more, we have proved, in treating of the broken cadence (chap. xvii.), that the diversification of bases produces effects totally different in a modulation which, in other respects, remains the same.

156. Can it be still necessary to adduce more convincing proofs? We have but to examine the different bases which may be given to this very simple modulation GC. It will be found susceptible of many, and each will give a different character to the modulation GC, though in itself it remains always the same. We may thus change the whole nature and effects of a modulation, without any other alteration than that of its fundamental bass.

M. Rameau has shown, in his New System of Music, printed at Paris 1726, p. 44, that this modulation GC, C, is susceptible of 20 different fundamental bases.

Now the same fundamental bass, as may be seen in our second part, will afford several continued or thorough bases. How many means, of consequence, may be practised to vary the expression of the same modulation? 157. From these different observations it may be concluded, 1. That an agreeable melody, naturally improves a bass extremely sweet and adapted for singing, and that reciprocally, as musicians express it, a bass of this kind generally prognosticates an agreeable melody (3 F).

2. That the character of a just harmony is only to form in some measure one system with the modulation.
MUSIC.

PART II. PRINCIPLES AND RULES OF COMPOSITION.

158. COMPOSITION, called also counterpoint, is not only the art of composing an agreeable air, but also
that of composing several airs in such a manner that when
beard at the same time, they may unite in producing an
effect agreeable and delightful to the ear; this is what
we call composing music in several parts.

The highest of these parts is called the treble, the
lowest is termed the bass; the other parts, when there
are any, are termed middle parts; and each in particu-
lar is signified by a different name.

CHAP. I. Of the Different Names given to the same
Interval.

159. In the introduction (art. 9), we have seen a
detail of the most common names given to the different
intervals. But particular intervals have obtained differ-
ent names, according to circumstances; which it is
proper to explain.

160. An interval composed of a tone and a semi-
tone, which is commonly called a third minor, is likewise
called a second redundant; such is the interval from C to D 
3
in ascending, or that of A to G 
3
descending.

This interval is so termed, because one of the sounds
which form it is always either, sharp or flat, and that,
if that sharp or flat be taken away, the interval will be
that of a second (3 C).

161. An interval composed of two tones and two
semitones, as that from B to 'C', is called a false fifth.
This interval is the same with the tritone (art. 9), since
two tones and two semitones are equivalent to three
tones. There are, however, reasons for distinguishing
them, as will appear below.

162. As the interval from C to D 
3
has been called a second redundant, we likewise call dandant,
the interval from C to G 
3
in ascending, a fifth redundant, what,
dant, or from B to E 
3
descending, each of which in-
tervals is composed of four tones (3 H).

This interval is, in the main, the same with that of Distin-
ct the sixth minor (art. 6); but in the fifth redundant gi
there is always a sharp or flat; insomuch, that if this sixth minor
true fifth.

163. For the same reason, an interval composed of Seventh di-
three tones and three semitones, as from G 
3
to 'F' in diminished,
ascending, is called a seventh diminished; because, if
we remove the sharp from G, the interval from G to
'F' will become that of an ordinary seventh. The in-
terval of a seventh diminished is in other respects the
same with that of the sixth major (art. 9) (3 I).

164. The major seventh is likewise sometimes called Seventh a seventh redundant (3 K).

CHAP. II. Comparison of the Different Intervals.

165. If we sing 'c' B in descending by a second, Notes in
and afterwards C B in ascending by a seventh, these different
two B's shall be octaves one to the other; or, as we octaves or
commonly express it, they will be replications one of the
scales replication

166. On account then of the resemblance between other
every
Principles every sound and its octave (art. 22.), it follows, that
of Composition.

Hence to rise by a seventh, or descend by a second, amount to
the same thing.

167. In like manner, it is evident that the sixth descending is nothing but a repetition of the third ascending, nor the fourth descending but a repetition of the fifth ascending.

168. The following expressions either are or ought to be regarded as synonymous.

To rise by a second.—To descend by a seventh.
To descend by a second.—To rise by a seventh.
To rise by a third.—To descend by a sixth.
To descend by a third.—To rise by a sixth.
To rise by a fourth.—To descend by a fifth.
To descend by a fourth.—To rise by a fifth.

169. Thus, therefore, we shall employ them indiscriminately the one for the other; so that when we say, for instance, to rise by a third, it may be said with equal propriety to descend by a sixth, &c.

CHAP. III. Of the Clefs; of the Value or Quantity; of the Rhythm; and of Syncope.

170. There are three clefs in music; the F clef, the C clef, and the G clef.

The F clef is placed on the fourth line (3 L.) or on and below the third; and the line on which this clef is placed gives place to the name of F to all the notes on that line.

The C clef is placed on the fourth, the third, the second, or the first line: and in these different positions (fig. 7.)

Our author has treated this part of his subject with somewhat less perspicuity than usual. He has neither described the staffs or systems of lines on which the clefs are placed, nor explained their relation to each other. We have therefore attempted to supply the deficiency.

Musical sounds, like language, are represented by written characters, by which their graveness or acuteness, their duration, and the other qualities intended to be assigned to them, are accurately distinguished.

The characters which denote the graveness or acuteness, or, as it is termed, the pitch of sounds, are intended to represent the ordinary limits of the human voice, in the exercise of which, or the employment of instruments of nearly the same compass with it, all practical music consists.

From the lowest distinct note, without straining, of the masculine voice, to the highest note generally produced by the female voice, there is an interval of three octaves, or twenty-two diatonic notes.

These notes are represented by characters described alternately on eleven parallel lines, and the spaces between them, forming what we shall here term the general system.

The characters representing the notes are differently formed according to their duration, but with this we have at present no concern. We shall employ the simplest, a small circle or ellipse.

The whole extent of the human voice, then, if described upon the general system, would be represented as at Plate CCLXV. fig. 1.

The masculine voice, rising from the lowest note of the general system, will, generally speaking, reach the note on the central line; and an ordinary female voice will reach the same note, descending from the highest.

Male voices more acute, and female voices graver than usual, will consequently execute this note with greater facility.

This central note, then, being producible by every species of voice, has been assumed as a fundamental or key note, by which all the others are regulated (art. 4.). And to it is assigned the name of C, by which, in the theory of harmony, (as we have seen,) the fundamental sound of the diatonic scale is distinguished.

The other notes take their denominations accordingly. The note below it is B, that above it 'd', &c.; and to distinguish this central C from its octaves, it is called the middle or tenor C.

As no human voice can execute the whole twenty-two notes, the general system is divided into portions of five lines, each portion representing the compass of an ordinary voice; and different portions are made use of, according to the graveness or acuteness of different voices.

The five lines in this state form what is called a staff. Each staff is subdivided into lines and spaces. On the lines, and in the spaces, the heads of the notes are placed. The lines and spaces are counted upwards, from the lowest to the highest; the lowest line is termed the first line; the space between it and the second line is denominated the first space, and so on. Both lines and spaces have the common name of degrees; the staff thus contains nine degrees, viz. five lines and four spaces.

To ascertain what part of the general system is formed by a staff, one of the clefs mentioned in the text is placed at the beginning of the staff, on one or other of the lines of it.

The C or tenor clef always denotes the line on which it is placed to be that which carries the tenor C. The G or treble clef distinguishes the line carrying 'g', the perfect fifth above the tenor C. And the F or bass clef ascends the line which represents the perfect fifth below the tenor C.

The figures of the clefs, (which are characters gradually corrupted from the Gothic C, G, and F), and their places in the general system, appear on Plate CCLXV. fig. 2.

By this disposition of the clefs, we see that the staff, which includes the line bearing the treble clef, is formed by the five highest lines of the general system; and that the staff which comprehends the bass clef consists of the five lowest.

The central line, which carries the tenor C, belongs neither to the treble nor the bass staves. But as that note frequently occurs in composition written on these staves, a small portion of the tenor line is occasionally introduced below the treble clef and above that of the bass (fig. 3.).
MUSIC.

The natural (marked thus ħ) restores to its natural value a note which had been raised or depressed by a semitone.

173. When a sharp or a flat is placed at the clef, all the notes upon the line or space on which this sharp or flat is marked, are sharp or flat. For instance, if in the clef of G a sharp be placed on the highest line, which is the place of 'f', the notes on that line will be 'f#'—to restore them to the original value of 'f' natural, a ħ must be placed before them.

In the same manner, if a flat be marked at the clef, all the notes on the same line or space with the flat will be flat; to restore them to their natural state, a ħ must be placed before them (3 m).

174. Every piece of music is divided into different bars and equal times, what,

As notes still more remote from the staff in use are sometimes introduced, small portions of the lines to which these lines belong are employed in the same manner. Thus, if in writing in the bass staff we want the note properly placed on the lowest line of the treble staff, we draw two short lines above the bass staff, one representing the tenor line, and the other the lowest line of the treble staff, and on this last short line we place the note in question (fig. 4).

On the other hand, if, in writing on the treble staff, we would employ a note properly belonging to the bass staff, we place it below the treble staff, and insert the requisite short lines, representing the corresponding lines of the general system (fig. 5).

The occasional short lines thus employed are termed leger lines.

The same expedient is used to represent notes beyond the limits of the general system. Thus, we write the F which is one degree lower than the lowest G of the bass staff, on the space below that G; the E immediately lower, or on a leger line below the bass staff, and so on. Notes in this position are termed double; thus, the F just mentioned is double F, or FF; the E, or double E, EE, &c.

Again, the 'c' above the highest 'g' of the treble staff is placed on a leger line above that staff. The 'b' is placed on the space above the leger line: The next note 'c' is set on a second leger line, and so on. These high notes are, in compositions for some instruments, carried more than an octave above the general system. Those in the first octave are said to be in alt; those beyond it, to be in altissimo.

The tenor or C clef is employed to form different intermediate staves between the treble and bass, according to the compass of the voice or instrument for which the staff is wanted.

Compositions for the gravest masculine voices and instruments are written on the bass clef, and those for feminine voices and instruments highest in tone, on the treble staff *.

For masculine voices next in depth to the bass, and for the higher octave of the violoncello and bassoon, a staff, called the tenor staff, is formed by adding to the tenor line the three highest lines of the bass staff and the lowest line of the treble (fig. 6. 1).

For the highest masculine voices, which are called counter tenor, and for the tenor violin, a staff is formed by the tenor line, the two highest lines of the bass, and the two lowest of the treble staff (fig. 6. 2).

For the gravest female voices, which are called mezzo soprano, the tenor line and four lowest lines of the treble form a staff (fig. 6. 3).

The relation of all the staves to the general system, and to each other, will appear from fig. 6.

The bass clef on the third line, the tenor clef on the second, and the treble clef on the first, rarely occur; except in old French music.

The tenor clef, and the staves distinguished by it, are now less frequently used than the treble and bass clefs. Those who cultivate music only as an amusement find it irksome to learn so many modes of notation. The tenor staves are accordingly banished from compositions for keyed instruments. Secular compositions for voices are likewise now written in the treble and bass staves only; although in this there is some inaccuracy, as the tenor parts now written in the treble staff, must often be sung an octave below that in which they appear. The chief use of the tenor clef is in chorals and compositions for the bassoon and tenor violin; and its principal advantage, the facility of reading ancient music, which is almost exclusively written in this clef, has seldom been deemed an insufficient recompense for the labour of acquiring it.

(3 m) The disposition of sharps or flats at the clef, which is termed the signature, depends upon the mode, or tone assumed in the composition as a fundamental or key note, and will be afterwards explained.

The sharps or flats of the signature affect not only the notes placed on the same degree with themselves, as mentioned in the text, but also all the notes of the same letter, in every octave throughout the movement.

The sharps or flats of the signature determine the scale in which the movement is composed, and are therefore said to be essential; those which occur in the course of the piece on an occasional change of the scale, are termed accidental.

* Compositions for French horns are written in the treble staff, although the tone of the instrument be very grave; but this is because the horn is borrowed from, and has the same natural intervals with the Trumpet; which is an open instrument.
MUSIC.

Part II.

There are properly two kinds of measures or modes of time; the measure of two times, or common time, marked by the figure 2 at the beginning of the time (fig. 10.); and the measure of three times, or triple time, marked by the figure 3 placed in the same manner (fig. 11.).

The different measures are distinguished by perpendicular lines (3 n), called bars.

In a measure, we distinguish between the strong and the weak time; the strong time is that which is beat; the weak, that in which the hand or foot is raised. A measure consisting of four times ought to be considered as compounded of two measures, each consisting of two times: thus there are in this measure two strong and two weak times. In general by the words strong and weak even the parts of the same time are distinguished; thus, the first note of each time is considered as strong and the others as weak.

175. The longest of all notes is a semibreve. A minim is half its value; that is to say, two minims are to of notes be performed in the time occupied by one semibreve.

A minim in the same manner is equivalent to two crotchets, the crotchet to two quavers (3 o).

176. A note which is divided into two parts by a syncopa- bar, that is, which begins at the end of a measure, and terminates in the measure following, is called a syncopated note (3 r).

A note followed by a point or dot is increased half its value. Thus a dotted semibreve is equivalent to a semibreve and a minim, a dotted minim, to a minia.

Chap.

(3 n) All the notes, therefore, contained between two bars constitute one measure; although in common language the word bar is improperly used for measure.

(3 o) The notes, in their figure, consist of a head and a stem, except the semibreve, which has a head only. The place of the note in the staff is determined by the head, which must be placed on the line, or in the space, assigned to the note. The stem may be turned either up or down.

The quaver is equivalent to two semiquavers, and the semiquaver to two demisemiquavers. In modern music the demi-semiquaver is also subdivided.

The quaver and the notes of shorter duration may be grouped together, by two, three, or four, &c. and joined by as many black lines across the ends of the stem as there are hooks in the single note (fig. 12.). This arrangement is convenient in writing, and assists the eye in performance.

When quavers, or the shorter notes, are to be repeated in the same degree for a time equal to the duration of a longer note, the iterations are, by a sort of musical short-hand, represented by writing the long note only, and placing over or under it, as many short lines as the short note has hooks (fig. 13.). And the repetition of a series of short notes is represented by merely writing for each repetition as many short lines as there are hooks to the short notes of which the series is composed (fig. 14.).

A note in the middle of a measure is also said to be syncopated when it begins on a strong, and ends on a weak part of the measure, (see fig. 15.) where D, C, and B are each of them syncopated.

A note which of itself occupies one, two, or more measures, is not said to be syncopated, but continued or protracted. See fig. 16.

(3 q) Notes have sometimes in modern music a double dot after them, which makes them longer by three-fourths. Thus a minim twice dotted is equal to three crotchets and a half, or seven quavers, &c.

Our author, in this chapter, has omitted the explanation of rests, and of the particular modifications of time.

Rests are characters indicating the temporary suspension of musical sounds. There are as many different rests as there are notes. Thus the semibreve rest indicates a pause of the duration of a semibreve; the minim rest, of a minim, &c. (fig. 18.).

The semibreve rest also denotes the silence of one entire measure, in triple as well as common time. The silence of several measures is marked as in fig. 18.; but where the silence exceeds three bars, the number is usually marked over the rests.

Common time is either of a semibreve, or of a minim to the measure.

Common time of a semibreve is indicated by the letter C at the clef, fig. 1. of Plate CCCLVI. When it is meant to be somewhat quicker than usual, a perpendicular line is drawn through the C, (fig. 2.).

Common time of a minim to the measure, which is called half time, is indicated by the fraction 2 or 2, that is, two-fourths of a semibreve, or two crotchets equal to a minim, (fig. 3.).

In triple time the measure consists of three minims, three crotchets or three quavers, six crotchets or six quavers, nine quavers or twelve quavers.

Triple time of three minims is marked at the clef, that is, three halves of a semibreve, (fig. 4.)

Triple time of three crotchets is indicated by the fraction 3 or 3, (three-fourths of a semibreve) (fig. 5.) and that of three quavers by 3 (three-eighths of a semibreve), (fig. 6.)

In the last three examples the measure is divided into three times, of which the first is strong, and the two others weak.

The measure of six crotchets is marked 2, (fig. 7.) and that of six quavers 2, (fig. 8.) In both there are two times, of which the first is strong, and the second weak.

The measure of nine quavers is marked 2, (fig. 9.) and is divided into one strong and two weak times. That of twelve quavers is marked 2, (fig. 10.) and is accented as if it were two measures of six quavers.

The measures of 2 and 2 rarely occur.

Three notes are often performed in the time of two of the same name, and are then termed triplets, (fig. 11.) where
MUSIC.

CHAP. IV. Definition of the principal Chords.

178. (3d.) The chord composed of a third, a fifth, and an octave, as C, E, G, C, is called a perfect chord (art. 32.).

If the third be major, as in C, E, G, C, the perfect chord is denominated major: if the third be minor, as in A, C, E, A, the perfect chord is minor. The perfect chord major constitutes the major mode; and the perfect chord minor, the minor mode (art. 31.).

179. A chord composed of a third, a fifth, and a seventh, as G, B, D, F, or D, F, A, C, &c., is called a chord of the seventh. Such a chord is wholly composed of thirds in ascending.

All chords of the seventh are practised in harmony, save that which might carry the third minor and the seventh major, as C E G B; and that which might carry a false fifth and a seventh major, B D F A (chap. xiv. Part I.).

180. As thirds are either major or minor, and as they may be differently arranged, it is clear that there are different kinds of chords of the seventh; there is even one, B D F A, which is composed of a third, a false fifth, and a seventh.

181. A chord composed of a third, a fifth, and a sixth, as F A C D, D F A B, is called a chord of the greater sixth.

182. Every note which carries a perfect chord is called a tonic; and a perfect chord is marked by an 8, or by a 5, which is written above the note; but frequently these numbers are suppressed. Thus in the example i. the two C's equally carry a perfect chord.

183. Every note which carries a chord of the seventh is called a dominant (art. 102.); and this chord is marked by a 7 written above the note. Thus in the example xi. D carries the chord D F A C, and G the chord G B D F.

It is necessary to remark, that among the chords of the seventh we do not reckon the chord of the Principles seventh diminished, which is only improperly called a of Composition chord of the seventh; and of which we shall say more below.

184. Every note which carries the chord of the great Sub-dominant (art. 97. and 42.) and what, and how it is marked with a 6. Thus in the example iii. F carries the chord of F A C D. The sixth should always be major, (art. 97. and 109.).

185. In every chord, whether perfect, or a chord of the fundamental, or of the great sixth, the note which is the keynote, carries this chord, and which is the flattest or lowest, is called the fundamental note. Thus C in the example i. D and C in the example ii. and F in the example iii. are fundamental notes.

186. In every chord of the seventh, and of the great Dissonance sixth, the note which forms the seventh or sixth above of a chord, the fundamental, that is to say, the highest note of the chord, is called a dissonance. Thus in the chords of the seventh G B D F, D F A C, F and C are the dissonances, viz. F with relation to G in the first chord, and C with relation to D in the second. In the chord of the great sixth F A C D, D is the dissonance (art. 120.); but that D is only, properly speaking, a dissonance with relation to C from which it is a second, and not with respect to F from which it is a sixth major (art. 17. and 18.).

187. When a chord of the seventh is composed of a third major followed by two thirds minor, the fundamental note of this chord is called the tonic dominant. In every other chord of the seventh the fundamental is called the simple dominant (art. 102.). Thus in the chord G B D F, the fundamental G is the tonic dominant; but in the other chords of the seventh, as C E G B, D F A C, &c. the fundamentals C and D are simple dominants.

188. In every chord, whether perfect, or of the seventh, or of the sixth, if it is meant that the third above the fundamental note should be major though deroed minor, a sharp must be placed above the root, and

3 Y

where the groups of quavers in the second measure are triplets, and each triplet occupies the time of two quavers only. Triplets also occur in triple time, fig. 12.

Certain other characters will be with propriety explained here.

The Pause signifies that the regular time is to be delayed, and the note marked with the pause protracted. See fig. 13. where the pause is on the last note of the second measure.

The Repeat, a character resembling an S, denotes, that the following part of the movement must be repeated. See fig. 14.

The Direct (fig. 15.) is placed at the end of the staff, to show upon what degree the first note of the following staff is placed.

When the inner sides of two bars are dotted, the measures between them are to be repeated (fig. 46.). The word bis is sometimes placed over such passages.

The double bar distinguishes the end of a movement or strain, (fig. 17.). If the double bar be dotted on one or both sides, the strain is to be repeated, (fig. 18.). The double bar does not affect the time; so that when the strain terminates before the end of a measure, as is often the case, the double bar only marks the conclusion of the strain, but the time is kept exactly as if it were not inserted. See fig. 19.

The graces of exertion and expression, such as the appoggiature, the shake, the slur, the crescendo, the diminuendo, &c. are not necessary to the consideration of the theory of music or principles of composition, but belong to the performer only. See Shake, &c.

(3d.) In this part of our subject, we shall, in mentioning the harmonies of the chords, make use of the capital letters only, as the general names of the notes, without distinguishing octaves by minuscule or Italic letters. The harmonies may be arranged in different octaves. Their different positions will be most easily seen and best understood from the examples in the plates.
MUSIC

Chap. VI. Rules for the Fundamental Basis.

190. All the notes of the fundamental bass being only capable of carrying a perfect chord, or the chord of the seventh, or that of the great sixth. Moreover it is formed according to the rules which we are now about to give.

Chap. V. Of the Fundamental Bass.

189. Let a modulation be invented at pleasure; and under this modulation let there be set a bass composed of different notes, of which some may carry a perfect chord, others that of the seventh, and others that of the great sixth, in such a manner that each note of the modulation which answers to each of the bass, may be one of those which enter into the chord of that note in the bass; this bass being composed according to the rules which shall be immediately given, will be the fundamental bass of the modulation proposed. See Part I where the nature and principles of the fundamental bass are explained.

Thus (Exa. xvi.) it will be found that this modulation, C D E F G A B C, has or may admit for its fundamental bass, C G C F C D G C.

In reality, the first note C in the upper part is found in the chord of the first note C in the bass, which chord is G E G C; the second note D in the treble is found in the chord G B D G; which is the chord of the second note in the bass, &c. and the bass is composed only of notes which carry a perfect chord, or that of the seventh, or that of the great sixth. Principles of Composition.

Moreover it is formed according to the rules which we are now about to give.

Rule I.

191. In every chord of the tonic, or of the tonic dominant, it is necessary that at least one of the notes which form that chord should be found in the chord that precedes it.

Rule II.

192. In every chord of the simple dominant, it is necessary that the note which constitutes the seventh, or dissonance, should likewise be found in the preceding chord.

Rule III.

193. In every chord of the sub-dominant, at least one of its consonances must be found in the preceding chord. Thus, in the chord of the sub-dominant F A C D, it is necessary that F, A, or C, which are the consonances

(9 s) We may only add, that there is no occasion for marking these sharps or flats when they are originally placed at the cleff. For instance, if the sharp be upon F which indicates the key of G (see Exam. x.) it is sufficient to place the sharp, to mark the perfect chord major of D, D F A D. In the same manner in the Example xii. where the flat is at the cleff upon B, which denotes the key of F, it is sufficient to write G, to mark the perfect chord minor of G B D G.

But where there is a sharp or a flat at the cleff, if we would render the chord minor which is major, or vice versa, we must place above the fundamental note a ♯ or natural. Thus the Example xii. marks the minor chord D F A D, and Example xiii. the major chord G B D G.—Sometimes, in lieu of a natural, a flat is used to signify the minor chord, and a sharp to signify the major. Thus Example xiv. in the key of G, marks the minor chord D F A D, and Example xvi. in F, the major chord G B D G.

When in a chord of the great sixth, the dissonance, that is to say, the sixth, ought to be sharp, and when the sharp is not found at the cleff, we write before or after the 6 a ♯; and if this sixth should be flat according to the cleff, we write a ♭.

In the same manner, if in a chord of the seventh of the tonic dominat, the dissonance, that is to say, the seventh, ought to be flat or natural, we write by the side of the seventh a ♭ or a ♯. Many musicians, when a seventh from the simple dominat ought to be altered by a sharp or a natural, have likewise written by the side of the seventh a ♯ or ♭; but M. Rameau suppresses these characters. The reason shall be given below, when we speak of chords by supposition.

If there be one sharp at the cleff, and if we would mark the chord G B D F ♯ or the chord A C E F ♯, we ought to place before the seventh or the sixth a ♯ or a ♭.

In the same manner, if there be one flat at the cleff, and if we would mark the chord C E G B ♭, we ought to place before the seventh a ♭ or a ♯; and so of the rest.

All these intricate combinations of figuring show the superior convenience of the modern method of writing the notes themselves instead of the figures, which has the farther advantage of exhibiting the proper arrangement of the chord, see Example 11.
MUSIC.

Art II.

Consonances of the chord, should be found in the chord preceding. The dissonance D may either be found in it or not.

Rule IV.

194. Every simple or tonic dominant ought to descend by a fifth. In the first case, that is to say, when the dominant is simple, the note which follows can only be a dominant; in the second it may be any one; or, in other words, it may either be a tonic, a tonic dominant, a simple dominant, or a sub-dominant. It is necessary, however, that the conditions prescribed in the second rule should be observed, if it be a simple dominant.

This last reflection is necessary, as will presently be seen. For, let us assume the succession of the two chords A C E G, D F A C (see Exam. XVII), this succession is by no means legitimate, though in it the first dominant descends by a fifth; because the C which forms the dissonance in the second chord, and which belongs to a simple dominant, is not in the preceding chord. But the succession will be admissible, if, without meddeling with the second chord, we take away the sharp carried by the C in the first; or if, without meddaling with the first chord, we render C and F sharp in the second (3 T); or, if we simply render the D of the second chord a tonic dominant, in causing it to carry F before instead of F (119 and 122).

It is likewise by the same rule that we ought to reject the succession of the two following chords, D F A C, G B D F;

(see Exam. XVIII). Rule V.

195. Every sub-dominant ought to rise by a fifth; and the note which follows it may, at pleasure, be either a tonic, a tonic dominant, or a sub-dominant.

Remark.

Of the five fundamental rules which have now been given, instead of the three first, one may substitute the three following, which are consequences from them.

Rule I.

If a note of the fundamental bass be a tonic, and rise by a fifth or a third to another note, that second note may be either a tonic (34. & 91.), see Examples. Principles XIX. and XX. (3 T); a tonic dominant (124.), see of Composition XXI. and XXII.; or a sub-dominant (124.), see XXIII. and XXIV.; or, to express the rule more simply, that second note may be any one, except a simple dominant.

Rule II.

If a note of the fundamental bass be a tonic, and descend by a fifth or a third upon another note, this second note may be either a tonic (34. & 91.) see Exam. XXV. and XXVI.; or a tonic dominant, or a simple dominant, yet in such a manner that the rule of Art. 192. may be observed (124.), see XXVII. XXVIII. XXX. and XXX.; or a sub-dominant (124.), see XXXI. and XXXII.

The succession of the bass C E F G, F A C E, is excluded by art. 192.

Rule III.

If a note of the fundamental bass be a tonic, and rise by a second to another note, that note ought to be a tonic dominant, or a simple dominant (101. & 102.). See XXXIV. and XXXV. (3 X).

We must here advert to our readers, that the examples XXXVI. XXXVII. XXXVIII. XXXIX. belong to the fourth rule above, art. 194.; and the examples XL. XLI. XLI. to the fifth rule above, art. 195. See the articles 34., 35., 121., 123., 124.

Remark I.

196. The transition from a tonic dominant to a perfect and tonic is called an absolute repose, or a perfect cadence imperfect (72.); and the transition from a sub-dominant to a cadence, what, and tonic is called an imperfect or irregular cadence (73.) when the tonic falls upon the accented part of the bar. See played.

XLI. XLIV. XLV. XLVI.

Remark II.

197. We must avoid, as much as we can, syncopation in the fundamental bass; that the ear may acquire only a faintly distinguish the primarily accented part of a measure, by means of a harmony different from that which had been perceived in the last unaccented part of the bar by preceding measure. Nevertheless syncopation may be license, sometimes admitted in the fundamental bass, but it is by a license (3 T).

Chap.
MUSIC.

Part II.

Principles of Composition.

Chapter VII. Of the Rules which ought to be observed in the Treble with relation to the Fundamental Bass.

198. The treble is nothing else but a modulation above the fundamental bass, and whose notes are found in the chords of that bass which corresponds with it (189.). Thus in Ex. xvi. the scale C D E F G A B C, is a treble with respect to the fundamental bass C G C F C D G C.

One note in the treble or bass may answer to its correspondent parts, and why.

199. We are about to give the rules for the treble; but first it is necessary to make the two following remarks.

1. It is obvious, that many notes of the treble may answer to one and the same note in the fundamental bass, when these notes belong to the chord of the same note in the fundamental bass. For example, this modulation C E G E C, may have for its fundamental bass the note C alone, because the chord of that note comprehends the sounds C, E, G, which are found in the treble.

2. In like manner, a single note in the treble may, for the same reason, answer to several notes in the bass. For instance, G alone may answer to these three notes in the bass, C G C (32).

Rule I. For the Treble.

200. If the note which forms the seventh in a chord of the simple dominant, is found in the treble, the note principle which precedes it must be the very same. This is what we call a discord prepared (122). For instance, let us suppose that the note of the fundamental bass shall be D, bearing the chord of the simple dominant D F A C; and that this C, which (art. 158. and 118.) is the dissonance, should be found in the treble; it is necessary that the note which goes before it in the treble should likewise be C.

201. According to the rules which we have given for the fundamental bass, C will always be found in the chord of that note in the fundamental bass which precedes the simple dominant D. See XLVIII. XIX. L.

In the first example the dissonance is C, in the second G, and in the third E: and these notes are already in the preceding chord (4 A).

Rule II.

202. If a note of the fundamental bass be a tonic dominant, or a simple dominant, and if the dissonance be found in the treble, this dissonance in the same treble ought to descend diatonically. But if the note of the bass be a sub-dominant, it ought to rise diatonically. This dissonance, which rises or descends diatonically, is what we have called a dissonance saved or resolved (129, 130.). See LXI. LXII. LIV.

203. According to the rules for the fundamental bass which we have given, the note upon which the dissonance

different harmony. For instance, the tonic C, after having carried the chord C E G C, may be followed by another C which carries the chord of the seventh, provided that this chord be the chord of the tonic dominant C E G B. In the same manner, the tonic C may be followed by the same tonic C, which may be rendered a sub-dominant, by causing it to carry the chord C E G A.

A dominant, whether tonic or simple, sometimes descends or rises to another by the interval of a tritone or false fifth. For example, the dominant F carrying the chord F A C E, may be followed by another dominant B carrying the chord B D F A. This is a licence in which the musician indulges himself, that he may not be obliged to depart from the scale in which he is; for instance, from the scale of C to which F and B belong. If one should descend from F to B by the interval of a just fifth, he would then depart from that scale, because B is not part of it.

(32) There are often in the treble several notes which may, if we choose, carry no chord, and be regarded merely as notes of passage, serving only to connect between themselves the notes that do carry chords, and to form a more agreeable modulation. These notes of passage are commonly quavers. See Example XLVII. (Plate CCCLVIII), in which this modulation C D E F G, may be regarded as equivalent to this other, C E G, as D and F are no more than notes of passage. So that the bass of this modulation may be simply C G.

When the notes are of equal duration, and arranged in a diatonic order, the notes which are accented ought each of them to carry chords. Those which are unaccented, are mere notes of passage. Sometimes, however, the unaccented note may be made to carry harmony; but the duration of this note is then commonly increased by a point placed after it, which proportionately diminishes the continuance of the accented note, and makes it pass more swiftly.

When the notes do not move diatonically, they ought generally all of them to enter into the chord which is placed in the lower part correspondent with these notes.

(4 A) There is, however, one case in which the seventh of a simple dominant may be found in a modulation without being prepared. It is when, having already employed that dominant in the fundamental bass, its seventh is afterwards heard in the modulation, while the dominant is still retained. For instance, let us imagine this modulation,

\[ C \quad D \quad B \quad C \quad D, \]

and this fundamental bass,

\[ C \quad D \quad G \quad C \quad C, \]

(see example L); the D of the fundamental bass answers to the two notes D C of the treble. The dissonance C has no need of preparation, because the note D of the fundamental bass having already been employed for the D which precedes C, the dissonance C is afterwards presented, below which the chord D may be preserved, or D F A C.
MUS I C.

CHAP. VIII. Of the Continued Bass and its Rules.

204. The continued bass is a fundamental bass whose chords are inverted. We invert a chord when we change the order of the notes which compose it. For example, if, instead of the chord G B D F, we should say B D F G or D F G B, &c. the chord is inverted.

The ways in which a PERFECT CHORD may be INVERTED.

205. The perfect chord C E G C may be inverted in two different ways.

1. E G C E, which we call a chord of the sixth, composed of a third, a sixth, and an octave; and in this case the bass note E is marked with a $\text{G}$. (See LXVI.)

2. G C E G, which we call a chord of the seventh and fourth, composed of a fourth, a sixth, and an octave; and it is marked with a $\text{G}$. (See LXVII.)

The perfect minor chord is inverted in the same manner.

The ways in which the CHORD of the SEVENTH may be INVERTED.

206. In the chord of the tonic dominant, as G B D F, the third major above the fundamental note G is called a sensible note (77.) and the inverted chord B D F G composed of a third, a false fifth and a sixth, is called the chord of the false fifth, and is marked as in examples LVIII and LIX.

The chord D F G B, composed of a third, a fourth, and a sixth, is called the chord of the sensible sixth, and marked as in Example LX. (4 C). In this chord, the third is minor, and the sixth major.

The chord F G B D, composed of a second, a tritone, and a sixth, is called the chord of the tritone, and is marked as in Example LXI. (4 D). In the chord of the simple dominant D F A C, we find,

1. F A C D, a chord of the great sixth, which is composed of a third, a fifth, and a sixth, and which is figured with a $\text{G}$. See LXII. (4 E).

2. A C D F, a chord of the lesser sixth, which is figured with a 6. See LXIII. (4 F).

3. C D F A, a chord of the second, composed of a second, a fourth, and a sixth, and which is marked with a 2. See LXIV. (4 G).

The ways in which the CHORD of the SUB-DOMINANT may be Inverted.

207. The chord of the sub-dominant, as F A C D, may be inverted in three different manners; but the method of inverting it which is most in practice is the chord of the lesser sixth A C D F (LXIII.), and the chord of the seventh D F A C. See LXV.

RULES for the CONTINUED BASS.

208. The continued bass is a fundamental bass, whose chords are only inverted in order to render it more in the taste of singing, and suitable to the voice. See LXVI., in which the fundamental bass which in itself is monotonous and little suited for singing, C G C G C G C, produces, by inverting its chords, this continued bass highly proper to be sung, C B C D E F E, &c. (4 H).

The continued bass then is properly a treble with respect to the fundamental bass. Its rules immediately follow, which are properly those already given for the treble.

RULE I.

210. Every note which carries the chord of the false fifth,
FROM PRINCIPLES OF COMPOSITION.

MUSIC.

RULE II.

211. Every note carrying the chord of the tritone should descend diatonically upon the subsequent note. Thus in the same example LXVI. F, which carries the chord of the tritone figured with a 4th, descends diatonically upon E (art. 202.).

RULE III.

212. The chord of the second is commonly put in practice upon notes which are syncopated in descending, because those notes are discords which ought to be prepared and resolved (200. 302.). See the example LXVIII. where the second C, which is syncopated, and which descends afterwards upon B, carries the chord of the second (4th).

CHAP. IX. OF SOME LICENSES ASSUMED IN THE FUNDAMENTAL BASS.

§ 1. OF BROKEN AND INTERRUPTED CADENCES.

213. The broken cadence is executed by means of a sub-dominant which rises diatonically upon another, or upon some other tonic by a license. See, in the example LXVIII. G, (132. and 134.)

214. The interrupted cadence is formed by a dominant of the second, viz. C, how inter-

observe the diatonic order, because this order is the most agreeable of all. We must therefore endeavour to preserve it as much as possible. It is for this reason that the continued bass in Example LXV. is much more in the taste of singing, and more agreeable, than the fundamental bass which answers to it.

§ 41. The continued bass being a kind of treble with relation to the fundamental bass, it ought to observe the same rules with respect to that bass as the treble. Thus a note, for instance D, carrying a chord of the seventh D F A C, to which the chord of the sub-dominant F A C D corresponds in the fundamental bass, ought to rise diatonically upon E, (art. 129. No 1. and art. 202.)

§ 42. When there is a repose in the treble, the note of the continued bass ought to be the same with that of the fundamental bass, (see Example LXVIII.). In the closes which are found in the treble at D and C (measures second and fourth), the notes in the fundamental and continued bass are the same, viz. G for the first cadence, and C for the second. This rule ought above all to be observed in cadences which terminate a piece or a modulation.

It is necessary, as much as possible, to prevent coincidences of the same notes in the treble and continued bass, unless the motion of the continued bass should be contrary to that of the treble. For example, in the first note of the second measure in Example LXIX. D is found at the same time in the continued bass and in the treble; but the treble rises from C to D, and from D to E, whilst the bass descends from E to D, and from D to C.

Two octaves, or two fifths, in succession, must likewise be avoided. For instance, in the treble sounds G E, the bass must be prevented from sounding G E, C A, or D B; because in the first case there are two octaves in succession, E against E, and G against G; and because in the second case there are two fifths in succession, C against E, and A against G, or D against G, and B against E. This rule, as well as the preceding, is founded upon this principle, that the continued bass ought not to be a copy of the treble, but to form a different melody.

Every time that several notes of the continued bass answer to one note alone of the fundamental, the composer satisfies himself with figuring the first of them. Nay he does not even figure it if it be a tonic; and he draws above the others a line, continued from the note upon which the chord is formed. See Example LXXII. (Plate CCLIX.) where the fundamental bass C gives the continued bass C E G E; the two E's ought in this bass to carry the chord 6, and G the chord 7; but as these chords are comprehended in the perfect chord C E G C, which is the first of the continued bass, we place nothing above C, only we draw a line over C E G E.

In like manner, in the second measure of the same example, the notes F and D of the continued bass, arising from the note G alone of the fundamental bass which carries the chord G B D F, we think it sufficient to figure F only, and to draw a line above F and D because the same harmony is used with both.

It should be remarked, that this F ought naturally to descend to E; but this note is considered as subsisting as long as the chord subsists; and when the chord changes, we ought necessarily to find the E, as may be seen by that example.

In general, whilst the same chord subsists in passing through different notes, the chord is reckoned the same as if the first note of the chord had subsisted; in such a manner, that, if the first note of the chord is, for instance, the sensible note, we ought to find the tonic when the chord changes. See Example LXXII. where this continued bass, C B D B G C, is reckoned the same with this, C, B, C. (Example LXXII.)

If a single note of the continued bass answers to several notes of the fundamental bass, it is figured with the different chords which agree to it. For example, the note G in a continued bass may answer to this fundamental bass C G C, (see example LXXIII.) in this case we may regard the note G as divided into three parts, of which the first carries the chord 7, the second the chord 5, and the third the chord 6.

We shall repeat here, with respect to the rules of the continued bass, what we have formerly said concerning the rules of the fundamental bass in the note upon the third rule, art. 192. The rules of the continued bass have exceptions, which practice and the perusal of good authors will teach. There are likewise several other rules which might require a considerable detail, and which will be found in the Treatise of Harmony, by M. Rameau.
MUSIC.

Of the different kinds of Chords by Supposition.

216. Chords by supposition are of different kinds. For instance, the chord of the tonic dominant G B D F gives:

1. By adding the fifth C, the chord C G B D F, called a chord of the seventh redundant, and composed of a fifth, seventh, ninth, and eleventh. It is figured with a 7; (4n) see LXXVI. (4n). This chord is not practised but upon the tonic. They sometimes leave out the sensible note, for reasons which we shall give in the note (4o), upon the art. 219; it is then reduced to C F G D, and marked with $\frac{3}{4}$ or $\frac{5}{4}$.

2. By adding the third E, we shall have the chord E G B D F, called a chord of the ninth, and composed of a third, fifth, seventh, and ninth. And it is figured with a 9. This third may be added to every third of the dominant. See LXXVII.

3. If

and elsewhere. These rules, which are proper for a complete dissertation, did not appear indispensably necessary in an elementary essay on music, such as the present. The books which we have quoted at the end of our preliminary discourse will more particularly instruct the reader concerning this practical detail.

(4l) One may sometimes, but very rarely, cause several tonics in succession to follow one another in ascending or descending diatonically, as E G C, D F A D, B b D F B b; but besides that this succession is harsh, it is necessary, in order to render it practicable, that the fifth below the first tonic should be found in the chord of the tonic following, as here F, a fifth below the first tonic C, is found in the chord D F A D, and in the chord B b D F B b (37. note 7).

(4m) Though supposition be a kind of license, yet it is in some measure founded on the experiment related in the note (s), where you may see that every principal or fundamental sound causes its twelfth and seventeenth major in descending to vibrate, whilst the twelfth and the seventeenth major ascending resound: which seems to authorize us in certain cases to join with the fundamental harmony this twelfth and seventeenth in descending; or, which is the same thing, the fifth or the third beneath the fundamental sound.

Even without having recourse to this experiment, we may remark, that the note added beneath the fundamental sound, causes that very fundamental sound be heard. For instance, C added beneath G, causes G to resound. Thus G is found in some measure to be implied at C.

If the third added beneath the fundamental sound be minor, for example, if to the chord G B D F, we add the third E, the supposition is then no longer founded on the experiment, which only gives the seventeenth major, or what is the same thing, the third major beneath the fundamental sound. In this case the addition of the third minor must be considered as an extension of the rule, which in reality has no foundation in the chords emitted by a sonorous body, but is authorized by the sanction of the ear and by practical experiment.

(4n) Many musicians figure this chord with a 7: M. Rameau suppresses this 2, and merely marks it to be the seventh redundant by a 7 or 7. But it may be said, how shall we distinguish this chord from the seventh major, which, as it would seem, ought to be marked with a 7? M. Rameau answers, that there is no danger or mistake, because in the seventh major, as the seventh ought to be prepared, it is found in the preceding chord; and thus the sharp subsisting already in the preceding chord, it would be useless to repeat it.

Thus D G, according to M. Rameau, would indicate D F A C, G B D F#. If we would change F# of the second chord into Fb, it would then be necessary to write D G. In notes such as C, whose natural seventh is minor, the figure 7 preceded or followed by a sharp will sufficiently serve to distinguish the chord of the seventh redundant C G B D F, from the simple chord of the seventh C E G B, which is marked with a 7 alone. All this appears just and well founded.

(4o) Supposition introduces into a chord dissonances which were not in it before. For instance, if to the chord E G B D, we should add the note of supposition C descending by a third, it is plain that, besides the dissonance between E and D which was in the original chord, we have two new dissonances, C B, and C D; that is to say, the seventh and the ninth. These dissonances, like the others, ought to be prepared and resolved. They are prepared by being syncopated, and resolved by descending diatonically upon one of the consonances of the subsequent chord. The sensible note alone can be resolved in ascending; but it is even necessary that this sensible note should be in the chord of the tonic dominant. As to the dissonances which are found in the primitive chord, they should always follow the common rules. (See art. 202).
Musical Principles of Composition.

If to a chord of the simple dominant, as D F A C, we should add the fifth G, we would have the chord G D F A C, called a chord of the eleventh, and which is figured with \( \frac{7}{2} \) or \( \frac{5}{3} \). (See LXXVII.)

Observations when re-entrenchments of chords are proper.

217. When the dominant is not a tonic dominant, we often take away some notes from the chord. For example, let us suppose that there is in the fundamental bass this simple dominant E, carrying the chord E G B D; if there should be added the third C beneath, we shall have this chord of the continued bass E G B D; but we suppress the seventh B, for reasons which shall be explained in the note upon art. 210. In this state the chord is simply composed of a third, fifth, and ninth, and is marked with a 9. See LXXIX.

218. In the chord of the simple dominant, as D F A C, when the fifth G is added, we frequently obliterate the sounds F and A, that too great a number of dissonances may be avoided, which reduces the chord to E G B D. This last is composed only of the fourth and the fifth. It is called a chord of the fourth, and it is figured with a 4 (47) (see LXXX).

219. Sometimes we only remove the note A, and then the chord ought to be figured with \( \frac{7}{2} \) or \( \frac{7}{3} \) (48).

220. Finally, in the minor mode, for example, in that of A, where the chord of the tonic dominant (109), is E G B D; if we add to this chord the third C below, we shall have E G B D, called the chord of the fifth redundant, and composed of a third, a fifth redundant, a seventh and a ninth. It is figured as in LXXXI.

§ 3. Of the Chord of the Diminished Seventh.

221. In the minor mode, for instance, in that of A, E a fifth below A is the tonic dominant (109), and carries the chord E G B D, in which G is the sensible note. For this chord we sometimes substitute G B D F, Principle (116), all composed of minor thirds; and which has the Composition for its fundamental sound the sensible note G. This chord is called a chord of the flat or diminished seventh, and is figured with a 7 in the fundamental bass, (see LXXXIV.) but it is always considered as representing the chord of the tonic dominant.

222. This chord by inversion produces in the continuation of the bass the following chords:

1. The chord B D F G, composed of a third, false fifth, and sixth major. They call it the chord of the tonic dominant, and sixth sensible and false fifth; and it is figured as in LXXXV. (Plate CCLX.)

2. The chord D F G B, composed of a third, a tritone, and a sixth. It is called the chord of the tritone and third minor; and marked as in LXXXVI.

3. The chord F G B D, composed of a second redundant, a tritone, and a sixth. It is called the chord of the second redundant, and figured as in LXXXVII.

223. Besides, since the chord G B D F represents the chord E G B D, it follows, that if we operate by supposition upon the first of these chords, it must be performed as one would perform it upon E G B D; that is to say, that it will be necessary to add to the chord E G B D F, the notes C or A, which are the third or fifth below E, and which will produce,

1. By adding C, the chord C G B D F, composed of a fifth redundant, a seventh, a ninth, and eleventh, which is the octave of the fourth. It is called a chord of the fifth redundant and fourth, and marked as in LXXXVIII.

2. By adding A, we shall have the chord A G B D F, composed of a seventh redundant, a ninth, an eleventh, and a thirteenth minor, which is the octave of the sixth minor. It is called the chord of the seventh redundant and sixth minor, and marked as in LXXXIX. It is of all chords the most harsh, and the most rarely practised (49).

(47) Several musicians call this last chord the chord of the ninth; and that which, with M. Rameau, we have simply called a chord of the ninth, they term a chord of the ninth and seventh. This last chord they mark with a \( \frac{7}{2} \); but the denomination and figure used by M. Rameau are more simple and can lead to no error; because the chord of the ninth always includes the seventh, except in the cases of which we have already spoken.

(48) In England it is figured \( \frac{7}{2} \).

(49) We often remove some dissonances from chords of supposition, either to soften the harshness of the chord, or to remove discords which can neither be prevented nor resolved. For instance, let us suppose, that in the continued bass the note C is preceded by the sensible note B carrying the chord of the false fifth, and that we should choose to form upon this note C the chord C E G B D, we must obliterate the seventh B, because in retaining it we should destroy the effect of the sensible note B, which ought to rise to C.

In the same manner, if to the harmony of a tonic dominant G B D F, one should add the note by supposition C, it is usual to retrench from this chord the sensible note B; because, as the D ought to descend diatonically to \( \frac{7}{5} \), and the B to rise to it, the effect of the one would destroy that of the other. This above all takes place in the suspension, concerning which we shall presently treat.

(47) Supposition produces what we call suspension; and which is almost the same thing. Suspension consists in retaining as many as possible of the sounds in a preceding chord, that they may be heard in the chord which succeeds. For instance, in Example LXXXI. the C bearing \( \frac{7}{2} \) is a supposition; but in Example LXXXII. it is a suspension, because it suspends or retards the perfect chord C E G C which the ear expects after the tonic dominant G B D F.

(4T) The chord of the diminished seventh, and the three derived from it, are termed chords of substitution. They are in general harsh, and proper for imitating melancholy objects.

(4V) As the chord of the diminished seventh G B D F, and the chord of the tonic dominant E G B D, only differ...
224. Sometimes in a treble, the dissonance which ought to have been resolved by descending diatonically upon the succeeding note, instead of destending, on the contrary rises diatonically; but in that case, the note upon which it ought to have descended must be found in some of the other parts. This license ought to be rarely practised.

In like manner, in a continued bass, the dissonance in a chord of the sub-dominant inverted, as in the chord A C E G, inverted from C E G A, may sometimes descend diatonically instead of rising as it ought to do, art. 129. No. 2; but in that case the note ought to be repeated in another part, that the dissonance may be there resolved in ascending.

225. Sometimes likewise, to render a continued bass more agreeable by causing it to proceed diatonically, we place between two sounds of that bass a note which belongs to the chord of neither. See Example xcii. in which the fundamental bass G C produces the continued bass G A B G C, where A is added on account of the diatonic modulation. This A has a line drawn above it, to show its resolution by passing under the chord G E B D.

In the same manner, (see xciii.) this fundamental bass C F may produce the continued bass C D E C F.

VOL. XIV. Part II.

where the note D, which is added, passes under the chord C E G C.

CHAP. XI. Containing the Method of finding the Fundamental Bass when the continued Bass is figured.

226. As the continued bass alone appears in practical compositions, it becomes necessary to know how to find the fundamental bass when the continued bass is figured. This problem may be easily solved by the following rules.

227. 1. Every note which has no figure in the continued bass, ought to be the same, and without a figure in the fundamental bass; it is either a tonic, or reckoned such (4 x).

2. Every note which in the continued bass carries a 6, ought in the fundamental bass to give its third below not figured*, or its fifth below marked with a 7. See Fi. We shall distinguish these two cases below. See LIX.

3. Every note carrying 7 gives in the fundamental bass its fifth below not figured. See LII.

4. Every note figured with a 7, or a 9, is the same in both basses, and with the same figure (4 y).

5. Every note figured with a 2 gives in the fundamental bass the diatonic note above figured with a 7. See LXXIV. (4 z).

6. Every note marked with a 4 gives in the fundamental bass its third above figured with a 6. For example, this continued bass A B C gives this fundamental bass G C G; but in this case it is necessary that the note figured with a 6 should rise by a fifth, as we see here C rise to G.

(4 x) We say a tonic, or reckoned such, because it may perhaps be a dominant from which the dissonance has been removed. But in that case one may know that it is a real dominant by the note which precedes it. For instance, if the note G, carrying a perfect chord, is preceded by D a simple dominant, carrying the chord D F A C, that note C is not a real tonic; because, in order to this, it would have been necessary that D should have been a tonic dominant, and should have carried the chord D F A C; and that a simple dominant, as D, carrying the chord D F A C, should only naturally descend to a dominant, (art. 194).

(4 y) Sometimes a note which carries a 7 in the continued bass, gives in the fundamental bass its third above figured with a 6. For example, this continued bass A B C gives this fundamental bass G C G; but in this case it is necessary that the note figured with a 6 should rise by a fifth, as we see here C rise to G.

(4 z) A note figured with a 2, gives likewise sometimes in the fundamental bass its fourth above, figured with a 6; but it is necessary in that case that the note figured with a 6, may even here rise to a fifth. (See note (4 y).)

The variations in the fundamental bass, as well in the chord concerning which we now treat, as in the chord figured with a 7, and in two others which shall afterwards be mentioned (art. 228. and 229.), are caused by a deficiency in the signs proper for the chord of the sub-dominant, and for the different arrangements by which it is inverted.

M. l'Abbé Roussignol, to redress this deficiency, had invented a new manner of figuring the continued bass. His method is most simple for those who know the fundamental bass. It consists in expressing each chord by only signifying the fundamental sound with that letter of the scale by which it is denominated, to which is joined a 7 or 9, or a 6, in order to mark all the discords. Thus the fundamental chord of the seventh D F A C is expressed by D; and the same chord, when it is inverted from that of the sub-dominant F A C D, is characterized by F; the chord of the second C D F A, inverted from the dominant D F A C, is likewise represented by D; and the same chord C D F A, inverted from that of the sub-dominant F A C D, is signified by F; the case is the
MUSIC.

Principles of Composition.

7. Every note figured with a $f$ gives its third below figured with a $7$. (See LXXVII.)

8. Every note marked with a $g$ gives the fifth below marked with a $7$; (see LXX) and it is plain by art. 187, that in the chord of the seventh, of which we treat in these three last articles, the third ought to be major, and the seventh minor, this chord of the seventh being the chord of the tonic dominant. (See art. 102.)

9. Every note marked with a $g$ gives its third above figured with a $7$. (See LXXVII. and LXXIX.)

10. Every note marked with a $g$ gives the fifth above figured with a $7$. (See LXXVIII.)

11. Every note marked with a $9$, or with a $4$, gives the third above figured with a $9$. (See LXXXI.)

12. Every note marked with a $9$ gives a fifth above figured with a $7$, or with a $9$. (See LXXVI.) It is the same case with the notes marked $4$, $9$, or $g$; which shows a retrenchment, either in the complete chord of the eleventh, or in that of the seventh redundant.

13. Every note marked with a $g$ gives a fifth above figured with a $7$, or a $9$. (See LXXX.)

14. Every note marked with a $9$ gives the third minor below, figured with a $9$. (See LXXXV.)

15. Every note marked with a $g$ gives the tritone above figured with a $9$. (See LXXXVI.)

16. Every note marked with a $9$ gives the second redundant above, figured with a $9$. (See LXXXVII.)

17. Every note marked with a $9$ gives the fifth redundant above, figured with a $9$. (See LXXXVIII.)

18. Every note marked with a $9$ gives the seventh redundant above, figured with a $9$. (See LXXXIX.)

REMARK.

228. We have omitted two cases, which may cause some uncertainty.

The first is that where the note of the continued bass principle is figured with a $6$. We now present the reason of the difficulty.

Suppose we should have the dominant $D$ in the fundamental bass, the note which answers to it in the continued bass may be $A$ carrying the figure $6$ (see LXIV.); that is to say, the chord $A C D F$; now if we should have the subdominant $F$ in the fundamental bass, the subdominant might produce in the continued bass, the same note $A$ figured with a $6$. When therefore we find in the continued bass a note marked with a $6$, it appears at first uncertain whether we should place in the fundamental bass the fifth below marked with a $7$, or the third below marked with a $6$.

229. The second case is that in which the continued bass is figured with a $g$. For instance, if there should be found $F$ in the continued bass, we may be ignorant whether we ought to insert in the fundamental bass $F$ marked with a $6$, or $D$ figured with a $7$.

230. This difficulty may be removed by leaving for solution an instant this uncertain note in suspense, and in examining the succeeding note of the fundamental bass; for if that note be in the present case a fifth above $F$, that is to say, if it be $C$ in this case, and in this alone, we may place $F$ in the fundamental bass. It is a consequence of this rule, that in the fundamental bass every sub-dominant ought to rise by a fifth (195).

CHAP. XII. What is meant by being in a Mode or Tone.

231. In the first part of this treatise (chap. vi.) we have explained, how by the means of the note $C$, and of its two-fifths $G$ and $F$, one in ascending, which is called the tonic dominant, the other in descending, which is called a sub-dominant, the scale $C D E F A B C$ may be found: the different sounds which form this scale compose the same when the chords are differently inverted. By this means it would be impossible to mistake either with respect to the fundamental bass of a chord, or with respect to the note which forms its dissonance, or with respect to the nature and species of that discord.

(5 A) We may only add, that here, and in the preceding articles of the text, we suppose, that the continued bass is figured in the manner of M. Rameau. For it is proper to observe, that there are not, perhaps, two musicians who characterize their chords with the same figures; which produce a great inconveniency to the person who plays the accompaniments: but here we do not treat of such accommodations. We prefer the continued bases of M. Rameau to all the others, as by them the fundamental bass will be most easily discovered.

M. Rameau only marks the lesser sixth by a $6$ without a line, when this lesser sixth does not result from the chord of the tonic dominant; in such a manner that the $6$ renders it uncertain whether in the fundamental bass we ought to choose the third or the fifth below; but it will be easy to see whether the third or the fifth is signified by that figure. This may be distinguished, 1. In observing which of the two notes is excluded by the rules of the fundamental bass. 2. If the two notes may with equal propriety be placed in the fundamental bass, the preference must be determined by the tone or mode of the treble in that particular passage. In the following chapter we shall give rules for determining the mode (note 3 z).

There is a chord of which we have not spoken in this enumeration, and which is called the chord of the sixth redundant. This chord is composed of a note, of its third major, of its redundant fourth or tritone, and its redundant sixth, as $F A B D g$. It is marked with a $6$. It appears difficult to find a fundamental bass for this chord; nor is it indeed much in use amongst us. (See the note upon the art. 115.)

This chord is called in England the chord of the extreme sharp sixth. When accompanied by the third only, it is called the Italian sixth. When the fifth is substituted for the tritone, it has been called the German sixth.
Part II.

Principles of Composition.

 compose the major mode of C, because the third F above C is major. If therefore we would have a modulation in the major mode of C, no other sounds must enter into it than those which compose this scale; in such a manner that if, for instance, we should find F# in this modulation, this F# discovers to us that we are not in the mode of C, or at least that, if we have been in it, we are no longer so.

232. In the same manner, if we form this scale in ascending A B C# D E F# G# A, which is exactly similar to the scale C D E F G A B C of the major mode of C, this scale, in which the third from A to C# is major, shall be in the major mode of A; and if we incline to be in the minor mode of A, we have only to substitute for C sharp C natural; so that the major third A C# may become minor A C: we shall have then

A B C D E F# G# A,

which is (85.) the scale of the minor mode of A in ascending; and the scale of the minor mode of A in descending shall be (92.),

A G F E C D B A,

in which the G and F are no longer sharp. For it is a singularity peculiar to the minor mode, that its scale is not the same in rising as in descending (86.).

233. This is the reason why, when we wish to begin a piece in the major mode of A, we place three sharps at the clef upon F, C, and G; and on the contrary, in the minor mode of A, we place none, because the minor mode of A, in descending, has neither sharps nor flats.

234. As the scale contains twelve sounds, each distant from the other by the interval of a semitone, it is obvious that each of these sounds can produce both a major and a minor mode, which constitute 24 modes upon the whole. Of these we shall immediately give a table, which may be very useful to discover the mode in which we are.

A TABLE of the DIFFERENT MODES.

Major Modes.

| of C | G, D, E, F, G, A, B, c, |
| of G | G#, A, B, c, d, e, f# g |

If the major mode of F, of C, and of G, are not much practised.

When a piece begins upon C, there ought to be seven sharps placed at the clef: but it is more convenient only to place five flats, and to suppose the key D♭, which is almost the same thing with C. For this reason we substitute here the mode of D♭, for that of C.

It is still much more necessary to substitute the mode of A♭ for that of G; for the scale of the major mode of G is,

G, A♭, B♭, C♭, D♭, E♭, F♭, G♭,

in which it appears that there are at the same time both a 'g' and a 'g♭': it would then be necessary, even at the same time, that upon G there should and should not be a sharp at the clef; which is inconsistent. It is true that this inconvenience may be avoided by placing a sharp upon G at the clef, and by marking the note G with a natural through the course of the music wherever it ought to be natural; but this would become troublesome, above all if there should be occasion to transpose. In the article 236. we shall give an account of transposition. We might likewise in this series, instead of G natural, which is the note immediately before the last, substitute F♮, that is to say, F twice sharp; which, however, is not absolutely the same sound with G natural, especially upon instruments whose scales are fixed, or whose intervals are invariable. But in that case two sharps must be placed at the clef upon F, which would produce another inconvenience. But by substituting A♭ for G, the trouble is elided.

The double sharp, however, is incidentally used, when in a composition in the key of F♮ there is an occasional modulation into the dominant of that key, and it is distinguished by the character X or ♯.
MUS I C.

236. Hence it follows,

1. That when there are neither sharps nor flats at all, the piece begins in the major mode of C, or in the minor mode of A.

2. That when there is one sharp, it will always be placed upon F, and that the piece begins in the major mode of G, or in the minor mode of E. In such a manner that it may be sung as if there were no sharp, by singing B instead of F#, and in singing the tone as if it had been in another clef. For instance, let there be a sharp upon F in the clef of G upon the first line; one may then sing the tone as if there were no sharp; and as if, instead of the clef of G upon the first line, it were the clef of C; for the F#, when changed into B, will require that the clef of G should be changed to the clef of C, as may be easily seen. This is what we call transposition (§ 5).

237. It is evident, that when F# is changed into B, the note a semitone above it.

(§ 5.) We have already seen, that in each mode, the principal note is called a tonic; that the fifth above that note is called a tonic dominant; or the dominant of the mode, or simply a dominant; that the fifth below the tonic, or, what is the same thing, the fourth above that tonic, is called a sub-dominant; and in short, that the note which forms a semitone below the tonic, and which is a third major from the dominant, is called a sensible note. The other notes have likewise in every mode particular names which it is advantageous to know. Thus a note which is a tone immediately above the tonic, as D in the mode of C, and B in that of A, is termed a super-tonic; the following note, which is a third major or minor from the tonic, according as the chord is major or minor, such as E in the major mode of C, and G in the minor mode of A, is called a mediant; and the note which is a tone above the dominant, such as A in the mode of C, and F# in that of A, is called a super-dominant.

(§ 5.) Though our author's account of this delicate operation in music will be found extremely just and copious; though it proceeds upon simple principles, and comprehends every possible contingency; yet as the manner of thinking upon which it depends may be less familiar to English readers, if not profoundly skilled in music, it has been thought proper to give a more familiar, though less comprehensive, explanation of the mass in which transposition may be executed.

It will easily occur to every reader, that if each of the intervals through the whole diatonic series were equal, in a mathematical sense, it would be absolutely indifferent upon what note any air were begun, if within the compass of the gamut; because the same equal intervals must always have the same effects. But since, besides the natural semitones, there is another distinction of diatonic intervals into greater and lesser tones; and since there vary their positions in the series of an octave, according as the note from whence you begin is placed, that note is consequently the best key for any tone whose natural series is most exactly correspondent with the intervals which that melody or harmony requires. But in instruments whose scales are fixed, notwithstanding the temperament and other expedients of the same kind, such a series is far from being easily found, and is indeed in common practice almost totally neglected. All that can frequently be done is, to take care that the ear may not be sensibly shocked. This, however, would be the case, if, in transposing any tune, the situation of the semitones, whether natural or artificial, were not exactly correspondent in the series to which your air must be transposed, with their positions in the scale from which you transpose it. Suppose, for instance, your air should begin upon C, requiring the natural diatonic series through the whole gamut, in which the distance between E and C, as also between B and C, is only a semitone. Again, suppose it necessary for your voice, or the instrument on which you play, that the same air should be transposed to G, a fifth above its former key; then because in the first series the intervals between the third and the fourth, seventh and eighth notes, are no more than semitones, the same intervals must take the same place in the octave to which you transpose. Now, from G, the note with which you propose to begin, the three tones immediately succeeding are full; but the fourth C is only a semitone; it may therefore be kept in its place. But from F, the seventh note above, to G, the eighth, the interval is a full tone, which must consequently be increased by raising the F a semitone higher. Thus the situations of the semitonic intervals in both octaves will be correspondent; and thus, by conforming the positions of the semitones in the octave to which you transpose, with those in the octave in which the original key of the tune is contained, you will perform your operation with as much success as the nature of fixed scales can admit.

The order to be observed, in these alterations of the intervals, is deduced from the relation which the fifth ascending and descending bear to the fundamental (art. 34, 35); and therefore the farther we depart from the natural fundamental C by a series of fifths ascending or descending, the alterations, and consequently the number of sharps or flats indicating them, will be the greater.

Thus if G, which is the perfect fifth ascending from C, is followed by the note most nearly allied to C (art. 39, 40),
MUSIC.

CHAP. XIII. To find the Fundamental Bass of a given Modulation.

238. As we have reduced to a very small number the rules of the fundamental bass, we shall have no difficulty in finding a bass, a given air not difficult, and why.

239. The perfect fifth above A is F$, and in that scale A, G, C, D, and E, must be sharp (7). And in the next scale C$ all the notes of the system are sharp (8).

The perfect fifth above B is F$, and in that scale F, C, G, D, A, and E, must be sharp (7). And in the next scale C$ all the notes of the system are sharp (8).

Returning to the natural scale of C, if instead of assuming G, the perfect fifth above, for a fundamental, we take F, the perfect fifth below F, which is the fourth note above F, and forms a tritone or sharp fourth to it, must, to become a perfect fourth, according to the laws of the diatonic scale (art. 60.) be made flat (12).

Proceeding with the series of fifths descending, if B$lat$, which is the perfect fifth below F, be taken for a fundamental; E, which, in its natural state, is the tritone or sharp fourth to B$lat$, must, to become the diatonic fourth (art. 60.) also be rendered flat (11).

If B$lat$, which is the perfect fifth below B$lat$, and the third in the series of fifths descending from C, be made the fundamental, A, the sharp fourth, must, to become the diatonic fourth, be made flat, and the flats marked at the clef are B, E, and A (10).

To form the next scale in the series of fifths descending, which is that of A flat, D must be flattened; and B; E, A, and D, are marked flat at the clef (9).

The next scale, that of D flat, is formed by flattening G, and adding its flat to the others at the clef (8). This is the scale recommended to be used rather than that of C$. (See note 5 b.)

We do not proceed farther with the series of fifths descending, since the next scale, that of G$lat$, would just or very nearly exhibit the sounds already represented by the scale of F$. (7.) This scale is, however, sometimes written in the key of C flat, and we even meet with the scale of its fifth below, C flat, and, with an occasional modulation from that into its fifth below, F flat, where B being necessarily twice flattened, is distinguished by this character B$lat$ or B$lat$, called a double flat.

We have thus seen, 1st, That each of the notes of the diatonic scale of G, and each of the semitones into which the whole tones of that scale are divided, may be taken for the fundamental note of a diatonic scale, called the scale of that note. 2nd, That the notes of the natural scale are more or less altered, as the note assumed for a fundamental is more or less distant from C, in a progression of fifths ascending or descending. 3rd, That in the progression by fifths ascending, the notes are altered by sharps, and in the progression by fifths descending, the alterations are by flats. 4th, That in the alteration by sharps, the last sharp is always on the seventh or sensible note of the scale; and where there are more than one, is always on the fifth above the sharp immediately preceding; and in the alteration by flats, the last flat is always on the fourth of the scale; and where there are more than one, is always on the fifth below the flat immediately preceding.

The signatures of sharps and flats at the clefs, belonging to the twelve major scales, are also used for their relative minor scales. The occasional elevation and depression of the sixths and sevenths of the minor scales, are denoted by occasional sharps and flats placed before these notes.

(5) Many musicians, and amongst others the ancient musicians of France, as Lulli, Campra, &c. place one flat less in the minor mode; so that in the minor mode of D, they place neither sharp nor flat at the clef; in the minor mode of G, one flat only; in the minor mode of C, two flats, &c.

This practice in itself is sufficiently indifferent, and scarcely merits the trouble of a dispute: Yet the method which we have here described, according to M. Rameau, has the advantage of reducing all the modes to two; and besides it is founded upon this simple and very general rule, That in the major mode, we must place as many sharps or flats at the clef, as are contained in the diatonic scale of that mode in ascending; and in the minor mode, as many as are contained in that same scale in descending.

Principles of Composition.

Difficulty of assigning general rules for ascertaining the mode of a melody whose fundamental base is sought.

Reasons why we may proceed without the knowledge of the mode, and how we may be preserved from deviating in composition.

Knowledge of the mode in beginning a piece indispensable, and why.

Investigation of the mode continued.

Musick.

Part II.

It is of the greatest utility in searching for the fundamental bass to know what is the tone or mode of the melody to which that bass should correspond. But it is difficult in this matter to assign general rules, and such as are absolutely without exception, in which nothing may be left that appears indifferent or discretionary; because sometimes we seem to have the free choice of referring a particular melody either to one mode or another. For example, this melody C G C D G may belong to all the modes, as well major as minor, in which G and C are found together; and each of these two sounds may even be considered as belonging to a different mode.

We may sometimes, as it should seem, operate without the knowledge of the mode, for two reasons:—

1. Because, since the same sounds belong to several different modes, the mode is sometimes considerably undetermined; above all, in the middle of a piece, and during the time of one or two bars. Without giving ourselves much trouble about the mode, it is often sufficient to preserve us from deviating in composition, if we observe in the simplest manner the rules above prescribed (chap. vi.) for the procedure of the fundamental bass.

2. In the mean time, it is above all things necessary to know in what mode we operate at the beginning of the piece, because it is indispensably that the fundamental bass should begin in the same mode, and that the treble and bass should likewise end in it; nay, that they should even terminate in its fundamental note, which in the mode of C is C, and in that of A, &c. Besides, in those passages of the modulation where there is a cadence, it is generally necessary that the mode of the fundamental bass should be the same with that of the part to which it corresponds.

To know upon what mode or in what key a piece commences, our inquiry may be entirely reduced to distinguishing the major mode of C from the minor of A. For we have already seen (art. 236. and 237.), that all the modes may be reduced to these two, at least in the beginning of the piece. We shall now therefore give a detail of the different means by which these two modes of composition may be distinguished.

1. From the principal and characteristic sound of the mode, which are C E G in the one, and D E G in the other; so that if a piece should, for instance, begin on C, G, E, A, it may be almost consequently concluded, that the tone or mode is in A minor, although the notes A C E belong to the mode of C.

2. From the sensible note, which is B in the one, and G in the other; so that if B appears in the first bars of a piece, we may be certain that we are in the mode A.

3. From the adjuncts of the mode, that is to say, the modes of its two-fifths, which for C are F and G, and D and E for A. For example, if after having begun a melody by some of the notes which are common to the modes of C and of A (as E D E F E D C B), we should afterwards find the mode of C, which we ascertain by the F G, or that of F which we ascertain by the B G or C B, we may conclude that we have begun in the mode of C; but if we find the mode of D, or that of E, which we ascertain by the B G or C B, or D G, &c., we conclude from thence that we have begun in the mode of A.

4. A mode is not usually changed, especially in the beginning of a piece, unless in order to pass into one or other of the modes most relative to it, which are the mode of its fifth below, and that of its third above, if the original mode be major, or its third below if it be minor. Thus, for instance, the modes which are most intimately relative to the major mode of C, are the major mode of G, and that of A minor. From the mode of C we commonly pass either into the one or the other of these modes; so that we may sometimes judge of the principal mode in which we are, by the relative mode which follows it, or which goes before it, when these relative modes are decisively marked. Besides these two relative modes, there are likewise two others into which the principal mode may pass, but less frequently, viz. the mode of its fifth below, and that of its third above, as F and E for the mode of C (5 c). The modes may still be likewise distinguished by the cadences of the melody. These cadences ought to occur at the end of every two, or at most of every four bars, as in the fundamental bass: now the note of the fundamental bass, which is most suitable to these.

(5 7) We often say, that we are upon a particular key or scale, instead of saying that we are in a particular mode. The following expressions therefore are synonymous; such a piece is in C major, or in the mode of C major, or in the key of C major, or in the scale of C major.

(5 c) It is certain that the minor mode of E has an extremely natural connection with the mode of C, as has been proven (art. 92.) both by arguments and by examples. It has likewise appeared in the note upon the art. 92. that the minor mode of D may be joined to the major mode of C: and thus in a particular sense, this mode may be considered as relative to the mode of C, but it is still less so than the major modes of G and F, or than those of A and E minor; because we cannot immediately, and without licence, pass in a fundamental bass from the perfect minor chord of C to the perfect minor-chord of D; and if you pass immediately from the major mode of C to the minor mode of D, in a fundamental bass, it is by passing, for instance, from the tonic C, or from E G C, to the tonic dominant of D, carrying the chord A C E G, in which there are two sounds, E G, which are found in the preceding chord, (Ex. xcvi.) or otherwise from C E G C to G B D E, a chord of the sub-dominant in the minor mode of D, which chord has likewise two sounds, G and E, in common with that which went immediately before it. See Ex. xcvi.
art II.

**M U S I C.**

551

Principles of Composition.

When the mode is ascertained, by the different signs which we have pointed out, the fundamental bass will cost little pain. For in each mode there are three fundamental sounds.

1. The tonic of the mode, or its principal sound, which carries always the perfect chord major or minor, according as the mode itself is major or minor. Major mode of C, C E G 'c'. Minor mode of A, A C E A.

2. The tonic dominant, which is a fifth above the tonic, and which, whether in the major or minor mode, always carries a chord of the seventh, composed of a third major followed by two thirds minor.

**Tonic dominant.**

Major mode of C, G B D 'f'.

Minor mode of A, E G B 'd'.

3. The sub-dominant, which is a fifth below the tonic, and which carries a chord composed of a third, fifth, and sixth major, the third being either greater or lesser, according as the mode is major or minor.

**Sub-dominant.**

Major mode of C, F A C 'd'.

Minor mode of A, D F A B.

These three sounds, the tonic, the tonic dominant, and the sub-dominant, contain in their chords all the notes which enter into the scale of the mode; so that when a melody is given, it may almost always be found which of these three sounds should be placed in the fundamental bass, under any particular note of the upper part. Yet it sometimes happens that not one of these notes can be used. For example, let it be supposed that we are in the mode of C, and that we had in the melody these two notes A B in succession; if we confine ourselves to place in the fundamental bass one of the three sounds C G F, we shall find nothing for the sounds A and B but this fundamental bass F G; now such a succession as F to G is prohibited by the fifth rule for the fundamental bass, according to which every sub-dominant, as F, shall rise by a fifth; so that F can only be followed by C in the fundamental bass, and not by G.

To remedy this, the chord of the sub-dominant E A C 'd' must be inverted into a fundamental chord of the seventh, in this manner, D F A 'c', which has been called the double employment (art. 105.) because it is a secondary manner of employing the chord of the sub-dominant. By these means we give to the modulation A B this fundamental bass D G; which procedure is agreeable to rules. See Ex. xcvi.

Here then are four chords, C E G 'c', G B D 'f', F A C 'd', D F A 'c', which may be employed in the major mode of C. We shall find in like manner, for the minor mode of A, four chords.

A C 'c a', E G B 'd', D F A B, B D 'f a'.

And in this mode we sometimes change the last of these chords into B D 'f a', substituting the 'f a' for 'f b'. For instance, if we have this melody in the minor mode of A, E F G A, we would cause the first note E to carry the perfect chord A C E A; the second note F to carry the chord of the seventh B D F A; the third note G, the chord of the tonic dominant E G B D, and the last the perfect chord A C E A. See Ex. xcvi.

On the contrary, if this melody is given always in the minor mode, A A G A, the second A being syncopated, it might have the same bass as the modulation E F G A, with this difference alone, that F might be substituted for F in the chord B D F A, to better mark out the minor mode. See Exam. xcix.

Besides these chords which we have just mentioned, and which may be regarded as the principal chords of the mode, there are still a great many others; for example, the series of dominants,

C A D G C F B E A D G C,

which are terminated equally in the tonic of C, either entirely belong, or at least may be reckoned as belonging (51) to the mode of C; because none of these dominants are tonic dominants, except G, which is the tonic dominant of the mode of C; and besides, because the chord of each of these dominants forms no other

---

(51) All these different manners of distinguishing the modes ought, if we may speak so, to give mutual light and assistance one to the other. But it often happens, that one of these signs alone is not sufficient to determine the mode, and may even lead to error. For example, if a piece of music begins with these three notes, E C G, we must not with too much precipitacy conclude from thence that we are in the major mode of C, although these three sounds, E C G, be the principal and characteristic sounds in the major mode of C: we may be in the minor mode of E, especially if the note E should be long.

(52) I have said, that they may be reckoned as belonging to this mode, for two reasons: 1. Because, properly speaking, there are only three chords which essentially and primitively belong to the mode of C, viz. C carrying the perfect chord, F carrying that of the sub-dominant, and G that of the tonic dominant, to which we may join the chord of the seventh, D F A C (art. 105.) but we here regard as extended the series of dominants in question, as belonging to the mode of C, because it preserves in the ear the impression of that mode. 2. In a series of dominants, there are a great many of them which likewise belong to other modes; for instance, the simple dominant A belongs naturally to the mode of G, the simple dominant B to that of A, &c. Thus it is only improperly, and by way of extension, as I have already said, that we regard here these dominants as belonging to the mode of C.
MUSIC.

2. When we find a sub-dominant, we are in the principle of the fifth above that sub-dominant; and the mode is major or minor, according as the third is the tonic of the sub-dominant is major or minor.

3. When we find a tonic dominant, we are in the mode of the fifth below that tonic dominant. As the tonic dominant carries always the third major, it cannot be ascertained from this dominant alone, whether the mode be major or minor; but it is only necessary to examine the following note, which must be the tonic of the mode in which it is; by the third of this tonic it will be discovered whether the mode be major or minor.

243. Every change of the mode supposes a cadence; and when the mode changes in the fundamental bass, it is almost always either after the tonic of the mode in which we have been, or after the tonic dominant of that mode, considered then as a tonic by favour of a close which ought necessarily to be found in that place: Whence it happens that cadences in a melody for the most part present a change of mode which ought to follow them.

244. All these rules, joined with the table of modes which we have given (art. 234.), will serve to discover in what mode we are in the middle of a piece, especially in the most essential passages, as cadences (§ 5).

CHAP. XIV. Of the Chromatic and Enharmonic.

245. We call that melody chromatic which is composed of several notes in succession, whether rising or descending by semitones. See cv. and cvi.

246. When an air is chromatic in descending, the most natural and ordinary fundamental bass is a connected series of tonic dominants; all of which follow one another in descending by a fifth, or, which comes to the same thing, in rising by a fourth. See Ex. cvi, fundamental bass.

(§ 5.) Two modes are so much more intimately relative, as they contain a greater number of sounds common to both; for example, the minor mode of C and the major of G, or the major mode of C and the minor of A: the contrary, two modes are less intimately relative as the number of sounds which they contain as common to both is smaller; for instance, the major mode of C and the minor of B, &c.

When the composer, led away by the current of the modulation, that is to say, by the manner in which the fundamental bass is constituted, into a mode remote from that in which the piece was begun, he ought to continue in it but for a short time, because the ear is always impatient to return to the former mode.

(§ 1.) We may likewise give to a chromatic melody in descending, a fundamental bass, into which may enter chords of the seventh and of the diminished seventh, which may succeed one another by the intervals of a false fifth and a fifth redundant: thus in the Example cvii., the continuos bass descends chromatically, it may easily be seen that the fundamental bass carries successively the chords of the seventh and of the seventh diminished, and that in this bass there is a false fifth from D to G, and a fifth redundant from G to C.

The reason of this licence is, as it appears to us, because the chord of the diminished seventh may be considered as representing (art. 231.) the chord of the tonic dominant; in such a manner that this fundamental bass

\[
\begin{align*}
A & \rightarrow D \rightarrow G \rightarrow C \rightarrow F \rightarrow B \rightarrow E \rightarrow A
\end{align*}
\]

(see Example cviii.) may be considered as representing (art. 116.) that which is written below,

\[
\begin{align*}
A \rightarrow D \rightarrow E \rightarrow C \rightarrow F \rightarrow B \rightarrow E \rightarrow A
\end{align*}
\]

Now this last fundamental bass is formed according to the common rules, unless that there is a broken cadence from D to E, and an interrupted cadence from E to C, which are licences (art. 213. and 214.)

CHAP. XV. Of Design, Imitation, and Fugue.

249. In music, the name of design, or subject, is generally given to a particular air or melody, which the composer intends should prevail through the piece; whether it is intended to express the meaning of words to which it may be set, or merely inspired by the impulse of taste and fancy. In this last case, design is distinguished into imitation and fugue.

250. Imitation consists in causing to be repeated the melody of one or several measures in one single part, or in the whole harmony, and in any of the various modes that may be chosen. When all the parts absolutely repeat the same air* or melody, and beginning one after the other, this is called a canon (5 M).

Fugue consists in alternately repeating that air in treble, and in the bass, or even in all the parts, if there are more than two.

VOL. XIV. Part II.

(5 M) Compositions in strict canon, where one part begins with a certain subject, and the other parts are bound to repeat the very same subject, or the reply, as it is called, in the unison, fifth, fourth, or octave, depend on the following rules, which are nothing more than a summary of the system explained by our author.

1. The chords to be employed are the tonic, and its two adjuncts; the subdominant, susceptible of an added sixth, and the dominant, susceptible of an added seventh.

2. The subject must begin in the harmony of the tonic, and as the fundamental progression from the dominant to the subdominant is not permitted (art. 33, 36.), the subdominant must follow the tonic, and the dominant the subdominant, thus,

\[ C, F, G, C, F, G, C, \ldots \]

3. As the diatonic scale consists of two tetrachords, of which the first is also the second tetrachord of the mode of the sub-dominant, and the second the first tetrachord of the dominant; so, in canon, when the reply is meant to be in the mode of the dominant, the subject must be in the first tetrachord of the tonic, by which means the corresponding first tetrachord of the dominant being the second tetrachord of the tonic, the whole piece is truly in that mode. On the other hand, if the reply is to be in the mode of the sub-dominant, the subject must be in the second tetrachord of the tonic, the corresponding tetrachord of the sub-dominant being the first tetrachord of the tonic, and the mode of the tonic being thus preserved.

4. For the same reason, where the reply is in the dominant, the subject is only allowed to modulate into the mode of the sub-dominant, and the reply of course into that of the tonic. And where the reply is in the dominant, the subject is to modulate only into the mode of the sub-dominant, the reply following of course into that of the tonic. Were the contrary modulation permitted, the reply would depart too far from the mode of the tonic.

Lastly, When the reply is to be in the mode of the dominant, it must commence in the measure bearing that harmony; and in the same way, the reply in the sub-dominant must begin in the measure which bears the harmony of the sub-dominant.

If these rules be observed, and due attention paid to the preparation and resolution of dissonances, composition in strict canon, in any number of parts, will be found to be by no means difficult. See Ex. cix. and cx.

(5 N) Yet there may be two fifths in succession, provided the parts move in contrary directions, or, in other words, if the progress of one part be ascending, and the other descending; but in this case they are not properly two fifths, they are a fifth and a twelfth: for example, if one of the parts in descending should sound F, D, and the other 'c' a' in rising, C is the fifth of F, and 'a' the twelfth of D.
search only of general information, and not a professed student of this particular science, would choose to rest satisfied.

The theory of musical sound, which only in the beginning of the present century was ultimately established by mathematical demonstration, is no other than that which distinguished the ancient musical sect who followed the opinions of Pythagoras on that subject.

No part of natural philosophy has been more fruitful of hypothesis than that of which musical sound is the object. The musical speculators of Greece arranged themselves into a great number of sects, the chief of whom were the Pythagoreans and the Aristoxenians.

Pythagoras supposed the air to be the vehicle of sound; and the agitation of that element, occasioned by a similar agitation in the parts of the sounding body, to be the cause of it. The vibrations of a string or any other sonorous body, being communicated to the air, affected the auditory nerves with the sensation of sound; and this sound, he argued, was acute or grave in proportion as the vibrations were quick or slow. He discovered by experiment, that of two strings equal in everything but length, the shorter made the quicker vibrations, and emitted the acuter sound: in other words, that the number of vibrations made in the same time by two strings of different lengths, was inversely as those lengths; that is, the greater the length the smaller the number of vibrations in any given time. Thus sound, considered in the vibrations that cause it, and the dimensions of the vibrating body, came to be reduced to quantity, and as such was the subject of calculation, and expressible by numbers. For instance, the two sounds that form an octave could be expressed by the numbers 1 and 2, which would represent either the number of vibrations in a given time, or the length of the strings; and would mean that the acuter sound vibrates twice, while the graver vibrates once; or that the string producing the lower sound is twice the length of that which gives the higher. If the vibrations were considered, the higher sound was &frac12; the lower as &frac1; and the reverse, if the length was alluded to. In the same manner, in the same sense, the 5th would be expressed by the ratio of 2 to 3, and the 4th by that of 3 to 4.

Aristoxenian, in opposition to the calculations of Pythagoras, held the ear to be the sole standard of musical proportions. That sense he accounted sufficiently accurate for musical, though not for mathematical purposes; and it was in his opinion absurd to aim at an artificial accuracy in gratifying the ear beyond its own power of distinction. He, therefore, rejected the velocities, vibrations, and proportions of Pythagoras, as foreign to the subject, in so far as they substituted abstract causes in the room of experience, and made music the object of intellect rather than of sensus.

Of late, however, as has been already mentioned, the opinions of Pythagoras have been confirmed by absolute demonstration; and the following propositions, in relation to musical sound, have passed from conjecture to certainty.

Sound is generated by the vibrations of elastic bodies, which communicate the like vibrations to the air, and these again the like to our organs of hearing. This is evident, because sounding bodies communicate tremors to other bodies at a distance from them. The vibrating motion, for instance, of a musical string, excites motion in others, whose tension and quantity of matter dispose their vibrations to keep time with the undulations of air propagated from it (the string first set in motion).

If the vibrations be isochronous, and the sound musical, continuing at the same pitch, it is said to be acuter, sharper, or higher, than any other sound whose vibrations are slower; and graver, flatter, or lower, than any other whose vibrations are quicker. For while a musical string vibrates, its vibrations become quicker by increasing its tension or diminishing its length; its sound at the same time will be more acute: and, on the contrary, by diminishing its tension or increasing its length, the vibrations will become slower and the sound graver. The like alteration of the pitch of the sound will follow, by applying, by means of a weight, an equal degree of tension to a thicker or heavier and to a smaller or lighter string, both of the same length, as in the smaller string the mass of matter to be moved by the same force is less.

If several strings, however, different in length, density, and tension, vibrate altogether in equal times, their sounds will have all one and the same pitch, however they may differ in loudness or other qualities. They are called unisons. The vibrations of unisons are isochronous.

The vibrations of a musical string, whether wider or narrower, are nearly isochronous. Otherwise, while the vibrations decrease in breadth till they cease, the pitch of the sound could not continue the same (which we perceive by experience it does), unless where the first vibrations are made very violently; in which case, the sound is a little acuter at the beginning than afterwards.

Lastly, the word vibration is understood to mean the time which passes between the departure of the vibrating body from any assigned place and its return to the same.

MUSIMON, in Natural History, the name of an animal esteemed a species of sheep, described by the ancients as common in Corsica, Sardinia, Barbary, and the north-east parts of Asia. It has been doubted whether the animal described under this name is now any where to be found in the world; and whether it was not probably a spurious breed between two animals of different species, perhaps the sheep and goat, which, like the mule, not being able to propagate its species, the production of them may have been discon- tinued.

Buffon supposes it to be the sheep in a wild state; and it is described as such by Mr. Pennant. These animals live in the mountains, and run with great swiftness among the rocks. Those of Kamtschatka are so strong, that 10 men can scarce hold one; and the horns are so large as sometimes to weigh 30 pounds, and
MUS

[555]

MUT

MUST, Mustum, sweet wine newly pressed from Musulman grape; or the new liquor pressed from the fruit before it is fermented. See WINE.

MUSTARD. See Sinapi, Botany Index.

MUSTARD SEED. For an account of its medical qualities, see Materia Medica Index.

MUSTELA, the Otter and Weasel; a genus of quadrupeds of the order of Fiss. See Mammalia Index.

MUSTER, in a military sense, a review of troops under arms, to see if they are complete and in good order; to take an account of their numbers, the condition they are in, viewing their arms and accoutrements, &c.

MUSTER-MASTER-GENERAL, or Commissary-General of the Musters; one who takes account of every regiment, their number, horses, arms, &c. reviews them, sees the horses be well mounted, and all the men well armed and accounted, &c.

MUSTER-ROLLS, lists of soldiers in each company, troop, or regiment, by which they are paid, and the strength of the army is known.

MUTABILITY is opposed to immutability. See Immutability.

MUTATION, the act of changing, or sometimes the change itself.

MUTATION, in the ancient music, is applied to the changes or alterations that happen in the order of the sounds which compose the melody.

MUTATIONES, among the Romans, post stages or places where the public couriers were supplied with fresh horses. The mutationes were wholly designed for the use of these couriers, or messengers of state; in which respect they differ from mansiones.

MUTCHKIN, a liquid measure used in Scotland; it contains four gills, and is the fourth part of a Scotch pint.

MUTE, in a general sense, signifies a person that cannot speak, or has not the use of speech.

Mute, in Law, a person that stands dumb or speechless when he ought to answer, or to plead. See Arraignment.

MUTES, in Grammar, a letter which yields no sound without the addition of a vowel. The simple consonants are distinguished into mutes and liquids, or semivowels. See the articles Consonant, Liquid, &c.

The mutes in the Greek alphabet are nine, three of which, viz. ι, ι, ι, are termed tenues; three α, ι, ι, termed medias; and three φ, χ, θ, termed aspirates. See the article Aspirate, &c.

The mutes of the Latin alphabet are also nine, viz. B, P, D, C, T, G, I, K, P, Q, T.

MUTILATION, the retrenching or cutting away any member of the body.

This word is also extended to statues and buildings, where any part is wanting, or the projection of any member, as a cornice or an impost, is broken off. It is sometimes also used in a more immediate manner for castration: (See Castration and Eunuch). The practice of this sort of mutilation is of various kinds: the Hottentots are said to cut away one testicle from their children upon supposition that they are thereby made lighter and more active for running. In other countries, poor people completely mutilate their boys,
MUT [556] MUT

Mutilation to prevent the misery and want which would attend their offspring. Those who have nothing in view but the improvement of a vain nature, or the formation of a voice which dishonours nature, as was the case formerly in Italy, are contented with cutting away the testicles. But in some countries of Asia, especially among the Turks, and in a part of Africa, those whom jealousy inspires with distrust would not think their wives safe in the custody of such eunuchs: They employ no slaves in their scragglies who have not been deprived of all the external parts of generation.

Amputation is not the only means of accomplishing this end. Formerly, the growth of the testicles was prevented, and their organization destroyed by simple rubbing, while the child was put into a warm bath made of a decoction of plants. Some pretend that by this species of castration the life is in no danger. Amputation of the testicles is not attended with much danger; but complete amputation of the external parts of generation is often fatal. This operation can only be performed on children from seven to ten years of age. Eunuchs of this kind, owing to the danger attending the operation, cost in Turkey five or six times more than others. Chardin relates, that this operation is so painful and dangerous after 15 years of age, that hardly a fourth part of those by whom it is undergone escape with life. Pietro della Valle, on the contrary, informs us, that in Persia those who suffer this cruel and dangerous operation as a punishment for rapes and other crimes of this kind, are easily cured though far advanced in life; and that nothing but ashes is applied to the wound.

There are eunuchs at Constantinople, throughout all Turkey, and in Persia, of a gray complexion: they come for the most part from the kingdom of Golconda, the peninsula on this side the Ganges, the kingdom of Assam, Aracan, Pegu, and Malabar. Those from the gulf of Bengal are of of olive colour. There are some white eunuchs who come from Georgia and Circassia, but their number is small. The black eunuchs come from Africa, and especially from Ethiopia. These, in proportion to their horrible appearance, are the more esteemed and cost dearer. It appears that a very considerable trade is carried on in this species of men; for Tavernier informs us, that when he was in the kingdom of Golconda, in the year 1657, 22,000 eunuchs were made it. In that country they are sold at the fairs.

The object of improving the voice by means of this species of mutilation, it is said, often fails; for of 2000 victims to the luxury and extravagant caprices of the art, hardly three are found who unite good talents with good organs. The other languishing and inactive wrecks are, in some measure, outcasts from both sexes, and paralytic members in the community. But let us pay the tribute which is due to that virtuous pontiff Pope Clement VIII. who, listening to the voice of modesty and humanity, proscribed and abolished this detestable and infamous practice. Mutilation, he declared was the most abominable and disgraceful of crimes.

MUTILLIA, a genus of insects belonging to the order of hymenoptera. See ENTOMOLOGY INDEX.

MUTINA, in Ancient Geography, a noble city of the Cispadana, made a Roman colony in the same year with Parma, situated between the rivers Cabellus and Scultena, on the Via Aemilia. Here D. Brutus being besieged by Antony, was relieved by the consul Hirtius and Pansa. The Greeks called it Mutine; except Pelybun, in whom it is Motine; and in Ptolomy Mutina, after the Roman manner. Now Modena, a city of Lombardy, and capital of a cognominial doxy. E. Long. 11. 20. N. Lat. 44 45.

MUTINY, in a military sense, to arise against authority. "Any officer or soldier who shall presume to use traiterous or disrespectful words against the sacred person of his majesty, or of the royal family, is guilty of mutiny.

"Any officer or soldier who shall behave himself with contempt or disrespect towards the general or other commander in chief of our forces, or shall speak words tending to their hurt or dishonour, is guilty of mutiny.

"Any officer or soldier who shall begin, excite, cause, or join in, any mutiny or sedition, in the troop, company, or regiment, to which he belongs, or in any other troop or company in our service, or in any party, post, detachment, or guard, on any pretence whatsoever, is guilty of mutiny.

"Any officer or soldier who, being present at any mutiny or sedition, does not use his utmost endeavours to suppress the same, or coming to the knowledge of any mutiny, or intended mutiny, does not without delay give information to his commanding officer, is guilty of mutiny.

"Any officer or soldier who shall strike his superior officer, or draw, or offer to draw, or shall lift up any weapon, or offer any violence against him, being in the execution of his office, on any pretence whatsoever, shall disobey any lawful command of his superior officer, is guilty of mutiny."

MUTIUS. See MILITARY STATE.

MUTIUS, CAIUS, surnamed Caelus, and afterwards Scævola, was one of the illustrious Roman family of the Muti, and rendered his name famous in the war between Porsea the king of Thucy and the Romans. That prince resolving to restore the family of Tarquins the Proud, went to besiege Rome; and C. Mutius resolved to sacrifice himself for the safety of his country; and boldly entering the enemy’s camp, killed Porsea’s secretary, whom he took for Porsea himself. Being seized and brought before Porsea, he told him boldly, that 300 young men like himself had sworn to murder him; but since this hand has missed thee, continued he, it must be punished; then putting his right hand on the burning coals, he let it burn with such constancy as astonished the beholders. The king, amazed at the intrepidity of this young Roman, ordered that he should have his freedom and return to Rome, and soon after concluded a peace with the Romans. From this action Mutius obtained the surname of Scævola, “or left-handed,” which was enjoyed by his family.

MUTIUS SCÆVOLA, Q. surnamed the Augur, was an excellent civilian, and instructed Cicero in the law. He was made praetor in Asia; was afterwards consul, and performed very important services for the republic.

He ought not to be confounded with Quinctius Mutius Scævola, another excellent civilian, who was pra-
MYCENAIAN, a town of Argolis, in Peloponnesus. The kingdom of the Argives was divided into two portions by Acrisius and his brother Pandarus. Argos and Mycenae were their capitals. These, as belonging to the same family, and distant only about 30 stadia or six miles and a quarter from each other, had one tutelary deity, Juno, and were jointly proprietors of her temple, the Heraeum, which was near Mycenae. It was here that Agamemnon reigned. He enlarged his dominions by his valour and good fortune, and possessed, besides Mycenae, the region about Corinith and Sicyon, and that called afterwards Achaea. On his return from Troy, he was slain with his companions at a banquet. Mycenae then declined: and under the Heraclidæ was made subject to Argos. (See ARGOS and ARGELIA.) The Mycenæans sending 80 men, partook with the Lacedæmonians in the glory acquired at Thermopylae. The jealousy of the Argives produced the destruction of their city, which was abandoned after a siege, and laid waste in the first year of the 78th Olympiad, or 466 years before Christ. Some part of the wall remained in the second century, with a gate on which were lions, a fountain, the subterraneous edifices where Atreus and his sons had deposited their treasures, and, among other sepulchral monuments, one of Agamemnon, and one of his fellow soldiers and sufferers.

MYCONE, an island of the Archipelago, situated in E. Long. 25° 51', N. Lat. 39° 25'. It is about 36 miles in circuit, and has a town of the same name, containing about 3200 inhabitants. The people of this island are said to be the best sailors in the Archipelago, and have about 150 vessels of different sizes. The island yields a sufficient quantity of barley for the inhabitants, and produces abundance of figs, and some olives; but there is a scarcity of water, especially in summer, there being but one well in the island. There are a great number of churches and chapels, with some monasteries.

MYCONIAN, in Ancient Geography, one of the islands called Cyclades, near Delos, under which the last of the Centaurs slain by Hercules are feigned to lie buried. Hence the proverb, Omnia sub une Myconum congrerere, applied to an injurious or unnatural farago. Myconiti, the people, noted for baldness. Hence Myconius, a bald person. According to Strabo, the inhabitants became bald at the age of 20 or 25; and Pliny says that the children were always born without hair. The island was poor, and the inhabitants very avaricious; whence Archilochus reproached a certain Pericles, that he came to a feast like a Myconian; that is without previous invitation. Now called Mycone, which see.

MYSTERIA, the JABIRU, a genus of birds belonging to the order of grallæ. See Ornithology Index.

MYGDONIA, in Ancient Geography, a district of Macedon; one of the northern groups of the Sibyes; and east of the river Axios, which separates it from Bottas, and west of the river Strymon (Pliny). Also a district of Mesopotamia, which took its name from that of Macedon, running along the Euphrates from Zeugma down to Tarsus, extending a great way east, because Nisibis was reckoned to it.

MYGINDA, a genus of plants belonging to the tetradium class; and in the natural method ranking with those of which the order is doubtful. See Botany Index.
MYIAGRUS DEUS, in the heathen mythology, a name sometimes given to Jupiter, and sometimes to Hercules, on occasion of their being sacrificed to for the driving away the vast numbers of flies which infested the sacrifices on certain public occasions. The word is usually spelt Myagrus; but this must be an error, as this word does not express the fly-destroyer, but the mouse-destroyer; and we have it sufficiently testified by the ancients, that flies were the only creatures against whom this deity was invoked. Pliny calls this deity also Myiodes; and tells us that the flies which used to pester the Olympic rites went away in whole clouds on the sacrificing a bull to this god. We find in Aeneid also, that this sacrificing to the god of flies at the Olympic games was a constant custom. Some distinguish these two deities, and tell us that the latter or Myiodes, used to visit the nations in vengeance, with a vast multitude of flies; and that, on paying him the due honours of a sacrifice, they all went away again; and this seems to agree with what Pliny tells us in some places.

At the time of the Olympic games, Jupiter was represented under the name of Apomnus or Myiagrus Deus to supplant the destruction of those troublesome creatures. This happened only once in many years, when the sacrifices were performed there; but the Eleans worshipped him continually under this name, to deprecate the vengeance of heaven, which usually sent, as they expressed it, an army of flies and other insects, toward the latter end of the summer, that infested the whole country with sickness and pestilence.

MYIODES-DEUS, in the heathen mythology, a name sometimes given to Hercules, but more frequently to Jupiter, to whom a bull was sacrificed, in order to make him propitious in driving away the flies that infested the Olympic games.

MYLE, in Ancient Geography, a Greek city situated on an isthmus of a cogginal peninsula, on the north-east side of the island. Mylae, or Mylenes, the people. A town built by those of Zancle (Strabo). Mylenus, the epithet, as Mylaenus Campus, mentioned by Polybius. Now called Milazzo, a port town of Sicily, in the Valle di Demone. E. Long. 15. 5. N. Lat. 32. 56.

MYLASA, or MYLASSA, in Ancient Geography, a noble city of Caria in Asia Minor, situated about three leagues from the Sinus Ceramicus. It was the capital of Hecatomnus king of Caria, and father of Mausolus. Pliny speaks of Menander king of Caria, and says that the Rhodians preserved with the greatest care his portrait painted by Apelles: but it was not in honour of this Menander that a Corinthian pillar was erected at Mylassa, which still exists, and on which it is to be seen the following inscription: "The people erected this pillar in honour of Menander, the son of Ulidas, and grandson of Euthydemus, the benefactor of his country, and whose ancestors rendered it great services also." Euthydemus, the grandfather of this Menander, lived in the time of Julius Caesar and Augustus. Caria was taken by Mithridates, and afterwards by Labienus, whose father had been one of Caesar's generals. Hybrias, whose eloquence and valour deservedly entitled him to a distinguished rank among his countrymen, in vain encouraged them to make a most obstinate defence while it was besieged by the latter. He himself was obliged to yield to necessity, and to take refuge at Mylasa: but scarcely had he quitted the city, when Hybrias returned, and restored liberty to his country. Not content with rendering it this service, he also destroyed the power of a dangerous citizen, whose riches and talents rendered him a necessary evil. Euthydemus, often banished, and as often recalled, always too powerful in a state the independence of which he threatened, saw his ambition checked by the zeal and activity of Hybrias. The Romans left to Mylassa the liberty of which it rendered itself so worthy, by the great efforts it made to preserve it. Pliny calls it Mylassa libera. Strabo informs us, that it was one of the most magnificent cities of antiquity, and one of those, the temples, porticoes, and other public monuments of which were highly admired. A quarry of white marble in the neighbourhood furnished it with abundance of materials for erecting these edifices.

The Mylasians had two temples dedicated to Jupiter, one situated in the city, which was named Ogea, and another built on a mountain, at the distance of 65 leagues. The latter was dedicated to Jove Stratus, Jupiter the Warrior. His state, which was very ancient, inspired great veneration; people came from all quarters to implore his protection; and for the greater accommodation of his votaries a paved way was constructed which reached from Mylassa to this venerable fabric. This city is now called Melasso, and, according to Dr. Chandler, is still a large place. The houses are numerous, but chiefly of plaster, and mean, with trees interspersed. The air is accoutred bad; and scorpions abound as anciently, entering often at the doors and windows, and lurking in the rooms. The plain is surrounded by lofty mountains, and cultivated. Round the towns are ranges of broken columns, the remnants of porticoes, now with rubbish bounding the vineyard. A large portion of the plain is covered with scattered fragments, and with piles of ordinary aqueducts; besides inscriptions, mostly ruined and illegible. Some altars dedicated to Hecatomnus have been discovered. Of all the ancient temples which formerly ornamented this city, one only escaped the power of time, the blind zeal of the early Christians, and the barbarous superstition of the Mahometans. This monument was dedicated to Augustus and the divinity of Rome. When Pococke visited Melasso, it was perfect and entire; but at present no traces of it remain, except a few fragments, which have been employed to construct a Turkish mosque.

MYLOGLOSSUM, in Anatomy. See Anatomy, Table of the Muscles.

MYLOHYOID/EUS. Ibid.

MYLOGY, (formed of μυς, χορός, "a muscle," and λόγος, "discourse"), in anatomy, a description of the muscles; or the knowledge of what relates to the muscles of the human body. Ibid.

MYOMANCY, a kind of divination, or method of foretelling future events by means of mice.

Some authors hold myomancy to be one of the most ancient kinds of divination; and think it is on this account that Isaiah, lxi. 17. reckons mice among the abominable things of the Idolaters. But, beside that, it is not certain that the Hebrew word דְּלָל used by the
MYR

the prophet signifies a mouse, it is evident it is not the

MYOPIS, a species of vision wherein objects are seen only at small distances. See Medicine, No. 361.

MYOSOTIS, Scorpion-grass; a genus of plants belonging to the pentandria class, and in the natural method ranking under the 24th order, Asperisit. See Botany Index.

MYOSORUS, a genus of plants belonging to the pentandria class, and in the natural method ranking under the 24th order, Commelinae. See Botany Index.

MYXUS, the Dormouse, a genus of quadrupeds belonging to the order of glises. See Mammalia Index.

MYRIAD, a term sometimes used to denote ten thousand.

MYRICA, Gale, or Sweet-willow, a genus of plants belonging to the diccia class, and in the natural method ranking under the 7th order, Ammocaceae. See Botany Index.

MYRIOPHYLLUM, a genus of plants belonging to the monoezia class, and in the natural method ranking under the 15th order, Linnaeae. See Botany Index.

MYRISTICA, the Nutmeg-tree, in Botany, a genus of plants belonging to the class diccia, and in the natural order, Lauri. The description of this genus having been omitted in its proper place under Botany, we shall here introduce a short account of it. The male calyx is monopbylli, strong, and parted into three laciniae of an oval shape, and ending in a point; it has no corolla. In the middle of the receptacle rises a column of the height of the calyx, to the upper part of which the anthers are attached. They vary in number from three to twelve or thirteen. The female calyx and corolla as in the male, on a distinct tree. The germen of an oval shape; the style short, with a bifid stigma, the laciniae of which are oval and spreading. The fruit is of that sort called drupa. It is fleshy, roundish, sometimes unilocal, sometimes bivalvate, and bursts when ripe at the side. The seed is enveloped with a fleshy and fatty membranous substance which divides into filaments (this, in one of the species, is the mace of the shore); the seed or nutmeg is round or oval shaped, unilocular, and contains a small kernel, variegated on the surface by the fibres running in the form of a screw.

Species.—There are five species of this genus according to some authors; but several of these being only varieties, may be reduced into three, viz.

1. Myristica fatua, or wild nutmeg: this grows in Tobago, and rises to the height of an apple-tree; has oblong, lanceolated, downy leaves, and hairy fruit: the nutmeg of which is aromatic, but when given inwards is narcotic, and occasions drunkenness, delirium, and madness, for a time.

2. The myristica sebifera, (Virola Schiifera Aublet, page 904, tab. 345.) a tree frequent in Guiana, rising to 40 or even to 60 feet high; on wounding the trunk of which, a thick, acrid, red juice runs out. Aublet says nothing of the nutmegs being aromatic; he only observes, that a yellow fat is obtained from them, which Myristica serves many economical and medical purposes, and that the natives make candles of it.

3. The myristica moschata, or nutmeg, rises to the height of 30 feet, producing numerous branches; the bark of the trunk is of a reddish brown, but that of the young branches is of a bright green colour: the leaves are nearly elliptical, pointed, undulated, obliquely nervet, on the upper side of a bright green, on the under whitish, and stand alternately upon footstalks. The flowers are small, and hang upon slender peduncles, proceeding from the axilae of the leaves: they are both male and female upon separate trees.

M. Schwartz, who has carefully examined this as well as the two first species, preserved in spirits, places them among the monadelphia.

The nutmeg has been supposed to be the comacum of Theophrastus, but there seems little foundation for this opinion; nor can it with more probability be thought to be the chrysobolamos of Galen. Our first knowledge of it was evidently derived from the Arabians; by Avicenna it was called jussuban, or jussuban, which signifies nut of Banda. Rumphius both figeret and described this tree; but the figure given by him is so imperfect, and the description so confused, that Linnæus, who gave it the generic name myristica, was unable to assign its proper characters. M. Lamarck informs us, that he received several branches of the myristica, both in flower and fruit, from the isle of France, where a nutmeg-tree, which was introduced by Monsieur Poivre in 1770, is now very large, and continually producing flowers and fruit. From these branches, both male and female, the Duke of the king's garden in that island, Lamarck has been enabled to describe and figure this and other species of the myristica. See Plate CXXIV. Botany.

Fig. a. A sprig with fructification. The drupæ of the natural size, and bursting open. Fig. b. The full-grown fruit cut lengthwise. Fig. c. Another section of the same. Fig. d. The nutmeg enveloped with its covering, the mace. Fig. e. The fatty membrane or mace spread out. Fig. f. The nutmeg of its natural size. Fig. g. The same with its external tegument removed at one end. Fig. h. The same with its outer tegument entirely removed. Fig. i. A transverse section of the nutmeg.

The seeds or kernels called nutmegs are well known, as they have been long used both for culinary and medical purposes. Distilled with water, they yield a large quantity of essential oil, resembling in flavour the spice itself; after the distillation an insipid sebaceous matter is found swimming on the water; the sebaceous matter, which is a condensation of an unctuous, very slightly bitterish taste, and with little or no astringency. Rectified spirit extracts the whole virtue of nutmegs by infusion, and elevates very little of it in distillation; hence the spirituous extract possesses the flavour of the spice in an eminent degree.

Nutmegs, when heated, yield to the press a considerable quantity of limpid yellow oil, which, on cooling concretes into a sebaceous consistence. In the shops we meet with three sorts of uncuous substances, called oil of mace, though really expressed from the nutmeg. The best is brought from the East Indies in stone jars; this is of a thick consistence, of the colour of
Myristica mace, and has an agreeable fragrant smell; the second sort, which is paler coloured, and much inferior in quality, comes from Holland in solid masses, generally flat, and of a square figure: the third, which is the worst of all, and usually called common oil of mace, is an artificial composition of sevum, palm oil, and the like, flavoured with a little genuine oil of nutmeg.

Method of gathering and preparing Nutmeg.—When the fruit is ripe the natives ascend the trees, and gather it by pulling the branches to them with long hooks. Some are employed in opening them immediately, and in taking off the green shell or first rind, which is laid together in a heap in the woods, where in time it putsrefies. As soon as the putrefaction has taken place, there spring up a kind of mushrooms called boleti moschatini, of a blackish colour, and much valued by the natives, who consider them as delicate eating. When the nuts are stripped of their first rind, they are carried home, and the mace is carefully taken off with a small knife. The mace, which is of a beautiful red, but afterwards assumes a darkish or reddish colour, is laid to dry in the sun for the space of a day, and is then removed to a place less exposed to his rays, where it remains for eight days, that it may soften a little. They afterwards moisten it with sea water, to prevent it from drying too much, or from losing its oil. They are careful, however, not to employ too much water, lest it should become putrid, and be devoured by the worms. It is last of all put into small bags, and squeezed very close.

The nuts which are still covered with their lignous shell, are for three days exposed to the sun, and afterwards dried before a fire till they emit a sound when they are shaken; then they beat them with small sticks in order to remove their shell, which flies off in pieces. These nuts are distributed into three parcels, the first of which contains the largest and most beautiful, which are destined to be brought to Europe; the second contains such as are reserved for the use of the inhabitants; and the third contains the smallest, which are irregular or unripe. These are burnt; and part of the rest is employed for procuring oil by pressure. A pound of them commonly gives three ounces of oil, which has the consistence of tallow, and has entirely the taste of nutmeg. Both the nut and mace, when distilled, afford an essential, transparent, and volatile oil, of an excellent flavour.

The nutmegs which have been thus selected would soon corrupt if they were not watered, or rather pickled, with lime-water made from calcined shell fish, which they dilute with salt water till it attain the consistence of fluid pap. Into this mixture they plunge the nutmegs contained in small baskets, two or three times, till they are completely covered over with the liquor. They are afterwards laid in a heap, where they heat, and lose their superfluous moisture by evaporation. When they have sweated sufficiently, they are then properly prepared, and fit for a sea voyage.

In the island of Banda, the fruit of the nutmeg tree is preserved entire in the following manner: When it is almost ripe, but previous to its opening, it is boiled in water and pierced with a needle. They next lay it in water to soak for ten days, till it has lost its sour and sharp taste. They then boil it gently in a syrup made of sugar, to which, if they wish it to be hard, a little lime is added. This operation is repeated for eight days, and each time the syrup is renewed. The fruit when thus preserved is put for the last time into a pretty thick syrup, and is kept in earthen pots closely shut.

These nuts are likewise pickled with brine or with vinegar; and when they intend to eat them, they first steep them in fresh water, and afterwards boil them in syrup of sugar, etc.

Uses.—Nutmegs preserved entire are presented as desserts, and the inhabitants of India sometimes eat them when they drink tea. Some of them use nothing but the pulp; others likewise chew the mace; but they generally throw away the kernel, which is really the nutmeg. Many who perform sea voyages to the north chew this fruit every morning.

The medicinal qualities of nutmeg are supposed to be aromatic, anodyne, stomachic, and restringent; and with a view to the last-mentioned effects, it has been much used in diarrhoeas and dysenteries.

Remarks on the trade of Nutmegs.—Nutmeg trees grow in several islands in the eastern ocean. The wood pigeon of the Moluccas is unintentionally a great planter of these trees, and disseminates them in places where a nation, powerful by its commerce, thinks it for its interest that they should be rooted out and destroyed. The Dutch, whose unwearied patience can surmount the greatest obstacles, formerly appropriated to themselves the crop of nutmeg, as well as that of cloves and cinamon growing in the islands of Ternate, Celso, &c. either by right of conquest or by paying subsidies to the islanders, who find these much more profitable than the former produce of their trees. It is nevertheless true, that they have prevailed upon or compelled the inhabitants of the Moluccas to cut down and root out all the clove trees, which they have preserved only is the islands of Amboyna and Ternate, which are in a great measure subject to them. We know for certain, that the Dutch pay 18,000 rixdollars yearly to the king of Ternate by way of tribute or gift, in order to recompense him for the loss of his clove trees in the other Molucca islands; and that they are moreover bound by treaty to take at 3½d. a pound, all the cloves brought by the natives of Amboyna to their magazines.

The Dutch had formerly immense and very rich magazines of these precious aromaticks, both in India and Europe. It is said, that they had actually by them the produce of 15 years, and never supplied their neighbours with the last, but always with the oldest crop; in 1760 they sold what was laid up in 1744; and when they had too great a quantity of cloves, nutmeg, &c. in their magazines, they threw them into the sea, or destroyed them by burning. On the 10th of June 1760, M. Bomare saw at Amsterdam, near the Admiralty, a fire, the fuel of which was valued at 8,000,000 of livres; and as much was to be burned on the day following. The feet of the spectators were bathed in the essential oil of these substances; but no person was allowed to gather any of it, much less to take any of the spices which were in the fire. Some years before, upon a similar occasion, and at the same place, a poor man
MYS is brought from the East Indies or from Abyssinia. See Materia Medica. Index.

It is affirmed by some, that the myrrh we have at present is not equal in quality to that of the ancients, and has not that exquisite smell which all authors ascribe to the latter. They aromatized their most delicious wines with it; and it was presented as a very valuable perfume to our Lord while he lay in the manger.

It was this gum also which was mingled with the wine given him to drink at his passion, to deaden his pains, and produce a stupor. (See Mark xv. 32.) The gall mentioned on the same occasion by St Matthew is probably the same with myrrh; for any thing bitter was usually distinguished by the name of gall. The Hebrews were accustomed to give those that were executed some stupefying draught. The difficulty which arises from the seeming difference between the two evangelists, by some is solved by saying, that St Matthew, writing in Syriac, made use of the word marra, which signifies "myrrh, bitterness, or gall"; but the Greek translator has taken it for gall, and St Mark for myrrh. Others think that our Saviour's drink was mingled with myrrh as a stupefying drug: but suppose that the soldiers out of wanton cruelty and inhumanity, infused gall; which was the reason, say they, why, when he had tasted, he refused to drink.

MYRRHINE, or MURRINE. See MURRINE.
MYRSINE, a genus of plants belonging to the pentandria class, and in the natural method ranking under the 18th order, Bicornes. See Botany Index.
MYRTIFORM, in Anatomy, an appellation given to several parts, from their resembling myrtle berries.
MYRTLE. See MYRTUS, Botany Index.
MYRTOM MARE, a part of the Ægean sea, lying between Euboea, Peloponnesus and Attica. It receives this name from Myrto a woman, or from Myrtos a small island in the neighbourhood, or from Myrtus the son of Mercury who was drowned there, &c.

MYRTUS, in Ancient Geography, a small island near Caryus in Euboea, which gave name to the mare Myrtum. Others, according to Pausanias, derive the appellation from Myrto, the name of a woman. Strabo extends this sea between Crete, Argia, and Attica. Pausanias beginning it at Euboea, joins it at Helena, a desert island, with the Ægean sea. Ptolemy carries it to the coast of Caria. Pliny says, that the Cyclades and Sporades are bounded on the west by the Mytosa coast of Attica.

MYRTUS, the Myrtle, a genus of plants belonging to the icosandria class; and in the natural method ranking under the 15th order, Hesperides. See Botany Index.

MYSIA, a country of Asia Minor, generally divided into Major and Minor. Mysia Minor was bounded on the north and west by the Propontis and Bithynia, and Phrygia on the southern and eastern borders. Mysia Major had Æolia on the south, the Ægean sea on the west, and Phrygia on the north and east. Its chief cities were Cyzicus, Lampscus, &c. The inhabitants were once very warlike; but they greatly degenerated, and the words Mysorum ultimus were emphatically used to signify a person of no merit. The ancients generally hired them to attend their funerals as mourners,

MYRMECOPHAGA, or Ant-bear, a genus of quadrupeds, belonging to the order of bruta. See Mammalia Index.

MYRMELEON, or Ant-lion, a genus of insects of the neuroptera order. See Entomology Index.

MYRMIDONS, MYRMIDONTES, in antiquity; a people in the southern borders of Thessaly, who accompanied Achilles to the Trojan war. They received their name from Myrmidon, a son of Jupiter and Eurymedusa, who married one of the daughters of Æolus, son of Helen. His son Actor married Ægina, the daughter of Æneas. He gave his name to his subjects, who dwelt near the river Penes in Thessaly. According to some, the Myrmidons received their name from their having arisen from ants or pismires, upon a prayer put up for that purpose by King Æacus to Jupiter, after his kingdom had been despoiled by a severe pestilence. According to Strabo, they received it from their industry, because they imitated the diligence of the ants, and like them were indefatigable, and were continually employed in cultivating the earth.

MYRMILLONES were gladiators of a certain kind at Rome, who fought against the Retiarii. Their arms were a sword, head piece, and shield. On the top of the head-piece they wore a fish embossed, called magnum, whence their name is by some supposed to be derived. The Retiarii, in their engagements, made use of a net, in which they endeavoured to entangle their adversaries; and sung during the fight, "Non te pede, piacem petam vit mi fugi, Galli?" "I am not at thee, but I aim at thy fish; why dost thou shun me, O Gaul!!" The Myrmillones were called Galli, because they wore Gallic armour. They were also named Secutores. This kind of gladiators was suppressed by Caligula. See GLADIATORS, RETIARI, &c.

MYROBALANS, a kind of medicinal fruit brought from the Indies, of which there are five kinds. 1. The cithron of a yellowish red colour, hard, oblong, and the size of an olive. 2. The black or Indian myrobalan, of the bigness of an acorn, wrinkled and without a stone. 3. Chebulic myrobalans, which are of the size of a date, pointed at the end, and of a yellowish brown. 4. Emblic, which are round, rough, the size of gall, and of a dark brown. 5. Baleric, which are hard, round, of the size of an ordinary prune, less angular than the rest, and yellow. They are all slightly purgative and astringent. The word comes from the Greek magos, "ointment," and Æcasis, "acorn," as being in the form of acorns, and used in medicine.

MYRON, an excellent Grecian statuary, flourished 442 B. C. The cow he represented in brass was an admirable piece of workmanship, and was the occasion of many fine epigrams in Greek.

MYROXYLON, a genus of plants belonging to the decandria class. See Botany Index.

MYRRH, a gummy-resinous concrete juice, which
RELIGION, in its original form, was simple and intelligible. It was intended for the instruction and education of all ranks of men; and of consequence its doctrines were on a level with vulgar capacities. The Jewish dispensation was openly practised: nothing was performed in secret; every article was plain, open, and accessible. The divine Author of the Christian economy commanded his disciples to preach his doctrine in the most public manner: "What ye have heard in secret (say he) preach openly; and what I have taught you in private teach ye publicly, and proclaim it on the house tops." Both are the charms of truth, and such the character of that religion which came down from heaven, that they, as it were, "delight, and lift up their voice in the streets, and cry in the chief places of assembly."

But such is the depravity of the nature of man, that the noblest institutions degenerate in his hands. Religion itself, originally pure, simple, and amiable, under his management has often been transformed into pollution, perplexity, and deformity. The ministers of religion, whose province it was to guard the sacred deposit, and to secure it from foreign and spurious intermixtures, have generally been the first innovators, and the fruit and most industrious agents in corrupting its integrity and tarnishing its beauty. Avarice and ambition prompted that class of men to deviate from the original simplicity and similitude of religious institutions, and to introduce articles, rites, and usages, which might furnish them with opportunities of gratifying these unhallowed and insatiable passions. Hence distinctions unknown to pure and undefiled religion were fabricated: and that heavenly institution, heretofore, one, simple, indivisible, was divided into two partitions: the one popular and public; the other dark, secret, and mysterious. The latter of these we intend to be the subject of this article.

The English word mystery is derived from the Greek mysterion; and in its modern acceptation imports something above human intelligence, something awful and enigmatical; anything artfully made difficult; the secret of any business or profession. The word is often used by the founder of the Christian religion; and more frequently by his apostles, especially St Paul. In these cases, it generally signifies those doctrines of Christianity which the Jews, prior to the advent of the Messiah, either did not or could not understand. The Trinity in Unity, and the Unity in Trinity; the incarnation of the Son of God; the union of two natures in one and the same person, &c. We generally call mysteries, because they are infinitely above human comprehension. All these significations are out of the question at present. Our intention in this article is merely to lay before our readers the fullest and fairest account of the mysteries, of the Pagan superstition, which were carefully concealed from the knowledge of the vulgar, and which are universally known under the denomination of mysteries.

The word mystery is evidently deduced from mysterion, but the origin of this last term is not altogether so obvious. The etymologies of it exhibited by the learned are various; some of them absurd and inconsistent, others foolish and futile. Instead of fatiguing our readers with a detail of these, which would be equally unenterprising and uninteresting, we shall only produce one, which, as we appear to come nearest the truth, the mysteries under consideration at present were certainly imported into Greece from the East. In those regions, then, we ought of course to look for the etymology of the word. Mister or mistar, in Hebrew, signifies "any place or thing hidden or concealed." As this word implies a kind of definition of the nature of the thing intended, and as it is one of the excellencies of original languages to apply vocables with propriety, we find ourselves strongly inclined to assign the word mystery as the root of the term mystery.

We have already observed, that the avarice and ambition of the Pagan priesthood probably gave birth to the institution of the mysteries. To this observation we may now add, that the ministers of that superstition might possibly imagine, that some articles of their ritual were too profound to be comprehended by the vulgar; others, too sacred to be communicated to a description of men, whom the institutions of civil society had placed in a situation not only subordinate but contemptible. They imagined, that things sacred and venerable would have contracted a taint and pollution by an intercourse with sordid and uninitiated souls. These appear to us the most probable motives for making that odious and pernicious distinction between the popular religion and that contained in the sacred and mysterious ritual.

The learned Bishop Warburton is positive, that the mysteries of the Pagan religion were the invention of legislators and other great personages, whom fortune or their own merit had placed at the head of the civil societies, which were formed in the earliest ages, in different parts of the world. It is with reluctance, and indeed...
MYSTERIES.

indeed with diffidence, that we presume to differ in our sentiments from such respectable authority. Whatever hypothesis this prelate had once adopted, so extensive was his reading, and so exuberant his intellectual resources, that he found little difficulty in defending it by an appearance of plausibility, if not of rational argumentation. The large quotations he has adduced from Plato and Cicero, do indeed prove that the sages and legislators of antiquity sometimes availed themselves of the influence derived from the doctrine of the mysteries, and from the authority they acquired by the opinion of their having been initiated in them; but that those men were the inventors and fabricators of them is a position for which his quotations do not furnish the most slender presumption. At the same time, we think it not altogether certain, that the doctrine of a divine Providence, and a future state of rewards and punishments, were revealed in the mysteries with all the clearness and cogency which is pretended by his lordship.

But granting that the fabric was raised by the hands of sages and legislators, we imagine it would be rather difficult to discover what emolument that description of men could propose to derive from the enterprise. The institution was evidently, and indeed confessedly, devised to conceal from the millions those very doctrines and maxims, which had they known and embraced them, would have contributed most effectually to dispose them to submit to those wise regulations which their governors or legislators wished most ardently to establish. Experience has taught, that nothing has a more commanding influence on the minds of the vulgar, than those very dogmas, which, according to the Bishop, were communicated to the initiated. A conviction of the unity of the Deity, of his wisdom, power, goodness, omnipresence, &c., the steady belief of the incorruptibility of the human soul, and of a future state of rewards and punishments, have in all ages, and in all countries, proved the firmest supports of legal authority. The very same doctrines, in the dawn of Christianity, contributed, of all other methods, the most effectually to tame and civilize the savage (A) inhabitants of the northern regions of Europe. Supposing those principles to have been inculcated by the mysteries, the most prudent plan legislators could have adopted, would have been to publish them to all mankind. They ought to have sent forth apostles to preach them to the savages whom they had undertaken to civilize. According to the learned prelate, they pursued the opposite course, and deprived themselves of those very arms by which they might have encountered and overthrown all the armies of savagism.

Of all the legislators of antiquity, the Cretans alone was prudent enough to foresee and adopt this rational plan. Diodorus the Sicilian informs us, that the mysteries of Eleusis, Samothracia, &c., which were elsewhere buried in profound darkness, were among the Cretans taught publicly, and communicate to all the world. Minos, however, was a successful legislator; and his intercourse with Jupiter Idaeus extended his influence and established his authority. He was not under the necessity of calling in the mysteries to his assistance: on the contrary, it is highly probable that the universal knowledge of the doctrines of the mysteries among his countrymen contributed in a considerable degree to facilitate his labour, and ensure his success.

The divine Author of the Christian economy, viewed in the light of a human legislator, saw the propriety of this procedure. Nothing was concealed in his institutions; nothing was veiled with mystery, or buried in darkness. The success was answerable to the wisdom of the plan. The million flocked to the evangelical standard: the gospel was preached to the poor, to the illiterate and the vulgar; and the meanest of mankind eagerly embraced its maxims. Wherever it prevailed, it produced civilization, morality, sobriety, loyalty, and every other private and social virtue.—Upon the supposition that the mysteries had contained and inculcated the principles and practices which the prelate supposes they did, the civiliizers of mankind, legislators, magistrates, and princes, ought to have combined to make them public for the sake of their own tranquillity, and the more effectual support of their authority and influence.

Upon the whole, we are inclined to believe that the Mysteries mysteries were the offspring of Egyptian priestcraft, to be found in other places. The history of the mysteries is the history of the order of men, to extend their influence, and enlarge their revenues. To accomplish these selfish projects, they applied every engine towards besetting the multitude with superstition and enthusiasm. They taught them to believe, that themselves were the distinguished favourites of heaven; and that celestial doctrines had been revealed to them, too holy to be communicated to the profane rabble, and too sublime to be comprehended by vulgar capacities. It is, we confess, exceedingly probable, that after the mysteries were instituted, and had acquired an exalted reputation in the world, legislators, magistrates, judges, and potentates, joined in the imposture, with the same views and from the same principles. Princes and legislators, who adopted by their own free choice, and who had found their advantage in overthrowing and humbling the legislators, &c., readily adopted a plan which they found so artfully fabricated to answer these very purposes. They had interest enough with the sacerdotal (a) mystagogues, to induce them to allow them to participate in those venerable rites which had already established the authority of that description of men in whose hands they were deposited. The views of both parties were exactly congenial. The respect, the admiration, and dependance on the million, were the ultimate objects of their ambition respectively.—Priests and princes were actuated by the very same spirit. The combination was advantageous, and of consequence harmonious. For these reasons we have taken the liberty of differing from his Lordship of Gloucester with respect to

(A) The Germans, Russians, and Scandinavians, who were never thoroughly civilized till the gospel was preached among them.

(b) The mystagogues were the ministers who acted the chief part in celebrating the mysteries.
Mysteries.

Another writer of considerable reputation in the republic of letters, is of opinion, that the mysteries were entirely commemorative; that they were instituted with a view to preserve the remembrance of heroes and great men; who had been deified in consideration of their martial exploits, useful inventions, public virtues, and especially in consequence of the benefits by them conferred on their contemporaries. According to him, the mysteries of Mithras were established for this very purpose. It would be no difficult matter to prove that the Persian deity of that name was the sun, and that his name and insignia jointly ascertain the truth of this assertion. The same writer extends this observation to the mysteries of the Egyptians, Phoenicians, Greeks, Hetruscans; and in a word, to all the institutions of that species throughout the world. In opposition to this singular opinion, it may be argued, we think, with some show of reason, that the method of preserving the memory of great and illustrious men generally adopted, was the establishing festivals, celebrating games, offering sacrifices, singing hymns, dances, &c. We can recollect no secret mysteries instituted for that purpose at least in their original intention. If any usage of the commemorative kind was admitted, it was superinduced at some period posterior to the primary institution. At the same time, upon the supposition that the orgia of Bacchus were the same with those of the Egyptian Osiris, and that the mysteries of Ceres exhibited at Eleusis were copied from those of the Egyptian Isis, and allowing that the former was the sun, and the latter the moon; it will be difficult to find out the human persons whose exploits, adventures, inventions, &c. were intended to be immortalized by those institutions. Upon the whole, the mysteries were performed in secret; they were intended to be communicated only to a few; of course had they been instituted with a view to immortalize the memory of heroes and great men, the authors would have acted the most foolish and inconsistent part imaginable. Instead of transmitting the fame of their heroes with eclat to posterity, they would by this procedure have consigned it to eternal oblivion.

We must then recur to our first position. The mysteries were the offspring of bigotry and priesthood; they originated in Egypt, the native land of idolatry. In that country the priesthood ruled predominating. The kings were engrafted into their body before they could ascend the throne. They were possessed of a third part of all the land of Egypt. The sacerdotal function was confined to one tribe, and was transmitted unalienably from father to son. All the orients, but more especially the Egyptians, delighted in mysterious and allegorical doctrines. Every maxim of morality, every tenet of theology, every dogma of philosophy, was wrapped up in a veil of allegory and mysticism. This propensity, no doubt, conceived with avarice and ambition to dispose them to a dark and mysterious system of religion. Besides, the Egyptians were a gloomy race of men; they delighted in darkness and solitude. Their sacred rites were generally celebrated with melancholy airs, weeping, and lamentation. This gloomy and unsocial bias of mind must have stimulated them to a congenial mode of worship. In Egypt then we are to search for the origin of the mysteries. Both the nature of the institution and the genius of the people confirm this position; and historians, both ancient and modern, are agreed, in admitting the certainty of the fact.

The Osiris of Egypt, every body knows, was the original Bacchus; as the Isis of the same country was and is of the Ceres of the Greeks. The rites of Osiris were Egypt the Bacchus and Ceres performed with loud shrieks and lamentations when he was put into the coffin; and with the most extravagant mirth, when he was in a manner raised from the dead, or supposed to be found again. Their hymns were upon the whole always composed in melancholy strains; and consisted of lamentations for the loss of Osiris, the mystic flight of Bacchus, the wanderings of Isis, and the sufferings of the gods. The Cenamites, who were a kindred tribe of the Mitzri and Osiris, imitated them in their sacred rites. At Eth Byblus, Beritys, Sidon, and afterwards at Tyre, they cosm. used particularly mournful dirges for the death of Adonis or Tamunux, who was the same with the Egyptian Osiris, i.e. the sun.

The Egyptians, then, naturally inclined to gloom and secrecy, instituted a mode of worship congenial with their natural disposition of mind. The recess of the sun towards the southern hemisphere, was the death of Osiris; the wanderings of Isis in search of her husband and brother, allegorically imported the longing of the earth for the return of the fruitgiving influence of the solar heat.

When that luminary returned towards the summer solstice, and grain, trees, fruits, herbs, and flowers adorned the face of nature, another festival was celebrated of a very different complexion from that of the former. In this season all Egypt was dissolved in the most extravagant mirth and jollity. During the celebration of those festivals, the priests formed allegorical representations of the sun and the earth (D). They personified the one and the other, and allegorized their motions, aspects, relations, sympathies, accesses, recesses, &c. into real adventures, peregrinations, sufferings, contests, battles, victories, defeats, and so forth. These, in process of time, were held up to the vulgar as real occurrences; and these in a few ages became the most essential articles of the popular creed. From this source were derived the conquests of Dionysus or Bacchus, so beautifully exhibited by Nonnus in his Dionysiaca.
MYSTERIES.

Dionysiaces; the wanderings of Io, wonderfully adorned by Aeschylus; and the labours of Hercules, afterwards worshipped by the Greeks.

Whether the Egyptians deified mortal men in the earliest ages has been much controverted. Jablonski has taken much pains to prove the negative. Dio-dorus assures us, that they paid their monarchs a kind of divine adoration, even in their lifetime. Plutarch tells us plainly, that some were of opinion that Isis, Osiris, Horus, Anubis, Typhon, were once mortal persons, who were exalted into demons after their death.

The Sicilian, in his history of Isis and Osiris, Pan, Hermes, &c. plainly represents them as human personages; and informs us, that the Egyptians imagined, that after their decease they transmigrated into particular stars. From these authorities, we are inclined to believe that the Egyptians, as well as the other Pagans, did actually deify persons who had distinguished themselves in their days of nature by prudence, wisdom, useful arts, and inventions. This was a constant practice among the Greeks, who probably learned it from the people in question.

The exploits of these heroes had been disguised by allegorical traditions and hieroglyphical representations. They had been magnified beyond all dimensions, in order to astonish and intimidate the vulgar. They had been interlarded with the most extravagant fables, in order to gratify their propensity towards the marvelous. All these secrets were developed in the mysteries. The catechumens were informed of every particular relating to the birth, the life, the exploits, the adventures, the misfortunes, and decease of those heroic personages, and when, and by what means, they had attained to the high rank of divinities. At the same time we think it highly probable, that those demi-gods were represented in their state of exaltation and heavenly splendour. The magicians of Egypt were abundantly qualified for exhibiting angels in machines. The souls of virtuous men, who had not been eminent enough to merit the honour of deification, were shown in all the perfection of Elysian felicity; and perhaps the soul of tyrants, and of the children of Typhon, were shown in Tartarus, suffering all the extremities of infernal punishment. From these exhibitions the mystagogues might naturally enough take occasion to read their pupils suitable lectures on the happy tendency of a virtuous conduct, and the dishonour and misery consequent upon a contrary course. They might set before them immortal renown, deification, and Elysium, on the one hand, and eternal infamy and misery on the other. This will probably be deemed the chief advantage accruing from this institution.

Besides the communications above mentioned, the catechumens were taught many secrets of physiology, or the nature of the phenomena of the world. This Phaenotus every where affirms, especially in his last book towards the end. Plutarch too informs us, that many of the Greek philosophers were of opinion, that most of the Egyptian fables were allegorical details of physical operations. Eusebius acquaints us, that the physiology, not only of the Greeks, but likewise of the barbarians, was nothing else but a kind of science of nature, a concealed and dark theology, involved in fable and fiction, whose hidden mysteries were so veiled over with enigmas and allegories, that the ignorant million were as little capable of comprehending what was said as what was suppressed in silence. This, says he, is apparent from the poems of Orpheus and the fable of the Phrygians and Egyptians. Dionysius of Halicarnassus likewise observes, that the fables of the Greeks detail the operations of nature by allegories. Proclus makes the same observation concerning the people in question. The Egyptians, says he, taught the latent operations of nature by fables.

These physiological secrets were no doubt expounded Physiological to the initiated; and that the Egyptian priests were deeply skilled in physiological science, can scarce be questioned, if we believe that Jannes and Jambres vailed Moses with their enchantments. The preceding detail comprehends all that was revealed to the Egyptians in the original Egyptian mysteries. What articles might have been introduced afterwards we cannot pretend to determine.

Be that as it may, one thing is certain, namely, that the vulgar were excluded from all those choice secrets, which were carefully reserved for the nobility and sacerdotal tribes. To them it was given to know the mysteries of the kingdom of darkness; but to those who were without, all was mystery and parable. While the laity fed on husks, the clergy and the quality feasted on royal dainties. The priests who had devised these allegories understood their original import, and bequeathed it as an inestimable legacy to their children. Here then we have the primary object of the mysteries, namely, to develop to the initiated the original and rational import of those allegorical and mystical doctrines which were tended to the uninitiated, wrapped up in inpenetrable allegory and obscurity. To the former, these were communicated and explained: The latter were obliged to stand at an awful distance, and retire as the Procul, O procul estis proponi, thundered in their ears.

These allegorical traditions originated in Egypt, (see Mythology.) It was the general bias of the oriental genius. The Egyptians, however, according to the most authentic accounts (g), were the greatest proficients in that science. The original subject of these institutions were, we imagine, the articles we have specified above: but in process of time, according to the natural course of things, numerous improvements were made, and many new rites, ceremonies, usages, and even doctrines, were superinduced, which were utterly unknown to the original hierophants, (h).

(h) Hierophant imports a priest employed in explaining the doctrines, rites, &c. communicated to the initiated.

---

(e) Catechumens were pupils who were learning the elements of any science.

(f) Typhon was the evil genius, or devil, of the Egyptians.

(g) As early as the age of Joseph, the Egyptians were skilled in the interpretations of dreams, divinations, &c. and in the age of Moses they became wise men, magicians, &c.

(h) Hierophant imports a priest employed in explaining the doctrines, rites, &c. communicated to the initiated.
for the most part, one of the distinguishing characters of
a new institution; but succeeding architects generally
imagine that something is still wanting to complete the
beauty, the regularity, the uniformity, the magnifi-
cence, and perhaps the convenience of the structure.
Hence, at length, it seemed to be so overloaded with ad-
ventitious drapery, that its primary elegance and sym-
metry are altogether defaced. This was the case with the
earliest Egyptian mysteries. Their subject was at
first simple and easy to be comprehended; in time it
became complex, intricate, and unintelligible.

In order to celebrate those mysteries with the greater
secrecy, their temples were so constructed as to favour
the artifice of the priests. The fauces, in which they
used to execute their sacred functions, and to perform
the rites and ceremonies of their religion, were sub-
terranean apartments, constructed with such wonder-
ful skill and dexterity, that every thing that appeared
in them breathed an air of solemn secrecy. Their
walls were covered with hieroglyphic paintings and
sculpture, and the altar was situated in the centre of
the apartment. Modern travellers have of late years
discovered some vestiges of them, and bear witness to
the above description of those dark abodes (1). In
those subterranean mansions, which the priests of that
ingenious nation had planned with the most consum-
mate skill, the kings, princes, and great men of the
state, encountered the dangers and hardships continued
to prove their prudence, fortitude, patience, abstinence,
&c. These were appointed to try their merits; and by
these the hierophants were enabled to decide whether or
not they were duly qualified for receiving that benefit.
Upon these occasions we may believe, abundance of
those magical tricks were exhibited, for which the ma-
gicians of Egypt were so much celebrated among the
ancestors. The strange and astonishing sights, the al-
ternate successions of light and darkness, the hideous
spectres exposed to view, the frightful howlings re-
echoed by these infernal domes, the scenes of Tartarus
and Elysium, exhibited alternately and in quick succes-
sion, must have made a deep and lasting impression on
the mind of the affrighted votary (k). These scenes
we shall describe more fully in the sequel.

From the scenes exhibited in celebrating the Egypt-
ian mysteries, especially those of Isis and Osiris, the
Greeks seem to have copied their ideas of the infernal
regions, and the subterraneous mansions of departed
souls. Many colonies of Egyptians settled in Greece.

From these the ãæous (l), or most early bards of
Greece, learned them imperfectly. Of course, we
find Homer's account of the infernal regions, and of
the state of departed souls, lame and incoherent. Suc-
ceeding bards obtained more full and more distinct in-
formation. Euripides and Aristophanes seem to have
paved the way for the prince of Roman poets. Plato (m)
and some of the other philosophers have shown by their
descriptions or allusions, that the whole apparatus of
Tartarus and Elysium had become a highly recondite topic
some centuries before Virgil was born. This incom-
parable poet borrowed his ideas from Homer, Aristo-
phanes, Euripides, Plato, &c. These, under his plas-
tic hand, in the sixth Æneid, grew into a system beau-
tiful, regular, uniform, and consistent. The materials
he has employed were created to his hand; he had
only to collect, polish, arrange, and connect them. —
The sentiments collected from the Platonic philosophy,
and the inimitable episode copied from the annals of
Rome, by the masterly skill which he has displayed in
the application of them, form the chief excellencies of
the piece. For the rest, he could well dispense with
going to Eleusis (n); every old woman in Athens and
Rome could repeat them.

Egypt was then the native land of mysteries as well as of idolatry. Every god and goddess respectively
had their mysteries, but as those of Isis and Osiris
were the most celebrated, they of course became prin-
cipal objects of pursuit as well as of imitation to the
neighbouring nations. These, as is generally believed,
were carried into Persia by Zoroaster, or Zerdusht,
by whom they were consecrated to Mithras. On these
we shall make some observations in the sequel. — Or-
phas imported them into Thrace; Cadmus brought
them into Creon, where they were sacred to Bacchus.
Inachus established them at Argos in honour of Jason,
the same with Isis (n); Cythera in Cyprus, where they
were dedicated to Venus. In Phrygia they were sacred
to Cybele, the mother of the gods.

Our learned readers, who will probably reflect
that the Egyptians were in ancient times inhospitable
to strangers, will perhaps be surprised that this fasti-
dous and jealous people were so ready to communicate
the arcana of their religion to foreigners. — But they
will please recollect, that a great part of Greece was
planted with colonies from Egypt, Phoenicia, Palestine,
&c. This we could easily prove, did the bounds pre-
scribed us admit such a depression. Orpheus, if not an
Egyptian, was at least of oriental extraction. Inachus,
Cadmus, and Melampus, are universally allowed to
have been Egyptians. Excrethius, in whose reign the
Eleusinian mysteries were established, was an Egyptian
by birth, or at least sprung from Egyptian ancestors.
The Egyptians, then, in those early ages, did not view
the Greeks in the light of aliens, but as a people
neatly related either to themselves or the Phoenicians,
who were their brethren. Upon this connexion we
imagine it was, that in later times most of the sages of

(1) See an excellent description of these subterraneous abodes, and of the process ofprobation carried on there,
in a French romance entitled the Life of Sethos.

(k) Persons who had descended into Trophonius's vault were said to have been so terrified with shocking sights,
that they never laughed during the remainder of their lives.

(l) These were strolling poets like our minstrels, who frequented the houses of the great men of Greece, and
entertained the company upon public occasions with singing and tales of other times.

(m) Bishop Warburton has, with much ingenuity, and a vast profusion of reading, endeavoured to prove that
Virgil borrowed the whole scenery of the sixth Æneid from the sources mentioned in the text.

(n) Isis was the moon, and the original Juno was the same planet.
MYSTERIES.

The grand festival of Mithras was celebrated six days in the middle of the month Mehr (s). Upon these days, it was lawful for the kings of Persia to get drunk and dance. On this festival, we imagine, the candidates for initiation, having duly proved their vocation, were solemnly admitted to the participation of the mysteries.

Zoroastres (r) worshipped Mithras, or the Sun, in a certain natural cave, which he formed into a temple, and fitted up in a manner exactly mathematical. There Mithras was represented as presiding over the lower world with all the pomp of royal magnificence. In it too were seen the symbols of Mithras and of the world, philosophically and mathematically exhibited, to be contemplated and worshipped. This deity was sometimes represented as mounted on a bull, which he is breaking, and which he kills with a sword. On some bas reliefs still existing, he appears as a young man with his tiara turned upward, after the manner of the Persian kings. He is clothed with a short tunic and breeches, after the Persian fashion. Sometimes he wears a small cloak. By his sides are seen other human figures, with tiaras of the same fashion on their heads, but without cloaks. One of these figures commonly holds in his one hand a torch lifted up; in the other, one turned downward. Sometimes over the cave are seen the chariots of the sun and moon, and divers constellations, such as cancer, scorpio, etc.

In one of these caves the ceremonies of initiation were performed; but before the candidate could be actually admitted, he was forced to undergo a course of probationary exercises, so numerous and so rigorous, that very few had courage and fortitude enough to go through them. He was obliged to live a life of virtue and abstinence for the space of seven years previous to the period of his initiation. Some months before it, he was obliged to submit to a long and austere fast, which continued fifty days. He was to retire several days to a deep and dark dungeon, where he was successively exposed to all the extremes of heat and cold. Meanwhile he frequently underwent the bastinado, which the priests applied without mercy. Some say this fustigation continued two whole days, and was repeated no less than 15 times. In the course of these probationary exercises, the candidate was generally reduced to a skeleton: and we are told, that there have been several instances of persons who have perished in the attempt.

Upon the eve of the initiation, the aspirant was obliged to brace his armour, in order to encounter

---

(o) Bacchus was the Osiris of the Egyptians, and Ceres was Isis of the same people.
(r) Mosheim, in his note on Cudworth's Intellectual System, p. 332. has taken much pains to prove that Mithras was a deified moarta; but we cannot agree with that learned man in this point.
(q) Isis and Osiris, p. 369. l. 20. from the bottom. This philosopher makes Zoroaster, according to some, 5000 years prior to the Trojan war. This date is certainly extravagant. We cannot, however, agree, with some moderns, who make him contemporary with Dareius Hystaspes, the immediate successor of Cambyses, because it contradicts all antiquity.
(n) M. Sildwette, Dissert. v. p. 17. asserts that Zoroastes was initiated among the Egyptians.
(S) The month Mehr began September 30, and ended October 30.
(r) See Dr. Hyde de Rel. vet. Pers. pages 16, 17. Mr. Bryant's Anot. vol. i. p. 232. Porphyry, de Astr. Nymph. p. 254. This philosopher often mentions the cave of Mithras, and always attributes the institution of his rites to Zoroaster.
Mysteries.

In those spacious subterraneous mansions a mock hunting was exhibited. The priests and all the subordinate officers of the temple, transformed into lions, tygers, leopards, bears, wolves, and other savage creatures, assailed him with loud howlings, roaring, and yelling, and every instance of ferine fury. In those mock combats, the hero was often in danger of being really worried, and always came off with bruises and wounds. Lampadius informs us, that when the emperor Commodus was initiated, he actually carried the joke too far, and butchered one of the priests who attacked him in the figure of a wild beast. The Persians worshipped Mithras or the Sun by a perpetual fire; hence the votary was obliged to undergo a fiery trial; that is, to pass seven times through the sacred fire, and each time to plunge himself into cold water. Some have made these probationary penances amount to 80: others have thought that they were in all only 8. As we find no good authority for either of these numbers, we think ourselves at liberty to hazard the following conjecture: The number seven was deemed sacred over all the east. The Mithriac penances we imagine were either seven, or if they exceeded it, were regulated by seven repetitions of that number. The candidate having undergone all these tortures was then considered as a fit subject for initiation, and was declared a proper subject for initiation. But before his admission he was obliged to bind himself by the most solemn oath, with horrible imprecations annexed, never to divulge any single article of all that he had been made acquainted with in the course of his initiation.

What are called or ineffable secrets were imparted to the initiated, it is impossible at this distance of time to discover with any tolerable degree of certainty. We may, however, rest assured, that the most authentic tradition concerning the origin of the universe; the nature, attributes, perfections, and operations of Oromad; the baleful influences of Armman; and the beneficent effects of the government of Mithras, were unfolded and inculcated. The secret phenomena of nature, as far as they had been discovered by the Magi, were likewise exhibited; and the application of their effects, to astonish and delude the vulgar, were taught both in theory and practice. The exercise of public and private virtues was warmly recommended; and advice represented in the most odious and frightful colours. Both these injunctions were, we may suppose, enforced by a display of the pleasures of Elysium and the pains of Tartarus, as has been observed above in describing the mysteries of the Egyptians.

Those initiations are mentioned by Lampadius in the life of Commodus, and likewise by Justin Ἰ and Tertullian Ἰ, who both flourished in the second century.

The last of these two speaks of a kind of baptism, which washed from the souls of the initiated all the stains which they had contracted during the course of their lives prior to their initiation. He at the same time mentions a particular mark which was imprinted upon them (ἵππος), of an offering of bread, and an emblem of the resurrection; which particulars, however, he does not describe in detail. In that offering, which was accompanied with a certain form of prayer, a vessel of water was offered up with the bread. The same father elsewhere informs us, that there was presented to the initiated a crown suspended on the point of a sword; but that they were taught to say, Mithras is my crown. By this answer was intimated, that they looked upon the service of that deity as their chief honor and ornament.

After that the Telece (ἵππος) were finished, the pupil was brought out of the cave or temple, and with great solemnity proclaimed a lion of Mithras (ἵππος); a title which imported strength and intrepid courage in the service of the deity. They were now consecrated to the god, and were supposed to be under his immediate protection; an idea which of course animates them to the most daring and dangerous enterprises.

The worship of Mithras was introduced into the Roman empire towards the end of the republic, where it made very rapid progress. When Christianity began to make a figure in the empire, the champions for Pan-ganism thought of proposing to men the worship of the power of benevolence, in order to counterbalance or annihilate that worship which the Christians paid to Jesus Christ the true Sun of righteousness. But this mode was soon abolished, together with the other rites of Pan-ganism. The Persian grandees often affected names compounded with Mithras; hence Mithridates, Mithrobarzanes, &c. Hence, too, the precious stone called Mithridat Ἰ, which by the reflection of the sun sparkled with a variety of colours. There is likewise a certain pearl of many different colours, which they call Mithras. It is found among the mountains near the Red sea; and when exposed to the sun, it sparkles with a variety of tye. We find likewise a king of Egypt of that name, who reigned at Heliopolis; who being commanded in a dream to erect an obelisk to the solar deity, reared a most prodigious one in the neighborhood of that city.

The votaries of Mithras pretended that he was sprung from a rock, and that therefore the place where the most mysterious ceremonies were communicated to the initiated was always a cave. Many different reasons have been assigned for the origin of this rock-born deity, most of which appear to us unsatisfactory. If our readers will be obliging enough to accept of a simple and obvious conjecture, they may take the following:

(u) In allusion to this practice of imprinting a sacred mark, probably on the forehead of the initiated, we find the injunction to the angel, Ezek. chap. ix. ver. 4. and The Revelation passim. (x) The mysteries were called Telece, which imports, "the rites which confer perfection." (y) Tertull. adv. Marc. p. 55. The priests of Mithras were called the lions of Mithras, and his priestesses lionesses; some say hyenas. The other inferior ministers were called eagles, hawks, ravens, &c. and on their festivals they wore masks corresponding to their titles, after the Egyptian manner, where the priests appeared at the ceremonies with masks resembling the heads of lions, apes, dogs, &c. a circumstance which furnishes a presumption that the mysteries of Mithras were of Egyptian original.
MYSTERIES.

A rock is the symbol of strength and stability (z); the dominion of Mithras, in the opinion of his votaries, was firm as a rock, and stable as the everlasting hills. If our readers should not admit the probability of this conjecture, we would beg leave to remind them of the learned Mr. Bryant's Analysis of Mythology, where they will find this point discussed with deep research and wonderful ingenuity. Whatever may have been the origin of this opinion with regard to the birth of Mithras, it is certain that some reverence to rocks and caves was kept up a long time even after the establishment of Christianity. Hence the prohibition given to some of the presbyters to that religion, that they should no more presume to offer up their prayers ad petras, at the rocks (A).

We shall conclude our account of the mysteries of Mithras, with a passage from M. Anquetil, to whom we are so much indebted for what knowledge we have of the Persian theology, and in which the functions of that deity are briefly and comprehensively delineated. "The peculiar functions of Mithras are to fight continually against Ahriman and the impure army of evil genii, whose constant employment is to scatter terror and desolation over the universe; to protect the frame of nature from the demons and their productions. For this purpose he is furnished with a thousand ears and a thousand eyes, and traverses the space between heaven and earth: his hands armed with a club or mace. Mithras gives to the earth light and sun: he traces a course for the waters: he gives to men corn, pastures, and children; to the world virtuous kings and warriors; maintains harmony upon earth, watches over the law." &c. As the history of Mithras and the nature of his mysteries, are not generally known, we imagined it would be acceptable to many of our readers to have the most important articles relating to that subject laid before them as it were in detail.

We now proceed to the orgia or mysteries of Bacchus, which we shall introduce with a brief history of that deity. The original Dionysus or Bacchus was the Osiris of the Egyptians, which last was the Sun (B). Whether there was an Egyptian monarch of that name, as Diodorus Siculus affirms, has no manner of connexion with the present disquisition. The Greek name of that deity is plainly oriental, being compounded of di, "bright," and nauta or nasa, in the Æolic dialect nus, a "prince." This name was imported from the east by Orpheus, Cadmus, or by whoever else communicated the worship of Osiris to the Greeks. That the Dionysus of the Greeks was the same with the Osiris of the Egyptians, is universally allowed. Herodotus tells us expressly, that Osiris is Dionysus in the Greek language: Martianus Capella, quoted above, expresses the very same idea. The original Osiris was then the sun; but the Dionysus or Bacchus Vol. XIV. Part II.

of the Greeks was the same with the Osiris of the Egyptians; therefore the Bacchus or Dionysus of the Greeks was likewise the same luminary.

The name Osiris has much embarrassed critics and etymologists. The learned Jablonski, instead of de Pauth. lineating the character, attributes, operations, adventures, exploits, and peculiar department assigned this deity by his votaries, has spent much of his pains on trying to investigate the etymology of his name. If it be granted, which is highly probable, that the Hebrew and Egyptian tongues are cognate dialects, we should imagine that it is actually the Chaldean or Osir of the former language, which imports, "to make rich, to become rich." Indeed the words Osiris and Isis were not the vulgar names of the sun and moon among the Egyptians, but only epithets importing their qualities. The name of the sun among that people was Phér or Phyr, and that of the moon Ioh, whence the Greek Jo. The term Osiris was applied both to the sun and to the river Nile; both which by their influence contributed respectively to enrich and fertilize the land of Egypt.

It was a general custom among the orientals to denominate their princes and great men from their gods, demigods, heroes, &c. When the former were advanced to divine honours, they were in process of time confounded with their archetypes. The original divinities were forgotten, and these upstart deities usurped their place and prerogatives. In the earliest periods of the Egyptian monarchy, there appeared two illustrious personages, Osiris and Isis. These were the children of Cronus; and being brother and sister, they were joined in marriage, according to the custom of the Egyptians. As the brother and husband had assumed the name of the Sun, so the sister and consort took that of Isis, that is, "the woman," a name which, the Egyptians applied both to the moon and to the earth, in consequence of the similarity of their nature, their mutual sympathy, and congenial fecundity. Osiris having left his consort Isis regent of the kingdom, with Hermes as her prime minister, and Hercules as general of her armies, quitted Egypt with a numerous body of troops, attended by companies of fauns (c), satyrs, singing women, musicians, &c. and traversed all Asia to the eastern ocean. He then returned homeward through the Upper Asia, Thrace, Pontus, Asia Minor, Syria, and Palestine. Wherever he marched he conferred numberless benefits on the savage inhabitants. He taught the art of cultivating the ground, preserving the fruits of the earth, and distinguishing the wholesome and nutritive from the unwholesome and poisonous. He instructed them in the culture of the vine; and where vines could not be produced, he communicated to them the method of producing a fermented liquor from barley, very little inferior to wine itself. He built many cities in different

(z) Our Saviour probably alludes to this emblem, when he talks of building his church on a rock; and adds, that the gates of hell should not prevail against it.

(A) The Caledonian druids seem to have regarded certain stones with a superstitious veneration, in which the Catholics imitated them. There are in several places of Scotland large stones, which the vulgar call leere stones, i. e. we imagine, lecture.

(c) Men and women dressed in the habits of those rural deities.
Mysteries.

Parts of the globe, planted numerous colonies (a), and wherever he directed his course instituted just and wholesome laws, and established the rites and ceremonies of religion, and left priests and catechists of his train to teach and inculcate the observance of them. In short, he left everywhere lasting monuments of his progress, and at the same time of his generosity and beneficence. Where he found the people docile and submissive, he treated them with kindness and humanity; if any showed themselves obstinate, he compelled them to submit to his institutions by force of arms.

At the end of three years, he returned to Egypt, where his brother Typhon, a wicked unnatural monster, had been forming a conspiracy against his life.

This traitorous design he soon after accomplished in the following manner: He invited Osiris, with some other persons whom he had gained over, to an entertainment. When the repast was finished, he produced a beautiful cofffer, hastily finished, and adorned with studs of gold; promising to bestow it on the person whom it should fit best. Osiris was tempted to make the experiment. The conspirators nailed down the cover upon him, and threw the coffin into the river. This coffin, which was now become the coffin of Osiris, was, they tell us, wafted by the winds and waves to the neighbourhood of Byblus, a city of Phoenicia, where it was cast on shore, and left by the waves at the foot of a tamarind tree.

In the mean time, disconsolate and forlorn, attended by Anubis, was ransacking every quarter in search of her beloved Osiris. At length being informed by her faithful attendant and guardian, that his body was lodged somewhere in the neighbourhood of Byblus, she repaired to that city. There, they say, she was introduced to the queen, and after (b) a variety of adventures she recovered the corpse of her husband, which, of course, she carried back with her to Egypt: but, her irreligious Typhon, ever on the watch, found her on the banks of the Nile; and having robbed her of her charge, cut the body into 14 parts, and scattered them up and down. Now, once more, according to the fable, Isis set out in quest of those parts, all of which, only one excepted, she found, and interred in the place where she found them; and hence the many tombs of Osiris in that country. These tombs were denominated toposis by the natives. Many other fabulous adventures were ascribed to those two personages, which it is not our province to enumerate at present. If our readers should wish to be more minutely informed on this subject, they may have recourse to the authors mentioned in the last-quoted author, or to the learned Mr. Bryant's Analysis of Ancient Mythology, and M. Coex de Gebelin, where they will find matter enough to gratify their curiosity.

To commemorate those adventures, the mysteries of Isis and Osiris were instituted; and from them both and others, those of Bacchus and Ceres, among the Greeks, were indirectly derived. Of the Egyptian solemnity, we have an exact epitome in one of the fathers of the church, to the following purpose: "Here follows (says he) an epitome of the mysteries of Isis and Osiris. They deplore annually, with deep lamentations and shaved heads, the catastrophe of Osiris over a buried statue of that monarch. They beat their breasts, mangle their arms, tear open the scars of their former wounds; that by annual lamentations the catastrophe of his miserable and fatal death may be revived in their minds. When they have practised these things a certain number of days, then they pretend that they have found the remains of his mangled body; and having found them, their sorrows are lulled asleep, and they break out into immoderate joy." What maxims of morality, secrets of physiognomy, or phenomena of astronomy, were couched under this allegorical process, is not our business to investigate in this place. We shall only observe, that, in all probability, Isis and Osiris were sovereigns of Egypt at a very early period; that they had conferred many signal benefits on their subjects, who, influenced by a sense of gratitude, paid them divine honours after their decease; that in process of time they were confounded with the sun and the moon; and that their adventures were at length magnified beyond all credibility, interlarded with fables and allegories, and employed in the mysteries as channels to convey a variety of instructions to the initiated.

Be that as it may, it is certain that the very same mode of worship was established at Byblus, and in after ages transferred to Tyre. The Mizrahim and Channaimit were nearly connected by blood, and their religious ceremonies were derived from the same source. By what medium the worship of Osiris, Abydus, and Tyre was connected, we shall leave to others to explain; we shall only observe, that among the Phoenicians this deity obtained the names Adonis and Bacchus. The former is rather an (f) epithet than a name: the latter is evidently an allusion to the weeping and lamentation (g) with which the rites were performed. We find another name of that divinity mentioned in Scripture (h); but that term is plainly of Egyptian original: we shall now proceed to the mysteries of Osiris as they were celebrated among the Greeks and Thracians, under the name of the Oryza of Dionysus or Bacchus.

Orpheus, the celebrated Thracian philosopher, had travelled into Egypt in quest of knowledge; and from that

---

(a) Many have thought this expedition fabulous; but the numberless monuments of Egyptian architecture, sculpture, and statuary, lately discovered in the east, confirm it.

(b) For the conquests and adventures of Osiris and Isis, we must send our learned readers to Diod. Sic. Bibl. i. and Plut. Isis et Osiris, p. 236, et seq. which we have been obliged to abridge, in consequence of the narrow limits prescribed us.

(f) Adonis is evidently the Hebrew Adoni, "my lord," and imports the sovereignty of the deity.

(g) Bacchus is derived from the Phoenician word bahah, "to weep." This was the name embraced by the Romans.

(h) Ezek. chap. viii. ver. 14. Tammuz is the name of one of the months of the Egyptian year.
MYSTERIES.

that country, according to the most authentic accounts, he imported the Bacchanalian rites and institutions. Some have affirmed that this same Orpheus being intimately acquainted with the family of Cadmus, communicated those rites to them, and endeavoured to transfer them to the grandson of that hero, which grandson became afterwards the Grecian Bacchus. It is, however, we think much more probable, that those rites were imported from Egypt or Phoenicia, by (1) Cadmus himself, who was a native of the former country, and is thought to have spent some time in the latter, before he emigrated in quest of a settlement in Boeotia. It is said that Semele, the daughter of Cadmus, and the mother of the Grecian Bacchus, was struck with lightning at the very instant of his birth. The child was, in all probability, denominated Bacchus (κ), from the sorrow and lamentation this melancholy accident had occasioned in the family. Cadmus, in order to conceal the dishonour of his daughter, might, we imagine, convey away his infant grandson to some of his relations in Phoenicia or Egypt. There he was educated and instructed in all the mysteries of Isis and Osiris, and at the same time initiated in all the magical or juggling tricks of the Egyptian priests and hierophants. Thus accomplished, when he arrived at manhood, he returned to Thebes with the traditional retinue of the original deity of the same name; and claimed divine honours accordingly. This claim, however, was not admitted without much opposition; Pentheus, another grandson of Cadmus, was torn to pieces by the frantic Bacchanalians upon Mount Citheron, because he attempted to interrupt them in celebrating the orgies. Some have thought that Cadmus lost his kingdom for the same reason; but this we think is by no means probable: we should rather imagine that the old prince was privy to the whole process, and that it was originally planned by him, with a view to attract the veneration of his new subjects, by making them believe that there was a divinity in his family.

Be that as it may, the vain-glorious Greeks attributed all the actions of the Egyptian hero to their new Bacchus; and according to their laudable practice, engaged him in numberless adventures in which his prototype had no share. Most of those are beautiful and uninteresting. The Greeks commonly adopted some oriental personage as the hero of their mythological rhapsodies. Him they naturalized and adopted into some Grecian family, and so he became their own. To him they ascribed all the adventures and exploits of the oriental archetype from whom he was copied. Consequently in the orgia (ἢ), every thing was collected that had been imported from the east relating to Osiris, and to that farrago was joined all that the Grecian rhapsodists had thought fit to invent, in order to amuse the credulous multitude. This, however, was not the whole of the misfortune: The adventures of Osiris were described by the Egyptian hierophants, veiled with allegorical and hieroglyphical mysteries. These the persons who imported them into Greece did not thoroughly comprehend; or, if they did, they were not inclined to communicate them sound and unsofisticated. Besides, many oriental terms were retained, the import of which was in process of time lost or distorted. Hence the religious ceremonies of the Greeks became a medley of inconsistencies. The mysteries of Bacchus, in particular, were deeply tintured with this meretricious colouring; the adventures of the Theban pretender were grafted upon those of the Egyptian archetype, and out of this combination was formed a tissue of adventures disgraceful to human nature, absurd, and inconsistent. Indeed the younger or Theban Bacchus seems to have been a monster of debauchery; whereas the Egyptian is represented as a person of an opposite character. Of course the mysteries of the former were attended with the most shocking abominations.

These mysteries, as has been observed above, were Mysteries first celebrated at Thebes the capital of Boeotia, under the auspices of the family of Cadmus. From this country they gradually found their way into Greece, and all the neighbouring parts of Europe. They were celebrated once every three years (ἕκταρ), because at the end of three years Osiris returned from his Indian expedition. As the Greeks had impudently transferred the actions of the Egyptian hero to their upstart divinity, the same period of time was observed for the celebration of those rites in Greece that had been ordained for the same purpose in Egypt.

When the day appointed for the celebration of the Process of orgia (ὦ) approached, the priests issued a proclamation of their celebration, enjoining all the initiated to equip themselves according to the ritual, and attend the procession on the
the day appointed. The votaries were to dress themselves in coats of deer-skins, to loose the fillets of their hair, to cover their legs with the same stuff with their coats, and to arm themselves with thyrsi, which were a kind of spears wholly of wood entwined with leaves and twigs of the vine or ivy. It is said that the Bacchanalesians, especially the Thracians, used often to quarrel and commit murder in their drunken revels; and that in order to prevent those unlucky accidents, a law was enacted, that the votaries, instead of real spears, should arm themselves with those sham weapons which were comparatively inoffensive. The statue of the deity, which was always covered with vine or ivy leaves, was now taken down from its pedestal, and elevated on the shoulders of the priests. The cavalcade then proceeded nearly in the following manner:

First of all, hymns were chanted in honour of Bacchus, who was called the Power of dances, smiles, and jests; while at the same time he was deemed equally qualified for the exploits of war and heroism. Horace, in some of his dithyrambic odes, has concisely pointed out the subjects of those Bacchanalesian songs. In the collection of hymns fabulously attributed to Orpheus, we find several addressed to this deity (r), each under a different title, derived from the different appellations of the god. All these names are of oriental original, and might easily be explained, did the bounds prescribed us admit of etymological disquisitions.

The hymns being finished, the first division of the votaries proceeded, carrying a pitcher of wine, with a bunch of the vine. Then followed the he-goat; an animal odious to Bacchus, because he ravages the vines. The chanting the hymns, the sacrificing the he-goat, and the revels, games, and diversions, with which the celebration of those rites was attended, gave birth to the dramatic poetry of the Greeks; as the persons inhabited in the dress of Fauns, Sylvia, and Satyrs (a), furnished the name of another species of poetry of a coarser, and more forbidding aspect.

Then appeared the mysterious casket or basket, containing the secret symbols of the deity. These were the phallicus (a), some grains of sesame, heads of poppies, pomegranates, dry stones, cakes baked of the meal of different kinds of corn, salt, carded wool, rolls of honey, and cheese; a child, a serpent (s), and a van (r). Such was the furniture of the sacred casket carried in the solemn Bacchanalesian procession. The inventory given by some of the fathers of the church is somewhat different. They mention the dye, the ball, the top, the wheel, the apples, the looking-glass, and the fleece. The articles first mentioned seem to have been Egyptian original; the last were certainly superinduced by the Greeks, in allusion to his being murdered and torn in pieces when he was a child by the machinations of Juno, who prevailed with the Titans to commit the horrid deed. Those last seem to have been memorials of his boyish playthings; for, says Materinus, "the Cretans acted every thing that the dying boy either said, or did, or suffered. They likewise (says he) tore a live ball in pieces with their teeth, in order to commemorate the dismembering of the boy." For our part, we think, that if such a beastly rite was practised, it was done in commemoration of the savage manner of life which had prevailed among men prior to the more humane diet invented and introduced by Isis and Osiris. Be that as it may, we learn from Porphyry (s), in the island of Cyprus, that they used to sacrifice a man to Bacchus, and that they used to mangle and tear him limb from limb. This was no doubt practised in commemoration of the catastrophe mentioned above.

The orgia of this Pagan god were originally simple enough; but this unsophisticated mode was of no long continuance, for riches soon introduced luxury, which quickly infected even the ceremonies of religion. On the day set apart for this solemnity, men and women crowned with ivy, their hair dishevelled, and their bodies almost naked, ran about the streets, roaring aloud. In this rout were to be seen people intoxicated at once with wine and enthusiasm, dressed like Satyrs, Fauns, and Sileni, in such scandalous postures and attitudes, with so little regard to modesty and even common decency, that we are persuaded our readers will readily enough forgive our omitting to describe them. Next followed a company mounted upon asses, attended by Fauns, Bacchanales, Thyades, Mimas, and the rest, who made the adjacent places echo to their frantic shrieks and howlings. Aften this tumultuous herd were carried the statues of Victory.

(r) These stand between the 42 and 52; one to Libnites, or the presser; one to Libnites, or the winnower; one to Beataereus, or the vintage; one to Caractaeus, or the god of rest; to Rhes, or the Mediator, &c.

(a) Dacier, Casaubon, and other French critics, have puzzled and perplexed themselves to little purpose about the origin of this word, without considering that it was coeval to dramatic poetry.

(r) The phallicus was highly respected by the Egyptians, and was used as the emblem of the fecundity of the human race.

(s) That reptile was in high veneration among the Egyptians. See Euseb. Prep. Evang. lib. i. page 25. Steph., where we have a minute detail of the symbolical properties of that creature, according to Taieus, the great legislator of that people.

(u) Servius in Georg. i, Virg. ver. 166. "Mystica vasa Ioachi. The van, says he, is an emblem of that purifying influence of the mysteries, by which the initiated were cleansed from all their former pollutions, and qualified for commencing a holy course of life.

(u) Clem. Alex. Coh. page 11. Pott. derives this word from Chau, the mother of mankind, who, first opened the gate to that and every other error; but we are rather inclined to believe that it comes from the oriental word Het, which signifies a "serpent," which among the Egyptians was sacred to the sun, and was likewise the emblem of life and immortality. It then imparted a prayer to Bacchus for life, vigour, health, and every other blessing.
Mysteries.

Victory and altars in form of vine-sets, crowned with ivy, smoking with incense and other aromatics. Then appeared several chariots loaded with thyrsi, arms, garlands, corks, pitchers, and other vases, tripods, and vases. The chariots were followed by young virgins of quality, who carried the baskets and little boxes, which in general contained the mysterious articles above enumerated. These, from their office, were called cistophores. The phallophori (x) followed them, with a chorus of iophonohoroi habitating like Fauns, counterfeiting drunk persons, singing in honour of Bacchus songs and catching suits to the occasion. The procession was closed by a troop of Bacchanales crowned with ivy, interwoven with branches of yew and with serpents*. Upon some occasions, at those scandalous festivals, naked women whipped themselves, and tore their skin in a most barbarous manner. The procession terminated on Mount Citharon, when it set out from Thebes; and in other places, in some distant frequented desert, where the votaries practised every species of debauchery with secrecy and impunity. Orpheus saw the degeneracy of these ceremonies; and in endeavouring to reform them he probably lost his life. Pentheus suffered in the like attempt, being torn in pieces by the Bacchanales on Mount Citharon, a merchant among whose principal and eldest members. The Greeks, who were an airy jovial people, seem to have paid little regard to the plaintive part of the orgia; or rather, we believe, they acted with bowing and frantic exclamations, often enhanced by a combination of drunkenness, ecstasy, and enthusiastic fury.

What secrets, religious, moral, political, or physical, were communicated to the votaries, it is impossible to determine with any degree of certainty.

One thing we may admit, namely, that the doctrines discovered and inculcated in the orgia, were originally the same which the apostles of the sect had imbibed in Egypt and Phenicia; and of which we have given a brief account near the beginning of this article. It is, however, probable, that the spurious or Theban Bacchus had superadded a great deal of his own invention, which we may believe, was not altogether so sound and salutary as the original doctrine. However that may be, we shall believe that they were to derive wonderful advantages from the participation of those rites, both in this life and that which is to come. Of this, however, we shall talk more at length by and by, in our account of the Eleusinian mysteries.

To detail the etymology of the names of this Pagan deity, the fables relating to his birth, his education, his transformations, his wars, peregrinations, adventures, the various and multifarious rites with which he was worshipped, would swell this article to a most immoderate size. If any of our readers should wish to be more minutely and more accurately acquainted with this subject, we must beg leave to refer them to Diod. Sic. Apollod. Bibl. Euripid. Bacchae, Aristophanis Rhet., Nonn. Dionys.; and among the moderns, to Ban. Mythol. Voss. de Orig. Idol. Mont. Fourmont, Reflets sur l'origine des anciens peuples, Mr Bryant's Analys. and especially to Mons. Cour de Gébelin, Calendries ou Almanach. That prince of etymologists, in his account of the festival of Bacchus, has given a most acute and ingenious explication of the names and epithets of that deity. For our part, we have endeavoured to collect and exhibit such as we judged most important, most entertaining, and most instructive, to the less enlightened classes of our readers.

We now proceed to the Eleusinian mysteries, which, among the ancient Greeks and Romans, were treated with a superior degree of awe and veneration. These were instituted in honour of Ceres; who, according to the most authentic accounts, was the Isis of the Egyptians. The mysteries of Osiris and Isis have been hinted at in the preceding part of this article. They were originally instituted in honour of the sun and moon, and afterwards consecrated to an Egyptian prince and princess; who, in consequence of their merits, had been deified by that people. We know of no more exact and brilliant description of the ceremonies of that goddess, in the most polished ages of the Egyptian superstitious, than what we meet with in the witty and florid Apuleius, to which we must take the liberty to refer our more curious readers. Our business at present shall be to try to investigate by what means, and upon what occasion, those mysteries were introduced into Attica, and established at Eleusis. A passage from Diodorus Siculus, which we shall here translate, will, we think, throw no considerable light on that abstruse part of the subject.

"In like manner with him (Cecrops), says that judicious historian, they tell us, that Erechtheus, a prince of Egyptian extraction, once reigned at Athens. Of this fact they produce the following evidence: A scourging drought, during the reign of this prince, prevailed over almost all the habitable world, except Egypt; which, in consequence of the humidity of its soil, was not affected by that calamity. The fruits of the earth were burned up; and at the same time multitudes of people perished by famine. Erechtheus, upon this occasion, as he was connected with Egypt, imported a vast quantity of grain from that country to Athens. The people, who had been relieved by his munificence, unanimously elected him king. Being invested with the government, he taught his subjects the mysteries of Ceres at Eleusis, and the mode of celebrating the sacred ceremonies, having transferred from Egypt the ritual for that purpose. In those times the goddess is said to have made her appearance at Athens three several times; because, according to tradition, the fruits of the earth, which bear her name were then imported into Attica. On this account the seeds and fruits of the earth were said to be the invention of that deity. Now the Athenians themselves acknowledge, that, in the reign of Erechtheus, the fruits of the earth having perished for want of rain, the arrival of Ceres in their country did actually happen, and that along with her the blessing of corn.

(x) The phallos was the symbol of the fructifying power of Nature. The itophallus was the type of that power in act.
Mysteries.

Corn was restored to the earth. They tell us at the same time, that the teute and the mysteries of that goddess were then received and instituted at Eleusis."

Here then we have the whole mystery of the arrival of Ceres in Attica, and the institution of her mysteries at Eleusis, unveiled. The whole is evidently an oriental allegory. The fruits of the earth had been destroyed by a long course of drought; Egypt, by its peculiar situation, had been preserved from that dreadful calamity. Erechtheus, in consequence of his relation to the Egyptians, imported from their country a quantity of grain, not only sufficient for the consumption of his own subjects, but also a great superfluous to export to other parts of Greece, Sicily, Italy, Spain, &c. Triptolemus, another Egyptian, was appointed by Erechtheus to export this superfluous store. That hero, according to Phercydes, was the son of Oceanus and Tellus, that is, of the sea and the earth; because his parents were not known, and because he came to Eleusis by sea. The ship in which he sailed, when he distributed his corn to the western parts of the world, was decorated with the figure of a winged dragon: therefore, in the allegorical style of his country, he was said to be wafted through the air in a chariot drawn by dragons. Those creatures, everybody knows, were held sacred by the Egyptians.

Wherever Triptolemus disposed of his corn, thither were extended the wanderings of Ceres. In order to elucidate this point, we must observe, that along with the grain imported from Egypt, Erechtheus, or Triptolemus, or both, transported into Attica a cargo of priests and priestesses from the temples of Busiris, a city which lay in the centre of the Delta, where the goddess Isis had a number of chapels erected for her worship. The presidents of these ceremonies, like all other bigots, gladly laid hold on this opportunity of propagating their religious rites, and disseminating the worship of the deities of their country. That the Egyptian priests were zealous in propagating the dogmas of their superstition, is abundantly evident from the extensive spreading of their rites and ceremonies over almost all Asia and considerable part of Europe. The Greek and Roman idolatry is known to have originated from them; and numberless monuments of their impious worship are still extant in Persia, India, Japan, Tartary, &c.

Our inference then is, that the worship of Isis was introduced into every country where Triptolemus sold or disposed of his commodities. Hence the wanderings of Ceres in search of her daughter Proserpine who is generally called Core. The famine occasioned by the drought destroying the fruit of the ground, imports the loss of Proserpine. The restoration of the corn in various parts of the earth, by fresh supplies from Egypt from time to time, imports the wanderings of Ceres in quest of Proserpine. The whole process is an oriental allegory. The disappearing of the fruits of the earth, by which Proserpine, or Persephone, or Persephone (α), is the emblem, in Hesiod, the allegorical rape of that goddess. She was seized and carried off by Pluto, sovereign of the infernal regions. The seed committed to the earth in that dry season appeared no more, and was, consequently, said to dwell under ground with Pluto. It was then that Ceres, that is, corn imported from Egypt, set out in quest of her daughter. Again, when the earth recovered her pristine fertility, the Core, or maid, was found by her mother Ceres, that is, the earth; for Isis, among the Egyptians, frequently signified the earth. The wanderings of Isis in search of Osiris furnished the model for the peregrinations of Ceres.

Ceres, the Roman name of the goddess of corn, was unknown to the modern Greeks. They always denominated her Damater (ζ), which is rather an epithet than a proper name. The Greeks, who always affected to pass for originals, we think, suppressed the Egyptian name on purpose, to conceal the country of that deity. As a proof of the probability of this conjecture, it may be observed, that they metamorphosed the wanderings of Isis in search of Osiris into the peregrinations of Ceres in quest of Proserpine. The Romans, who were less ambitious of the character of originality, retained one of her oriental names (Α.) Ceres, says Diodorus, appeared thrice in Attica during the reign of Erechtheus; which seems to import, that fleets laden with corn had thrice arrived in that country from Egypt during that period.

Cecrops, the first king of Attica, had established the worship of the Saitic Athena or Minerva in that region, and consecrated his capital to that deity. Erechtheus, in his turn, introduced the worship of Isis, or Damater, who in all appearance was the tutelar deity of Busiris his native city. The subjects of Cecrops were a colony of Siets, and readily embraced the worship of Minerva; but the aborigines of that district being accustomed to a maritime, perhaps to a piratical course of life, were more inclined to consecrate their city to Neptune, the god of the sea, and to constitute him their guardian and protector. Cecrops by a stratagem secured the preference to Minerva his favourite divinity; Erechtheus, in order to give equal importance to his patroness.
Mysteries.

When this company of propagandists arrived at Eleusis, they were entertained by some of the most respectable persons who then inhabited that district. Their names, according to Clem. Alexand., were Banbo, Dysaulis, Tripolius, Eumolpus, and Eubulus. From Eumolpus were descended a race of priests called Eumolpidae, who figured at Athens many ages after. Tripolius was an ox herder, Eumolpus a shepherd, and Eubulus a swine herd. These were the first apostles of the Eleusinian mysteries. They were instructed by the Egyptian missionaries; and they, in their turn, instructed their successors. Erechtheus, or, as some say, Pandion, countenanced the seminary, and built a small temple for its accommodation in Eleusis, a city of Attica, a few miles west from Athens, and originally one of the twelve districts into which that territory was divided. Here then we have arrived at the scene of those renowned mysteries, which for the space of near 2000 years were the pride of Athens and the wonder of the world.

The mysteries were divided into the greater and lesser Eleusinian. The latter were celebrated at Agrae, a small town on the river Ilissus: the former were celebrated in the third month which the Athenians called Boedromion (cc); the latter in the month Anthesterion (DD). The lesser mysteries, according to the fabulous legends of the Greeks, were instituted in favor of the celebrated Hercules. That hero being commanded by Euystheus to bring up Cerberus from the infernal regions, was disposed of being initiated in the Eleusinian mysteries before he engaged in that perilous undertaking. He addressed himself to Eumolpus the hierophant for that purpose. There was a law among the Eleusinians prohibiting the initiation of foreigners. The priest not daring to refuse the benefit to Hercules, who was both a friend and benefactor to the Athenians, advised the hero to get himself adopted by a native of the place, and so to elude the force of the law. He was accordingly adopted by one Pyolus, and so was initiated in the lesser mysteries, which were instituted for the first time upon that occasion. This account has all the air of a fable. The lesser mysteries were instituted by way of preparation for the greater.

The person who was to be initiated in the lesser mysteries, as well as in the greater, was obliged to and rite to practise the virtue of chastity a considerable time previous to his admission. Besides, he was to bind himself by the most solemn vows not to divulge any part of the mysteries. At the same time, he was, according to the original institution, to be a person of unblemished moral character. These were preliminaries indispensably necessary in order to his admission. A bull was sacrificed to Jupiter, and the hide of that animal, called by a peculiar name (δόξα καλος) was carefully preserved and carried to Eleusis, where it was spread under the feet of the initiated. The candidate was then purified by bathing in the river Ilissus, by aspersions with salt water or salt, with laurel, barley, and passing through

(bb) Apollod. Bib. ubi supra. Clem. Alexand. Cohort. page 17, where the story is told with very little reserve.

(cc) The third month of the Athenian year, answering to our September.

(dd) The eighth month, answering to our February, but Murenius makes it November.
MYSTERIES.

through the fire; all which rites were attended with incantations and other usages equally insignificant and ridiculous. Last of all, a young sow was sacrificed to Ceres; and this animal, according to the ritual, beloved to be with pigs; and before it was killed it was to be washed in Calanthus, one of the three harbours which formed the Piræus.

All these ceremonies duly performed, the candidate was carried into the hall appointed for the purpose of initiation. There he was taught the first elements of those arcanæ which were afterwards to be more fully and more clearly revealed in the more august mysteries of Eleusis. The pupils of Aigæus were called Mystes, which may intimate probationers; whereas those of Eleusis were denominated Epoptæ, importing that they saw as they were seen.

The lesser mysteries were divided into several stages, and candidates were admitted to them according to their quality and capacity respectively. Those who were initiated in the lowest were obliged to wait five years before they were admitted to the greater. Those who had partaken of the second kind underwent a noviciate of three years; those who had been admitted to the third, one of two years; and those who had gone through the fourth were admitted to the greater at the end of one year; which was the shortest period of probation a candidate for that honour could legally undergo. Such was the process generally observed in administering the lesser mysteries.

With respect to the greater mysteries, it is probable that originally none but the natives of Attica were admitted to partake of them. In process of time, however, the pale was extended so far and wide as to comprehend all who spoke the Greek language. All foreigners were debarred from those sacred rites. They tell us, however, that Hercules, Bacchus, Castor and Pollux, Ἀθηναίοι, and Hippocrates, were initiated in an extraordinary manner, from a regard to their high character and heroic exploits. All barbarians, too, were excluded; yet Anacharsis the Scythian was indulged that privilege, in consequence of his reputation for science and philosophy. All persons guilty of manslaughter, though even accidentally or involuntarily, all magicians, enchanters; in a word, all impious and profane persons, were expressly prohibited the benefit of this Pagan sacrament. At last, however, the gate became wider, and crowds of people, of all nations, kinds, and languages, provided their character was fair and irreproachable, rushed in by it. In process of time the Athenians initiated even their infants; but this, we imagine, must have been a kind of lustration or purification, from which it was supposed that they derived a kind of moral ablation from vice, and were thought to be under the peculiar protection of the goddess.

The celebration of the mysteries began on the 13th day of the month Boedromion; and, according to most ancient authors, lasted nine days. Muretus has enumerated the transactions of each day, which are much too numerous to fall within the compass of this article; we must therefore refer our curious reader to the author just mentioned. Some days before the commencement of the festival, the praepones, or public seers, invited all the initiated, and all the pretenders to that honour, to attend the festival, with clean hands and a pure heart, and the knowledge of the Greek language.

The chief minister of these far-famed mysteries was the hierophant. He was styled King, and enjoyed that dignity during life, and was always by both an Athenian. He presided in the solemnity, as is evident from his title. This personage, as we learn from Eusebius, represented the Demiurgus, or Creator of the world. "Now in the mysteries of Eleusis (says that father) the hierophant is dressed out in the figure of the demiurgus." What this demiurgus was, we learn from the same writer. As this whole institution was copied from the Egyptians, we may rest assured that the figure of the Eleusinian Demiurgus was borrowed from the same quarter. "As for the symbols of the Egyptians (says he, quoting from Porphyr 1), they are of the following complexion. The Demiurgus, whom the Egyptians call Καμηλ, is figure..."
Mysteries.

as a man of an azure colour, shaded with black, holding in his right hand a sceptre and in his left a girdle, and having on his head a royal wing or feather wreathed round. Such, we imagine, was the equipment of the Eleusinian hierophant. This person was likewise styled Prophet. He was to be of the family of the Eumolpidæ; was obliged to make a vow of perpetual chastity; and even his voice, hair, and attitude, were adjusted to the ritual.

The next minister was the dux ducis, or torch-bearer; who, according to the father above quoted, was attired like the sun. This minister resembled the sun, because that luminary was deemed the visible type of the supreme Demiurgus, and his vicegerent in governing and arranging the affairs of this lower world.

The third was the person who officiated at the altar. He was habited like the moon. His office was to explore the favours of the gods for all the initiated. We should rather imagine, that the person at the altar, as he resembled the moon, was intended to represent the goddess herself: for the Egyptian Isis, who was the archetype of Ceres, was sometimes the moon sometimes the earth.

The sacred herald was another principal actor in this solemn exhibition. His province was to recite anything, that, according to the ritual, was to be communicated to the novices; and he probably represented Thoth or Thoth, that is Hermes or Mercury, the interpreter of the gods.

Besides these, there were five epimeleis or curators, of whom the king was one, who jointly directed the whole ceremonial. Lastly, there were ten priests to offer the sacrifices. There were no doubt many officers of inferior note employed upon these occasions; but these were only significant appendages whose departments have not been transmitted to posterity.

After this detail of the ministers of this solemn service, we return to the mystæ, or candidates for initiation. Some of the fathers of the church mention a hymn composed by the celebrated Orpheus, which was sung by the mystagogue or king upon that occasion. This hymn appears to us one of those spacious compositions which abounded in the first ages of Christianity, and which the pious apologists often adopted without sufficient examination. That same sacred hymn was chanted upon that occasion, we think highly probable; but that the one in question was either composed by Orpheus, or used at the opening of these ceremonies, to us appears somewhat problematical.

Before the ceremony opened, a book was produced, which contained every thing relating to the telea. This was read over in the ears of the mystæ; who were ordered to write out a copy of it for themselves. This was burnt in a sacred repository, formed by two stones exactly fitted to each other, and of a very large size. This repository was called petromia. At the annual celebration of the greater mysteries, these stones were taken asunder, and the book taken out; which, after being read to the mystæ, was replaced in the same casemate.

The initiations began with a representation of the wanderings of Ceres, and her bitter and loud lamentations for the loss of her beloved daughter. Upon this occasion, no doubt, a figure of that deity was displayed to the mystæ, while loud lamentations echoed from every corner of the sanctuary. One of the company having kindled a firebrand at the altar, and sprung to a certain place in the temple, waving the torch with the utmost fury, a second snatched it from him, roaring and waving it in the same frantic manner; and a third, fourth, &c. in the most rapid succession. This was done to imitate Ceres, who was said to have perambulated the globe of the earth with a flaming pine in her hand, which she had lighted at Mount Etna.

When the pageant of the goddess was supposed to arrive at Eleusis, a solemn pause ensued, and a few put to the trifling questions were put to the mystæ: What these questions were, is evident from the answers. "I have fasted; I have drunk the liquor; I have taken the contents out of the coffers; and having performed the ceremony, have put them into the hamper: I have taken them out of the hamper, and put them again in the coffers." The meaning of these answers, we conjecture, was this: "I have fasted, as Ceres fasted while in search of her daughter; I have drunk of the worts as she drank when given her by Bacchus; I have performed what Ceres taught her first disciples to perform, when she committed them to the sacred hamper and coffers." After these interrogatories, and the suitable responses, the mundus Ceres was displayed before the eyes of the mystæ, and the mystagogue or hierophant, or perhaps the sacred herald by his command, read a lecture on the allegorical import of those sacred symbols. This was heard with the most profound attention; and a solemn silence prevailed throughout the fane. Such was the first act of this religious farce, which perhaps consisted originally of nothing more.

After the exposition of the mundus Ceres, and the traditions respecting her wanderings, many traditions were communicated to the mystæ concerning the origin of the universe and the nature of things. The doctrines del. of the universe in the greater mysteries, says Clem. Alex. "sive unde hominum genus, et pecudes, unde timber et ignes.

Universe.

What system of cosmogony those hierophants adopted, is evident from the passage above quoted from Eusebius; and from the account immediately preceding, it was that of the most ancient Egyptians, and of the orientals in general. This cosmogony is beautifully and energetically exhibited in Plato's Timeus, and in the genuine spirit of poetry by Ovid in the beginning of his Metamorphoses.

The next scene exhibited upon the stage, on this solemn occasion, consisted of the exploits and adventures of the gods, of the gods, demigods, and heroes, who had from time...
MYSTERIES.

to time, being advanced to divine honours. These
were displayed as passing before the mystae in pageants
fabricated for that important purpose. This was
the original mode among the Egyptians, and no doubt
followed by their Eleusinian pupils. These adventures
were probably demonstrated to have been allegorical,
symbolical, hieroglyphical, &c. At least they were exhib-
ted in such a favourable point of view as to dispel
those absurdities and inconsistencies with which they
were sophisticated by the poets and the vulgar.

With respect to the origin of those factitious deities,
it was discovered that they had been originally men
who had been exalted to the rank of divinity, in con-
sequence of their heroic exploits, their useful inventions,
their beneficent actions, &c. This is so clear from the
two passages quoted from Cicero, by Bishop Warbur-
ton†, that the fact cannot be contradicted. But
that prelate has not informed us so precisely, whether the
mystagogues represented them as nothing more than
dead men, in their present state, or as beings who were
actually existing in a defied state, and executing the
functions assigned them in the rubric of Paganism. An-
other query naturally occurs; that is, to what purpose
did the mystagogues apply this communication? That
the hierophants did actually represent those defied mor-
tals in the latter predicament, is obvious from another
passage quoted from Cicero by the same prelate, which
we shall transcribe as translated by him: "What
think you of those who assert that valiant, or famous,
or powerful men, have obtained divine honours after
death; and that these are the very gods now become
the objects of our worship, our prayers, and adoration?
Euhemerus tells us, when these gods died, and where
they lie buried. I forbear to speak of the sacred and
august rites of Eleusis. I pass by Samothrace and the
mysteries of Lemnos, whose hidden rites are celebrated
in darkness, and amidst the thick shades of groves and
forests." If, then, those defied mortals were become
the objects of worship and prayers, there can be no
doctrine of the belief of their defied existence. The allu-
sions to the Eleusinian and other Pagan mysteries to-
wards the close of the quotation, places the question
beyond the reach of controversy. But though, accord-
ing to this account, "there were gods many and lords
many;" yet it is evident from the passage quoted from
Eusebius, in the preceding part of this article, that the
unity of the Supreme Being was maintained, exhibited,
and inculcated. This was the original doctrine of the
hierophants of Egypt: It was maintained by Thales
and all the retainers of the Ionian school. It was the
doctrine of Pythagoras, who probably gleaned it up in
the country just mentioned, in connexion with many
other dogmas which he had the assurance to claim as
his own.

But however the unity, and perhaps some of the most
obvious attributes, of the Supreme Author of nature,
might be illustrated and inculcated, the tribute of ho-
mage and veneration due to the subordinate deities
was by no means neglected. The initiated were taught
to look to the litus mystagogum gentium with a superior de-
gree of awe and veneration, as beings endowed with an
infallible measure of power, wisdom, purity, goodness,
&c. These were, if we may use the expression, the
prime favourites of the Monarch of the universe, who
were admitted into his immediate presence, and who
received his bequests from his own mouth, and com-
municated them to his subordinate officers, prefects, lie-
tenants, &c. These they were exhort to adore; in
them they were to offer sacrifices, prayers, and every
other act of devotion, both on account of the excellence
of their nature and the high rank they bore at the
court of heaven. They were instructed to look up to
hero gods and demigods, as being exalted to the high
rank of governors of different parts of nature, as the
immediate guardians and protectors of the human race;
in short, as gods near at hand, as prompters to a virtu-
ous course, and assistants in it; as ready upon all occa-
sions to confer blessings upon the virtuous and deserving.
Such were the doctrines taught in the teutec with re-
spect to the nature of the Pagan deities, and the
worship and devotion enjoined to be offered them by the
mysteries.

As the two principal ends proposed by these initi-
ation were the exercise of heroic virtues in men
and the practice of sincere and uniform piety by the
candidates for immortal happiness, the hierophants
had adopted a plan of operations excellently accom-
modated to both these purposes. The virtuous con-
duct and heroic exploits of the great men and de-
gods of early antiquity, were magnified by the most
pompous eulogiums, enforced with suitable exhorta-
tions to animate the votaries to imitate so noble and
alluring an example. But this was not all: the he-
roes and demigods themselves were displayed in
grants, or vehicles of celestial light. Their honour,
offices, habitations, attendants, and other appendages,
in the capacity of demons, were exhibited with all
the pomp and splendour that the sacerdotal college were
able to advise. The sudden glare of mimick light, the
melting music stealing upon the ear, the artificial
thunders reverberated from the roof and walls of the
temple, the appearance of fire and ethereal radiance,
the vehicles of flame, the effigies of heroes and de-
mons adorned with crowns of laurel emitting rays
from every sprig, the fragrant odours and aromatic
pales which breathed from every quarter, all destruc-
tiously counterfeited by sacerdotal mechanism, must
have filled the imagination of the astonished votaries
with pictures at once tremendous and transporting.
Add to this, that every thing was transacted in the
deaf of night amidst a dismal gloom; whence the
most bright effulgence instantaneously burst upon the
sight. By this arrangement the aspirants to initia-
tion were wonderfully animated to the practice of
virtue while they lived, and inspired with the hope
of a blessed immortality when they died. At the
same time, their awe and veneration for the gods of
their country were wonderfully enhanced by reflecting
on the appearances above described. According
Strabo very judiciously observes, "that the mystical
secrecy of the sacred rites preserves the majesty of the
Deity, imitating its nature, which escapes our appre-
hension. For these reasons, in celebrating the teutec,
the demons were introduced in their defied or glorified
state.

But as all the candidates for initiation might not
aspire to the rank of heroes and demigods, a more
easy and a more attainable mode of conduct, in order
to arrive at the palace of happiness, behoved to be
opened. Private virtues were inculcated, and these

MYSTERIES.

which may appear to us of less importance, which, however, in the symbolical style of the Egyptians, were abundantly significant. The initiated were "commanded to abstain from the flesh of certain birds and fishes; from beans, from pomegranates and apples, which were deemed equally polluting. It was taught, that to touch the plant of asparagus was as dangerous as the most deadly poison. Now, says Porphyry, whoever is versed in the history of the 

The initiated then bound themselves by dreadful oaths. The initiates were bound to observe most conscientiously and to practise every precept tendered to them in the course of the telete; and at the same time never to divulge one article of the instruction all that had been heard or seen by them upon that occasion. This they were so excessively jealous, that the mystae
eus the tragedian was in danger of capital punishment, for having only alluded to one of the Eleusinian scenes in a tragedy of his; and one of the articles of indictment against Diogoras the Melian was, having spoken disrespectfully of the mysteries, and dissuaded people from partaking of them. It must then be allowed, that the institution of the mysteries was of infinite advantage to the Pagan world. They were indeed a kind of sacraments, by which the initiated bound themselves by a solemn vow to practise piety towards the gods, justice and humanity towards their fellow men, and gentleness and tenderness towards the insensitive part of the brute creation. The Pagans themselves were so thoroughly convinced of this fact, that in their disputes with the apologists for Christianity, they often appealed to the telete, and contrasted their maxims with the most sublime doctrines of that heavenly institution.

In order to impress these maxims the more deeply upon the minds of the novices, and to fix their attention more steadfastly upon the lectures which were delivered by the mystagogues or the sacred herald, a mechanical operation was played off at proper intervals during the course of the celebration. "Towards the end of the celebration (says Stobæus), the whole scene is terrible; all is trembling, shuddering, sweat, and astonishment. Many horrible spectres are seen; horrible and strange cries and howlings uttered. Light succeeds darkness; and again the blackest darkness the most glaring light. Now appear open plains, flowery alternate meads, and waving groves; where are seen dances and 
dchoras; and various holy phantasies enchant the sight. Melodious notes are heard from far, with all the sublime symphony of the sacred hymns. The pupil now is completely perfect, is initiated, becomes free, released, and walks about with a crown on his head, and is admitted to bear a part in the sacred rites." Aristides de Myst. Eleus. calls Eleusis "a kind of temple of the whole earth, and of all that man beholds done in the most dreadful and the most exhilarating manner. In what other place have the records of fable sung of things more marvellous? or in what region upon earth have the objects presented to the eye borne a more exact resemblance to the sounds which strike the ear? What object of sight have the numberless generations of men and women beheld comparable to these exhibited in the ineffable mysteries?" To the same purpose, Pletho, in the oracles of Zoroastres, informs us,
MYSTERIES.

"that frightful and shocking apparitions, in a variety of forms, used to be displayed to the mystae in the course of their initiation." And a little after, he adds, "that thunder and lightning and fire, and every thing terrible which might be held symbolic of the divine presence, were introduced." Claudian, in his poem De Nupta Proserpina, gives an elegant, though brief, description of this phenomenon, which throws some light on the passages above quoted.

Jam mihi ceruntur trpudia delubra mouvr
dein et clarum die pergere culmina lucem,
Adventum testata Deo, jam magnus ab imix
Auditor fremitus terris, templanque remugit
Cecropidum.

The sight of those appearances was called the Antopsis, or "the real presence:" hence those rites were sometimes called Époptica. The Épopte were actually initiated, and were admitted into the Sanctum Sanctorum, and bore a part in the ceremonial: whereas the mystae, who had only been initiated in the lesser mysteries at Argae, were obliged to take their station in the porch of the temple. The candidates for initiation bathed themselves in holy water, and put on new clothes, all of linen, which they continued to wear till they were quite torn, and then they were consecrated to Ceres and Proserpine. From the ceremony of bathing they were denominatized Hydrami; and this again was a kind of baptismal ablution. Whether the phrases of washing away sin, putting on the Lord Jesus Christ, putting off the old man with his deeds, putting on a robe of righteousness, being buried in baptism, the words must reperfect, perfection, which occur so frequently in the New Testament, especially in the writings of the apostle St Paul, are borrowed from the pagan mysteries, or from usages current among the Jews, we leave to our more learned readers to determine.

The Épopte having sustained all those fiery trials, heard and seen everything requisite, taken upon them the vows and engagements above narrated, and, in a word, having shown themselves good soldiers of Ceres and Proserpine, were now declared perfect men. They might, like Cebes's virtuous man, travel wherever they chose; those wild beasts (the human passions) which tyrannise over the rest of mankind, and often destroy them, had no longer dominion over them. They were now not only perfect but regenerated men. They were now crowned with laurel, as was said above, and dismissed with two barbarous words, ἔρχομαι, ἐκποθεύομαι, of which perhaps the hierophants themselves did not comprehend the import. They had been introduced by the first Egyptian missionary, and retained in the sacra after their signification was lost. This was a common practice among the Greeks. In the administration of their religious ceremonies, they retained many names of persons, places, things, customs, &c. which had been introduced by the Phoenicians and Egyptians, from whom they borrowed their system of idolatry. These terms constituted the language of the gods, so often mentioned by the prince of poets. To us the words in question appear to be Syriac, and to signify, Be vigilant, be innocent.

Numerous and important were the advantages supposed to redound to the initiated, from their being admitted to partake of the mysteries, both in this life and that which is to come. First, They were highly honoured, and even revered by their contemporaries. Indeed, they were looked up to as a kind of sacred persons: they were, in reality, consecrated to Ceres and Proserpine. Secondly, They were obliged by their oath to practise every virtue, religious, moral, political, public, and private. Thirdly, They imagined, that sound advice and happy measures of conduct were suggested to the initiated by the Eleusinian goddesses. Accordingly, says Pericles the celebrated Athenian statesman, "I am convinced, that the deities of Eleusis inspired me with this sentiment, and that this stratagem was suggested by the principle of the mystic rites." There is a beautiful passage in Aristophanes's 'comedy of the Acte Rane to the very same purpose, of which we shall subjoin the following periphrasis. It is sung by the chorus of the initiated.

Let us to flow'r meads repair,
With deathless roses blooming,
Whose balmy sweets impregn the air,
Both hills and dales perfuming.
Since fate benign our choir has join'd,
We'll trip in mystic measure;
In sweetest harmony combin'd
We'll quaff full draughts of pleasure.
For us along the power of day
A milder light dispenses;
And she's benign a mellow'd ray
To cheer our ravish'd senses:
For we behold the mystic show,
And brav'd Eleusis's dangers.
We do and know the deeds we owe
To neighbours, friends, and strangers.

Euripides, in his Bacchae (2), introduces the chorus extolling the happiness of those who had been acquainted with God, by participating in the holy mysteries, and whose minds had been enlightened by the mystical rites. They boast, "that they had led a holy and unblemished life, from the time that they had been initiated in the sacred rites of Jupiter Idaeus, and from the time that they had relinquished celebrating the nocturnal rites of Bacchus, and the banquets of raw flesh torn off living animals." To this sanctity of life they had no doubt engaged themselves, when they were initiated in the mysteries of that god. The Eleusinian Epopte derived the same advantages from their sacramental engagements. Fourthly, The initiated were imagined to be the peculiar wards of the Eleusinian goddesses. These deities were supposed to watch over them, and often to avert impending danger, and to rescue them when beset with troubles.—Our readers will not imagine that the initiated reap'd much benefit from the protection of his Eleusinian tutelary deities; but it was sufficient that they believed

(2) Act I. near the beginning, and in many other places.
MYSTERIES.

ed the fact, and actually depended upon their inter-
position. Fifthly, The happy influences of the telete,
were supposed to administer consolation to the Epope,
in the hour of dissolution; for, says Isocrates, "Ceres
bestowed upon the Athenians two gifts of the greatest
importance; the fruits of the earth, which were the
cause of our no longer leading a savage course of life;
and the telete, for they who partake of these entertain
more pleasant hopes both at the end of life, and etern-
ity afterwards." Another author,† tells us, "that the
Athenians were not only often rescued from many hard-
ships in their lifetime, but at death entertained hopes
that they should be raised to a more happy condition."

Sixthly, After death, in the Eleusinian fields, they were
to enjoy superior degrees of felicity, and were to bask
in eternal sunshine, to quaff nectar, and feast upon
ambrosia, &c.

The priests were not altogether disinterested in this
salutary process. They made their disciples believe,
that the souls of the uninitiated, when they arrived in
the infernal regions, should roll in mire and dirt, and
with very great difficulty arrive at their destined man-

†
Hence Plato introduces Socrates, observing,
that the sages who introduced the telete had posi-
tively affirmed, that whatever soul should arrive in the
infernal mansions unhouseled and unmanned, should lie
there immersed in mire and filth." And as to a future
state (says Aristides), "the initiated shall not roll in
mire and grope in darkness; a fate which awaits the
unhappy and uninstructed." It is not hard to conceive
with what a commanding influence such doctrines as
these must have operated on the generality of man-
kind.

When the Athenians advised Diogenes to get him-
self initiated, and enforced their arguments with the
above considerations, "It will be pretty enough (re-
plied the philosopher) to see Aegesilas and Epaminon-
das wallowing in the mire, while the contemptible
rascals who have been initiated are strutting in the
islands of bliss."

When Antisthenes was to be initiated in the Or-
phic mysteries, and the priest was boasting of the many
astonishing benefits which the initiated should enjoy
in a future state; "Why, forsooth, (says Antis-
thenes), "to wonder your reverence don't even hang
yourself in order to come up at the sooner.""

When such benefits were expected to be derived
from the mysteries, no wonder if all the world crowed
to the Eleusinian standard. After the Macedonian
conquests, the hierophants abated much of their orig-
inal strictness. By the age of Cicero, Eleusis was a
temple whither all nations resorted to partake of the
benefits of that institution. We find that almost all
the great men of Rome were initiated. The hiero-
phants, however, would not admit Nero on account of
the profligacy of his character. Few others were
refused that honour; even the children of the Athe-
nians were admitted. But this, we think, was rather
a lustration or consecration, than an initiation. Per-
haps it paved the way for the more august ceremony,
as the Christian baptism does among us for the other
sacrament.

That this institution gradually degenerated, can
hardly be questioned; but how much, and in what
points, we have not been able to investigate. The fa-
thers of the church, from whom that charge is chiefly
to be collected, are not always to be trusted, espe-
cially when they set themselves to arraign the institu-
tions of Paganism. There were indeed several an-
cient authors, such as Melanthon, Menander, So-
tales, &c. who wrote purposely on the subject in
question; but their works are long since irrecoverably
lost. For this reason, modern writers, who have pro-
fessedly handled it, have not always been successful in
their researches. The two who have laboured most
and perhaps most successfully, in this field, are Meursius and Warburton. The former, in
his Liber Singularis, has collected everything that can
be gleaned from antiquity relating to the ceremoni-
of these institutions, without, however, pointing out
their original, or elucidating the end and import of their
establishment. The latter has drawn them into the
vortex of a system which has in many instances led him
to ascribe to them a higher degree of merit than we
think they deserve. These instances we would will-
ingly have noticed in our progress, had the limits prescribed
us admitted such a discussion.

If we may believe Diodorus the Sicilian, these my-
steries, which were celebrated with such wonderful se-
crecy at Eleusis, were communicated to all mankind
among the Cretans. This, however, we think, is ra-
ther problematical. We imagine that excellent histo-
rian has confounded the mysteries of Cybele with those
of the Eleusinian Ceres. These two deities were un-
doubtedly one and the same, that is, the moon or the
moon. Hence it is probable, that there was a striking
resemblance between the sacred mysteries of the Cre-
tans and Eleusinians.

This institution continued in high reputation to
the age of St Jerome, as appears from the following
passage: "Hierophante quoque Atheniensium legatit
usque hodie cicutae sorbitome castriam." The em-
peror Valentinianus intended to have suppressed them;
but Zosimus informs us, that he was diverted from
his design by the proconsul of Greece. At length
Theodosius the elder, by an imperial edict, prohibited
the celebration of these as well as of all the other sa-
cra of Paganism. These mysteries, instituted in the
reign of Erechtheus, maintained their ground to the
period just mentioned, that is, near 2000 years; dur-
ing which space, the celebration of them never had
been interrupted but once. When Alexander the
Great massacred the Thebans and razed their city,
the Athenians were so much affected with this melan-
choly event, that they neglected the celebration of that
event.

There were almost numberless other mysterious in-
stitutions among the ancient Pagans, of which these sto-
ries are sketched above were the most celebrated. The Sa-
mothracian mysteries, instituted in honour of the Ca-
birides, were likewise of considerable celebrity, and were
supposed to confer much the same blessings with the
Eleusinian, but were not of equal celebrity. The
Cabiri were Phoenician and likewise Egyptian dei-
ties. The learned Bochart has explained their or-
igin and number, names, and some part of their worship.

The Orphic mysteries were likewise famous among
the Thracians. Orpheus learned them in Egypt, and
they were nearly the same with the sacra Paschonialis
of the Greeks. There were likewise the mysteries
of
MYSTERIES.

of Jupiter Idaeus in great request among the Cretans, those of the Magna Mater or Cybele, celebrated in Phrygia. To enumerate and detail all these would require a complete volume. We hope our readers will be fully satisfied with the specimen exhibited above. We are convinced many things have been omitted which might have been inserted, but we have collected the most curious and the most important.—Every one of the positions might have been authenticated by quotations from authors of the most undoubted credibility, but that process would have swelled the article beyond all proportion.

MYSTICAL, something mysterious or allegorical. Some of the commentators on the sacred writings, besides a literal find also a mystical meaning. The sense of Scripture, say they, is that immediately signified by the words and expressions in the common use of language; or it is mediate, sublime, typical, and mystical. The literal sense they again divide into proper literal, which is contained in the words taken simply and properly; and metaphorical literal, where the words are to be taken in a figurative and metaphorical sense. The mystical sense of scripture they divide into three kinds: the first corresponding to faith, and called allegorical; the second to hope, called analogical; and the third to charity, called the tropological sense. And sometimes they take the same word in Scripture in all the four senses; thus the word Jerusalem literally signifies the capital of Judæa: allegorically, the church militant: tropologically, a believer: and analogically, heaven. So, that passage in Genesis, let there be light, and there was light, literally signifies corporeal light; by an allegory, the Messiah; in the tropological sense, grace; and analogically, beauty, or the light of glory.

MYSTICS, mystics, a kind of religious sect, distinguished by their professing pure, sublime, and perfect devotion, with an entire disinterested love of God, free from all selfish considerations.

The mystics, to excuse their fanatic ecstasies and amorous extravagancies, allege that passage of St Paul, The Spirit prays in us by sighs and groans that are unutterable. Now, if the spirit, say they, pray in us, we must resign ourselves to its motions, and be swayed and guided by its impulse, by remaining in a state of mere inaction.

Passive contemplation is that state of perfection to which the mystics all aspire.

The authors of this mystic science which, sprung up towards the close of the third century, are not known; but the principles from which it was formed are manifest. Its first promoters proceeded from the known doctrine of the Platonic school, which was also adopted by Origen and his disciples, that the divine nature was infused through all human souls, or that the faculty of reason, from which proceed the health and vigour of the mind, was an emanation from God into the human soul, and comprehended in it the principles and elements of all truth, human and divine. They denied that men could by labour or study excite this celestial flame in their breasts; and therefore they disapproved highly of the attempts of those, who by definitions, abstract theorems, and profound speculations, endeavoured to form distinct notions of truth, and to discover its hidden nature. On the contrary, they maintained that silence, tranquillity, repose, and solitude, accompanied with such acts as might tend to

M.Y.T

extend and exhaust the body, were the means by which the hidden and internal word was excited to produce its latent virtues, and to instruct men in the knowledge of divine things. For thus they reasoned; those who behold with a noble contempt all human affairs, who turn away their eyes from terrestrial vanities, and shut all the avenues of the outward senses against the contagious influences of a material world, must necessarily return to God, when the spirit is thus disengaged from the impediments that prevented that happy union. And in this blessed frame they not only enjoy inexpressible raptures from their communion with the Supreme Being, but also are invested with the inestimable privilege of contemplating truth undisguised and uncorrupted in its native purity, while others behold it in a vitiated and delusive form.

The number of the mystics increased in the fourth century, under the influence of the Grecian fanatic, who gave himself out for Dionysius the Areopagite, disciple of St Paul, and probably lived about this period; and by pretending to higher degrees of perfection than other Christians, and practising greater austerity, their cause gained ground, especially in the eastern provinces, in the fifth century. A copy of the pretended works of Dionysius was sent by Balbus to Lewis the Meek, in the year 824, which kindled the holy flame of mysticism in the western provinces, and filled the Latins with the most enthusiastic admiration of this new religion.

In the twelfth century, these mystics took the lead in their method of expounding Scripture; and by searching for mysteries and hidden meaning in the plainest expressions, forced the word of God into a conformity with their visionary doctrines, their enthusiastic feelings, and the system of discipline which they had drawn from the excursions of their irregular fancies. In the thirteenth century, they were the most formidable antagonists of the schoolmen; and towards the close of the fourteenth, many of them resided and propagated their tenets almost in every part of Europe. They had, in the fifteenth century, many persons of distinguished merit in their number; and in the sixteenth century, previous to the Reformation, if any sparks of real piety subsisted under the despotic empire of superstition, they were only to be found among the mystics.

The principles of this sect were adopted by those called Quietists in the seventeenth century, and, under different modifications, by the Quakers and Methodists.

MYSTRUM, a liquid measure among the ancients, containing the fourth part of the cyathus, and weighing two drachms and a half of oil, or two drachms two scruples of water or wine. It nearly answers to our spoonful.

MYTELENE. See Metylene.

MYTHOLOGY.
MYTHOLOGY

A term compounded of two Greek words, and in its
original import it signifies any kind of fabulous doc-
trine: In its more appropriated sense, it means those
fabulous details concerning the objects of worship which
were invented and propagated by men who lived in the
early ages of the world, and by them transmitted to
succeeding generations, either by written records or by
oral tradition.

As the theology and mythology of the ancients are
almost inseparably connected, it will be impossible for
us to develop the latter, without often introducing
some observations relating to the former. We must
therefore entreat the indulgence of our readers, if upon
many occasions we would hazard a few strictures on
the names, characters, adventures, and functions of such
Pagan divinities as may have furnished materials for
those fabulous narrations which the nature of the sub-
ject may lead us to discuss.

With respect to fable, it may be observed in gene-
ral, that it is a creature of the human imagination,
and derives its birth from that love of the marvelous
which is in a manner congenial to the soul of man.—
The appearances of nature which every day occur, ob-
jects, actions, and events, which succeed each other
by a kind of routine, are too familiar, too obvious, and
uninteresting, either to gratify curiosity or to excite
admiration. On the other hand, when the most com-
mon phenomena in nature or life are new-modelled by
the plastic power of a warm imagination; when they are
diversified, compounded, embellished; or even ar-
ranged and moulded into forms which seldom or per-
haps never occur in the ordinary course of things,—
novelty generates admiration, a passion always attended
with delightful sensations. Here then we imagine we
have discovered the very source of fiction and fable.—
They originated from that powerful propensity in our
nature towards the new and surprising, animated by the
delight with which the contemplation of them is gen-
erally attended.

Many circumstances contributed to extend and es-
ablish the empire of fable. The legislator laid hold on
this bias of human nature, and of course employed
fable and fiction as the most effectual means to civilize
a rude, unpolished world. The philosopher, the the-
ologist, the poet, the musician, each in his turn, made
use of this vehicle to convey his maxims and instruc-
tions to the savage tribes. They knew that truth, sim-
plicity, and unadorned, is not possessed of charms power-
ful enough to captivate the heart of man in his present
corrupt and degenerate state. This consideration, which
did indeed result from the character of their audience,
naturally led them to employ fiction and allegory. From
this was derived the allegorical taste of the ancients,
and especially of the primary ages of the east.

Though almost every nation on the face of the globe,
however remote from the centre of cultivation, how-
ever savage and averse from cultivation, has fabricat-
ed and adopted its own system of mythology; the Or-
ientals, however, have distinguished themselves in a
peculiar manner, by the boldness, the inconsistency,
and the extravagance of their mythology. The genial
warmth of those happy climes, the fertility of the soil,
which afforded every necessary, every conveniency,
and often every luxury of life, without depressing their
spirits by laborious exertions; the face of nature per-
petually blooming around them, the skies smiling with
uninterrupted serenity; all contributed to inspire the
Orientals with a glow of fancy and a vigour of ima-
gination rarely to be met with in less happy regions.
Hence every object was swelled beyond its natural di-
mensions. Nothing was great or little in moderation,
but every sentiment was heightened with incredible hy-
perbolic. The magnificent, the sublime, the vast, the
enormous, the marvellous, first sprung up, and were
brought to maturity, in those native regions of fable
and fairy land. As nature, in the ordinary course of
her operations, exhibited neither objects nor effects
adequate to the extent of their romantic imaginations,
they naturally deviated into the fields of fiction and fa-
bles. Of consequence, the custom of detailing fabulous
adventures originated in the east, and was from thence
transplanted into the western countries.

As the allegorical taste of the eastern nations had
sprung from their propensity to fable, and as that propen-
sity had in its turn originated from the love of the
marvellous; so did allegory in process of time contrib-
tue its influence towards multiplying fables and fiction al-
most in infinitum. The latent import of the allegorical
doctrines being in a few ages lost and obliterated, what
was originally a moral or theological tenet, assumed the
air and habit of a personal adventure.

The propensity towards personification, almost uni-
versal among the orientals, was another fruitful source to personi-
fication a source of fable and allegory. That the people of the east
were strongly inclined to personify inanimate objects and abstract ideas, we imagine will be readily granted,
when it is considered, that in the formation of language
they have generally annexed the affection of sex to
those objects. Hence the distinction of grammatical
genders, which is known to have originated in the
eastern parts of the world. The practice of personifying
virtues, vices, religious and moral affections, was
necessary to support that allegorical style which uni-
versally prevailed in those countries. This mode of writ-
ing was in high reputation even in Europe some cen-
turies ago; and to it we are indebted for some of the
most noble poetical compositions now extant in our own
language. Those productions, however, are but faint
imitations of the original mode of writing still current
among the eastern nations. The Europeans derived
this species of composition from the Moorish inhabitants
of Spain, who imported it from Arabia, their original
country.

The general use of hieroglyphics in the east, must
have contributed largely towards extending the em-
ployed in this method of delineating the signs of
ideology was in a great measure arbitrary, mistakes must
have
have been frequently committed in ascertaining the notions which they were at the first intended to represent. When the development of these arbitrary signs happened to be attended with uncommon difficulty, the expounders were obliged to have recourse to conjecture. Those conjectural expositions were for the most part tinctured with that bias towards the marvellous which universally prevailed among the primitive men. This we find is the case even at this day, when moderns attempt to develop the purport of emblematical figures, preserved on ancient medals, entanglements, &c.

The wise men of the east delighted in obscure enigmatical sentences. They seem to have disdained every sentiment obvious to vulgar apprehension. The words of the wise, and their dark sayings, often occur in the most ancient records both sacred and profane. The sages of antiquity used to vie with each other for the prize of superior wisdom, by propounding riddles, and dark and mysterious questions, as subjects of investigation. The contest between Solomon and Hiram, and that between Amasis king of Egypt and Polycrates tyrant of Samos, are universally known.

As the import of those enigmatical propositions was often absolutely lost, in ages when the art of writing was little known, and still less practised, nothing remained but fancy and conjecture, which always verged towards the regions of fable. This then, we think, was another source of mythology.

The Pagan priests, especially in Egypt, were probably the first who reduced mythology to a kind of system. The sacerdotal tribe, among that people, were the grand depositories of learning as well as of religion. That order of men monopolized all the arts and sciences. They seem to have formed a conspiracy among themselves, to preclude the laity from all the avenues of intellectual improvement. This plan was adopted with a view to keep the laity in subjection, and to enhance their own importance. To accomplish this end, they contrived to perform all the ministrations of their religion in an unknown tongue, and to cover them with a thick veil of fable and allegory. The language of Ethiopia became their sacred dialect, and hieroglyphics their sacred character. Egypt, of course, became a kind of fairy land, where all was jugglery, magic, and enchantment. The initiated alone were admitted to the knowledge of the occult mystical exhibitions, which, in their hands, constituted the essence of their religion. From these the vulgar and profane were prohibited by the most rigorous penalties (see Mysteries). The Egyptians, and indeed all the ancients without exception, deemed the mysteries of religion too sacred and solemn to be communicated to the herd of mankind, naked and unreserved: a notion by which they imagined those sacred and sublime oracles would have been defiled and contamined.

Procul, & procul esto profani—Odi profanum vulgus et arceo. Egypt was the land of graven images; allegory and mythology were the veil which concealed religion from the eyes of the vulgar; fable was the groundwork of that impenetrable covering.

In the earliest and most polished stage of society we cannot suppose fable to have existed among men. Fables are always tales of other times, but at this period other times did not reach far enough backward to afford those fruits of the imagination sufficient time to arrive at maturity. Fable requires a considerable space of time to acquire credibility, and to rise into reputation. Accordingly, we find that both the Chinese and Egyptians, the two most ancient nations whose annals have reached our times, were altogether unacquainted with fabulous details in the most early and least improved periods of their respective monarchies. It has been shown almost to a demonstration, by a variety of learned men, that both the one and the other people, during some centuries after the general deluge, retained and practised the primitive Noachic religion, in which fable and fancy could find no place; all was genuine unsophisticated truth.

As soon as the authentic tradition concerning the origin of the universe was either in a good measure lost, or at least adulterated by the invention of men, fable and fiction began to prevail. The Egyptian Thoth or Thoyno, or Mercury Trismegistus, and Moses, Faborchus the Pheenician, undertook to account for the formation and arrangement of the universe, upon principles purely mechanical. Here fable began to usurp the place of genuine historical truth. Accordingly, we find that all the historians of antiquity, who have undertaken to give a general detail of the affairs of the world, have ushered in their narration with a fabulous cosmogony. Here imagination ranged unconfined over the boundless extent of the primary chaos. To be convinced of the truth of this assertion, we need only look into Sanchoniatho's Cosmogony, Euseb. Prep. Evang. l. 1. sub init. and Diodorus Sic. l. 1. From this we suppose it will follow, that the first race of fables owed their birth to the erroneous opinions of the formation of the universe.

Having now endeavoured to point out the origin of mythology, or fabulous traditions, we shall proceed to lay before our readers a brief detail of the mythology of the most respectable nations of antiquity, following the natural order of their situation.

The Chinese, if any credit be due to their own annals, or to the missionaries of the church of Rome, who pretend to have copied from them, were the first of the nations. Their fabulous records reach upwards many myriads of years before the Mosaic era of the creation. The events during that period of time, if any had been recorded, must have been fabulous as the period itself. These, however, are buried in eternal oblivion. The missionaries, who are the only sources of our information with relation to the earliest periods of the Chinese history, represent those people as having retained the religion of Noah many centuries after the foundation of their empire. Upon this supposition, their cosmogony must have been sound and genuine, without the least tincture of those fabulous ingredients which have both disguised and disgraced the cosmogonies of most other nations.

According to the most authentic accounts, Fak-kia or Fakh laid the foundation of that empire about 4000 years ago. This emperor, according to the Chinese, was conceived in a miraculous manner. His mother, say they, one day as she was walking in a desert place, was surrounded by a rainbow; and, being impregnated by this meteor, was in due time delivered of that celebrated legislator. This personage, like the Athenian Cecrops, was half a man and half a serpent. His
MYTHOLOGY.

His intellectual powers were truly hyperbolical. In one day he discovered 50 different species of poisonous herbs. He taught his countrymen the whole art of agriculture in the space of a very few years. He instructed them how to sow five different sorts of grain. He invented boats, and nets for fishing, the art of fabricating porcelain, the management of silk worms, the manufacturing of silk, &c. In a word, that wonderful personage was inspired by Heaven with knowledge, which qualified him for composing that incomparable body of laws which are even at this day the wonder of the world. Our readers will admit, that this whole detail is fabulous and chimerical. The most learned part of them will readily observe, that the Chinese in ascribing the invention of all the useful arts to their Fo, are perfectly agreed with almost all the other nations of antiquity. The Indians ascribe every invention to Budha, or Vishnou, or Fo; the Persians to Zerdusht, or Zoroaster; the Chaldrens to man of the sea, whom they call Oannes; the Egyptians to Thoth or Thypo; the Phcenicians to Melcicerta; the Greeks to the family of the Titans; and the Scandinavians to Odin, &c.

About 551 years before the Christian era, appeared the famous Chinese philosopher Con-fu-tse or Confucius. Concerning the birth of this prince of philosophers, the Chinese have propagated the following legendary tale. His mother, walking in a solitary place, was impregnated by the vivifying influence of the heavens. The babe, thus produced, spake and reasoned as soon as it was born. Confucius, however, wrought no miracles, performed no supernatural exploits, but lived an anseretic ascetic life, taught and inculcated the doctrines of pure morality, and died, remarkable only for superior wisdom, religious, moral, and political.

About the year of Christ 601, flourished the secretary Lao-kiu. His mother carried him 90 years in her womb, and was at last delivered of him under a plum-tree. This philosopher was the Epicurus of the Chinese. His disciples, who were denominated Foo-se, i. e. heavenly doctors, were the first who corrupted the religion of the Chinese. They were addicted to magic, and introduced the worship of good and bad demons. Their doctrine was embraced by a long succession of emperors. One of these princes, called You-ti, had been deprived by death of a favourite mistress, whom he loved with the most extravagant passion. The emperor, by the magical skill of one of these doctors, obtained an interview with his deceased mistress, a circumstance which rivetted the whole order in the affection and esteem of the deluded prince. Here our readers will observe the exact counterpart of the fable of Eurydice, so famous in the mythology of the Greeks and Romans. That such a system of religion, principles must have abounded with mythological adventures is highly probable; but as the missionaries, to whom we are chiefly indebted for our information relating to the religion of the Chinese, have not taken the pains to record them, we find it impossible to gratify the curiosity of our readers on that head.

The worship of the idol Fo, or Foe, was transplanted from India into China about the 56th year of the Christian era, upon the following occasion. One of the doctors of the Foo-see had promised a prince of the family of Tchou, and brother of the emperor Ming-ti, to make him enter into communion with the spirits. At his solicitation an ambassador was despatched into India, in order to inquire where the true religion was to be found. There had been a tradition, say the missionaries, ever since the age of Confucius, that the true religion was to be found in the west.—The ambassador stopped short in India; and finding that the god Foe was in high reputation in that country, he collected several images of that deity painted on chintz, and with it 42 chapters of the canonical books of the Hoodos, which, together with the images, he laid on a white elephant, and transported into his native country. At the same time he imported from the same quarter the doctrine of the transmigration of souls, which is firmly believed in China to this day. The doctrine and worship of Foe, thus introduced, made a most rapid progress all over China, Japan, Siam, &c. The priests of Foe are called among the Siamese Tulponts; by the Tartars, Lamas; by the Chinese, Hon-chang; and by the people of Japan, Bousse. By this last appellation they are generally known in Europe.

An infinitude of fables was invented and propagated by the disciples of Foe, concerning the life and adventures of their master. If the earlier ages of the Chinese history are barren of mythological incidents, the later periods, after the introduction of the worship of Foe, furnish an inexhaustible store of miracles, monsters, fables, intrigue, exploits, and adventures, of the most villainous complexion. Indeed, most of them are so absurd, so ridiculous, and at the same time so impious and profane, that we are convinced our readers will easily dispense with a detail from which they could reap neither entertainment nor instruction. Such as may find themselves disposed to rake into this abominable puddle, we must refer to the revered fathers Du Halde, Complet, Amiot, Kircher, and other members of the propaganda, in whose writings they will find wherewithal to satisfy, and even to surfeit, their appetite.

The Hoodos, like the other nations of the east, for Hindustans, a long time retained the worship of the true God. At theology, however, idolatry broke in, and, like an impetuous torrent, overwhelmed the country. First of all, the genuine history of the origin of the universe was either utterly lost, or disguised under a variety of fictions and allegories. We are told that Brintha, the supreme divinity of the Hoodos, after three several efforts, at last succeeded in creating four persons, whom he appointed to rule over all the inferior creatures.—Afterwards Brintha joined his efficient power with Bishon and Ruler; and by their united exertions they produced ten men, whose general appellation is Minnos; that is, the inspired. The same being, according to another mythology, produced four other persons, as imaginary as the former; one from his breast, one from his back, one from his lip, and one from his heart. These children were denominated Bongs; the import of which word we cannot pretend to determine. According to another tradition, Brintha produced the Brumins from his mouth, to pray, to read, to instruct; the Chiltern from his arms, to draw the bow, to fight, to govern; the Bice from his belly or thighs, to nourish, to provide the necessities of life by agriculture and commerce; the Soder from his feet, for
MYTHOLOGY.

The Hindoos have likewise some mythological opinions which seem to relate to the general deluge. They tell us, that desiring the preservation of herds and of brahmanas, of genii and of virtuous men, of vedas of law, and of precious things, the Lord of the universe assumes many bodily shapes; but though he perverses, like the air, a variety of beings, yet he is himself unvaried, since he has no quality in him subject to change. At the close of the last calpa, there was a general destruction, occasioned by the sleep of Brahme, whence his creatures in different worlds were drowned in a vast ocean. Brahme being inclined to slumber after a lapse of so many ages, the strong demon Hyaqri-us, came near him, and stole the vedas which had flowed from his lips. When Hyaqri-us, the preserver of the universe, discovered this deed of the prince of Deivaas, he took the shape of a minute fish called Sap-hari. After various transformations, and an enormous increase of size in each of them, the Lord of the universe loving the rightous man (A), who had still adhered to him under all these various shapes, and intending to preserve him from the sea of destruction caused by the depravity of the age, thus told him how he was to act: "In seven days from the present time, 0 thou tamer of enemies! the three worlds will be plunged in an ocean of death; but in the midst of the destroying waves a large vessel sent by me for thy use shall stand before thee." The remaining part of the mythology so nearly resembles the Mosaic history of Noah and the general deluge, that the former may be a strong confirmation of the truth of the latter. To dry up the waters of the deluge, the power of the Deity descends in the form of a boor, the symbol of strength, to draw up and support on his tusks the whole earth, which had been sunk beneath the ocean. Again, the same power is represented as a tortoise containing the globe, which had been convulsed by the violent assaults of demons, while the gods charmed the sea with the mountain Mandar, and forced it to disgorge the sacred things and animals, together with the water of life which it had swallowed. All these stories, we think, relate to the same event, shadowed by a moral, a metaphysical, and an astronomical allegory; and all three seem connected with the hieroglyphical sculptures of the old Egyptians.

The Hindoos divide the duration of the world into four yuge or yugas, or jogues, each consisting of a prodigious number of years. In each of those periods, the age and stature of the human race have been gradually diminished; and in each of them mankind has gradually declined in virtue and piety, as well as in age and stature. The present period they call the Celler, i.e. the corrupt jogue, which they say is to last 400,000 years, of which near 5000 years are already past. In the last part of the preceding jogue, which they call the devpaar, the age of man was contracted into 1000 years, as in the present it is confined to 100. From this proportional diminution of the length of the human life, our readers will probably infer, that the two last joggas bear a pretty near resemblance to the Mosaic history of the age of the antediluvian and postdiluvian patriarchs; and that the two first are imaginary periods prior to the creation of the world, like those of the Chinese, Chaldeans, and Egyptians.

According to the mythology of the Hindoos, the world system of the world is subject to various dissolutions and resuscitations. At the conclusion of the Celler, say they, a grand revolution will take place, when the solar system will be consumed by fire, and the elements all reduced to their original constituent atoms. Upon the back of these revolutions, Brima, the supreme deity of the Hindoos, is sometimes represented as a new born infant, with his toe in his mouth, floating on a camala or water flower, sometimes only on a leaf of that plant, on the surface of the vast abyss. At other times he is figured as coming forth of a winding shell; and again as blowing up the mundane foam with a pipe at his mouth. Some of these emblematical figures and attitudes, our learned readers will probably observe, nearly resemble those of the ancient Egyptians.

But the vulgar religion of the ancient Hindoos was of a very different complexion, and opens a large field of mythological adventures. We have observed above, that the Fo or Foe of the Chinese was imported from India; and now we shall give a brief detail of the mythological origin of that divinity. We have no certain account of the birth-place of this imaginary deity.—

His followers relate, that he was born in one of the kingdoms of India near the line, and that his father was one of that country. His mother brought him into the world by the left side, and expired soon after her delivery. At the time of her conception, she dreamed that she had swallowed a white elephant; a circumstance which is supposed to have given birth to the veneration which the Kings of India have always shown for a white animal of that species. As soon as he was born, he had strength enough to stand erect without assistance. He walked abroad at seven, and, pointing with one hand to the heavens, and with the other to the earth, he cried out, "In the heavens, and on the earth, there is no one but me who deserves to be honoured." At the age of 30, he felt himself all at a sudden filled with the divinity; and now he was metamorphosed into Fo or Fagod, according to the expression of the Hindoos. He had no sooner declared himself a divinity, than he thought of propagating his doctrine, and proving his divine mission by miracles. The number of his disciples was immense; and they soon spread his dogmas over all India, and even to the higher extremities of Asia.

One of the principal doctrines which Fo and his Disciples propagated, was the metempsychosis or transmigration of souls. This doctrine, some imagines, has been given

(A) He was Sovereign of the world. His name was Mana, or Stagavwrat; his patronymic name was Vissvata, or Child of the Sun.
given rise to the multitude of idols venerated in every country where the worship of Fo is established. Quadrupeds, birds, reptiles, and the vilest animals, had temples erected for them; because, say they, the soul of the god, in his numerous transmigrations, may have at one time or other inhabited their bodies.

Both the doctrine of transmigration and of the worship of animals seems, however, to have been imported from Egypt into India. If the intercourse between these two countries was begun at so early a period as some very late writers have endeavoured to prove, such a supposition is by no means improbable. The doctrine of the transmigration of souls was early established among the Egyptians. It was, indeed, the only idea they formed of the soul's immortality. The worship of animals among them seems to have been still more ancient. If such an intercourse did actually exist, we may naturally suppose that colonies of Egyptian priests found their way into India, as they did afterwards into Asia Minor, Italy, and Greece. That colonies of Egyptians did actually penetrate into that country, and settle there, many centuries before the Nativity, is a fact that cannot be called in question, for reasons which the bounds prescribed us in this article will not allow us to enumerate. We shall only observe, that from the hieroglyphical representations of the Egyptian deities seem to have originated those monstrous idols which from time immemorial have been worshipped in India, China, Japan, Siam, and even in the remotest parts of Asiatic Tartary.

Fo is often called Budha or Budda, and sometimes Vishno, perhaps, indeed, he may be distinguished by many other names, according to the variety of dialects of the different nations among which his worship was established. An infinitude of fables was propagated by his disciples concerning him after his death. They pretended that their master was still alive; that he had been already born 8000 times, and that he had successively appeared under the figure of an ape, a lion, a dragon, an elephant, a boar, &c. These were called the incarnations of Vishno. At length he was confounded with the supreme God; and all the titles, attributes, operations, perfecions, and ensigns of the Most High were ascribed to him. Sometimes he is called Amida, and represented with the head of a dog, and worshipped as the guardian of mankind. He sometimes appears as a princely personage, issuing from the mouth of a fish. At other times, he wears a lute and on his head, in which are seen cities, mountains, towers, trees, in short, all that the world contains. These transformations are evidently the children of allegorical or hieroglyphical emblems, and form an exact counterpart to the symbolical worship of the Egyptians.

The enormous mass of mythological traditions which have in a manner deluged the vast continent of India, would fill many volumes: We have selected the preceding articles as a specimen only, by which our readers may be qualified to judge of the rest. If they find themselves disposed to indulge their curiosity at greater length, we must remit them to Thavenot's and Hamilton's Travels, to Mons Anquetil's in his Zond Avesta, Halls's Introduction to his Translation of the Code of Gentoo Laws, Col. Dow's History of Hindostan, Grose's Voyage to the East Indies, Asiatic Researches, vol. i. and ii.

The mythology of the Persians is, if possible, still more extravagant than that of the Hindoos. It supposes the world to have been repeatedly destroyed, and repopulated by creatures of different formation, who were successively annihilated or banished for their disobedience to the supreme Being. The monstrous griffin Sinerga tells the hero Catherman that she had already lived to see the earth seven times filled with creatures, and seven times a perfect void: that before the creation of Adam, this globe was inhabited by a race of beings called Peri and Dives, whose characters formed a perfect contrast. The Peri are described as beautiful and benevolent; the Dives as deformed, malevolent, and mischievous, differing from infernal demons only in this, that they are not as yet confined to the pit of hell. They are for ever ranging over the world, to scatter discord and misery among the sons of men. The Peri nearly resemble the fairies of Europe: and perhaps the Dives gave birth to the giants and magicians of the middle ages. The Peri and Dives wage incessant war; and when the Dives make any of the Peri prisoners, they shut them up in iron cages, and hang them on the highest trees, to expose them to public view, and to the fury of every chilling blast.

When the Peri are in danger of being overpowered by their foes, they solicit the assistance of some mortal hero; which produces a series of mythological adventures highly-ornamental to the strains of the Persian bards, and which, at the same time, furnishes an inexhaustible fund of the most diversified machinery.

One of the most celebrated adventurers in the mythology of Persia is Zabamuran, one of their most ancient monarchs. This prince performs a variety of exploits, while he endeavours to recover the fairy Merjan. He attacks the Dive Demrushi in his own cave; where having vanquished the giant or demon, he finds vast piles of hoarded wealth; these he carries off with the fair captive. The battles, labours, and adventures of Rostan, another Persian worthy, who lived many ages after the former, are celebrated by the Persian bards with the same extravagance of hyperbole with which the labours of Hercules have been sung by the poets of Greece and Rome.

The adventures of the Persian heroes breathe all Persia the wildness of achievement recorded of the knights of chivalry of Gothic romance. The doctrine of enchantments, and transformations, &c. exhibited in both, is a characteristic symptom of one common original. Persia is the genuine classic ground of eastern mythology, and the exercise of the ideas of chivalry and romance; from which they were propagated to the regions of Scandinavia, and indeed to the remotest corners of Europe towards the west.

Perhaps our readers may be of our opinion, when we offer it as a conjecture, that the tales of the war of the Peri and Dives originated from a vague tradition concerning good and bad angels: nor is it, in our opinion, improbable, that the fable of the war between the gods and giants, so famous in the mythology of Greece and Italy, was imported into the former of these countries from the same quarter. For a more particular account of the Persian mythology, our readers may consult Dr Hyde.
HYDE RELIG. VET. PERS. MERO AN D D’HERBELOT’S BIBL. ORIENT. AND MR. RICHARDSON’S INTRODUCTION TO HIS PERSIAN AND ARABIC DICTIONARY.

"IN THE BEGINNING (SAYS BEROSUS, COPYING FROM Oannes, OF WHOM WE SHALL GIVE A BRIEF ACCOUNT LATER) THERE WAS NOTHING BUT A KILLING ABYSS OF WATER; WHEREIN RESIDED HIDEOUS BEINGS PRODUCED FROM A TWO-FACED PRINCIPLE. MEN APPEARED WITH TWO WINGS; SOME WITH TWO AND SOME WITH FOUR FACES. THEY HAD ONE BODY, BUT TWO HEADS; ONE OF A MAN, THE OTHER OF A WOMAN. OTHER HUMAN FIGURES WERE TO BE SEEN, FURNISHED WITH LEGS AND HORNS OF GOATS. SOME HAD THE FEET OF HORSES BEHIND, BUT BEFORE WERE FASHIONED LIKE MEN, RESPECTING HOMOCENTURUS." THIS REMARKABLE PART OF MYTHOLOGY IS MUCH OF THE COMPLEXION; INDEED SO EXTRAVAGANT, THAT WE IMAGINE OUR READERS WILL READILY ENOUGH DISPENSE WITH OUR TRANSLATING THE SEQUEL.

"OF ALL THESE (SAYS THE AUTHOR) WERE PRESERVED DELINEATIONS IN THE TEMPLE OF BELUS AT BABYLON. THE PERSON WHO WAS SUPPOSED TO PRECEDE OVER THEM WAS CALLED OOMORE. THIS WORD, IN THE CHALDEAN LANGUAGE, IS THOLATH, WHICH THE GREEKS CALL OMEDEAN, BUT IT MORE PROPERLY IMPORTS THE MOON. MATTERS BEING IN THIS SITUATION, THEIR GOD (SAYS EUSEBIUS), THE GOD (SAYS SYNCELUS) CAME AND CLEARED THE WOMAN ASSUMING; AND OUT OF ONE OF HER HANDS, HE FORMED THE ANIMAL OUT OF THE OTHER HE MADE THE HEAVENS; AND, AT THE SAME TIME, HE DESTROYED THE MONSTERS OF THE ABYSS." THIS WHOLE MYTHOLOGY IS AN ALEGORICAL HISTORY Copied FROM HIEROGLYPHICAL REPRESENTATIONS, THE REAL PURPORT OF WHICH COULD NOT BE DECRYPTED BY THE AUTHOR. SUCH, IN GENERAL, WERE THE CONSEQUENCES OF THE HIEROGLYPHICAL STYLE OF WRITING.

Oannes, the great civilizer and legislator of the Chaldeans, according to Apollodorus, who copied from Berossus, was an amphibious animal of a heterogeneous appearance. He was endowed with reason and a very uncommon acuteness of parts. His whole body resembled a fish. Under the head of a fish he had also another head, and feet below similar to those of a man, which were subjoined to the tail of the fish. His voice and language were articulate and perfectly intelligible, and there was a figure of him still extant in the days of Berossus. He made his appearance in the Erythrean or Red Sea, where it bordered upon Babylonia. This monstrous being conversed with men by day; but at night he plunged into the sea, and remained concealed in the water till next morning. He taught the Babylonians the use of letters, and the knowledge of all the arts and sciences. He instructed them in the method of building houses, constructing temples, and all other edifices. He taught them to compile laws and religious ceremonies, and explained to them the principles of mathematics, geometry, and astronomy. In a word he communicated to them everything necessary, useful, and ornamental; and so universal were his instructions, that not one single article had ever been added to them since the time they were first communicated. Helladius is of opinion that this strange personage, whom he was, came to be represented under the figure of a fish, not because he was actually believed to be such, but because he was clothed with the skin of a seal.

By this account our readers will see that the Babylonian Oannes is the exact counterpart of the Fohi of the Chinese, and the Thoth or the Mercury Trismegistus of the Egyptians. It is likewise apparent that the idea of the monster composed of the man and the fish has been generated from some hieroglyphic of that form grafted upon the appearance of man. Some modern mythologists have been of opinion that Oannes was actually Noah the great preacher of righteousness; who, as some think, settled in Shinar or Chaldea after the deluge, and who, in consequence of his connexion with that event, might be properly represented under the emblem of the Man of the Sea.

The Nativity of Venus, the goddess of beauty and love, is another piece of mythology famous among the Babylonians and Assyrians. An egg, say they, of prodigious size, descended from heaven into the river Euphrates. Some doves settled upon this egg, after that the fishes had rolled it to the bank. In a short time this egg produced Venus, who was afterwards called Dea Syrie, the Syrian goddess. In consequence of this tradition (says Hyginus), pigeons and fishes became sacred to this goddess among the Syrians, who abstained from eating the one or the other. Of this imaginary being we have a very exact and entertaining history in the treatise De Dea Syrie, generally ascribed to Lucian.

In this mythological tradition our readers will probably discover an allusion to the celebrated Muschenegg; and at the same time the story of the fishes will lead them to anticipate the connexion between the sea and the moon. This same deity was the Atargatis of Ascalon, described by Diodorus the Sicilian; the one half of her body a woman and the other a fish. This was no doubt a hieroglyphic figure of the moon, importing the influence of that planet upon the sea and the sex. The oriental name of this deity evidently points to the moon; for it is compounded of two Hebrew words (n), which import the queen of the host of heaven.

The fable of Semiramis is nearly connected with the preceding one. Diodorus Siculus has preserved the mythological history of this deity, which he and all the writers of antiquity have confounded with the Babylonian princes of the same name. That historian informs us that the word Semiramis, in the Syrian dialect, signifies a wild pigeon; but we apprehend that this term was a name or epitaph of the moon,
MYTHOLOGY.

589

moon, as it is compounded of two words (c) of an import naturally applicable to the lunar planet. It was a general practice among the Orientals to denominate their sacred animals from that deity to which they were consecrated. Hence the moon being called Semiramis, and the pigeon being sacred to her divinity, the latter was also called by the name of the former.

We should now proceed to the mythology of the Arabians, the far greatest part of which is, however, buried in the abyss of ages; though, when we reflect on the genius and character of that people, we must be convinced that they too, as well as the other nations of the east abound in fabulous relations and romantic compositions. The natives of that country have always been enthusiastically addicted to poetry, of which fable is the essence. Wherever the Muses have erected their throne, fables and miracles have always appeared in their train. In the Koran we meet with frequent allusions to well-known traditional fables. These had been transmitted from generation to generation by the bards and rhapsodists for the entertainment of the vulgar. In Arabia, from the earliest ages, it has always been one of the favourite entertainments of the common people, to assemble in the sacred evenings around their tents, or on the platforms where their houses are generally covered, or in large halls erected for the purpose, in order to amuse themselves with traditional narrations of the most distinguished actions of their most remote ancestors. Oriental imagery always embellished their romantic details. The glow of fancy, the love of the marvellous, the propensity towards the hyperbolical and the vast, which constitute the essence of oriental description, must ever have drawn the relation aside into the devious regions of fiction and fairy land. The religion of Mahomet beat down the original fabric of idolatry and mythology together. The Arabian fables current in modern times are borrowed or imitated from Persian compositions; Persia being still the grand nursery of romance in the east.

In Egypt we find idolatry, theology, and mythology, almost inseparably blended together. The inhabitants of this region, as well as others of the vicinity of the centre of population, adhered for several centuries to the worship of the true God. At last, however, conscious of their own ignorance, impurity, imperfection, and total unfitness to approach an infinitely perfect Being, distant, as they imagined, and invisible, they began to cast about for some beings more exalted, and more perfect than themselves, by whose mediation they might prefer their prayers to the supreme Majesty of heaven. The luminaries of heaven, which they imagined were animated bodies, naturally presented themselves. These were splendid and glorious beings. They were thought to partake of the divine nature: they were revered as the satraps, prefects, and representatives of the supreme Lord of the universe. They were visible, they were beneficent; they dwelt nearer to the gods, they were near at hand and always accessible. These were, of course, employed as mediators and intercessors between the supreme Divinity and his humble subjects of this lower world. Thus employed, they might obtain a just and ample share of worship, which was accordingly assigned them. In process of time, however, that worship, which was originally addressed to the supreme Creator by the mediation of the heavenly bodies, was in a great measure forgotten, and the adoration of mankind ultimately terminated on those illustrious creatures. To this circumstance, we think, we may ascribe the origin of that species of idolatry called Zabism, or the worship of the host of heaven, which overspread the world early and almost universally. In Egypt this mode of worship was adopted in all its most absurd and most enthusiastic forms: and at the same time the most heterogeneous mythology appeared in its train. The mythology of the ancient Egyptians was so various and multiform, so complicated and so mysterious, that it would require many volumes even to give a superficial account of its origin and progress, not only in its mother country, but even in many other parts of the eastern and western world. Besides, the idolatry and mythology of that wonderful country are so closely connected and so inseparably blended together, that it is impossible to describe the latter without at the same time developing the former. We hope, therefore, our readers will not be disappointed, if, in a work of this nature, we touch only upon some of the leading or most interesting articles of this complicated subject.

The Egyptians confounded the revolutions of the heavenly bodies with the reigns of their most early monarachs. Hence the incredible number of years included in the reign of their eight superior gods, who, according to them, filled the Egyptian throne successively in the most early periods of time. To these, according to their system, succeeded twelve demigods, who likewise reigned an amazing number of years. These imaginary reigns were no other than the periodical revolutions of the heavenly bodies preserved in their almanacks, which might be carried back, and actually were carried back, at pleasure. Hence the fabulous antiquity of that kingdom. The imaginary exploits and adventures of these gods and demigods furnished an inexhaustible fund of mythological romances. To the demigods succeeded the kings of the cyncic cycle, personages equally chimerical with the former. The import of this epithet has greatly perplexed critics and etymologists. We apprehend it is an oriental word importing royal dignity, elevation of rank. This appellation intimat-ed, that the monarchs of that cycle, admitting that they actually existed, were more powerful and more highly revered than their successors. After the princes of the cyncic cycle comes another race, denominated Nefyes, a title likewise implying royal, splendid, glorious. These cycles

(c) Shem or Sem, " a sign," and ramah, " high."
cycles figure high in the mythological annals of the Egyptians, and have furnished materials for a variety of learned and ingenious disquisitions. The wars and adventures of Osiris, Isis, Typhon, and other allegorical personages who figure in the Egyptian rubric; the wanderings of Isis, the sister and wife of Osiris; the transformation of the gods into divers kinds of animals; their birth, education, peregrinations, and exploits—compose a body of mythological fictions so various, so monstrous, so ridiculous, as to appear so apparently absurd, that all attempts to develop and explain them have hitherto proved unsuccessful. All, or the greatest part, of those extravagant fables, are the offspring of hieroglyphical or allegorical emblems devised by the priests and sages of that nation, with a view to conceal the mysteries of their religion from that class of men whom they stigmatized with the name of the uninstructed rabble.

The worship of brute animals and of certain vegetables, universal among the Egyptians, was another exuberant source of mythological adventures. The Egyptian priests, many of whom were likewise profound philosophers, observed, or pretended to observe, a kind of analogy between the qualities of certain animals and vegetables, and those of some of their subordinate divinities. Such animals and vegetables they adopted, and consecrated to the deities to whom they were supposed to bear this analogical resemblance; and in process of time they considered them as the visible emblems of those divinities to which they were consecrated. By these the vulgar addressed their archetypes: in the same manner, as in other countries, pictures and statues were employed for the very same purpose. The mob, in process of time, forgetting the emblematical character of those brutes and vegetables, addressed their devotion immediately to them; and of course these became the ultimate objects of vulgar adoration.

After these objects, animate or inanimate, were consecrated as the visible symbols of the deities, it soon became fashionable to make use of their figures to represent those deities to which they were consecrated. This practice was the natural consequence of the hieroglyphical style which universally prevailed among the ancient Egyptians. Hence Jupiter Ammon was represented under the figure of a ram, Apis, under that of a cow, Osiris of a bull, Pan of a goat, Thoth or Mercury of an ibis, Bubastis or Diana of a cat, &c. It was likewise a common practice among those deluded people to dignify those objects, by giving them the names of those deities which they represented: by this mode of dignifying these sacred emblems, the veneration of the rabble was considerably enhanced, and the ardour of their devotion inflamed in proportion. From these two sources, we think, are derived the fabulous transformation of the gods, so generally celebrated in the Egyptian mythology, and from it imported into Greece and Italy. In consequence of this practice, their mythological system was rendered at once enormous and unintelligible.

Their Thoth, or Mercury Trismegistus, was, in our opinion, the inventor of this unhappy system. This personage, according to the Egyptians, was the original author of letters, geometry, astronomy, music, architecture; in a word, of all the elegant and useful arts, and of all the branches of science and philosophy. He it was who first discovered the analogy between the divine affections, influences, appearances, operations, and the corresponding properties, qualities, and instincts of certain animals, and the propriety of dedicating particular kinds of vegetables to the service of particular deities.

The priests, whose province it was to explain the mysteries of that allegorical hieroglyphical religion, (see MYSTERIES), gradually lost all knowledge of the primary import of the symbols. To supply this defect, and at the same time to veil their own ignorance, the sacerdotal instructors had recourse to fable and fiction. They heaped fable upon fable, till their religion became an accumulated chaos of mythological absurdities.

Two of the most learned and most acute of the ancient philosophers have attempted a rational explanation of the laest import of the Egyptian mythology; but both have failed in the attempt; nor have the moderns, who have laboured in the same department, performed their part with much better success. Instead, therefore, of prosecuting this inexplicable subject, which would swell this article beyond all proportion, we must beg leave to refer those who are desirous of further information to the following authors, where they will find enough to gratify their curiosity, if not to inform their judgment: Herodotus, lib. ii. Dio- dorus Siculus, lib. i. Plut. Isis et Osiris; Ambibuch de Myst. Egypt. Horapollo Hieroglyphs Egypt. Macrob. Sat. cap. 23. among the ancients, and among the moderns, Kircher's Oedip. Voss. de Orig. et Prog. Idol. Mr Bryant's Analysis of Anc. Mythol. Mers. Gебelin Monde Prim. ; and above all, to the learned Jabloński's Panth. Egyptorum.

The elements of Phoenician mythology have been preserved by Eusebius, Præp. Evang. sub. init. In the large extract which that learned father had copied from Philo Bibrus's translation of Sanchonianthos's History of Phoenicia, we are furnished with several articles of mythology. Some of these throw considerable light on several passages of the sacred history; and all of them are strictly connected with the mythology of the Greeks and Romans. There we have preserved a brief but entertaining detail of the fabulous adventures of Uranus, Cronus, Dagon, Tyroth or Mercury, probably the same with the Egyptian hero of that name. Here we find Muth or Plato, Æphestus or Vulcan, Æsculapius, Poseidon, Neptune, &c. Astarte, or Venus Urania, makes a conspicuous figure in the catalogue of Phoenician worthies; Pallas or Minerva is planted on the territory of Attica; in a word, all the branches of the family of the Titans, who in after ages figured in the rubric of the Greeks, are brought upon the stage, and their exploits and adventures briefly detailed.

By comparing this fragment with the mythology of Greece and the Atlantidæ and that of the Cretans preserved by Diodorus the Sicilian, lib. v. we think there is good reason to conclude, that the family of the Titans, the several branches of which seem to have been both the authors and objects of a great part of the Grecian idolatry, originally emigrated from Phoenicia. This conjecture will receive additional strength, when it is considered, that almost all their names recorded in the fabulous records of Greece, may be easily traced up to a Phoenician
MYTHOLOGY.

Phcenician original. We agree with Herodotus, that a considerable part of the idolatry of Greece may have been borrowed from the Egyptians; at the same time, we imagine it highly probable, that the idolatry of the Egyptians and Phcenicians was, in its original constitution, nearly the same. Both systems were Sabiism, or the worship of the host of heaven. The Pelasgi, according to Herodotus, learned the names of the gods from the Egyptians; but in this conjecture he is certainly warped by his partiality for that people. Had those names been imported from Egypt, they would no doubt have betrayed their Egyptian original; whereas, every etymologist will be convinced that every one is of Phcenian extraction.

The adventures of Jupiter, Juno, Mercury, Apollo, Diana, Mars, Minerva or Pallas, Venus, Bacchus, Ceres, Proserpine, Pluto, Neptune, and the other descendents and coadjutors of the ambitious family of the Titans, furnish by far the greatest part of the mythology of Greece. They left Phcenicia, we think, about the age of Moses; they settled in Crete, a large and fertile island; from this region they made their way into Greece, which, according to the most authentic accounts, was first inhabited by a race of strangers. The arts and inventions which they communicated to the natives; the mysteries of religion which they inculcated; the laws, customs, polity, and good order, which they established; in short, the blessings of humanity and civilization, which they everywhere disseminated, in process of time inspired the unpolished inhabitants with a kind of divine admiration. Those ambitious mortals improved this admiration into divine homage and adoration. The greater part of that worship, which had been formerly addressed to the luminaries of heaven, was now transferred to those illustrious personages. They claimed and obtained divine honours from the deluded rabble of enthusiastic Greeks. Hence sprung an inexhaustible fund of the most inconsistent and irreconcilable fictions.

The foibles and frailties of the deified mortals were transmitted to posterity, incorporated as it were with the pompous attributes of supreme divinity. Hence the heterogeneous mixture of the mighty and the mean which constitutes the character of the heroes of the Iliad and Odyssey. The Greeks adopted the oriental fables, the import of which they did not understand. These they accommodated to heroes and illustrious personages, who had figured in their own country in the earliest periods. The labours of Hercules originated in Egypt, and evidently relate to the annual progress of the sun in the zodiac, though the vain-glorious Greeks accommodated them to a hero of their own, the reputed son of Jupiter and Alcmena. The expedition of Osiris they borrowed from the Egyptians, and transferred to their Bacchus, the son of Jupiter and Semele the daughter of Cadmus. The transformation and wanderings of Io are evidently transcribed from the Egyptian romance of the travels of Isis in quest of the body of Osiris, or of the Phcenician Astarte, drawn from Sanchoniathon. Io or Is is in reality the Egyptian name of the moon, and Astarte was the name of the same planet among the Phcenicians. Both these fables are allegorical representations of the anomalies of the lunar planet, or perhaps of the progress of the worship of that planet in different parts of the world. The fable of the conflagration occasioned by Phaeton is clearly of oriental extraction, and alludes to an excessive drought which in the early periods of time scorched Ethiopia and the adjacent countries. The fabulous adventures of Perseus are said to have happened in the same regions, and are allegorical representations of the influence of the solar luminary; for the original Perseus was the sun. The rape of Proserpine and the wanderings of Ceres; the Eleusinian mysteries; the orgia or sacred rites of Bacchus; the rites and worship of the Cabiri—were imported from Egypt and Phcenicia; but strangely garbled and disfigured by the hierophants of Greece. The gigantic, or war between the gods and the giants, and all the fabulous events and varieties of that war, form an exact counterpart to the battles of the Peri and Dives, celebrated in the romantic annals of Persia.

A considerable part of the mythology of the Greeks sprang from their ignorance of the oriental languages. They disdained to apply themselves to the study of those languages spoken by people whom, in the pride of their hearts, they stigmatized with the epithet of barbarians. This aversion to every foreign dialect was highly detrimental to their progress in the sciences. The same neglect or aversion has, we imagine, proved an irreparable injury to the republic of letters in all succeeding ages. The acids, or strolling bards, laid hold on those oriental legends, which they sophisticates and with their own additions and improvements, in order to accommodate them to the popular taste. These wonderful tales figured in their rhapsoidal compositions, and were greedily swallowed down by the credulous vulgar. Those fictions, as they rolled down, were constantly augmented with fresh materials, till in process of time their original import was either forgotten or buried in impenetrable darkness. A multitude of these Hesiod has collected in his Theogonia, or Generation of the Gods, which unhappily became the religious creed of the illiterate part of the Greeks. Indeed fable was so closely interwoven with the religion of that airy volatile people, that it seems to have contaminated not only their religious and moral, but even their political tenets.

The far-famed oracle of Dodona was copied from oracle of that of Ammon at Thebes in Egypt; the oracle of Dodona. Apollo at Delphos was an emarnation from the same source: The celebrated Apollo Pythius of the Greeks was no other than Ob or Aob of the Egyptians, who denominated the basilisk or royal snake Oub Cai, because it was held sacred to the sun. Ob or Aob is still retained in the Coptic dialect, and is one of the many names or epithets of that luminary. In short, the ground-work of the Grecian mythology is to be traced in the east. Only small part of it was fabricated in the country; and what was imported pure and genuine was miserably sophisticated by the hands through which it passed, in order to give it a Grecian air, and to accommodate its style to the Grecian taste. To enlarge upon this topic would be altogether superfluous, as our learned readers must be well acquainted with it already, and the unlearned may without much trouble borrow or expence furnish themselves with books upon the mythology from the Greeks.
M Y T H O L O G Y.

The mythology of the northern nations, i.e. of the
Norwegians, Danes, Swedes, Icelanders, &c., is
uncommonly curious and entertaining. The Edda
and Voluspa contain a complete collection of fables which have not the smallest affinity with those of the Greeks and Romans. They are wholly of an oriental complexi-
Onion or Odin, or Woden or Woden, was the supreme
divinity of those people. His exploits and adventures
furnish the far greater part of their mythological creed.
That hero is supposed to have emigrated from the east;
but from what country or at what period is not cer-
tainly known. His achievements are magnified bey-
ond all credibility. He is represented as the god of
battles, and as slaughtering thousands at a blow. His
palace is called Valhalla: it is situated in the city of
Midgard, where, according to the fable, the souls of
heroes who had bravely fallen in battle enjoy supreme
certainty. They spend the day in mimic hunting
matches, or imaginary combats. At night they as-
semble in the palace of Valhalla, where they feast on
the most delicious viands, dressed and served up by the
Valkyries, virgins adorned with celestial charms, and
flushed with the bloom of everlasting youth. They
solace themselves with drinking mead out of the skulls
of enemies whom they killed in their days of nature.
Mead, it seems, was the nectar of the Scandinavian
heroes.

Sleipnir, the horse of Odin, is celebrated along
with his master. Hel, the hell of the Scandinavian
nations, affords a variety of fables equally shocking and
heterogeneous. Loke, the evil genius or devil of the
northern people, nearly resembles the Typhon of the
Egyptians. Siga or Sinna is the consort of Loke;
from this name the English word sin is derived. The
giants Weymur, Ferbanter, Beluper, and Hellunda,
perform a variety of exploits, and are exhibited in the
most frightful attitudes. One would be tempted to
imagine, that they perform the exact counterpart of the
giants of the Greek and Roman mythologists.

The word Voluspa imports, "the prophecy of Vola" or
"Fola." This was, perhaps, a general name for the
prophetic ladies of the north, as Sibyl was appropriated
to women endowed with the like faculty in the south.
Certain it is, that the ancients generally connected
morality with the prophetic faculty. Of this we have two
certified examples: the one in Lycophrion's Alex-
andra, and the other in the Sibyl of the Roman poet.
The word vola signifies "mad or foolish;" whence the
English words fool, foolish, folly. Spas, the latter part
of the composition, signifies "to prophesy," and is still
current among the common people in Scotland, in the
word Spar, which has nearly the same signification.

The Voluspa consists of between 300 and 300 lines.
The prophetess having imposed silence on all intelli-
The northern
god, and the world was created by him. From this,
the people of his time call Nornes; the functions of the
devils, their most memorable adventures, their disputes
with Loke, and the vengeance that ensued. She at
last concludes with a long and indeed animated
description of the final state of the universe, and its
dissolution by a general conflagration.

In this catastrophe, Odin and all the rabble of the
Pagan deities, are to be confounded in the general
ruin, no more to appear on the stage of the universe.
Out of the ruins of the former world, according to the
Voluspa, a new one shall spring up, arrayed in all the
bloom of celestial beauty.

Such is the doctrine exhibited in the fabulous Vo-
luspa. So congenial are some of the details therein
delivered, especially those relating to the final dissolu-
tion of the present system, and the succession of a new
heaven and a new earth, that we find ourselves strong-
ly inclined to suspect, that the original fabricator of the
work was a Semitic writer, much of the same complexi-
with the authors of the Sibylline oracles, and of some other apocryphal pieces which appeared in the
world during the first ages of Christianity.

In America, the only mythological countries are Mex-
ico and Peru. The other parts of that large
continent were originally inhabited by savages, many
of them as remote from religion as from civilization.
The two vast empires of Mexico and Peru had existed
about 400 years only before the Spanish invasion. In
neither of them was the use of letters understood; and
of course the ancient opinions of the natives relating
to the origin of the universe, the changes which suc-
ceded, and every other monument of antiquity, were
obliterated and lost. Clavigero has indeed enumerated
a vast canaille of sanguinary gods worshiped by the
Mexicans.
MYTHOLOGY.

Mexican; but produces nothing either entertaining or interesting with respect to their mythology. The information to be derived from any other quarter is little to be depended upon. It passes through the hands of bigoted missionaries or other ecclesiastics, who were so deeply tinctured with fanaticism, that they viewed every action, every sentiment, every custom, every religious opinion and ceremony of those half-civilized people, through a false medium. They often imagined they discovered resemblances and analogies between the rites of those savages and the dogmas of Christianity, which nowhere existed but in their own hested imagination.

The only remarkable piece of mythology in the annals of the Peruvians, is the pretended extraction of Manco Capac the first Inca of Peru, and of Mama Ocala his consort. These two illustrious personages appeared first on the banks of the lake Titicaca. They were persons of a majestic stature, and clothed in decent garments. They declared themselves to be the children of the Sun, sent by their beneficent parent, who beheld with pity the miseries of the human race, to instruct and to reclaim them. Thus we find these two legislators availed themselves of a pretext which had often been employed in more civilized regions to the very same purposes. The idolatry of Peru was gentle and beneficent, that of Mexico gloomy and sanguinary. Hence we may see that every mode of superstition, where a divine revelation is not concerned, borrows its complexion from the characters of its professors.

In the course of this article, our readers will observe, that we have not much enlarged upon the mythology of the Greeks and Romans; that subject we imagine to be so universally known by the learned, and so little valued by the vulgar, that a minute discussion of it would be altogether superfluous. Besides, we hope it will be remembered, that the narrowness of the limits prescribed us would scarce admit of a more copious detail. We would flatter ourselves, that in the course of our disquisition, we have thrown out a few reflections and observations, which may perhaps prove more acceptable to both descriptions of readers.

MYTILUS, the Mussel, a genus of animals, belonging to the order of vermes testaceae. See CONCHOLOGY Index.

MYTTOTON, a coarse kind of food, used by the labouring people among the Greeks, and sometimes among the Romans. It was made of garlic, onions, eggs, cheese, oil, and vinegar, and reckoned very wholesome.

MYUS, in Ancient Geography, one of the twelve towns of Icria; seated on the Meander, at the distance of 30 stadia from the sea. In Strabo's time it was incorporated with the Milesians, on account of the paucity of inhabitants, from its being formerly overwhelmed with water: for which reason the Ionians consigned its suffrage and religious ceremonies to the people of Miletus. Artaxerxes allotted this town to Themistocles, in order to furnish his table with meat: Magnesia was to support him in bread, and Lampsacus in wine. The town now lies in ruins.

MYXINE, the Hag; a genus of animals belonging to the order of vermes intestina. See HELMINTHOLOGY Index.

N.

The n is a nasal consonant; its sound is that of a d, passed through the nose; so that when the nose is stopped by a cold, or the like, it is usual to pronounce d for n. M. Abbe De Dangeau observes, that in the French, the n is frequently a mere nasal vowel, without any thing of the consonant in it. He calls it the Slavonic vowel. The Hebrews call their n nun, which signifies child, as being supposed the offspring of m; partly on account of the resemblance of sound, and partly on that of the figure. Thus from the m, by omitting the last column, is formed the Greek minacle n. Hence from binnaies, &c. the Latins frequently use bimus, &c. and the same people convert the Greek n, at the end of a word, into an m, as symmen, pharmaceut, &c. See M.

N before n, b, and m, the Latins change into m, and frequently into l and r; as in in ludum, illud; in rigo, irigo, &c.: in which they agree with the Hebrews, who, in lieu of nun, frequently double the following consonants: and the Greeks do the same; as when for Manlius, they write Malmus, &c. The Greeks also, before n, y, x, changed the n into y: in which they were followed by the ancient Romans; who, for Angulus, wrote Aggulus; for anceps, angeps, &c.

The Latins retrench the n from Greek nouns ending...
being embraced by it, was thus tortured into compliance. To render his tyranny less unpopular, Nabis made an alliance with Flaminius the Roman general, and pursued with the most inveterate enmity the war which he had undertaken against the Achaeans. He besieged Gythium, and defeated Philopoemen in a naval battle. His triumph was short, the general of the Achaeans soon repaired his losses, and Nabis was defeated in an engagement, and killed as he attempted to save his life by flight, about 194 years before the Christian era.

NABLOUS, a province of Syria, anciently celebrated under the name of the kingdom of Samaria. Its capital, likewise called Nabous, is situated near to Sichem on the ruins of the Nepolis of the Greeks, and is the residence of a sheik, who is subordinate to the pacha of Damascus, from whom he farms the tribute of the province.

NABLUM, in Hebrew, Nebel, was an instrument of music among the Jews. It had strings like the harp, and was played upon by both hands. Its form was that of a Greek A. In the Septuagint and Vulgate, it is called nobiam, palterion, lyra; and sometimes cithara.

NABO, or NEBO, in Mythology, a deity of the Babylonians, who possessed the next rank to Bel. It is mentioned by Isaiah, chap. xlviii. Vossius apprehends that Nabo was the moon, and Bel the sun: but Grotius supposes that Nabo was some celebrated prophet of the country; which opinion is confirmed by the etymology of the name, signifying, according to Jerome, "one that presides over prophecy."

NABOB, properly NAOB, the plural of Nabi, a deputy. As used in Bengal, it is the same as NAZIM. It is a title also given to the wives and daughters of princes, as well as to the princes themselves.

NABONASSAR, first king of the Chaldeans or Babylonians; memorable for the Jewish era which bears his name, which is generally fixed in 3257, beginning on Wednesday, February 26th, in the 367th of the Julian period, 747 years before Christ. The Babylonians revolting from the Medes, who had overthrown the Assyrian monarchy, did, under Nabonassar, found a dominion, which was much increased under Nebuchadnezzar. It is probable, that this Nabonassar is that Baladan in the second of Kings, xx. 12. father of Merodach, who sent ambassadors to Hezekiah. See 2 Chron. xxxii.

NABOPOLASSAR, king of Babylon: he joined with Astyages the Mede, to destroy the empire of Assyria; which having accomplished, they founded the two empires of the Medes under Astyages, and the Chaldeans under Nabopolassar, 627 B.C.

NABUCHADNEZZAR, or Nabuchodonosor II. king of Assyria, son of Nabopolassar, and styed the Great, was associated by his father in the empire, 607 B.C. and the following year he took Jehoiakim king of Judah; prisoner to carry him and his subjects in captivity into Babylon; but upon his submission, and promising to hold his kingdom under Nabuchodonosor, he was permitted to remain at Jerusalem In 603 B.C. Jehoiakim attempted to shake off the Assyrian yoke, but without success; and this revolt brought on the general captivity. Nabuchadnezzar having subdued the Ethiopians, Arabs, Idumæans, Philistines, Syrians, Persians, Medes, Assyrians,
NAE, almost all Asia; being puffed up with pride, caused a golden statue to be set up, and commanded all to worship it; which Daniel's companions refusing to do, they were cast into the fiery furnace.

But as he was admiring his own magnificence, by divine sentence he was driven from men, and in the Scripture style is said to have eaten grasses oxen: i.e. he was seized with the disease called by the Greeks lyconthropy, which is a kind of madness that causes persons to run into the fields and streets in the night, and sometimes to suppose themselves to have the heads of oxen, or to be made of glass. At the end of seven years his reason returned to him, and he was restored to his throne and glory. He died 562 B.C. in the 43rd year of his reign; in the 4th of which happened that eclipse of the sun mentioned by Ptolemy, which is the surest foundation of the chronology of his reign.

NADIR, in Astronomy, that point of the heavens which is diametrically opposite to the zenith or point directly over our heads.

N.ENA, the goddess of funerals at Rome. Her temple was without the gates of the city. The songs which were sung at funerals were also called nenia. They were generally filled with the praises of the deceased; but sometimes they were so unmeaning and improper, that the word became proverbial to signify nonsense.

NAERDEN, a strong town of Holland, seated at the head of the canals of the province. The foundations of it were laid by William of Bavaria, in 1350. It was taken by the Spaniards in 1572, and by the French in 1672; but it was retaken by the prince of Orange the next year. It stands at the south end of the Zuyder Zee, in E. Long. 5° 3'. N. Lat. 51° 22'.

NÆVUS, a mole on the skin, generally called a mother's mark; also the tumour known by the name of a wen.

All preternatural tumours on the skin, in the form of a wart or tubercle, are called excrescences; by the Greeks they are called acrothymia; and when they are born with a person, they are called navi materni, or marks from the mother. See TUMOURS, SURGERY INDEX.

NAGERA, or Nagar, a town of Spain, in Old Castile, and the territory of Rioja, with the title of a duchy and fortress; famous for a battle fought in its neighbourhood in 1369. It is situated in a fertile country, on a brook called Nuerilla. W. Long. 2° 20'. N. Lat. 42° 45'.

NAGRACUT, a town of India, the capital of a kingdom of the same name in the dominions of the Great Mogul, with a rich temple to which the Indians go in pilgrimage. It is seated on the river Ravi. E. Long. 78° 10'. N. Lat. 33° 12'.

NAHUM, or the Prophecy of Nahum, a canonical book of the Old Testament.

Nahum, the seventh of the 12 lesser prophets, was a native of Elkoshai, a little village of Galilee. The subject of his prophecy is the destruction of Nineveh, which he describes in the most lively and pathetic manner; his style is bold and figurative, and cannot be excelled by the most perfect masters of oratory. This prophecy was verified at the siege of that city by Assyges, in the year of the world 3378, 622 years before Christ.

NAIAD, in fabulosity, certain inferior deities who presided over rivers, springs, wells, and fountains. The Naiades generally inhabited the country, and resorted to the woods or meadows near the stream over which they presided. They are represented as young and beautiful virgins, often leaning upon an urn, from which flows a stream of water. Aegle was the fairest of the Naiades, according to Virgil. Their name seems to be derived from nym, "to flow." They were held in great veneration among the ancients; and often sacrifices of goats and lambs were offered to them, with libations of wine, honey, and oil. Sometimes they received only offerings of milk, fruit, and flowers.

NAIANT, in Heraldry, a term used in blazoning fishes, when borne in a horizontal posture, as if swimming.

NAIAS, a genus of plants belonging to the dicot class; and in the natural method ranking with those of which the order is doubtful. See BOTANY INDEX.

NAID, the interior of the great desert of Arabia, inhabited by a few scattered tribes of feeble and wretched Arabs. See ARABIA.

NAIL, in Anatomy, which see.

NAILS, in building, &c. small spikes of iron, brass, &c. which being driven into wood, serve to bind several pieces together, or to fasten something upon them.

Nails were made use of by the ancient Hebrews for cancelling bonds; and the ceremony was performed by striking them through the writing. This seems to be alluded to in Scripture, where God is said by our crucified Saviour to have "blotted out the hand-writing of ordinances that was against us, and to have taken it out of the way, nailing it to his cross." Col. ii. 14. For the cause and ceremony of driving the annual nail, or clavis annalis, among the Romans, see ANNALIS CLAVIS.

NAIL, is also a measure of length, containing the 16th part of a yard.
Nailing of Cannon. When circumstances make it necessary to abandon cannon, or when the enemy's artillery are seized, and it is not however possible to take them away, it is proper to nail them up, in order to render them useless; which is done by driving a large nail or iron spike into the vent of a piece of artillery, to render it unserviceable. There are various contrivances to force the nail out, as also sundry machines invented for that purpose, but they have never been found of general use; so that the best method is to drill a new vent.

One Gasper Vimercatus was the first who invented the nailing of cannon. He was a native of Bremen, and made use of his invention first in nailing up the artillery of Sigismund Malatesta.

NAIN, LEWIS SEBASTIAN DE, a French critic and historian, was the son of a master of the requests, and was born at Paris in 1637. At ten years old he went to school at Port Royal, and became one of the best writers of that institution. Sacÿ, his intimate friend and counsellor, prevailed with him in 1676 to receive the priesthood; which he seems, his great humility would not before suffer him to aspire to. This virtue he seems to have possessed in the extreme; so that Bossuet, seeing one of his letters to Father Damé, with whom he had some little dispute, besought him merely "not to be always upon his knees before his adversary, but raise himself up now and then." He was solicited to push himself forward in the church, and Buzanval, bishop of Beauvais, wished to have him for his successor; but Nain, regardless of dignities, wished for nothing but retirement, so that he might indulge in the mortifications of a religious life and the indefatigable cultivation of letters. He died in 1698, aged 61. His principal works are, 1. Memoirs on the ecclesiastical history of the six first ages of the church, 16 vols. 4to. 2. The history of the emperors, 6 vols. 4to. These works are deduced from original sources, and composed with the utmost fidelity and accuracy.

Nain, or NAIRN, situated at the bottom of Mount Hermon on the north side, was anciently a city of the tribe of Issachar, in the province of Galilee. It was near the gate of this city that our Saviour restored to life the only son of a widow, and where he inspired Mary Magdalen to come and mourn for her sins at his feet. These features alone make this place worthy of notice; for at present Nain is only a hamlet inhabited by Christians, Mahometans, and Hebrews, where there is not a single monument to attract the curiosity of the traveller.

NAIRES, NAHERS, or NAYERS, in modern history, a name which is given by the Malabarians to the military of their country, who form a very numerous class or tribe, out of which the sovereigns of Malabar choose their body guard.

NAIRN, a county of Scotland, comprehending the western part of the province of Murray. It is bounded on the north by the Murray frith, on the west and south by Inverness, and on the east by Elgin. The length is about 18 miles, and the breadth about 14. The air is temperate and salubrious, and the winters are remarkably mild. The face of the country is rough and mountainous: yet there are some fruitful valleys which produce good crops of oats and barley; but in general the country is much better adapted for pasturage. Here are also large woods of fir, and other trees, that afford shelter to the game, of which there is great plenty. The most remarkable straths or valleys in this county, are Strathnairn, on the river of the name, in the south-west part of the shire; and on the south-east side, Strathrin, on both sides of Findhorn river. Nairn is well watered with streams, rivulets, and lakes abounding with fish. In the southern part there is a small lake, called Moy. The greatest part of the shire is peopled by the Frazeri, a warlike Highland clan, whose chief, the Lord Lovat, lost his life on the scaffold for having been concerned in the rebellion of 1745. Here are a great number of villages; but no towns of note except Nairn, supposed to be the Theaurus of Ptolemy, situated at the mouth of the river which bears the same name; a royal borough, which gave the title of lord to an ancient family, forfeited in the rebellion of 1715. The harbour, which opened in the Murray frith, is now choked up with sand; and the commerce of the town is too inconsiderable to deserve notice. About four miles from Nairn stands the castle of Calder on the river of that name, belonging to a branch of the family of Campbell; and six miles to the north-west of Nairn stands Fort George.

The following is the population of the parishes of this county, according to the Statistical History of Scotland.

In the returns for 1811 the population of Nairn is stated to be 8257. See Nairn, Supplement.

NAISSANT, in Heraldry, is applied to any animal issuing out of the midst of some ordinary, and showing only his head, shoulders, fore feet, and legs, with the tip of his tail; the rest of his body being hid in the shield, or some charge upon it: in which it differs from issuant, which denotes a living creature arising out of the bottom of any ordinary or charge.

NAISSUS, in Ancient Geography, a town of Dardanae, a district of Mysia Superior, said to be the birthplace of Constantine the Great, which seems probable from his often residing at that place. Naisius, the
the people (Coeis). Now called Nissa, a city of Serbia. E. Long. 23. N. Lat. 43.

NAKED SEEDS, in Botany, those that are not enclosed in any pod or case.

NAKIB, in the oriental dignities, the name of an officer who is a deputy to the cadiliskier, or, as he may be called, the lord high chancellor of Egypt, appointed by the grand signior. His office is to carry the standard of Mahomet.

NAKOS, an Egyptian musical instrument, made like two plates of brass, and of all sizes, from two inches to a foot in diameter; they hold them by strings fastened to their middles, and strike them together so as to beat time. They are used in the Coptic churches and in the Mahometan processions.

NAMA, a genus of plants belonging to the pentandria class, and order digynia; and, in the natural method, ranking under the 13th order, Sucequalentia. See Botany Index.

NAME, denotes a word whereby men have agreed to express some idea; or which serves to denote or signify a thing or subject spoken of. See Word.

This is an operation usually called a noun, nomen, although their noun is not of quite so much extent as our name. See Lib. ii. de Beneficiis. Observes, that there are a great number of things which have no name; and which, therefore, we are forced to call by other borrowed names. Ingea est (says he) rerum copia sine nomine, qua sum propriis appellatibus signare non possumus, alienae accommodatori utimur: which may show why, in the course of this dictionary, we frequently give divers senses to the same word.

Names are distinguished into proper and appellative.

Proper Names are those which represent some individual thing or person, so as to distinguish it from all other things of the same species; as, Socrates, which represents a certain philosopher.

Appellative or General Names, are those which signify common ideas; or which are common to several individuals of the same species; as, horse, animal, man, oak, &c.

Proper names are either called Christian, as being given at baptism; or surnames: The first imposed for distinction of persons, answering to the Roman praenomen; the second, for the distinction of families, answering to the nomen of the Romans, and the patronymicum of the Greeks.

Originally every person had but one name; as among the Jews, Adam, &c.; among the Egyptians, Busiris; among the Chaldees, Nimus; the Medes, Astyages; the Greeks, Diomedes; the Romans, Romulus; the Gauls, Divitius; the Germans, Ariovistus; the Britons, Cassibelion; the English, Hengist, &c. And thus of other nations, except the savages of Mount Atlas, whom Piny and Marcellinus represent as anonymi, nameless.

The Jews gave the name at the circumcision, viz. eight days after the birth: the Romans, to females the same day, to males the ninth; at which time they held a feast, called nominalia.

Since Christianity has obtained, most nations have followed the Jews, baptizing and giving the name on the eighth day after the birth; except our English ancestors, who, till of late, baptized and gave the name on the birth day.

The first imposition of names was founded on different views, among different people; the most common was to mark the good wishes of the parents, or to entitle the children to the good fortune a happy name seemed to promise. Hence, Victor, Castor, Faustus, Statius, Probus, &c.

Accordingly, we find such names, by Cicero called bona nomina, and by Tacitus fausta nomina, were first enrolled and ranged in the Roman musters; first called to serve at the sacrifices, in the foundation of colonies, &c.—And, on the contrary, Livy calls Atrius Umber, abominari omnis nomen: and Plautus, on occasion of a person named Lyco, i.e. "greedy wolf," says:

Vosmet nunc susea conjecturar ceterum
Quid si sit hominis, cui Lyco nomen sit.

Hence, Plato recommends it to men to be careful in giving happy names; and the Pythagoreans taught expressly, that the minds, actions, and successes of men, were according to their names, genius, and fate. Thus Panmini, ex bona nomine or bona præsumptio; and the common proverb, Bonus nomen bonum omen; and hence the foundation of the onomantia. See Onomantia.

It is an observation deserving attention, says the abbé Barthelami, that the greater part of names found in Homer are marks of distinction. They were given in honour of the qualities most esteemed in the heroico-ages. From the word polemos, which signifies war, have been formed Tlepolemus and Acheleopdes, the names of two heroes mentioned in the Iliad. The former name signifies able to support, and the latter, able to direct, the labours of war. By adding to the word mache, or battle, certain prepositions and different parts of speech, which modify the sense in a manner always honourable, are composed the names Amphimachus, Antinachus, Promeachus, Telemachus. Proceeding in the same way, with the word honor, "strength or intrepidity," they formed the names Agapenor, "he who esteems valour," Agenor, "he who directs it." From tos, "swift," are derived, Alcahestes, Panthoetes, Periokes, &c. From nous, "mind or intelligence," come Asynothes, Arinoothes, Atanoeotes, &c. From medes, "counsel," Agamedes, Eumedes, Lycomedes, Thraeymedes; and from citois, "glory," Amphiclies, Agacies, Iphicles, Patrocles, Ciribalus, with many others.

Hence Camden takes it for granted, that the names, in all nations and languages, are significative, and not simple sounds for mere distinction's sake. This holds not only among the Jews, Greeks, Latins, &c. but even the Turks; among whom, Abdala signifies God's servant; Soliman, peaceable; Mahomet, glorified, &c. And the savages of Spaniards, and throughout America, who, in their languages, name their children, Glistering Light, Sun, Bright, Fine Gold, &c.; and they of Congo, by the names of precious stones, flowers, &c.;

To suppose names given without any meaning, however by the alteration of language their signification may be lost, that learned author thinks is to reproach our ancestors; and that contrary to the sense of
of all ancient writers. Porphyry notes, that the barbarous names, as he calls them, were very emphatical, and very concise: and accordingly it was esteemed a duty to be *paramonos*, or *su nominis nominis*: *as Severus, Probus, and Aurelius, are called su nominis imperatores.*

It was the usual way of giving names, to wish the children might discharge their names. Thus when Gunthram king of France named Clotharius at the font, he said, *Crocat puere, et huysis sit nominis executor.*

The ancient Britons, Camden says, generally took their names from colours, because they painted themselves; which names are now lost, or remain hid among the Welsh. When they were subdued by the Romans, they took Roman names, some of which still remain corrupted; though the greatest part became extinct upon the admission of the English Saxons, who introduced the German names, as *Edda, Pendo, Oswald, Edward,* &c. — The Danes, too, brought with them their names; *as Sweyn, Harold, Knute,* &c. The Normans, at the Conquest, brought in other German names, as originally using the German tongue; *such as Robert, William, Richard, Henry, Hugh,* &c. after the same manner as the Greek names *Aspasius, Bonthius, Symmachus,* &c. were introduced into Italy upon the division of the empire. After the Conquest, our nation, which had ever been averse to foreign names, as deeming them unlucky, began to take Hebrew names; *as Matthew, David, Samuel,* &c. The various names anciently or at present obtaining among us, from what language or people soever borrowed, are explained by Camden in his Remains. As to the period when names began to be multiplied, and surnames introduced, &c. see SURNAME.

Of late years it has obtained among us to give surnames for Christian names; which some dislike, on account of the confusion it may introduce. Camden relates it as an opinion, that the practice first began in the reign of Edward VI. by such as would be godfathers, when they were more than half fathers. Upon which some were persuaded to change their names at confirmation; which, it seems, is usual in other countries.

Thus, two sons of Henry II. of France, christened *Alexander and Hercules*, changed them at confirmation into *Henry and Francis*. In monasteries, the religious assume new names at their admission, to show they are about to lead a new life, and have renounced the world, their family, and even their name: *v. g.* sister Mary of the Incarnation, brother Henry of the Holy Sacrament, &c. The popes also changed their names at their election to the pontificate; a custom first introduced by Pope Sergius, whose name till then, as Platina informs us, was *Switne's-swoot*. But Onuphrius refers it to John XII. or XIII. and at the same time adds a different reason for it from that of Platina, viz. that it was done in imitation of St Peter and St Paul, who were first called *Simon and Saul*.

Among the ancients, those deified by the Heathen consecrations had new names given them; as Romulus was called *Quirinus*; Melicertes, *Portunus or Portumnus,* &c.

New names were also given in adoptions, and sometimes by testament? Thus L. Emilius, adopted by Scipio, took the name of *Scipio Africanus*; and thus Augustus, who was at first called C. Octavius Thurinus, being adopted by the testament of Julius Caesar into his name and family, took the name of *Caesius Julius Caesar Octavius.*

Names were also changed at enfranchiseisments into new cities. Thus Lucumo, at his first being made free of Rome, took the name *Lucius Turquinius Priscus,* &c.; and slaves when made free, usually assumed their masters' names. Those called to the equestrian order, if they had base names, were always new named, *namely ingeniorum veterumque Romanorum.* And among the primitive Christians, it was the practice to change the names of the catechumens: Thus the renegade Lucanus, till his baptism, was called *Lucius.*

Towards the middle of the 15th century, it was the fancy of the wits and learned men of the age, particularly in Italy, to change their baptismal names for classical ones. As Sannazzarius, for instance, who altered his own plain name *Jacopo to Actius Syrianus.* Numbers did the same, and among the rest Platina the historian at Rome, who, not without a solemn ceremonial, took the name of *Callimachus instead of Philip.* Pope Paul II. who reigned about that time, unluckily chosen to be suspicious, illiterate, and heavy of comprehension. He had no idea that persons could wish to alter their names unless they had some bad design, and actually scrupled not to employ imprisonment and other violent methods to discover the fancied mystery. Platina was most cruelly tortured on this frivolous account: he had nothing to confess: so the pope, after endeavoring in vain to convict him of heresy, sedition, &c. released him after a long imprisonment.

NAMPTWICH, or NANTWICH, a town of Cheshire in England, situated on the river Weaver, 14 miles S. E. from Chester, and 162 miles from London. It lies in the Vale Royal, and is one of the largest and best built towns in the county, the streets being very regular, and adorned with many gentlemen's houses. The inhabitants amounting in 1811 to 3999, trade in corn, cattle, cheese, fine white salt, and shoes. It is governed by a constable, &c. who are guardians of the salt springs. It is divided into two equal parts by the Weaver, which is navigable to Winsford bridge. The Chester canal, terminates in a large basin near this place. In this town were several religious foundations, now no more. The church is a handsome pile of building in the form of a cross, with an octagonal tower in the middle.

NAMUR, a province in the kingdom of the Netherlands, lying between the rivers Sambre and Meuse; bounded on the north by Brabant, on the east and south by Lorraine, and on the west by Haune. It is very fertile; has several forests, marble quarries, and mines of iron, lead, and pit coal; and is about 30 miles long and 20 broad. Namur is the capital town.

NAMUR, a large, rich, and very strong town of the Netherlands, capital of the county of Namur, with a strong castle, several forts, and a bishop's see. It contains 15,400 inhabitants. The most considerable forts are, Fort William, Fort Maesie, Fort Coquet, and Fort Espinor. The castle is built in the middle of the town, on a craggy rock. It was besieged by King William in 1695, who took it in the sight of a army of 100,000 French, though there were 16,000 men in the garrison. It was ceded to the house of Austria
in 1713, but taken by the French in 1746; and
and restored by the treaty of Aix-la-Chapelle. It was
again taken by the French in 1794, and remained in
their possession till 1814, when it was ceded to the
king of the Netherlands. It is situated at the con-
fluence of the rivers Measse and Sambre, in E. Long.
4 57, N. Lat. 50. 25.

NAN-TCHANG-FOU, the capital of Kiang-si, a pro-
vince of China. This city has no trade but that of
porcelain, which is made in the neighbourhood of Jao-
tseou. It is the residence of a viceroy, and com-
prehends in its district eight cities; seven of which are of
the third class, and only one of the second. So much of
the country is cultivated, that the pastures left are
scarcely sufficient for the flocks.

NANCY, a town of France, in the department of
Meurthe, situated near the river Meurthe, and con-
taining 29,740 inhabitants in 1800. It is divided into
the Old and New Towns. The first is irregularly
built, and contains the ducal palace; the streets of the
New Town are as straight as a line, adorned with
handsome buildings, and a very fine square. The pri-
matial church is a magnificent structure, and in
that of the Cordeliers are the tombs of the ancient dukes.
The manufactures are cloths, woollen stuffs, silks, hats,
iron ware, &c. The town was very well fortified, but
the king of France demolished the fortifications. It
has been taken and retaken several times; but has be-
longed to France ever since 1736. E. Long. 6. 17.
N. Lat. 48. 31.

NANCOWRY, or SOWRY, one of the Nicobar
islands, lying at the entrance of the bay of Bengal. See
NICOBAR.

NANI, JOHN BAPTIST, was born in 1616. His
father was procurator of St Mark, and ambassador from
Venice to Rome. He was educated with attention,
and made considerable improvement. Urban VIII. a
just valuer of merit, soon perceived that of young
Nani. He was admitted into the college of senators in
1641, and was shortly after nominated ambassador in
France, where he signalized himself by his compliant
manners. He procured considerable succours for the
war of Candia against the Turks; and became, after
his return to Venice, superintendent of the war office
and of finances. He was afterwards ambassador to the
empire, where he rendered those services to his coun-
try, which, as a zealous and intelligent citizen, he was
well qualified to discharge. He was again sent into
France in 1660 to solicit fresh succours for Candia;
and on his return was appointed procurator of St Mark.
He died November 5, 1768, at the age of 63, much
regretted by his countrymen. The senate had appoint-
ed him to write the History of the Republic; which he
executed to the satisfaction of the Venetians, although
the work was less admired by foreigners, who were not
proper judges of the accuracy with which he stated the
facts, of the purity of his diction, nor of the simplicity
of his style; although it must be acknowledged that
his narrative is much interrupted by too frequent paren-
theses. In writing his history of Venice he has given
an universal history of his times, especially with respect
to the affairs of the French in Italy. This history,
which is continued from 1613 to 1671, was printed at
Venice in 2 vol. 4to, in the years 1662 and 1679.

NAN-KING, a city of China, and capital of the pro-
vince of Kiang-nan, is said to have been formerly one of
the most beautiful and flourishing cities in the
world. When the Chinese speak of its extent, they
say, if two horsemen should go out by the same gate,
and ride round it on full speed, taking different direc-
tions, they would not meet before night. This account
is evidently exaggerated; but it is certain, that Nan-
kang surpasses in extent all the other cities of China.
We are assured that its walls are five leagues and a half
in circumference.

This city is situated at the distance of a league from
the river Yang-tse-kiang: it is of an irregular figure;
the mountains which are within its circumference hav-
ing prevented its being built on a regular plan. It was
formerly the imperial city; for this reason it was called
Nan-King, which signifies, the Southern Court;" but
since the six grand tribunals have been transferred
from hence to Peking, it is called Kiang-ning in all the
public acts.

Nan-kang has lost much of its ancient splendour: it
had formerly a magnificent palace, no vestige of which
is now to be seen; an observatory at present neglected,
temples, tombs of the emperors, and other superb
monuments, of which nothing remains but the resem-
brance. A third of the city is deserted, but the rest is
well inhabited. Some quarters of it are extremely pop-
ulous and full of business; particularly the manufac-
ture of a species of cotton cloth, of which great quan-
tities are imported into Europe under the name of Nan-
kang. The streets are not so broad as those of Peking,
they are, however, very beautiful, well paved, and
bordered with rich shops.

In this city resides one of those great mandarins
called Tsong-giou, who takes cognizance of all impor-
tant affairs, not only of both the governments of the
province, but also of those of the province of Kiang-si.
The Tartars have a numerous garrison here, command-
ed by a general of their own nation; and they occupy
a quarter of the city, separated from the rest by a plain
wall.

The palaces of the mandarins, whether Chinese or
Tartars, are in this city neither larger nor better built
than those in the capital cities of other provinces. Here
are no public edifices corresponding to the reputation
of so celebrated a city, excepting its gates, which are
very beautiful, and some temples, among which is the
famous porcelain tower. It is 200 feet high, and di-
vided into nine stories by plain boards within, and
without by cornices and small projections covered with
green varnished tiles. There is an ascent of 40 steps
to the first story; between each of the others there
are 21.

The breadth and depth of the river Yang-tse-kiang
formerly rendered the port of Nan-kang very com-
modious; but at present large barks, or rather Chinese
junks, never enter it: whether it be that it is shut up
by sand banks, or that the entrance of it has been for-
bid, in order that navigators may insensibly lose all
knowledge of it.

In the months of April and May a great number of
excellent fish are caught in this river near the city,
which are sent to court; they are covered with ice,
and transported in that manner by barks kept entirely
on purpose. Although this city is more than 200
leagues from Peking, these boats make such expedition,
that they arrive there in eight or nine days. This city, although the capital of the province, has under its particular jurisdiction only eight cities of the third class. The number of its inhabitants is said to be 1,000,000 without comprehending the garrison of 40,000 men.

E. Long. 119. 24. N. Lat. 32. 46.

NANSIO, an island of the Archipelago, a little to the north of the island of Santorino, 16 miles in circumference; but has no harbour. The mountains are nothing but bare rocks, and there are not springs sufficient to water the fields. There is a vast number of partridges, whose eggs they destroy every year to preserve the corn, and yet vast numbers of them are always produced. The ruins of the temple of Apollo are yet to be seen, and consist chiefly of marble columns.

E. Long. 26. 20. N. Lat. 36. 15.

NANTES, an ancient, rich, and very considerable town of France, in the department of Lower Loire, containing 73,870 inhabitants in 1800. It is situated on the north side of the Loire, about 40 miles from its mouth, at the confluence of the Erdre. It is the chief place of the department, the see of a bishop, and the seat of several tribunals. The atmosphere is pure, and the surrounding country is rich and beautiful. Nantes is a town of extensive trade. Vessels under 100 tons ascend to the city; those above that size discharge their cargoes at Paimboeuf, 25 miles below, and have them conveyed up in boats. The manufactures are cordage, canvas, linen, calico, leather, refined sugar, bottle-glass, &c. By the Loire, this town has an extensive communication with the interior of France; and supplies Orleans and other towns with foreign commodities. The Spaniards trade here in wine, fine wool, iron, silk, oil, oranges, and lemons; and they carry back cloth, stuffs, corn, and hard ware. The Dutch send salt fish, and all sorts of spices; and in return have wine and brandy. The Swedes bring copper; and the English, lead, tin, &c. It was in this place that Henry IV. promulgated the famous edict of 1598, called the Édit de Nantes, and which was revoked in 1685. Nantes was anciently, like almost every considerable city in Europe, very strongly fortified. Peter de Dreux, one of the dukes of Bretagne, surrounded it with walls, which have only been demolished within these few years. The bridge is an object of curiosity. It is near a mile and a half in length, being continued across all the little islands in the Loire, from north to south.

W. Long. 1. 45. N. Lat. 47. 12.

NANTWICH. See NMWTWCH.

NAPHE_PA, a genus of plants belonging to the polvadelphia class; and in the natural method ranking under the 37th order, Cumnifera. See BOTANY Index.

NAPHTHA, an inflammable substance of the bituminous kind. See CHEMISTRY and MINERALOGY.

NAPHTHALI, or NEPHTHALI (Josh. xix.); one of the tribes of Israel; having Zabulon on the south, Asher on the west, the Jordan on the east, and the north Antilbanus.

NAPIER, JOHN, baron of Merchiston in Scotland, inventor of the logarithms, was the eldest son of Sir Archibald Napier of Merchiston, and born in the year 1550. Having given early discoveries of great natural parts, his father was careful to have them cultivated by a liberal education. After going through the ordinary courses of philosophy at the university of St Andrew's, he made the tour of France, Italy, and Germany. Upon his return to his native country, his literature and other fine accomplishments soon rendered him conspicuous, and might have raised him to the highest offices of the state; but declining all civil employments, and the bustle of the court, he retired from the world to pursue literary researches, in which he made an uncommon progress, so as to have favored mankind with sundry useful discoveries. He applied himself chiefly to the study of mathematics; but at the same time did not neglect that of the Holy Scriptures. In both these he hath discovered the most extensive knowledge and profound penetration. His essay upon the book of the Apocalypse, indicates the most acute investigation, and an uncommon strength of judgment; though time hath discovered, that his calculations concerning particular events hath proceeded upon fallacious data. This work has been printed abroad in several languages; particularly in France at Rochelle in the year 1592, 8vo, announced in the title, as revised by himself. Nothing, says Lord Buchan, could be more agreeable to the Rochellers or to the Huguenots of France at this time, than the author's announcement of the pope as antichrist, which in this book he has endeavoured to set forth with much zeal and erudition. But what has principally rendered his name famous, was his great and fortunate discovery of logarithms in trigonometry, by which the ease and expedition in calculation have so wonderfully assisted the science of astronomy and the arts of practical geometry and navigation. That he had begun about the year 1593 the train of inquiry which led him to that great achievement in arithmetic, appears from a letter to Cruguerus from Kepler in the year 1624; where, mentioning the Canon Mirificus, he writes thus; "Nil autem supra Neperiam rationem esse puto: etsi Sextus quidem literis ad Tychonom, anno 1564, scripsit spem fecit Canonem Sylvis mirificum\" which statement agrees with the account given by Wood in his Athenae Oxonienses, and explains it in a way perfectly consonant to the rights of Napier as the inventor.

When Napier had communicated to Mr Henry Briggs, mathematical professor in Gresham college, his wonderful canon for the logarithms, that learned professor set himself to apply the rules in his Inns De Neperes; and in a letter to Archbishop Usher in the year 1615, he writes thus: "Napier, baron of Merchiston, hath set my head and hands at work with his new and admirable logarithms. I hope to see him this summer, if it please God; for I never saw a book which pleased me better, and made me more wonder. The following passage from the life of Lily the astrologer is quoted by Lord Buchanan, as giving a picturesque view of the meeting betwixt Briggs and the inventor of the logarithms at Merchiston near Edinburgh: "I will acquaint you (says Lily) with one memorable story related unto me by John Marr, an excellent mathematician and geometrical, whom I conceive you remember. He was servant to King James L and Charles I. When Merchiston first published his logarithms, Mr Briggs, then reader of the astronomy lectures at Gresham college in London, was so much surprised with admiration of them, that he could have no quietness in himself until he had seen that noble person whose
The last literary exertion of this eminent person was the publication of his *Rabdologia and Promtuary* in the year 1617, which he dedicated to the Chancellor Serton; and soon after died at Merchiston on the 30th of April. Of the same year, in the 68th year of his age and 23d of his happy invention.—The particular titles of his works published are: 1. A plain discovery of the Revelation of St John. 2. *Mirifici ipsius canomorum constructio et logartihorum, ad naturales ipsorum numerorum habitudines.* 3. *Appendix de ania atque praestantiori logartihorum species constiutuenda, in qua secilicet unitas logartihorum est.* 4. *Rhabdologia, seu numerationes per virgulas, libri duo.* 5. *Propositiones quaedam eminensstissimae, ad triangula sphericatae factae resistendo.* To which may be added, 6. His Letter to Anthony Bacon (the original of which is in the archbishop's library at Lambeth), entitled, "Secret inventions, profitable and necessary in these days for the defence of this island, and withstanding strangers enemies to God's truth and religion," which the earl of Buchan has caused to be printed in the Appendix to his Account of Napier's Writings. This letter is dated June 2. 1596, about which time it appears the author had set himself to explore his logarithmic canon.

This eminent person was twice married. By his first wife, who was a daughter of Sir James Stirling of Keir, he had only one son named Archibald, who succeeded to the estate. By his second wife, a daughter of Sir James Chisholm of Cromlix, he had a numerous issue. Archibald Napier, the only son of the first marriage, was a person of fine parts and learning. Having more a turn to public business than his father had, he was raised to be a privy councilor by James VI. under whose reign he also held the offices of trea-ner-depute, justice-clerk, and senator of the college of justice. By Charles I. he was raised to the peerage by the title of Lord Napier.

*NAPIER'S RODS, or Bone*, an instrument invented by Baron Napier, whereby the multiplication and division of large numbers is much facilitated.

As to the Construction of Napier's Rods: Suppose the common table of multiplication to be made upon a plate of metal, ivory, or pasteboard, and then conceive the several columns (standing downwards from the digits on the head) to be cut asunder: and these are what we call Napier's rods of multiplication. But then there must be a good number of each; for as many times as any figure is in the multiplicand, so many rods of that species (i.e. with that figure on the top of it) must we have; though six rods of each species will be sufficient for any example in common affairs: there must be also as many rods of 0's.

But before we explain the way of using these rods, there is another thing to be known, viz. that the figures on every rod are written in an order different from that in the table. Thus the little square space or division in which the several products of every column are written, is divided into two parts by a line across from the upper angle on the right to the lower on the left; and if the product is a digit, it is set in the lower division; if it has two places, the first is set in the lower, and the second in the upper division; but the spaces on the top are not divided; also there is a rod of digits, not divided, which is called the index rod, and of this we need but one single rod. See the figure of all the different rods, and the index, separate from one another, in Plate CCLXIX. fig. 1.

*Multiplication by Napier's Rods.* First lay down the index rod; then on the right of it set a rod, whose top
top is the figure in the highest place of the multiplicand; next to this again, set the rod whose top is the next figure of the multiplicand; and so on in order to the first figure. Then is your multiplicand tabulated for all the nine digits; for in the same line of squares standing against every figure of the index rod, you have the product of that figure; and therefore you have no more to do but to transfer the products and sum them. But in taking out these products from the rods, the order in which the figures stand obliges you to a very easy and small addition; thus, begin to take out the figure in the lower part, or units place, of the square of the first rod on the right; add the figure on the upper part of this rod to that in the lower part of the next, and so on; which may be done as fast as you can look on them. To make this practice as clear as possible, take the following example.

Example: To multiply 4768 by 385. Having set the rods together for the number 4768 (fig. 2) against 5 in the index, I find this number by adding according to the rule,

Against 8, this number - - 38144
Against 3, this number - - 14304.

Total product - - 1833680

To make the use of the rods yet more regular and easy, they are kept in a flat square box, whose breadth is that of ten rods, and the length that of one rod, as thick as to hold six (or as many as you please), the capacity of the box being divided into ten cells, for the different species of rods. When the rods are put up in the box (each species in its own cell distinguished by the first figure of the rod set before it on the face of the box near the top), as much of every rod stands without the box as shows the first figure of that rod: also, upon one of the flat sides without and near the edge, upon the left hand, the index rod is fixed; and along the foot there is a small ledge; so that the rods when applied are laid upon this side, and supported by the ledge, which makes the practice very easy; but in case the multiplicand should have more than nine places, that upper face of the box may be made broader. Some make the rods with four different faces, and figures on each for different purposes.

Division by Napier's Rods. First tabulate your divisor; then you have it multiplied by all the digits, out of which you may choose such convenient divisors as will be next less to the figures in the dividend, and write the index answering in the quotient, and so continually till the work is done. Thus 2179788, divided by 6123, gives in the quotient 356.

Having tabulated the divisor 6123, you see that 6123 cannot be had in 2179; therefore take five places, and on the rods find a number that is equal or next less to 21797, which is 18369; that is, 3 times the divisor; wherefore set 3 in the quotient, and subtract 18369 from the figures above, and there will remain 34288; to which add 8, the next figure of the dividend, and seek again on the rods for it, or the next less, which you will find to be five times; therefore set 5 in the quotient, and subtract 30615 from 34288, and there will remain 3673; to which add 8, the last figure in the dividend, and finding it to be just six times the divisor, set six in the quotient.

NAPLES, a kingdom of Italy, comprehending the ancient countries of Samnium, Campania, Apulia, and Magna Graecia. It is bounded on all sides by the Mediterranean and Adriatic, except on the north-east, where it terminates on the Ecclesiastical state. Its greatest length from south-east to north-west is about 280 English miles; and its breadth from north-east to south-west, from 96 to 120.

The ancient history of this country falls under the articles Rome and Italy; the present state of it, as well as of the rest of Italy, is owing to the conquest of Charlemagne. When that monarch put an end to the kingdom of the Lombards, he obliged the dukes of Friuli, Spoleto, and Benevento, to acknowledge him as king of Italy; but allowed them to exercise the same power and authority which they had enjoyed before his conquest. Of these three dukedoms Benevento was by far the most powerful and extensive, as it comprehended almost all the present kingdom of Naples; that part of Farther Calabria beyond the rivers Savoia and Petro, a few maritime cities in Hither Calabria, with the city of Acerpo, and the promontory in the neighbourhood called Culo di Lina; and lastly, the dukedoms of Gaeta, Naples, and Amalfi, which were very inconsiderable, and extended along the shore only about 100 miles, and were interrupted by the Castello or county of Capua.

This flourishing and extensive dukedom was at the time governed by Archis, who had married one of the daughters of the last king of the Lombards, and had submitted, and taken the oath of allegiance to the emperor Charles. However, a few years after, he renounced his allegiance to the Franks, declared himself an independent sovereign, and was acknowledged as such by all the inhabitants of his duchy. To strengthen himself against Pepin king of Italy, who resided at Ravenna, he enlarged and fortified the city of Benevento, and likewise built Salerno on the sea coast, surrounding it with a very strong and high wall. He engaged in several wars with the Greeks, whom he sometimes obliged to give him hostages; but having invaded the territories of the pope, whom Pepin could not assist, Charlemagne was prevailed on to return to Italy. Archis, unable to oppose such a formidable enemy, sent his eldest son, Romuald, to Rome, with an offer of submission; but, at the instigation of the pope, Charles refused the offer, and detained his son prisoner; after which he ravaged the country, and made himself master of Capua. Other deputies, however, proved more successful; and, in the year 787, a peace was concluded on these conditions: That Archis and the Beneventans should renew their allegiance to the Franks; that he should pay a yearly tribute to Pepin; deliver up all his treasury; and give
NAP [ 603 ]

NAP

 gave his son Grimoald and his daughter Adelgisa, with twelve others, as hostages for his fidelity: however, after many entreaties, Adelgisa was restored to her father.

Charies had no sooner left Italy, than Arechis forgot all his engagements, and began to negotiate with Irene, empress of Constantinople, and her son Constantine, for expelling the Franks out of Italy. For himself, he desired the honour of the patriciate, and the dukedom of Naples with all its dependencies; and, in return, promised to acknowledge the Greek emperor as his sovereign, and to live after the manner of the Greeks. He required, however, to be supported by a Greek army, and that his brother-in-law Adalgisus, son to Desiderius the last king of the Lombards, should be sent over into Italy, to raise a party among his countrymen. These conditions were readily accepted, on condition that Prince Romuald should be sent as an hostage; ambassadors were sent to Naples with the ensigns of the Patrician order, namely, the mantle of cloth of gold, the sword, the comb, and the sandals: but before the ceremony could be performed, Prince Romuald died, and soon after him his father; whose death was supposed to have been hastened by that of his son.

After the death of Arechis, the Beneventans sent a most submissive embassy to Charlemagne, entreaty him to send them Grimoald, the late king's son, and only lawful heir to his crown; threatening at the same time to revolt if their prince was denied them. Charles readily granted their request, and allowed Grimoald to depart, after he had agreed to the following conditions, viz. That he should oblige the Lombards to shave their beards; that, in writings, and on money, the name of the king should be put before that of the prince; and that he should cause the walls of Salerno, Acerenza, and Consia, to be entirely abdosed.—The new king was received by his subjects with the utmost joy; and for some time continued faithful to his engagements, excepting only the last article, which he either neglected or eluded. So far, however, was he from assisting the Greeks, that he gave notice of their machinations to Pepin king of Italy; raised an army to oppose his uncle Adalgisus; and being joined by Hildebrand duke of Spoleto, and Vinigise the general of Pepin, he attacked the Greeks in Calabria soon after they had landed, entirely defeated and took his uncle prisoner, and, as is said, put him to a cruel death. Yet in a short time Grimoald contracted an alliance with the Greek emperor by marrying his niece Wanizia; and in the fifth year of his reign a war broke out between him and Pepin, which continued for twelve years; at the end of which time a truce was concluded. Grimoald survived this pacification only three years, and was succeeded by his treasurer Grimoald II, who submitted to Charlemagne after the death of Pepin; and from this time the Beneventans were looked upon as tributaries of the western emperors. As yet, however, the city of Naples did not own allegiance to the dukes of Benevento, but was held by the stern emperors; and frequent wars took place between the Beneventans and Neapolitans. This happened to be the case when Grimoald II ascended the throne. He concluded a peace with them; which, however, was of no long continuance; for Theodore, governor of Naples, having granted protections to Daiferius a noble Beneventan, who had been concerned in a conspiracy against his prince, Grimoald marched against the city of Naples, and invested it by sea and land. Theodore still refused to deliver up the traitor, and a general engagement both by land and sea was the consequence; in which the Neapolitans were defeated with so great slaughter, that the sea was stained with their blood for more than seven days. Theodore then consented to deliver up Daiferius, with 8000 crowns for the expense of the war; and Grimoald not only pardoned Daiferius, but received him into favour: The traitor, however, reflecting on the heiminess of his crime, was seized with remorse; and went a pilgrimage to the holy land, carrying a large stone in his mouth, by way of penance, which he never took out but at his meal.

In the year 821, Grimoald was murdered by Radielchis count of Consia, and Sico Gastald of Acerenza, the latter of whom succeeded to the dukedom of Benevento. Radielchis being soon after seized with remorse, became a monk; while Sico associated his son Sicardo with him in the government; and both, being of an ambitious and restless disposition, sought a pretence for attacking the Neapolitans. This was Naples being soon found, and the city invested by sea and land. The walls were furiously battered; and part of them being beat down, Sico prepared for a general assault. Stephen, at that time duke of Naples, pretended to submit; but, that he might prevent the city from being pillaged, entreated Sico to put off his entry till the morning, and in the mean time sent out his mother and his two children as hostages. Sico consented to his request; but next morning found the breach built up, and the Neapolitans prepared for their defence. Exasperated at their perfidy, he renewed his attacks with vigour, but without any success; the besieged defending themselves with the utmost obstinacy. At last, perceiving that they should not be able to hold out much longer, they consented to a peace on the following conditions, viz. That the Neapolitans should pay an annual tribute to the princes of Benevento, and consent of the transporting of the body of St Janarius from his church without the walls of Naples to Benevento. These conditions being ratified, Sico returned with great honour to Benevento; but soon after renewed the war, under pretence that the Neapolitans had neglected to pay the stipulated sum; and hostilities continued till his death, which happened in 833.

Sico was succeeded in the government of Benevento by his son Sicardo, who had married the daughter of Daiferius; and being influenced by the evil counsels of Roffred his wife's brother, oppressed his subjects to such a degree that they conspired against his life. He besieged Naples with a powerful army, and took possession of Acerza and Atella, both of which he fortified. But Bonus, the Neapolitan duke, defended himself so vigorously, that the Beneventans were obliged to retire, and even to abandon Acerza and Atella, the fortifications of which were immediately demolished. At last Sicardo agreed to a peace for five years, on the intercession of Lothaire, emperor and king of Italy; but his chief motive was thought to have been the fear of the Saracens, whom the duke of Naples had called over from Africa to his assistance; for no sooner were they
The Saracens called in by the duke of Naples.

they sent back than Sicardo attempted to delay the conclusion of the treaty; but the emperor interposing his authority, a peace was concluded in the year 836, after the war had continued, with very little intermission, for 16 years.

Soon after the conclusion of this peace, the Saracens landed at Brindisi; and having made themselves masters of the place, ravaged all the neighbouring country. Sicardo marched against them with a numerous army; but the Saracens having dug a great number of ditches which they slightly covered over, found means to draw the Beneventans in among them, whereby they were repulsed with great loss. However, Sicardo, having reinforced his army, marched again to attack them; but the Saracens, despairing of success, pillaged and burnt Brindisi, and then retired with their booty, and a great many captives to Sicily. Sicardo, then, without any apparent provocation, attacked the city of Amalfi, levelled its walls with the ground, carried off all its wealth, and the body of its tutelar saint Triphomen. A great many of the inhabitants were transported to Salerno; and by promoting alliances between the inhabitants of both places, he endeavoured to unite Amalfi to his own principality as firmly as possible.

During all these transactions, Sicardo had tyrannized over his subjects in such a manner, that at last he became intolerable. Among other acts of injustice, he imprisoned his own brother Siconolphus; consigned him to turn priest; and afterwards sent him bound to Tarento, where he caused him to be shut up in an old tower that had been built for a cistern. By such acts of tyranny his nobles were provoked to conspire against him; and in the year 839 he was murdered in his tent.

On the death of Sicardo, Radelchis, his secretary or treasurer, was unanimously elected prince of Benevento; but Siconolphus, the last king's brother, having regained his liberty, formed a great party against the new prince. Radelchis did not fail to oppose him with a formidable army; and a most ruinous civil war ensued. Both parties by turns called in the Saracens; and these treacherous allies acted sometimes against one, and sometimes against the other; or, turned their arms against both, as seemed most suitable to their own interest. Thus the war continued with the utmost animosity for 12 years, during which time the principality was almost entirely ruined; till at last the emperor Lewis interposed, and obliged the competitors to agree to a partition of the principality. By this treaty, Radelchis promised to acknowledge Siconolphus and his successors as lawful princes of the principality of Salerno, which was declared to contain Tarento, Latino, Cassano, Cosenza, Laino, Lucania, Conisia, Montella, Rota, Salerno, Sarno, Giraterrium, Forcalco, Capua, Feano, Sora, and the half of the Gaudente of Avenza, where it joins Latino and Conisia. The boundary between Benevento and Capua was fixed at St Angelo ad Cerro; Alli Perezgrini was made the boundary between Benevento and Salerno, and Staffolo between Benevento and Conisia. The monasteries of Monte Cassino and St Vincent were declared to be immediately under the protection of the emperor: both princes stipulated that no hostilities should be committed by either against the subjects of each other; and promised to join their forces in order to drive out the Saracens. Soon after this pacification, however, both Radelchis and Siconolphus died; the former appointing his son Radelgar, or Radelcar, to succeed him; and the latter leaving an infant son, Sico, to the care of his godfather, Peter.

The war with the Saracens proved very unsuccessful: neither the united efforts of the princes, nor the aid of the emperor's assistance, the emperor Lewis himself, being unable to expel the infidels; and in 854, Adelgise the second son of Radelchis, who had now succeeded, on the death of his brother Radelcar, to the principality of Benevento, was obliged to pay them an annual subsidy. Two years after, Lando, count of Capua, revolted from the prince of Salerno, and could not be reduced. In the mean time, Sico, the lawful prince of Salerno, had been poisoned by Count Lando, and the principality usurped by Ademarius, the son of Peter above mentioned; but in 861, Ademarius himself was seized and imprisoned by Gaufridus, the son of Daunierus formerly mentioned. This was occasioned by his cruelty and rapaciousness, which entirely alienated the hearts of his subjects from him, and encouraged Gaufridus to become the head of the conspirators. The Saracens in the mean time committed terrible ravages throughout the Beneventan territories, which at last obliged Adelgise to enter into an alliance with Gaufridus, and both together sent a most humble embassy to the emperor Lewis, requesting him to take under his protection. About the same time an embassy arrived from Constantinople, proposing a junction of the forces of the eastern and western empire against the infidels; upon which Lewis gave orders for assembling a formidable army. But in the mean time Adelgise fell off from his alliance, and made peace with the Saracens; nay, according to some, he encouraged them in their incursions, and it was at his desire that they invaded the duchy of Capua, and afterwards that of Naples, which they ravaged in a most barbarous manner. The Neapolitans, in conjunction with the duke of Spoletto and the count of Marsi, endeavoured to oppose them; but being defeated, the Saracens continued their ravages with redoubled fury, and retired to Bari, which was their capital city, with an immense booty.

In 866, Lewis arrived at Sora with his army; and having marched to Capua, was there joined by Landulph, the bishop and count, with a body of Capuans; but Landulph soon after persuading his countrymen to desert, Lewis marched against that city, which he took after a siege of three months, and almost totally destroyed. In the end of the year he was joined by Gaufridus with his quota of troops, having ordered the eyes of Ademarius to be put out in his absence. Lewis confirmed him in the principality, and marched with his army to Benevento, where Adelgise received him with great respect. Having reduced some inconsiderable places belonging to the Saracens, Lewis soon after invested Bari; but as the Saracens received continual supplies from their countrymen settled in Sicily, and besides were protected by the Neapolitans, he could not reduce the place till the year 871, though he had received considerable assistance from his brother Ludarius, and the Greek emperor had sent him a fleet of 200
The expulsion of the Saracens was completed the same year by the taking of Tarento; after which the emperor returned with great glory to Benevento, resolving next to carry his arms into Sicily, and expel the infidels from thence also. But his future schemes of conquest were frustrated by a quarrel between him and Adelgise. The latter, pretending to have been insulted by the empress, and oppressed by the French, seized the emperor himself, and kept him prisoner for 40 days. His imprisonment would probably have been of much longer continuance, had not a body of Saracens arrived from Africa, who, being joined by such of their countrymen as had concealed themselves in Italy, laid siege to Salerno with an army of 30,000 men, ravaging the neighbouring country at the same time with the utmost barbarity. By this new invasion Adelgise was so much alarmed, that he set the emperor at liberty, but first obliged him to swear that he would not revenge the insult that had been offered him, and that he would never return to Benevento. Lewis having then joined his forces to those of the prince of Salerno, soon obliged the Saracens to raise the siege of Salerno; but though they were prevented from taking that city, they had destroyed the inhabitants of Calabria, leaving it, according to the expression of one of the historians of that time, "as desolate as it was at the flood."

In the year 873, Lewis being absolved from his oath by the pope, went to Benevento, and was reconciled to Adelgise; but soon after this reconciliation he died, and the Saracens continued their ravages to such a degree that the inhabitants of Bari were constrained to deliver up their city to the Greeks. At the same time, the Salernitans, Neapolitans, Cajetans, and Amalfitans, having made peace with the Saracens, were compelled to agree to their proposal of invading the territories of the Roman pontiff. His holiness exicted himself to the utmost, both with spiritual and temporal weapons, in order to defend his right; but was at last reduced to the necessity of becoming a tributary to the infidels, and promising to pay them a large sum annually.

In the mean time, all Italy was thrown into the greatest confusion by the death of Charles the Bald, who died of poison at Paris, as he was coming to the pope's assistance. Sergius duke of Naples continued a firm friend to the infidels; nor could he be detached from their interests even by the thunder of a papal excommunication: but unluckily happening to fall into the hands of his brother Athanasius bishop of Naples, the zeal of that prelate prompted him to put out his eyes, and send him a close prisoner to Rome; for which the highest encomiums were bestowed on him by the holy father.

In 876, Adelgise was murdered by two of his nephews; one of whom, by name Gauderin, seized the principality. About the same time Landolph bishop of Capua dying, a civil war ensued among his children, though their father's dominions had been divided among them according to his will. The princes of Salerno and Benevento, the duke of Spoleto, and Gregory the Greek governor of Bari and Otranto, took different sides in the quarrel, as they thought most proper; and to complete the confusion, the new bishop was expelled, and his brother, though a layman, chosen to that office, and even consecrated by the pope, who wrote to Gauferius, forbidding him to attack Capua under pain of excommunication. But though Gauferius was, in general, obedient to the pope's commands, he proved refractory in this particular, and laid siege to Capua for two years successively.

Thus the Capuan territories were reduced to the most miserable situation; being obliged to maintain at the same time the armies of the prince of Benevento and the duke of Spoleto. The Saracens, in the mean time, took the opportunity of strengthening themselves in Italy; and Athanasius, notwithstanding the great commendations he had received from the pope for putting out his brother's eyes, consented to enter into an alliance with them, in conjunction with whom he ravaged the territories of the pope, as well as those of Benevento and Spoleto, plundering all the churches, monasteries, towns, and villages, through which they passed. At the same time the prince of Salerno was obliged to grant them a settlement in the neighbourhood of his capital; the duke of Gaeta invited them to his assistance, being oppressed by the count of Capua; and even the pope himself was obliged to make peace with them, and to grant them a settlement on the north side of the Cariglians, where they fortified themselves, and continued for more than 40 years.

To put a stop to the confusion which reigned in Italy, the pope now thought proper to restore the bishop of Capua, who had been expelled, but allowed his brother to reside in the city, and govern one half of the diocese; but notwithstanding this partition, the civil dissensions continued with the utmost violence, the nearest relations murdering or banishing each other, according as the fortune of the one or the other prevailed. Athanasius, notwithstanding all the pope's remonstrances, continued his alliance with the Saracens; in conjunction with whom he ravaged the territory of Benevento, and fomented the divisions in Capua, in hopes of being able to make a conquest of it. At last his holiness thought proper to issue a sentence of excommunication against him: but this attached him to the Saracens more than ever; insomuch that he sent to Suchaim, king of the Saracens in Sicily, desiring him to come over and command a great body of his countrymen who had settled at the foot of Mount Venusius. Suchaim accepted the invitation, and immediately turned his arms against Athanasius; allowing his troops to live at discretion in the territory of Naples, where they ravished the women, and plundered the inhabitants. These calamities were, by the superstitious Neapolitans, imagined to be a consequence of the sentence of excommunication; and therefore they used their utmost endeavours to persuade the prelate to conclude a league with some Christian prince, and renounce all connexion with the infidels. In this they at last proved successful, and Athanasius concluded an alliance with Guaimarius prince of Salerno; in consequence of which the Saracens were obliged to quit the Neapolitan territories, and retire to Agropoli. Athanasius then directed his force against Capua, of which he made himself master in the year 882. The Saracens, however, still continued their incursions, and ravaged several provinces in such a manner, that they became entirely desolate.

These confusions continued for a long time; during which
which the Greeks found an opportunity of making
themselves masters of Benevento, and well nigh became
masters also of Salerno; but in this they failed through
the treachery of the bishop, and in the year 996 they
were totally expelled by the bishop, four years after
they had become masters of it. In 915 the Saracens
received such an overthrow at Carigliano, that scarce
one of them remained. However, a new body soon ar-
vived from Africa, and restored the state of things for
sometime longer. A war also ensued between Landolph
and the Greeks; which concluded disadvantageously
for the former, who was obliged to submit to the em-
peror of Constantinople in 943.

In 961, Otho the Great, king of Germany, invaded
Italy with a powerful army against Berengarius III.
and, marching to Rome, received the imperial crown
from the hands of the pope. In 964, he erected Ca-
pua into a principality, received homage from the
other princes of Lombardy, and formed a design of re-
covering Puglia and Calabria from the Greeks. But
in this last scheme he failed; and after various hostili-
ties a treaty was concluded, and the young princess
Theophania married to Otho's son, afterwards em-
peror.

All this time the Saracens continued their incursions;
and the Greeks had gained ground so much, that they
were now in possession of two-thirds of the present
kingdom of Naples; but in the year 1002 or 1003, the
Normans first began to be remarkable in Italy. They
had, about a century before, embraced Christianity, and
become very zealous in all the superstitions which were
then practised. They were particularly zealous in visit-
ing sacred places, especially Rome, and the holy se-
pulchre at Jerusalem; and being naturally of a very
martial disposition, they forced through great bodies of
Greeks and Saracens who opposed their passage. A-
about this time 40, or, as others write, 100, of these
Normans, returning from Jerusalem by sea, landed at
Salerno in the habit of pilgrims, where they were ho-
nourably received by Guaimarius. During their resi-
dence at Salerno, a great body of Saracens landed, and
invested the city. Guaimarius, not being in a con-
dition to oppose the invaders by force, was preparing to
pay them a large sum of money, which they demanded
when the Normans proposed to attack them; and, hav-
ning got arms and horses from the prince, they engaged
the infidels with such fury and bravery, that they en-
tirely defeated them, and obliged them to fly to their
ships. By this complete victory Guaimarius was filled
with such admiration of the valour of those strangers,
that he entertained them to remain in his country; offer-
ing them lands, and the most honourable employ-
ments: but not being able to prevail with them to stay
in Italy, or even accept of his presents; at their depart-
ure he sent some ambassadors with them to Normandy,
in vessels loaded with exquisite fruits, rich furniture for
horses, &c. in order to allure the valiant Normans to
leave their own country. This kind invitation encou-
raged a Norman chief, named Osmond Drengot, to set-
tle in Italy about the year 1015; having killed another
lord in a duel, which obliged him to leave his own
country, in order to avoid the resentment of his sove-
ign, Robert duke of Normandy. In the mean time,
the city of Bari had revolted from the Greeks, and
chosen one Mello for their leader, whose wife and
children happened soon after to fall into the hands of
their enemies, and were sent prisoners to Constantinople.

No sooner, therefore, did Mello hear of the arrival of
these adventurers, than he engaged them to assist him
and having drawn together a considerable army, defeat-
ed the Greeks with great slaughter, and obliged them
to abandon their camp. In this engagement the Nor-
mans distinguished themselves by their bravery; and
the news of their success was brought to the Greeks by
an innumerable multitude of their countrymen, with
their wives and children. By this reinforcement,
Mello gained two other victories, took a great many
towns, and obliged the Greeks to abandon a large
territory; but, in 1019, they were utterly defeated,
and every thing recovered by the Greeks. The Greek
general, Bajanus, continued to go on with such sur-
prising success, that he almost entirely re-established
the affairs of his countrymen in Italy, and made a dis-
tinct province of the western part of Puglia, which
he called Capitanata, and which to this day retains
the name of Cepitanata. His great progress at last alarmed
the emperors of Germany; and, in 1027, Pandul-
phus prince of Capua made himself master of Naples;
but was obliged, three years afterwards, to leave it by
the Normans, who built the city of Aversa, which
was now erected into a county. In consequence of this
piece of good fortune, great numbers of Norman ad-
vengers migrated into Italy; among whom were Wil-
liam, Drogo, and Humbert, three of the sons of Tancred
duke of Hauteville; from the都应该 is that those
princes were descended, who first conquered the island of Sicily
from the Saracens, and formed the present kingdom of
Naples.

In 1040, the Greek emperor Michael Paleologo,
in order to secure the affection of his fickle subjects,
undertook the conquest of Italy from the Saracens,
and for that purpose sent a general named Michael Maniaca
into Sicily. This commander, hearing of the
great reputation of the Normans, sent to Guaimarius,
prince of Salerno, entreating him to grant him some of
those warriors. His request was most willingly beat-
ted to by the prince of Salerno, who, to encourage
the Normans to engage in the expedition, promised
them some additional rewards besides the emperor's pay.
William, Drogo, and Humbert, accordingly marched
from Salerno with 300 of their countrymen; and, pas-
sing over into Sicily, distinguished themselves most
remarkably in the conquest of that island. Maniaca
is known to have been that the recovery of Messina was chiefly
owed to their valour; and William with his Normans
achieved a complete victory over the Saracens before Sy-
racuse, where he killed the governor of the city in
single combat. Maniaca made himself master of Sy-
racuse, and almost entirely reduced the whole island;
but, being accused of treason, was next year carried
prisoner to Constantinople. His successor Docaes,
being a man of no abilities, quickly lost the whole
island except Messina, and treated his Norman assis-
ataries with the utmost contempt. He would not al-
low them any share of the booty; and even caused one
Ardoin, a noble Lombard, and associate and inter-
preter of the Normans, to be whipped round the camp,
because he refused to part with the horse of a Saracen
whom he had slain in single combat. The conseque-
ce of this tyrannical behaviour were very fatal to the
Greeks.
Greeks. Ardoni soon after obtained leave to return to Italy under a pretence of a vow, and all the Normans embarked at night along with him; but instead of going to Rome, Ardoni went immediately to Aversa, where he persuaded Count Rainulfus, sovereign of that province, to join with him in the design he had formed of attacking the Greek provinces in Italy, which he showed him would be an easy conquest, as the inhabitants submitted with great reluctance to the Greeks, and the provinces were at that time almost entirely defenceless. Rainulfus approved of the scheme, and raised 300 soldiers, whom he sent under 12 officers to join the other Normans under the sons of Tancred; and made an agreement with Ardoni, that the conquest should be equally divided among the chief leaders. Their first enterprise was the reduction of Melfi, one of the strongest cities in Puglia, which presently surrendered; and they increased its fortifications so much, that it thenceforth became impracticable. Soon after this they made themselves masters of Venusia, Acoli, and Lavella, with very little opposition. Docaenus, alarmed with the rapidity of their conquests, immediately left Sicily, and marched with his army into Puglia, where he attacked the invaders near the river Olevio; but after a short engagement, he was obliged to retire with considerable loss. The Greeks were soon after defeated a second time at Canne, and in a third engagement, which happened near the river Ofanto, the army of Docaenus was entirely routed, and he himself obliged to fly to Bari. On this bad success Docaenus was ordered to return to his command in Sicily, and another general was sent with an army into Puglia. This new commander, however, had no better success than his predecessor; for his army was entirely defeated in an engagement with the Normans, and he himself taken prisoner. Atenulphus, brother to one of the princes of Benevento on whom the Normans had conferred the chief command, set at liberty the captive general without consulting them, on receiving from him a considerable sum of money. With this the Normans were so much displeased that they deprived Atenulphus of his command, and bestowed it on Argyrus son to the late Mello, who had escaped from Constantinople, and now assumed the title of duke and prince of Italy. Before this time also Maniaca, whom we have formerly mentioned, had returned to Italy; and to strike the greater terror into the revolted cities, had executed a number of people of all ages and sexes with great inhumanity. Soon after this Maniaccus openly rebelled against the Greek emperor Constantius, and prevailed upon his own army to proclaim him emperor, beginning hostilities immediately against the Greek cities. Argyrus at the same time took and gave Tarento; but soon after besieged Maniaccus himself in Tarento; but he, being afraid of falling into the hands of the Normans, fled to Otranto, and from thence to Bulgheria, where being entirely defeated by one of the emperor's generals, he was taken prisoner, and had his head struck off.

The Normans having now conquered the greatest part of Puglia, proceeded to make a division of their conquest, in which, after each commander had got his proper share, the city of Melfi was left common to all, and appropriated as a place for assembling to consult about the most important affairs of the nation. Argyrus alone was neglected in this division; but he, having gained a favour of the emperor by expelling the rebel Maniaccus from Italy, was by him created duke of Bari, on purpose to check the power of the Normans, with the title of prince and duke of Puglia. The Normans, however, were too powerful to be much awed by Argyrus, and behaved with great insolence to the neighbouring princes; but as they could not be expelled by force, and were confirmed in their conquests by Henry II. emperor of Germany in 1047, the Greek emperor attempted to get rid of them, by sending Argyrus with large sums of money to bribe them to enter into his service against the Persians. But they, perceiving the snare, replied that they were resolved to leave Italy unless they were expelled by force: upon which Argyrus made use of the same money in bribing the Puglians to assassinate these invaders. This brought on a massacre, in which greater numbers of Normans perished than had fallen in all the late wars. Argyrus attempted to take advantage of the confusion produced by this massacre, but was defeated; after which he had recourse to Pope Leo, beseeching him to deliver Italy from these cruel tyrants; but this scheme proved still more unsuccessful than the others had been; for the pope himself was defeated and taken prisoner; and, in consequence of the respect shown him by the Normans, they were confirmed by the Pope in all their conquests.

Soon after this, the Norman power became extremely formidable; the famous Robert Guiscard ascended the throne in 1056. He made great progress in the south of Italy, and in 1062, he took Calabria, and after most of the cities which held out for the Greeks in these parts. About the same time the counts of Capua were expelled from their territory; and the abbot Desiderius mentions his having seen the children of Lanulphus V. the last count, going about as vagabonds, and begging for their support. The pope alarmed by these conquests, excommunicated the Normans in wholesale, pretending that they had seized some of the territories belonging to the church; but by the pretended submission of Robert, he not only was persuaded to take off the sentence of excommunication, but to invest him with the provinces of Apulia, Calabria, and Sicily. After this, he continued the war against the Greeks with great success. In 1071, in conjunction with his brother Roger, he conquered the island of Sicily, and carried the investiture of the whole island to him with the Robert title of count, reserving to himself only the half of Palermo, Messina, and the valley of Demona. The like success attended his arms against Salerno in 1074; but after this, having unadvisedly taken some places from the pope, he again fell under the sentence of excommunication; yet he was reconciled to him in 1080, and received a second time the investiture of all his dominions. The next year he undertook an expedition against the Greeks; and though the emperor was assisted by a Venetian fleet, Robert made himself master of the island of Corfu, reduced Durazzo, and great part of Romania; insomuch that by the success of his arms, and his near approach to Constantinople, he struck an universal terror among the Greeks. But while Robert was thus extending his conquests, he was alarmed.
Naples alarmed by the news of a formidable rebellion in Italy, and that the emperor Henry had taken the city of Rome, and closely shut up the pope in the castle of St. Angelo. Robert, therefore, leaving the command of the army to his son Boemund, returned to Italy, where he immediately dispersed the rebels, and released the pope, while his son gained a considerable victory over the Greeks. After this Robert made great preparations for another expedition into Greece, in order to second his son Boemund. Alexius Comnenus, who was about this time declared emperor by the Greek army, being assisted by the Venetian fleet, endeavoured to oppose his passage; but was entirely defeated, with the loss of a great many galleys. But a final stop was now put to his enterprises by his death, which happened in the island of Corfu in 1085.

Though the power of the Normans was thus thoroughly established in Italy and Sicily, and though the prince of Benevento was in 1130 invested by the pope with the title of king of Sicily, yet by reason of the civil discusions which took place among themselves, and the general confusion which reigned in Italy in those ages, they were obliged, notwithstanding all their valour, to submit to the emperor in 1195. By him the Sicilians were treated with so great cruelty, that the empress Constance was induced to conspire against him in 1197, took him prisoner, and released him only on condition of his sending off his army immediately for the Holy Land. This was complied with; but the emperor did not long survive the reconciliation, being poisoned, as was supposed, by order of the empress.

In 1254 the pope claimed the kingdom as a fief descended on the church in consequence of a sentence of deposition pronounced against King Frederick at the council of Lyons; and, in 1263, the kingdom was, in consequence of this right, conferred on Charles of Anjou. After much contention and bloodshed, the French thus became masters of Sicily and Naples. Their government was insupportably tyrannical; and at the same time the haughtiness of their king so provoked the pope, that he resolved to humble him. Charles had resolved on an expedition against Constantineople; and for this purpose had fitted out a fleet of 100 galleys, 30 large ships, 200 transports, besides many other smaller vessels, on board of which he intended to embark 10,000 horse, and a numerous army of foot. This formidable armament greatly alarmed the emperor Michael Paleologus; for which reason he entered into a negotiation with John di Procida, a noble Salernitan, lord of the isle of Procida in the bay of Naples, who had formed a scheme for a general revolt in the island of Sicily. John, though a nobleman, was also a physician, and had been counsellor to two former princes, and even to King Charles himself; but being stripped of his estate by the king under pretence of treason, and his wife being debarred by the French, he retired to Constantia queen of Arragon, where he was created a baron of the kingdom of Valencia, by her husband King Peter, and lord of Luxen, Benizzano, and Palma. As he was greatly exasperated against the French, he employed many spies both in Puglia and Sicily; and having informed that the Sicilians were totally disaffected to the French, he came to the island in disguise, and concerted a plan with the most powerful of the malecontents for a revolution in favour of Constantia, though she derived her right only as being the daughter of a former usurper named Manfred. Procida then set out for Constantineople, where in some private conferences with the emperor, he persuaded him, that the most probable means of defeating Charles’s scheme was by assisting the Spaniards and Sicilian malecontents. Paleologus accordingly granted him a large sum of money, and on his departure sent one of his secretaries along with him, who, landing in Sicily, had a conference with the chief conspirators. John, having received letters from them, disguised himself in the habit of a Franciscan, and went to Siriano in the neighbourhood of Rome. As he well knew the enmity which subsisted between the pope and King Charles, he disclosed his design to his bosom, who readily entered into his measures, wrote to Peter to hasten his armament, promising him the investiture of the island as soon as he had taken possession of it; and, by refusing the assistance he had promised to Charles, obliged him for the present to delay his expedition. In the beginning of the year 1281, Procida returned to Arragon, and by showing the letters from the pope and Sicilian barons, prevailed on Peter to embark in his design, by assuring him of the assistance of Paleologus. This king of Arragon accordingly prepared a formidable fleet under pretence of invading Africa, and is even said to have received 20,000 contracts from Charles, in order to assist him in his preparations.

But while John went on thus successfully with his scheme, all his measures were in danger of being broke by the death of Pope Nicholas. The new pope, Martin IV., was entirely in the interest of Charles, on whom, in 1281, he conferred the senatorial dignity of Rome. Procida, however, still resolved to prosecute his scheme; and, leaving Italy, had another conference with the conspirators in Sicily; after which, he again went to Constantineople, and obtained from Paleologus 30,000 ounces of gold, with which he immediately returned to Arragon. The death of Nicholas had damped the ardour of Peter; but being urged with great earnestness by John, he again renewed his preparations; which alarmed the pope and the king of France. In consequence of this they sent a message to him, desiring to know against what Saracens he designed to employ his armament. In this particular Peter refused to satisfy them; upon which they earnestly counselled Charles to guard against an invasion; but he neglected their advice, being wholly intent on his eastern expedition, and encouraged by a revolt which had happened in Greece; and to facilitate his expedition, he prevailed on the pope to excommunicate the Greeks, on pretence that they had broken some of the articles of union concluded at the council of Lyons a few years before. Peter in the mean time continued his preparations with great diligence, intending to put to sea the following summer. Procida had returned to Palermo, to wait for a favourable opportunity of putting his design in execution, which was soon afforded him by the French. On Easter Monday, March 30, 1282, the chief conspirators assembled at Palermo; and, after dinner, both the Palermians and French went in a grand procession to the church of Monreale, about three miles without the city. While they were
Naples— [ 609 ]

Naples—

sporting in the fields, a bride happened to pass by with
— her train, who being observed by one Drochetus, a
Frenchman, he ran to her, and began to use her in a
— rude manner, under pretence of searching for concea-
el ed arms. A young Sicilian, exasperated at this
affront stabbed him with his own sword; and a tumult
— ensuing, 200 French were immediately murdered. The
— enraged populace then ran to the city, crying out,
"Let the French die, Let the French die;" and, with-
out distinction of age or sex, slaughtered all of that
nation they could find, even such as had fled to the
churches. The conspirators then left Palermo, and excited the
— inhabitants to murder the French all over the island, ex-
— cepting in Messina, which city at first refused to be con-
— cerned in the revolt. But, being invited by the Paler-
— misans to throw off the French yoke, a few weeks after,
the citizens in a tumultuous manner destroyed some of
the French; and pulling down the arms of King Charles,
and erecting those of the city, chose one Baldwin for
their governor, who saved the remaining French from
the fury of the populace, and allowed them to transport
themselves, with their wives and children to Italy. Eight
— thousand persons are said to have been murdered
on this occasion.

Immediately after this massacre, the Sicilians offered
their allegiance to the king of Aragon; who accepted
of the invitation, and landed with his forces at Trapani.
From thence he went to Palermo, where he was crowned
— king of Sicily with great solemnity, and Charles left the
island with precipitation. The day after he landed
his army in Italy, the Aragonian fleet arrived, took
— 29 of his galleys, and the next day burnt 80 transports
in presence of his army. Soon after this Charles sent
— an embassy to Peter, accusing him of perfidy, in invading
his dominions in time of peace; and, according to some,
— challenged him at the same time to decide the matter
— by single combat. Others say that the challenge was
— given by Peter. Certain it is, however, that a chal-
— lenge was given, and to appearance accepted; but Pe-
— ter determined to employ much more effectual means
— in support of his pretensions than trusting to a duel; and
— therefore pushed on his operations most vigorously,
while his adversary tilled away his time: and thus he
— at last became master of the contested kingdom; which,
— however, he did not long enjoy, dying about the end
— of the year 1285.

By his will, Peter left the kingdom of Aragon to
his eldest son Alphonso, and Sicily to Don James
— his other son, who was also to succeed to the kingdom
of Aragon in case Alphonso should die without male
— issue. Accordingly, Don James was solemnly crown-
— ed at Palermo the 3rd of February 1286. In 1295,
— however, he deserted them, and tamely resigned up his
right to Charles, son to him above mentioned, in a
manner perhaps unparalleled. On his resignation the
Sicilians conferred the crown upon his brother Don
— Frederic; after which the war continued with great
violence till the year 1302, when a peace was concluded,
and the kingdoms of Naples and Sicily formally dis-
— joined; Frederic being allowed to keep the latter, under
— the name of Trinacria; and Charles being confirmed
in the possession of the former, which he quietly enjoy-
— ed till his death in 1309.

Naples continued to be governed by its own kings

Vol. XIV. Part II.
before the festival they were very diligent in reviewing and training their followers, who were armed with sticks and reeds; but a small and unforeseen accident tempted them to begin their enterprise without waiting for the festival.

On the 7th of July a dispute happening in the market-place between the tax-gatherers and some gardeners of Pozzuolo who had brought some figs into the city, whether the buyer or seller should pay the duty; after the tumult had continued several hours, Massaniello, who was present with his company, excited the mob to pillage the office built in the market for receiving the duty, and to drive away the officers with stones. The elect of the people, who, by deciding against the gardeners, had increased the tumult, ran to the palace, and informed the viceroy, who most imprudently neglected all means of putting a stop to the commotion. Massaniello, in the mean time, being joined by great numbers of people, ordered his young troop to set fire to all the offices for the taxes through the city; which command being executed with despatch, he then conducted them directly to the palace, where the viceroy, instead of ordering his Spanish and German guards to disperse them, encouraged their insolence by timidly granting their demands. As they rushed into the palace in a furious manner, he was escaped by a private door, and endeavoured to save himself in Castel del Ovo; but being overtaken by the rioters in the streets, he was trampled upon by them, and pulled by the hair and whiskers. However, by throwing some handfuls of gold among them, he again escaped, and took sanctuary in a convent of Minims, where, being joined by the archbishop of Naples, Cardinal Filomarini, and several nobles, by their advice he signed a billet, by which he abolished all taxes upon provisions. As a means to quell the tumult, he likewise desired the cardinal to offer Massaniello a pension of 2400 crowns, who generously rejected the bribe; and declared, that if the viceroy would keep his word, he would find them obedient subjects.

It was now expected that the tumult would cease; but Massaniello, upon his return to the market-place, being joined by several malecontents, among whom were Genuino and one Peronne, who had formerly been a captain of the Shirri, he was advised by them to order the houses of those concerned in raising the tax to be burned; which were accordingly in a few days reduced to ashes, with all their rich furniture. Massaniello being now absolute master of the whole city, and being joined by great numbers of people of desperate fortunes, he required the viceroy, who had retired to the Castel Nuovo, to abolish all the taxes, and to deliver up the writ of exemption granted by Charles V. This new demand greatly embarrassed the viceroy; but to appease the people, he drew up a false deed in letters of gold, and sent it to them by their favourite the duke of Matalone, who had before been in confinement. The fraud, however, being discovered, the duke was pulled from his horse and maltreated by the mob, and at length committed as a prisoner to Peronne. This accident, to the great joy of the viceroy, enraged the people against the nobility, several of whom they killed, burnt the houses of others, and threatened to extirpate them all. Massaniello, in the mean time, tattered and half naked commanded his followers, who were now well armed, and reckoned about 100,000 men, with a most absolute sway. He ate and slept little, gave his orders with great precision and judgement, appeared full of moderation, without ambition and interested views. But the duke of Matalone having procured his liberty by bribing Peronne, the viceroy imitated his example, and directly proceeded against his chief. A conspiracy was accordingly formed against Massaniello by Matalone and Peronne; the duke, who was equally exasperated against the viceroy, proposing, that after his death his brother D. Joseph should head the rebels. Massaniello in the mean time, by means of the cardinal archbishop, was negotiating a general peace and accommodation; but while both parties were assembling in the convent of the Carmelites, the banditti hired by Matalone made an unsuccessful attempt upon Massaniello's life. His followers immediately killed 150 of them. Peronne and D. Joseph being discovered to be concerned in the conspiracy, were likewise put to death, and the duke with great difficulty escaped. Massaniello by this conspiracy was rendered more suspicious and severe. He began to abuse his power by putting several persons to death upon slight pretences; and, to force the viceroy to an accommodation, he cut off all communication with the castles, which were supplied with provisions and ammunition. - The viceroy likewise being afraid lest the French should take advantage of the commotion, earnestly desired to agree to a treaty; which was accordingly concluded on the fifth day of the insurrection, by the mediation of the archbishop. By the treaty it was stipulated, that all duties imposed since the time of Charles V. should be abolished; that the writ of exemption granted by that emperor should be delivered to the people; that for the future no new taxes should be imposed; that the vote of the elect of the people should be equal to the votes of the nobility; than an act of oblivion should be granted for all that was past; and that the people should continue in arms under Massaniello till the ratification of the treaty by the king.

By this treaty, no less than 10,000 persons who fattened upon the blood of the public were ruined. The people, when it was solemnly published, manifested an extreme joy, believing they had now recovered all their ancient rights and privileges. Massaniello, at the desire of the viceroy, went to the palace to visit him, accompanied by the archbishop, who was obliged to threaten him with execution, before he would consent to lay aside his rags and assume a magnificent dress. He was received by the duke with the greatest demonstrations of respect and friendship, while the duchess entertained his wife, and presented her with a robe of cloth of silver, and some jewels. The viceroy, to preserve some shadow of authority, appointed him captain-general; and at his departure made him a present of a golden chain of great value, which with great difficulty he was prevailed upon to accept; but yielded at length to the entreaties of the cardinal. Next day, in consequence of the commission granted him by the viceroy, he began to exercise all the functions of sovereign authority; and having caused a scaffold to be erected in one of the streets, and several
...veral giblets, he judged all crimes, whether civil or military, in the last resort; and ordered the guilty to be immediately put to death, which was the punishment he assigned to all offences. Though he neglected all forms of law, and even frequently judged by physiognomy, yet he is said not to have overlooked any criminal, or punished any innocent person.

His grandeur and prosperity were of very short continuance; for his mind becoming distracted and delirious for two or three days, he committed a great many mad and extravagant actions; and on the 18th of July he was assassinated with the consent of the viceroy.

The tumult did not end with the death of Massa- niello: on the contrary, the people now expelled the Spaniards from most of the cities throughout the kingdom; and this general insurrection being the subject of discourse at Rome, the duke of Guise, who happened then to be at the pope's court, took the opportunity, at the instigation of his holiness, to offer his service to the Neapolitans against the Spaniards. The duke was prompted by his ambition to engage in this enterprise, especially as he himself had some distant pretensions to the crown. The Spaniards in the mean time made a vigorous attack on the city; but were repulsed by the people, who now formally renounced their allegiance to them. In a short time, however, their city being surprised by the new viceroy, the count d'Onnate, and the duke of Guise himself taken prisoner, the people returned to their allegiance; and thus all the attempts of the French on Naples were frustrated. From that time the Spaniards continued in peaceable possession of the kingdom till the year 1707, when it was taken from them by Prince Eugene. It was formally ceded to the emperor by the treaty of Rastadt in 1713; but was recovered by the Spaniards in 1734, and a branch of the family of Spain has reigned there since that time. For a particular account of these revolutions, see the articles SPAIN and SICILY.

Naples, and the other states of Europe, has experienced many revolutions within the last thirty years. She took part in the alliance against France in 1793, but was little affected by the war till 1796, when the progress of the French arms in Italy induced her to conclude a peace. The continual encroachments of the French, however, made her take up arms again in concert with Austria in 1798; but her forces commanded by General Mack sustained repeated defeats, and the French gained possession of the capital. The king retired to Palermo in Sicily in December 1798, till the successes of Suvarow compelled the French to withdraw their troops, after which he re-entered his capital in 1799. After the treaty of Lunville, Naples obtained peace from France on the condition of giving up the port of Otranto. In 1806 the king admitted some British and Russian troops into his dominions, and this was made a pretext by Bonaparte for de-throning him. The kingdom of Naples was given to Joseph Bonaparte, who retained it till he was promoted to the crown of Spain in 1808, when Naples was given to Joachim Murat. From this period Naples followed the fortunes of France, and furnished men and money for her wars. After the disasters of the Russian campaign, Murat who had received some insults from Bonaparte shook off his authority, and entering into terms with the allies obtained a recognition of his independence. In the beginning of 1814 he assisted the Austrians in overthrowing the French viceroy in Italy; but repenting of this course, or distrusting the intentions of the allies, he declared for Bonaparte when the latter returned to France in 1815. Fortune however did not favour him; he was defeated, and fled to France in May 1815. In a fit of rash enthusiasm he set out with a small band of 400 adventurers, landed in Naples in October, but instead of meeting with support was immediately taken and executed. Since that time Ferdinand IV. has had peaceable possession of the kingdom.

The climate of Naples is extremely hot, especially in July, August, and September. In winter there is seldom any ice or snow, except on the mountains. On account of its fertility, it is justly termed an earthly paradise; for it abounds with all sorts of grain, the finest fruit and garden productions of every kind, with rice, flax, oil, and wine, in the greatest plenty and perfection. It affords also saffron, manna, alum, vitriol, sulphur, rock crystal, marble, and several sorts of minerals, together with fine wool, and silk. The horses of this country are famous, and the flocks and herds very numerous. Besides these products, of which a considerable part is exported, there are manufactures of snuff, soap, and glass ware. Waistcoats, caps, stockings, and gloves, are also made of the hair or filaments of a shell fish, which are warmer than those of wool, and of a beautiful glossy green. In this kingdom likewise is found that called the Phrygian stone, or petra fungifera, which, being laid in a damp shady place, will yield mushrooms, sometimes of a very large size, especially if the stone is sprinkled with hot water. See AGARICUS.

As to the mountains of this country, the principal are the Apennines, which traverse it from south to north; and Mount Vesuvius, which, as is well known, is a noted volcano, five Italian miles from Naples. The side of this mountain next the sea is called Vico, and particularly the two famed wines called Vino Greco and Lacrimum Christi. One of the greatest inconveniences to which this kingdom is exposed is earthquakes, which the eruptions of Mount Vesuvius contribute, in some measure, to prevent. Another inconvenience, which, however, is common to it with other hot countries, is the great number of reptiles and insects, of which some are very poisonous.

With respect to religion, it is on a very bad foot- ing here. The number of convents and monasteries is astonishing. It is said, the clergy and convents possess two thirds of the whole kingdom: nay, some maintain, that were the kingdom divided into five parts, four would be found in the hands of the church. Notwithstanding this power and influence of the clergy, they have not been able hitherto to get the inquisition established here. In the year 1731, measures were taken for licensing the number of convents; and lastly, the order of Jesuits hath been suppressed. The papal bulls cannot be made public without the king's permission; nor are Protestants compelled to kneel in the churches, or at meeting the host; and in Lent they can very easily procure flesh meat. In the year 1750, the Jews were allowed to settle in the kingdom during the term of 50 years, and several privileges were granted them during that period; at the expiration of which,
The grant was supposed to be renewed, unless they were expressly ordered to quit the country.

The king of Naples, or of the two Sicilies, is an hereditary monarch. The high colleges are, the council of state, the privy council, the treasury, the Sicily council, the council of war, &c. This kingdom is a papal fief; and the king, in acknowledgment of the pope's feudal right, sends him every year a white palmyra, and a purse of 6000 ducats. The title of the king's eldest son is Prince of Calabria. The number both of the high and low nobility in the kingdom of Naples is very great. "I am assured (says Dr Moore") that the king of Naples counts among his lovers 100 persons with the title of prince, and a still greater with that of duke. Six or seven of these have estates which produce from 10 to 12 or 15,000l. a-year; a considerable number have fortunes of about half that value; and the annual revenue of many is not above 1000l. or 2000l. The inferior orders of the nobility are much poorer. Many counts and marquises have not above 300l. or 400l. a-year of paternal estate: many have still less; and not a few enjoy the title without any estate whatever. These nobles, however, are excessively fond of splendour and show, which appears in the brilliancy of their equipages, the number of their attendants, the richness of their dress, and the grandeur of their titles. The finest carriages are painted, gilt, varnished, and lined, in a richer and more beautiful manner than has yet become fashionable either in England or in France. They are often drawn by six and sometimes by eight horses. Before the carriage, it is the custom to have two or three footmen, and behind three or four servants in the richest livery. The ladies and gentlemen within the coaches glitter in all the brilliancy of lace, embroidery, and jewels. This finery is not confined to the persons within and without the coaches; it is extended to the horses, whose heads, manes, and tails, are ornamented with the rarest plumage, and set off with ribbons and artificial flowers.

The population of Naples in 1769 was 393,098; in 1783 it was 467,537, including 45,525 secular priests, 24,694 religious of the male sex, and 20,973 of the female. (Mentelle et Malte Brun.)

In the kingdom of Naples, the hereditary jurisdiction of the nobles over their vassals subsists in the full vigour of the feudal government. The peasants therefore are poor; and it depends entirely upon the personal character of the master, whether their poverty be not the least of their grievances. As this power is too often abused, the importance of the nobility depends in a great measure on the favour of the king, who, under pretence of any offence, can confine them to their estates, or imprison them at pleasure. Unless this prince were so very impolitic as to disgust all the nobility at once, and so unite the whole body against him, he has little to fear from their resentment. Even in case of such an union, as the nobles have lost the affection of their vassals, what could they do in opposition to a standing army of 30,000 men, entirely devoted to the crown? The government of Naples, therefore, is in fact a despotic monarchy, though something like the form of a feudal constitution in its ancient purity is still kept up by the biennial summons of the general assembly. This convention, which consists of the nobility and commons, is called together every two years, to deliberate on the customary free gift to the crown.

The inhabitants of this country have at all times borne but an indifferent character among other nations. "From the few hints dropped by the classic authors, we collect that the ancient Neapolitans were a race of epicures, of a soft indolent turn, adverse from martial exercises, passionately fond of theatrical amusements and music, expert in all the refined arts that administer to the caprices of luxury, extravagant in their expressions and gestures, and dopes in various sorts of superstition. If we make allowance for a quantity of northern blood which has joined the original Grecian stream, and imparted a roughness not yet worn off by the mildness of the climate, we shall find the modern Neapolitans very like the ancient. -Provisions being here plentiful and cheap, the lower class of people work but little. Their delight is to bask in the sun, and do nothing. Persons of a middle rank frequent places of public resort; and very few of any rank attend to their proper business with the zeal and activity we are wont to meet with in the professional men of colder countries. Gluttony is a predominant vice, while instances of eloquence are comparatively rare. In the female sex, the passion for finery is almost superior to every other; and, though chastity is not the characteristic virtue of the country, Mr. Swinburne doubts whether a Neapolitan woman would not nine times out of ten prefer a present to a lover. That furious jealousy for which the nation was once so remarkable, is now greatly abated. The breach of the conjugal vow sometimes occasions quarrels and assassinations among an inferior station; and in the metropolis, assassinations are often perpetrated from much less cogent motives. Of these vices, many are doubtless owing to that slavery and oppression under which they groan, and to a radical defect in the administration of justice, though the kingdom is divided into 12 provinces or jurisdictions.

NAPLES, anciently Parthenope, afterwards Neapolis, the capital of the kingdom of that name in Italy, lies in the province called Terra de Lavora, which is the richest and best inhabited of the whole kingdom, and comprehends a part of the ancient Campania Felix or the Happy. This city is famed to owe its foundation to a Syren, and to have received its ancient name from its supernatural foundress. Whatever be its origin, it is the first for neatness, and the second for extent, of all the cities in Italy. It was formerly a place of strength; but its walls at present being of no real defence, its safety depends of course upon the force of its armies. It is most advantageously situated, having a delicious country on one side, and a noble sheet of the Mediterranean on the other, with an excellent harbour. The circumference, including the suburbs, is said not to be less than 18 Italian miles, and the number of the inhabitants therein little less than 300,000. The houses are of stone, flat roofed, and generally lofty and uniform; but many of them have balconies, with lattice windows. The streets are well paved; but they are not lighted at night; and in the day time are diversified, in many places, by stalls, on which provisions are exposed to sale. Here are a great number of fine churches, convents, fountains, and palaces of the nobility,
NAPLES [ 613 ]

acity, many of whom constantly reside here. It is usual to walk on the tops of the houses in the evenings, to breathe the sweet cool air, after a hot sultry day. The climate here is so mild and warm, even in the winter, that plenty of green peas, artichokes, asparagus, and other vegetables, may be had so early as the beginning of the new year, and even all the winter. This city swarms with monks and nuns of all sorts, to such a degree, that there are no less than 149 convents. There are also 34 poorhouses, 11 hospitals, 43 parish churches, and 70 other churches. The magnificence of many of the churches exceeds imagination. In a cloister of the Carthusian monastery is a crucifix, said to be done by Michael Angelo, of inimitable workmanship.

To repel hostile attempts by sea, which from its situation, maritime powers might be tempted to make, Naples has, to the west, the Castel del Ovo, a con
densed pile of ancient buildings, and some modern batteries. The rock upon which this fortress stands was originally called Megara, then Lucullusium; and it was considered as a place of strength so early as the year 475. Along the line of the shore towards the east are some batteries on the points of land, the bastions of the arsenal, and above it the lofty wall of the Castel Nuovo. This last fortress has been the usual refuge of the sovereigns and viceroys in all civil wars and tumults; for which reason they have long fixed their residence near its walls. A blockhouse and batteries defend the mouth of the harbour, and at the eastern extremity of the town is the Torrione de Carmine, better known by the figure it made in Massaniello's rebellion than by its extent or military strength. The castle of St Elmo commands Naples in every direction, and is in reality calculated rather to annoy and awe the citizens than to defend them from foreign invaders. The city is indeed far from being secure against a bombardment; for the sea is so deep, that a large vessel may come up to the very mole in defiance of the blockhouse and batteries, &c. Pictures, statues, and antiquities, are not so common in Naples as might be expected in a great and ancient a city, many of the most valuable pieces having been sent to Spain by the viceroy. The bay is one of the finest in the world, being almost of a round figure, about 30 miles in diameter, and three parts of it sheltered with a noble circuit of woods and mountains. The city stands in the bosom of this bay, in as pleasant a situation, perhaps, as is in the world. Mr. Keys says, they reckon about 18,000 donne liber, or countesses, in the city; and Dr. Moore computes the number of lazararoni, or blackguards at above 30,000. The greater part of these wretches have no dwelling houses, but sleep every night under porticoes, piazzas, or any kind of shelter they can find. Those of them who have wives and children, live in the suburbs of Naples near Feusilippo, in huts, or in caverns or chambers dug out of that mountain. They are generally represented as a lazy, licentious, and turbulent set of people, as indeed by far the greater part of the rabble are, who prefer begging or robbing, or running errands, to any fixed and permanent employment. Yet there are in Naples some flourishing manufactures, particularly of silk stockings, soap, snuff-boxes of tortoise shells and the jas of Mount Vesuvius, tables, and ornamental furniture of marble. The city is supplied with a vast quantity of water, by means of a very costly aqueduct, from the foot of Mount Vesuvius. Mr. Addison says, it is incredible how great a multitude of retainers to the law there are in Naples, who find continual employment from the fiery temper of the inhabitants. There are five piazzas or squares in the city, appropriated to the nobility, viz. those called Coppauna, Nido, Montagna, Porto, and Porta Nova. Of all the palaces, that of the king is not only the most magnificent, but also in the best style of architecture. The cathedral, though Gothic, is a very grand splendid edifice. It is here that the head and blood of St. Januarius, the tutelary saint of Naples, are kept, the latter in two glass or crystal vials. The pretended liquefaction of the dried blood, as soon as brought near the head of the saint, is a thing well known; Mr. Addison says, it is one of the most bungling tricks he ever saw. The harbour is spacious, and kept in good repair. It is fortified with a mole, which runs about a quarter of a mile into the sea, and at the extremity has a high lantern to direct ships safely into the harbour. Luxury here is restrained by severe sumptuary laws, and the women are more closely confined than in any other city of Italy. Here is an university and two academies of wits, the one called Gli Ardentii, and the other Gli Ottiosi. The nunnery for ladies of quality is said to be the largest in the whole world, containing no less than 350 nuns, besides servants. The Mount of Pity, or the office for advancing money to the poor, on pledges, at a low interest, or without any, has an income of upwards of 50,000 ducats. The arsenal is said to contain arms for 30,000 men. The walls of the city consist of hard black quarry stones, called piperma. Instead of ice, vast quantities of snow are used for cooling their liquors, not so much as water being drunk without it; so that, it is said, a scarcity of it would as soon occasion a mutiny as a dearth of corn or provisions. Certain persons, who farm the monopoly of it from the government, supply the city all the year round from a mountain about 18 miles off, at so much the pound. In the beginning of 1799, it was taken by a body of French troops under General Championet. The streets of this city were lighted for the first time on the 16th December, 1806. Naples stands 110 miles south-east from Rome, 164 north-east from Palermo in Sicily, 217 south-east from Florence, and 300 from Venice. E. Lon. 14. 20. N. Lat. 40. 55.

NARBO, in Ancient Geography, a town of the Volscet Tectosages, called also Narbo Martius, from the Legio Martia, the colony led thither 59 years before the consulate of Caesar, (Velleius) increased with a colony of the Documani or tenth legion by Caesar. An ancient trading town on the Atax, which discharges itself into the sea through the Locus Rubresus, or Rubrensis. Capital of Gallia Narbonensis; surnamed Colonia julia Paterna, from Julius Caesar, the father of Augustus by adoption. Now called Narbonne, a city of Languedoc.

NARBONNE, is a city of France, in the department of Aude, with an archbishop's see, and is particularly famous for its honey. It is seated on a canal cut from the river Aude, which being but three miles from the sea, vessels come up it laden with merchandise, which renders
NAR [ 614 ]

Narbonne renders it a place of some trade. But though it pretends to the most remote antiquity under the Celtic kings, in ages anterior even to the Roman conquests, which under these latter masters gave its name to all Gallia Narbonensis, and was a colony of the first consideration, it is now dwindled to a wretched solitary town containing 9000 inhabitants, of whom three-fourths are priests and women. The streets and buildings are mean and ruinous; it has indeed a communication with the Mediterranean, from which Narbonne is only about three leagues distant, by means of a small river which intersects the place; but their commerce is very limited, and chiefly consists in grain which they export to Cethe and Marseilles. No marks of Roman magnificence remain, except several inscriptions in different parts of the city. It is divided into the city and the town, which are joined together by a bridge, with houses on each side, in which the richest merchants live. There are several churches and convents; the metropolitan church has a handsome steeple. E. Long. 33° 15' N. Lat. 43° 17'.

NARCISSEUS. In a fabulous history, the son of the river Cephissus and Liriope the daughter of Oceanus, was a youth of great beauty. Tiresias foretold that he should live till he saw himself. He despised all the nymphs of the country; and made Echo languish till she became a mere sound, by refusing to return her passion: but one day coming weary and fatigued from the chase, he stopped on the bank of a fountain to quench his thirst: when, seeing his own form in the water, he became so in love with the shadowy image, that he languished till he died. On which the gods, being moved at his death, changed him into the flower which bears his name.

Narcissus, a genus of plants belonging to the hexandria class; and in the natural method ranking under the 9th order, Spathecaceae. See Botany Index.

NARCOtICS, in Medicine, soporiferous drugs, which bring on a stupefaction. Among narcotics the most eminent are those usually prepared for medicinal uses from the poppy, especially opium; as also those prepared from mandragora, hyoscyanus, stramonium and datura. See Materia Medicæ Index.

Nardo, a pretty populous town in the kingdom of Naples, and in the Terra d’Otranto, with the title of a duchy and a bishop’s see. E. Long. 18° 27’. N. Lat. 43° 28’.

In this little city are 8000 inhabitants. The steeple of its cathedral is built in a very uncommon but showy style of Gothic architecture. Luca Giordano and Solimena have adorned the church with some agreeable paintings. This place was a part of the Balzo estate. The Aquavivas were the next possessors; they are thought to have come from the Marca di Ancora. In 1401, in consideration of their relationship to Pope Boniface IX. Ludovisius erected their manor of Atri into a dukedom, an honour till then seldom granted to any but princes of the blood royal. Claudiu Aquaviva, a famous general of the Jesuits, who died in 1615, was of this family.

NARDUS, a genus of plants belonging to the triandria class; and in the natural method ranking under the 4th order, Gramina. See Botany Index.

This plant was highly valued by the ancients, both as an article of luxury and medicine. The ungumentum mardinum, was used at baths and feasts as a favourite perfume. Its value is evident from that passage of Scripture, where our Saviour’s head was anointed with a box of it, with which Judas found fault. From a passage in Horace, it appears that this ointment was valuable among the Romans, that as much as could be contained in a small box of precious stone was considered as a sort of equivalent for a large vessel of wine, and a proper quota for a guest to contribute at an entertainment, according to the ancient custom:

——Nardo vina mercere,
Nardi paremus onyx ciferet cadum.

NAREA, the most southerly province of the empire of Abyssinia; a kingdom still governed by its own princes, who have the title of Benares. Its territory was formerly more extensive than at present, the Galla having almost quite surrounded it, especially on the south-east and north. The country to the west is the most unknown part of Africa; the kingdom itself stands like a fortified place in the middle of a plain, being a high and mountainous country. A great many rivers, rising in the fourth and fifth degrees of north latitude, spread themselves over the level part of the country, and fill it with marshes all the way from south to east to north or north-west.—These marshes are bounded by mountains, of which those nearest the marshes are overgrown with coffee trees, the largest, if not the only ones, which grow in this country. The kingdom of Narea Proper is interspersed with small, unwholesome, but very fertile valleys. The mountainous country of Caffa adjoins immediately to Narea, and is said to be governed by a separate prince; but the Galla having settled themselves in all the flat ground to the very edge of the marshes, have in a great measure cut off the communication with Abyssinia for a long time past. The Nareans who inhabit the mountainous country have the lightest complexion of any people in Abyssinia; but those who inhabit the borders of the marshes are perfectly black, and have the features and woolly heads of negroes; but the mountaineers of Narea, and much more those of Caffa, are fair complexioned, and so than even the Nareans Proper. It is said that snow has been seen to lie on some of the mountains of Caffa; but Mr Bruce imagines this to be a mistake, and thinks that it must have been hail.

Narea abounds with cattle, grain, and all kinds of provisions, both in the high and low country. The medium of commerce is gold, which they sell by weight; but the principal articles of trade are coarse cotton cloths, antimony, beads, and incense, which are carried from this country to the kingdom of Angola, and the parts of the African continent towards the Atlantic. The people are exceedingly brave; and though they have been driven out of the low country by multitudes of Galla, they now bid them defiance, and drive them from their frontiers whenever they come too near. The Narean prisoners taken in the skirmishes are sold to the Mahometan merchants at Gondar; and at Constantinople, Cairo, or in India, the women are more esteemed than those of any other part of the world. Both sexes have a cheerful kind of affection, and attach themselves inviolably to their masters, if properly treated. The people of Narea and Caffa speak a language peculiar to themselves.

NAPRATON,
NARRATION, in oratory, poetry, and history, a recital or rehearsal of a fact as it happened, or as it is supposed to have happened. See ORATORY, No 26.

Concerning Narration and Description we have the following rules and observations in the Elements of Criticism.

1. The first rule is, That in history the reflections ought to be chaste and solid; for while the mind is intent upon truth, it is little disposed to the operation of the imagination. Strada’s Belgic history is full of poetical images, which being discordant, with the subject, are unpleasant; and they have a still worse effect by giving an air of fiction to a genuine history. Such flowers ought to be scattered with a sparing hand, even in epic poetry; and at no rate are they proper till the reader be warmed, and by an enlivened imagination be prepared to relish them: in that state of mind, they are agreeable; but while we are sedate and attentive to an historical chain of facts, we reject with disdain every fiction.

2. Vida, following Horace, recommends a modest commencement of an epic poem; giving for a reason that the writer ought to husband his fire. Besides bold thoughts and figures are never relished till the mind be heated and thoroughly engaged, which is not the reader’s case at the commencement. Homer introduces not a single simile in the first book of the Iliad, nor in the first book of the Odyssey. On the other hand, Shakespeare begins one of his plays with a sentiment too bold for the most heated imagination:

Bedford. Hung be the heav’n with black, yield day to night!
Comets, importing change of times and states,
Brandish your crystal tresses in the sky,
And with them scourge the bad revolving stars,
That have consented unto Henry’s death!
Henry the Fifth, too famous to live long!
England never lost a king of so much worth.

First part Henry VI.

The passage with which Strada begins his history, is too poetical for a subject of that kind; and at any rate too high for the beginning of a grave performance.

3. A third rule or observation is, That where the subject is intended for entertainment solely, not for instruction, a thing ought to be described as it appears, not as it is in reality. In running, for example, the impulse upon the ground is proportioned in some degree to the celerity of motion; though in appearance it is otherwise, for a person in swift motion seems to skim the ground, and scarcely to touch it. Virgil, with great taste, describes quick running according to appearance; and raises an image far more lively than by adhering scrupulously to truth:

Hos super adventit Volscia de gente Camilla,
Agmen agens equitum, et florentes xere cætivars,
Bellatrix: non illa colo calathis Minervæ
Fœminæs assuetæ manus; sed praemia virgo
Dura pati курсuque pedum praevertere ventos.
Illa vel intactæ segetis per summa volaret
Grama, nec teneras cursu lessinas aristas:
Vulnere per medium, fluctu suspensa tumenti,
Perret iter, celleres nec tingeret squere planta.

Æneid, viii. 803.

4. In narration as well as in description, objects ought to be painted so accurately as to form in the mind of the reader distinct and lively images. Every useless circumstance ought indeed to be suppressed, because every such circumstance loads the narration; but if a circumstance be necessary, however slight, it cannot be described too minutely. The force of language consists in raising complete images, which have the effect to transport the reader as by magic into the very place of the important action, and to convert him as it were into a spectator, beholding everything that passes. The narrative in an epic poem ought to rival a picture in the liveliness and accuracy of its representations: no circumstance must be omitted that tends to make a complete image; because an imperfect image as well as any other imperfect conception, is cold and uninteresting. We shall illustrate this rule by several examples, giving the first place to a beautiful passage from Virgil:

Qualis populâs xere Philomela sub umbra
Amisos quaeritur xces, quos durus arator
Observans nido impleras detraxit.

Georg. lib. iv. 511.

The poplar, ploughman, and unfledged young, though not essential in the description, tend to make a complete image; and upon that account are an embellishment.

Again:

Hic viridem Æneas frondentis ex ilia metam
Constituit, signum nautis. Æneid, v. 129.

Horace addressing to Fortune:

Te pauper ambit sollicita prece
Ruris colonos: te dominam sequoris,
Quiunque Bithynâ lacesit
Carpabat pelagus carind.

Carm. lib. i. ode 35.

Hic ex menibus hosticis
Matrona belliantia tyranni
Prosperius, et adules virgo,
Suspiet: Etiam, ne rudis agminum
Sponsorias lacesat regius asperum
Tacta leonem, quem cruenta
Per medias rapit ira cæsae.

Carm. lib. iii. ode 2.

Shakespeare says, “You may as well go about to turn the sun to ice by fanning in his face with a peacock’s feather.” The peacock’s feather, not to mention the beauty of the object, completes the image: an accurate image cannot be formed of that fanciful operation, without conceiving a particular feather; and one is at a loss when this is neglected in the description. Again, “The rogues slighted me into the river with as little remorse, as they would have drown’d a bitch’s blind puppies, fifteen i’ th’ litter.”

Old Lady. You would not be a queen?

Anne. No, not for all the riches under heaven.

Old Lady. ‘Tis strange: a threepence bow’d would hire me, old as I am, to queen it.

Henry VIII. act ii. sc. 5.

In the following passage, the action, with all its materi-
Narration.

In all circumstances, it is represented so much to the life, that it would scarce appear more distinct to a real spectator; and it is the manner of description that contributes greatly to the sublimity of the passage—

He spake; and, to confirm his words, out flew
Millions of flaming swords, drawn from the thighs
Of mighty cherubim; the sudden blaze
Far round illum’d hell: highly they raged
Against the Highest, and fierce with grasped arms,
Clash’d on their sounding shields the din of war,
Hurling defiance toward the vault of heav’n.

Milton, book i.

The following passage from Shakespeare fails not much short of that now mentioned in particularity of description:

"O you hard hearts! ye cruel men of Rome!
Knew you not Pompey? Many a time and oft
Have you climb’d up to walls and battlements,
To towers and windows, yes, to chimney tops,
Your infants in your arms, and there have sat
The live-long day with patient expectation
To see great Pompey pass the streets of Rome;
And when you saw his chariot but appear,
Have you not made an universal shout?
That Tyber trembled underneath his banks,
To hear the replication of your sounds,
Made in his concave shore?"

Julius Cæsar, act i. sc. i.

The following passage is scarcely inferior to either of those mentioned:

"Far before the rest, the son of Ossian comes:
bright in the smiles of youth, fair as the first beams of
His long hair waves on his back: his dark
Brow is half beneath his helmet. The sword hangs
 Loose on the hero’s side; and his spear glitters as he
Moves. I fled from his terrible eye, king of high
Temora."

Fingal.

The Henriade of Voltaire errs greatly against the foregoing rule: every incident is touched in a summary way, without descending to circumstances. This manner is good in a general history, the purpose of which is to record important transactions; but in a fails it is cold and uninteresting; because it is impracticable to form distinct images of persons or things represented in a manner so superficial.

It is observed above, that every useless circumstance ought to be suppressed. The crowding such circumstances is, on the one hand, not less to be avoided than the conciseness for which Voltaire is blamed, on the other. In the Æneid, Barce, the nurse of Sicarius, whom we never hear of before nor after, is introduced for a purpose not more important than to call Anna to her sister Dido: and that it might not be thought unjust in Dido, even in this trivial circumstance, to prefer her husband’s nurse before her own, the poet takes care to inform his reader, that Dido’s nurse was dead. To this may be opposed a beautiful passage in the same book, where, after Dido’s last speech, the poet, without detaining his readers by describing the manner of her death, hastens to the lamentation of her attendants:

Dixerat: atque illum media inter talia ferre
Collapsam aspiciant comites, enseque crouunt
Spumantem, sparsaque manus. It clamor ad atra
Atria; coccumusse bacchatur fama per urben;
Lamentis gemiturque, et femineo ululatu
Tecta fremunt, resonat magnus plangoribus oter.

Lib. iv. 665.

As an appendix to the foregoing rule, may be added the following observation, that to make a sudden and strong impression, some single circumstance, happily selected, has more power than the most laboured description. Macbeth, mentioning to his lady some voices he heard while he was murdering the King, says,

There’s one did laugh in’s sleep, and one cry’d
Murder!
They wak’d each other; and I stood and heard
Them:
But they did say their prayers, and address them
Again to sleep.

Lady. There are two lodg’d together.

Macbeth. One cry’d, God bless us! and, Amen.
the other;
As they had seen me with these hangman’s hands,
Listening their fear. I could not say Amen,
When they did say, God bless us.

Lady. Consider it not so deeply.

Macbeth. But wherefore could not I pronounce
Amen!
I had most need of blessing, and Amen
Stuck in my throat.

Lady. These deeds must not be thought
After these ways; so, it will make us mad.

Macbeth. Methought, I heard a voice cry, Sleep
no more!
Macbeth doth murder sleep, &c.

Act ii. sc. 3.

Describing Prince Henry:

I saw young Harry, with his beaver on,
His cuisses on his thighs, gallantly arm’d,
Rise from the ground like feather’d Mercury;
And vaulted with such ease into his seat,
As if an angel dropt down from the clouds,
To turn and wind a fiery Pegasus,
And witch the world with noble horsemanship.

First Part Henry IV. act iii. sc. 2.

King Henry. Lord Cardinal, if thou think’st on
Heaven’s blin,
Hold up thy hand, make signal of thy hope.
He dies, and makes no sign!

Second Part Henry VI. act iii. sc. iii.

The same author, speaking ludicrously of an army
Debilitated with diseases, says,

"Half of them dare not shake the snow from
their cassocks, lest they shake themselves to pieces."

"I have seen the walls of Balcloths, but they were
Desolate. The flames had resounded in the halls: and
The voice of the people is heard no more. The stream
Of Clutha was removed from its place by the fall of
The walls. The thistle shook there its lonely head; the
Moss whistled to the wind. The fox looked out from the
Windows: and the rank grass of the wall waved
ground"
NAR [ 617 ]

Sir Sampson. Dick, body o’me, Dick has been dead these two years. I writ you word when you were at Leghorn.

Ben. Mess, that’s true; marry I had forgot. Dick’s dead, as you say.

Act iii. sc. 6.

Falstaff speaking of Ancient Pistol:

“’E’s no Swaggerer, hostess; a tame cheater I’faith; you may stroke him as gently as a puppy greyhound; he will not swagger with a Barbary hen, if her feathers turn back in any show of resistance.”

Second part Henry IV. act ii. sc. 4.

Ossian, among his other excellencies, is eminently successful in drawing characters; and he never fails to delight his reader with the beautiful attitudes of his heroes. Take the following instances:

“O Oscar! bend the strong in arm; but spare the feeble hand. Be thou a stream of many tides against the foes of thy people; but like the gale that moves the grass to those who ask thine aid—so Treanor lived; such Thralwas; and such has Fingal been. My arm was the support of the injured; and the weak rested behind the lightning of my steel.”

“We heard the voice of joy on the coast, and we thought that the mighty Cathmor came. Cathmor the friend of strangers! the brother of red-haired Cairbar! But their souls were not the same; for the light of heaven was on the bosom of Cathmor. His towers rose on the banks of Atha: seven paths led to his halls: seven chiefs stood on those paths, and called the stranger to the feast. But Cathmor dwelt in the wood to avoid the voice of praise.”

“Dermid and Oscar were one: they reaped the battle together. Their friendship was strong as their steel; and death walked between them to the field. They rush on the foe like two rocks falling from the brow of Arden. Their swords are stained with the blood of the valiant: warriors faint at their name. Who is equal to Oscar but Dermid? who to Dermid but Oscar?”

“Son of Comhal, replied the chief, the strength of Morni’s arm has failed: I attempted to draw the sword of my youth, but it remains in its place: I throw the spear, but it falls short of the mark: and I feel the weight of my shield. We decay like the grass of the mountain, and our strength returns no more. I have a son, O Fingal! his soul has delighted in the actions of Morni’s youth; but his sword has not been fitted against the foe, neither has his fame begun. I come with him to battle, to direct his arm. His renown will be a sun to my soul, in the dark hour of my departure. O that the name of Morni were forgot among the people! that the heroes would only say, Behold the father of Gaul.”

Some writers, through heat of imagination, fall into contradiction; some are guilty of downright absurdities; and some even rave like madmen. Against such capital errors one cannot be more effectually warned than by collecting instances; and the first shall be of a contradiction, the most venial of all. Virgil speaking of Neptune,
Jupiter in wrath puffing up both cheeks, is a low and even ludicrous expression, far from suitable to the gravity and importance of the subject: every one must feel the discordance. The following couplet, sinking far below the subject, is no less ludicrous:

Not one looks backward, onward still he goes,
Yet ne'er looks forward farther than his nose.

On the other hand, to raise the expression above the tone of the subject, is a fault which none is more common. Take the following instances:

Orcan le plus fidèle à servir ses desseins,
Ne sous le ciel brûlant des plus noirs Africains.

Boisaret, act iii. sc. 8.

Les ombres par trois fois ont obscurci les cieux
Depuis que le sommeil n'est entré dans vos yeux;
Et le jour a trois fois chassé la nuit obscure
Depuis que votre corps languit sans nourriture.

Phèdre, act i. sc. 3.

Assueris. Ce mortel, qui montra tant de zèle pour moi, Vit-il encore?

Asaph. — Il voit l'astre qui vous éclaire.

Esther, act ii. sc. 3.

Oui, c'est Agamemnon, c'est ton roi qui t'évèille;
Vieux, reconnais la voix qui frappe ton oreille.

Iphigénie.

No jocund health that Denmark drinks to-day,
But the great cannon to the clouds shall tell;
And the king's rowse the heav'n shall bruit again,
Respeaking earthly thunder.

Hamlet, act i. sc. 2.

———In the inner room
I spy a winking lamp, that weakly strikes
The ambient air, scarce kindling into light.

SOUTHERNE, Fate of Cupid, act iii.

In the Funeral Orations of the Bishop of Meaux, the following passages are raised far above the tone of the subject:

"L'Ocean etonné de se voir traversé tant de fois, en des appareils si divers, et pour des causes si différentes, &c."

Pag. 6.

"Grande reine, je satisfais à vos plus tendres desirs,
quand je célèbre ce monarque; et son cœur qui n'a jamais vécu que pour lui, s'éveille, tout poudre qu'il est,
et devient sensible, même sous ce drap mortuaire, as nom d'un epoux si cher."

Pag. 32.

The following passage, intended, one would imagine, as a receipt to boil water, is altogether burlesque by the laboured elevation of the diction:

A massy cauldron of stupendous frame
They brought, and plac'd it o'er the rising flame:
Then heap the lighted wood; the flame divides
Beneath the vases, and climbs around the sides:
In its wide womb they pour the rushing stream:
The boiling water bubbles to the brim.

Iliad, xvi. 405.

In a passage at the beginning of the 4th book of Telemachus, one feels a sudden bound upward without preparation, which accords not with the subject:

"Calypso,
My waking thought admits no balmy rest,
Nor the sweet bliss of soft oblivion share;
But-watchful woe distracts my aching breast,
My heart the subject of corroding care:
From haunts of men with wandering steps and slow
I solitary steal, and soothe my pensive woe.

Here every substantive is faithfully attended by some timid epithet.

We proceed to a second remark, not less important
than the former. No person of reflection but must be
sensible, that an incident makes a stronger impression on
an eye witness, than when heard at second hand. Writers
of genius, sensible that the eye is the best avenue to
the heart, represent every thing as passing in our sight;
and, from readers or hearers, transform us as it were
into spectators: a skilful writer conceals himself, and
presents his personages: in a word, every thing becomes
dramatic as much as possible. Plutarch, de gloria Atheniensium, observes, that Thucydides makes his reader
a spectator, and inspires him with the same passions as
if he were an eye witness.

In the fine arts, it is a rule to put the capital objects
in the strongest point of view; and even to present them
often than once, where it can be done. In history
painting, the principal figure is placed in the front, and
in the best light: an equestrian statue is placed in a
centre of streets, that it may be seen from many places
at once. In no composition is there greater opportunity
for this rule than in writing:

Sequitur pulchererrimus Astur,
Astur equo fides et versicoloribus armis.

Fall many a lady
I've ey'd with best regard, and many a time
Th' harmony of their tongues hath into bondage
Brought my too diligent ear: for several virtues
Have I lik'd several women: never any
With so full soul, but some defect in her
Did quarrel with the noblest grace he ow'd,
And put it to the foil. But you, O you,
So perfect, and so peerless, are created
Of every creature's best.

Orlando.———Whate'er you are
That, in the desert inaccessible,
Under the shade of melancholy boughs,
Lose and neglect the creeping hours of time;
If ever you have look'd on better days;
If ever been where bells have knoll'd to church;
If ever sat at any good man's feast;
If ever from your eyelids wip'd a tear,
And known what 'tis to pity, and be pity'd;
Let gentleness my strong enforcement be,
In the which hope I blush, and hide my sword.

Duke Sem. True is it that we have seen better days,
And have with holy bell been knoll'd to church;
And sat at good men's feasts; and wip'd our eyes
Of drops that sacred pity had engender'd;
And therefore sit you down in gentleness,
And take upon command what help we have,
That to your wanting may be minist'red.

As you like it.

With thee conversing I forget all time;
All seasons and their change, all please alike.

Sweet.
Sweet is the breath of morn, her rising sweet,
With charm of earliest birds; pleasant the sun
When first on this delightful land he spreads
His orient beams on herbs, tree, fruit, and flower,
Glist'ring with dew; fragrant the fertile earth
After soft show'rs; and sweet the coming on
Of grateful ev'ning mild, the silent night
With this her solemn bird, and this fair moon,
And these the gems of heav'n, her starry train:
But neither breath of morn, when she ascends
With charm of earliest birds, nor rising sun
On this delightful land, nor herb, fruit, flower,
Glist'ring with dew, nor fragrance after show'rs,
Nor grateful ev'ning mild, nor silent night,
With this her solemn bird, nor walk by moon
Or glittering star light, without thee is sweet.

*Paradise Lost*, book iv. l. 634.

"What meanst ye, that ye use this proverb, The fathers have eaten sour grapes, and the children's teeth are set on edge? As I live, saith the Lord God, ye shall not have occasion to use this proverb in Israel. If a man keep my judgments to deal truly, he is just; he shall surely live. But if he be a robber, a shedder of blood: if he have eaten upon the mountains, and defiled his neighbour's wife: if he have oppressed the poor and needy, have spoiled by violence, have not restored the pledge, have lift up his eyes to idols, have given forth upon usury, and have taken increase: shall he live? he shall not live: he shall surely die; and his blood shall be upon him. Now, lo, if he beget a son, that seeth all his father's sins, and considereth, and doth not such like; that hath not eaten upon the mountains, hath not lift up his eyes to idols, nor defiled his neighbour's wife, hath not oppressed any, nor witheld the pledge, neither hath spoiled by violence, but hath given his bread to the hungry, and covered the naked with a garment: that hath not received usury nor increase, that hath executed my judgments, and walked in my statutes: he shall not die for the iniquity of his father; he shall surely live. The soul that sinneth, it shall die; the son shall not bear the iniquity of the father, neither shall the father bear the iniquity of the son; the righteousness of the righteous shall be upon him, and the wickedness of the wicked shall be upon him. Have I any pleasure that the wicked should die, saith the Lord God; and not that he should return from his ways, and live?"  
*Ezekiel* xvii.

A concise comprehensive style is a great ornament in narration; and a superfluity of unnecessary words, not less than of circumstances, a great nuisance. A judicious selection of the striking circumstances, clothed in a nervous style, is delightful. In this style, Tacitus excels all writers, ancient and modern. Instances are numberless: take the following specimen:

"Cæsara hic preclara, et æquitis in modum latrocinii per saltus, per paludes; ut cuique fors aut virtus: temere, proviso, oh iram, ob pradam, jussu, et aliquando ignarum decibus."  
*Annals*, lib. xii. § 39.

After Tacitus, Ossian in that respect justly merits the place of distinction. One cannot go wrong for examples in any part of the book.

If a concise or nervous style be a beauty, tautology must be a blemish; and yet writers, fettered by verse,

are not sufficiently careful to avoid this slovenly practice: they may be pitied, but they cannot be justified.

Take for a specimen the following instances, from the best poet, for versification at least, that England has to boast of:

High on his helm celestial lightnings play,
His beamy shield emits a living ray;
Th' unwearied blaze incessant streams supplies,
Like the red star that fires the autumnal skies.

Strength and omnipotence invest thy throne.

So silent fountains, from a rock's tall head,
In sable streams soft trickling waters shed.

His clanging armour rung.

*Ibid.* xii. 94.

Fear on their cheek, and horror in their eye.

The blaze of armour flash'd against the day.

As when the piercing blasts of Boreas blow.

And like the moon, the broad refugent shield
Blaz'd with long rays, and gleam'd athwart the field.

No—could our swiftness o'er the winds prevail,
Or beat the pinions of the western gale,
All were in vain——

The humid sweat from every pore descends.

We close this article with a curious inquiry. An object, however ugly to the sight, is far from being so when represented by colours or by words. What is the cause of this difference? With respect to painting, the cause is obvious: a good picture, whatever the subject be, is agreeable by the pleasure we take in imitation; and this pleasure overbalancing the disagreeableness of the subject, makes the picture upon the whole agreeable. With respect to the description of an ugly object, the cause follows. To connect individuals in the social state, no particular contributes more than language, by the power it possesses of an expeditious communication of thoughts, and a lively representation of transactions. But nature hath not been satisfied to recommend language by its utility merely: independent of utility, it is made susceptible of many beauties, which are directly felt, without any intervening reflection. And this unfolds the mystery; for the pleasure of language is so great, as in a lively description to overbalance the disagreeableness of the image raised by it. This, however, is no encouragement to choose a disagreeable subject; for the pleasure is incomparably greater where the subject and the description are both of them agreeable.

The following description is upon the whole agreeable, though the subject described is in itself dismal:

Nine times the space that measures day and night
To mortal men, he with his horrid crew

*Laf.*
Of fiery darts in flaming volleys flew,
And flying vaulted either host with fire.
So under fiery cope together rush'd
Both battles main, with ruinous assault
And unextinguishable rage: all heaven
Resounded, and had earth been then, all earth

*Ghost.*——But that I am forbid
To tell the secrets of my prison-house,
I could a tale unfold, whose lightest word
Would harrow up thy soul, freeze thy young blood,
Make thy two eyes, like stars start from their spheres,
Thy knotty and combined locks to part,
And each particular hair to stand on end,
Like quills upon the fretful porcupine:
But this eternal blazon must not be
To ears of flesh and blood. *Hamlet,* act i. sc. 8.

*Gratiano.* Poor Desdemona! I'm glad thy father's dead:
Thy match was mortal to him; and pure grief
Shore his old thread in twain. Did he live now,
This sight would make him do a desperate turn:
Yea, curse his better angel from his side,
And fall to reprobation. *Othello,* act v. sc. 8.

Objects of horror must be excepted from the foregoing theory; for no description, however lively, is sufficient to overbalance the disgust raised even by the idea of such objects. Every thing horrible ought therefore to be avoided in a description.

NARES, the eunuch who rivalled Belisarius in heroism under the reign of the emperor Justinian, emerged from obscurity A.D. 538. From the domestic service of the palace, and the administration of the private revenue, he was suddenly exalted to the head of an army. He is ranked among the few eunuchs who have rescued that unhappy name from the contempt and hatred of mankind. A feeble diminutive body concealed the soul of a statesman and a warrior. His youth had been employed in the management of the loom and distaff, in the cares of the household, and the service of female luxury; but, while his hands were busy, he secretly exercised the faculties of a vigorous and discerning mind. A stranger to the schools and the camp, he studied in the palace to dissemble, to flatter, and to persuade; and as soon as he approached the person of the emperor, Justinian listened with surprise and pleasure to the manly counsels of his chamberlain and private treasurer. The talents of Nares were tried and improved in frequent embassies; he led an army into Italy, acquired a practical knowledge of the war and the country, and presumed to strive with the genius of Belisarius. Twelve years after his return, the eunuch was chosen to achieve the conquest which had been left imperfect by the first of the Roman generals. Instead of being dazzled by vanity or emulation, he seriously declared, that unless he were armed with an adequate force, he would never consent to risk his own glory and that of his sovereign. Justinian granted to the favourite what he might have denied to the hero: the Gothic war was rekindled from its ashes, and the preparations were not unworthy of the ancient majesty of the empire.

Nares defeated the Goths, the Franks, and the Alamanni:
Nasau-Hadam, a country of Germany, which, till the year 1711, had princes of its own; but now belongs wholly to William V. prince of Orange.

Nassau, prince of Orange. See MAURICE.

NATES, in Anatomy, a term expressing those two fleshy exterior parts of the body, vulgarly called the buttocks. See Anatomy.

NAT, a collective term, used for a considerable number of people inhabiting a certain extent of land, confined within fixed limits, and under the same government.

NATIONAL DEBT: the money owing by government.

Our limits permit us to give but a very general sketch of this subject: However, as it is of considerable importance to every inhabitant of those kingdoms, we shall endeavour to give as clear and comprehensive a view of it as the bounds necessarily prescribed us will admit. In order to this, it may not be improper to refer back to the times that have gone before us, that we may the better discover the nature of public revenues, the manner of their expenditure, and the causes of public debt.

In that rude state of society which precedes the extension of commerce and the improvements of manufactures, when those expensive luxuries which commerce and manufactures can alone introduce, are altogether unknown; the person who possesses a large revenue can spend or enjoy that revenue in no other way than by maintaining nearly as many people as it can maintain. Among our feudal ancestors, the long time during which estates used to continue in the same family, sufficiently demonstrates the general disposition of the people to live within their income. Though the rustic hospitality constantly exercised by the great landholders may not to us in the present times seem consistent with that order which we are apt to consider as inseparably connected with good economy, yet we must certainly allow them to have been at least so far frugal as not commonly to have spent their whole income. Some part of this money, perhaps, they spent in purchasing the few objects of vanity and luxury with which the circumstances of the times could furnish them: but some part of it they seem commonly to have hoarded. They could not well indeed do any thing else but hoard whatever money they saved. To trade was disgraceful to a gentleman; and to lend money at interest, which at that time was considered as usury and prohibited by law, would have been considered...
The same disposition to save and to hoard prevailed in the sovereign as well as in the subjects. Among nations to whom commerce and manufactures are little known, the sovereign is in a situation which naturally disposes him to the parsimony requisite for accumulation. In that situation the expence even of a sovereign cannot be directed by that vanity which delights in the gaudy finery of a court. The ignorance of the times afford but few of the trinkets in which that finery consists. Standing armies are not then necessary; so that the expence even of a sovereign, like that of any other great lord, can be employed in scarce any thing but bounty to his tenants and hospitality to his retainers. But bounty and hospitality very seldom lead to extravagance: though vanity almost always does. All the ancient sovereigns of Europe accordingly had treasures. Every Tartar chief in the present times is said to have one.

In a commercial country abounding with every sort of expensive luxury, the sovereign, in the same manner as almost all the great proprietors in his dominions, naturally spends a great part of his revenue in purchasing those luxuries. His own and the neighbouring countries supply him abundantly with all the costly trinkets which compose the splendid but insignificant pageantry of a court. His ordinary expence becomes equal to his ordinary revenue, and it is well if it does not frequently exceed it. The amassing of treasure can no longer be expected: and when extraordinary exigencies require extraordinary expences, he must necessarily call upon his subjects for an extraordinary aid. The late king of Prussia and his father are the only great princes of Europe who, since the death of Henry IV. of France in 1610, are supposed to have amassed any considerable treasure. The parsimony which leads to accumulation has become almost as rare in republican as in monarchical governments. The Italian republics, the United Provinces of the Netherlands, are all in debt. The canton of Berne is the single republic in Europe which has amassed any considerable treasure. The other Swiss republics have not.

The taste for some sort of pageantry, for splendid buildings at least and other public ornaments, frequently prevails as much in the apparently sober senate house of a little republic as in the dissipated court of the greatest king.

The want of parsimony in time of peace imposes the necessity of contracting debt in time of war. When war comes, there is no money in the treasury but what is necessary for carrying on the ordinary expence of the peace establishment. In war an establishment of three or four times that expence becomes necessary for the defence of the state, and consequently a revenue three or four times greater than the peace revenue. Supposing that the sovereign should have what he scarce ever has, the immediate means of augmenting his revenue in proportion to the augmentation of his expence; yet still the produce of the taxes, from which this increase of revenue must be drawn, will not begin to come into the treasury till perhaps ten or twelve months after they are imposed. But the moment in which war begins, or rather the moment in which it appears likely to begin, the army must be augmented, he fleets must be fitted out, the garrisoned towns must be put into a posture of defence: that army, that fleet those garrisoned towns, must be furnished with arms, ammunition, and provisions. An immediate and great expence must be incurred in that moment of immediate danger, which will not wait for the gradual and slow returns of the new taxes. In this exigency government can have no other resources but in borrowing.

The same commercial state of society which, by the operation of moral causes, brings government in this manner into the necessity of borrowing, produces in the subjects both an ability and an inclination to lend. If it commonly brings along with it the necessity of borrowing, it likewise brings along with it the facility of doing so.

A country abounding with merchants and manufacturers, necessarily abounds with a set of people through whose hands not only their own capitals, but the capitals of all those who either lend them money or trust them with goods, pass as frequently and more frequently than the revenue of a private man, who without trade or business lives upon his income, passes through his hands. The revenue of such a man can regularly pass through his hands only once in a year. But the whole amount of the capital and credit of a merchant who deals in a trade of which the returns are very quick may sometimes pass through his hands two, three, or four times in a year. A country abounding with merchants and manufacturers, therefore, necessarily abounds with a set of people, who have it at all times in their power to advance, if they choose to do so, a very large sum of money to government. Hence the ability in the subjects of a commercial state to lend.

The progress of the enormous debts which at present oppress, and will in the long-run probably ruin, all the great nations of Europe, has been pretty uniform. In England, after the Revolution, when new connexions with Europe introduced a new system of foreign politics, the expences of the nation not only in settling the new establishment, but in maintaining long wars, as principals, on the continent, for the security of the Dutch barrier, reducing the French monarchy, settling the Spanish succession, supporting the house of Austria, maintaining the liberties of the Germanic body, and other purposes, increas'd to an unusual degree: insomuch that it was not thought advisable to raise all the expences of any one year by taxes to be levied within that year, lest the unacquainted weight of them should create murmurs among the people. It was therefore the policy of the times to anticipate the revenues of their posterity, by borrowing immense sums for the current service of the state, and to lay no more taxes upon the subject than would suffice to pay the annual interest of the sums so borrowed; by this means converting the principal debt into a new species of property, transferable from one man to another at any time: and in any quantity. This system indeed seems to have had its original in the state of Florence, A. D. 1344; which government then owed about 60,000l. sterling; and being unable to pay it, formed the principal into an aggregate sum, called metaphorically a mount or bank, the shares whereof were transferable like our stocks, with interest at 5 per cent. the prices varying according to the exigencies of the state.
NAT [ 624 ]

NATIONAL DEBT.

This laid the foundation of what is called the national debt; for a few long annuities created in the reign of Charles II. will hardly deserve that name.

Nations, like private men, have generally begun to borrow upon what may be called personal credit, without assigning or mortgaging any particular fund for the payment of the debt; and when this resource has failed them, they have gone on to borrow upon assignments or mortgages of particular funds.

What is called the unfunded debt of Great Britain, as contracted in the former of those two ways. It consists partly in a debt which bears, or is supposed to bear, no interest; and which resembles the debts that a private man contracts upon account; and partly in a debt which bears interest, and which resembles what a private man contracts upon his bill or promissory note. The debts which are due either for extraordinary services, or for services either not provided for or not paid at the time when they are performed; part of the extraordinaries of the army, navy, and ordnance, the arrears of subsidies to foreign princes, those of seamen's wages, &c. usually constitute a debt of the first kind. Navy and exchequer bills, which are issued sometimes in payment of a part of such debts and sometimes for other purposes, constitute a debt of the second kind; exchequer bills bearing interest from the day on which they are issued, and navy bills six months after they are issued. The bank of England, either by voluntarily discounting those bills at their current value, or by agreeing with government for certain considerations to circulate exchequer bills, that is, to receive them at par, paying the interest which happens due upon them, keeps up their value, and facilitates their circulation, and thereby frequently enables government to contract a very large debt of this kind. During the great recoinage in King William's time, when the bank of England thought proper to put a stop to its usual transactions, exchequer bills and tallies are said to have sold from 25 to 60 per cent. discount, owing partly, no doubt, to the supposed instability of the new government established by the Revolution, but partly too to the want of the support of the bank of England.

When this resource is exhausted, and it becomes necessary, in order to raise money, to assign or mortgage some particular branch of the public revenue for the payment of the debt, government has upon different occasions done this in two different ways. Sometimes it has made this assignment or mortgage for a short period of time only, a year or a few years, for example; and sometimes for perpetuity. In the one case, the fund was supposed sufficient to pay within the limited time both principal and interest of the money borrowed: In the other, it was supposed sufficient to pay the interest only, or a perpetual annuity equivalent to the interest; government being at liberty to redeem at any time this annuity upon paying back the principal sum borrowed. When money was raised in the one way, it was said to be raised by anticipation; when in the other, by perpetual funding, or, more shortly, by funding.

In the reign of King William, when the debt began to be amassed, and during a great part of that of Queen Anne, before we had become so familiar as we are now with the practice of perpetual funding, the greater part of the new taxes were imposed but for a short period of time (for four, five, six, or seven years only), and a great part of the grants of every year consisted in loans upon anticipation of the produce of those taxes. The produce being frequently insufficient for paying within the limited term the principal and interest of the money borrowed, deficiencies arose to make good which it became necessary to prolong the term.

On the 31st of December 1697, the funded and unfunded debts amounted to 21,515,742l. 13s. 8d.; at the same time, 1714, they were 53,681,076l. 2s. 6d. In 1755, before the breaking out of the war, they amounted to 72,829,675l.; and on the 7th of January 1763, at the conclusion of the peace, they had accumulated to 123,603,336l. 8s. 2d. of funded debt, and of unfunded 13,027,589l. 2s. 2d. more. In 1775, they were very nearly 120 millions; and the last American war added upwards of 120 millions more to that enormous sum: to pay the interest of which, and the charges of management, amounting annually to nearly eight millions and a half, the extraordinary revenues elsewhere enumerated (excepting only the land-tax, quit-rent, and annual malt tax) are in the first place mortgaged and made perpetual by parliament. Perpetual, we say; but still redeemable by the same authority that imposed them: which, if it at any time can pay off the capital, will abolish those taxes which are raised to discharge the interest.

By this means, then, the quantity of property in the kingdom is greatly increased in idea compared with former times; yet, if we coolly consider it, not at all increased in reality. We may boast of large forces, and the stock of money, and the funded debts. But where does this money exist? It exists only in name, in paper, in public faith, in parliamentary security: and that is undoubtedly sufficient for the creditors of the public to rely on. But then what is the pledge which the public faith has pawned for the security of these debts? The land, the trade, and the personal industry of the subject; from which the money must arise that supplies the several taxes. In these, therefore, and these only, the property of the public creditors does really and intrinsically exist; and of course the land, the trade, and the personal industry of individuals, are diminished in their true value just so much as they are pledged to answer. If A's income amounts to 10l. per annum; he is so far indebted to B, that he pays him 50l. per annum for his interest; one half of the value of A's property is transferred to B the creditor. The creditor's property exists in the demand which he has upon the debtor, and nowhere else; and the debtor is only a tenant of the creditor for one half of the value of his income. In short, the property of a creditor of the public consists in a certain portion of the national taxes; by how much therefore he is the richer, by so much the nation, which pays these taxes, is the poorer.

The only advantage that can result to a nation from public debts, is the increase of circulation, by multiplying the cash of the kingdom, and creating a new species of currency, assignable at any time and in any quantity; always therefore ready to be employed in any beneficial undertaking, by means of this its transferrable quality; and yet producing some profit even when
NATIVITY, or NATAL Day, the day of a person's birth. The word nativity is chiefly used in speaking of the saints; as, the nativity of St John the Baptist, &c. But when we say the Nativity, it is understood of that of Jesus Christ, or the feast of Christmas.

Nativity, nativitas, in ancient law books, signifies bondage or servitude.

Nativity, in Astrology, the theme or figure of the heavens, and particularly of the twelve houses, at the moment when a person was born; called also the horoscope.

Casting the nativity, or by calculation seeking to know how long the queen should live, &c., was made felony, an. 23. Eliz. c. 2.

NATIVO HABENDO, in Law, a writ directed to the sheriff, for a lord who claimed inheritance in any villain, when a villain was run away from him, for the apprehending and restoring him to the lord.

NATIX, in Natural History, a name given by some old writers to the natrix.

NATOLIA, the modern name of the Lesser Asia, being the most westerly part of Turkey in Asia, and consisting of a large peninsula, which extends from the river Euphrates as far as the Archipelago, the sea of Marmora, the straits of Gallipoli and of Constantinople, which separate it from Europe on the west. It is bounded on the north by the Black sea, and on the south by the Mediterranean.

NATRIX, in Zoology, the name of the common or water-snake, called also torquata, from the ring about its neck. See Ophiology Index.

NATRUM, or NATRON, the nitre of the ancients, one of the fixed alkalies. See Soda, Chemistry Index.

It is found in great abundance in many parts of Asia, where the natives sweep it up from the surface of the ground, and called soap earth. The earliest account we have of it is in the scriptures, where we find that the salt called nitre in those times would ferment with vinegar, and possessed a detestable quality, so that it was used in baths and in washing. Solomon compares the singing of songs with a heavy heart, to the contrariety of vinegar and nitre: and Jeremiah says, that if the sinner wash himself with nitre, his sin is not cleansed off. These are properties that perfectly agree with this salt, but not at all with our saltpetre, which is the nitre of the moderns.

NATTER-JACK, a species of Rana, which see, Herpetology Index.

NATURAL, in general, something that relates to nature. See Nature.

NATURAL Children, are those born out of lawful wedlock. See Bastard.

NATURAL Functions, are those actions whereby the aliment are changed and assimilated so as to become a part of the body.

NATURAL, in Heraldry, is used where animals, fruits, flowers, &c. are blazoned with the colours they naturally have, though different from the common colours of
of heraldry: and this is to prevent their armories being accused of falsity, when blazoned with the names of colours unknown in heraldry.

**Natural Note** in Music, is used in opposition to flat and sharp notes, which are called artificial notes. See Note, Scale, &c.

Natural is also used for something coming immediately out of the hands of nature: in which sense it stands opposed to fictitious or artificial, which signifies something wrought by art. See Artificial.

Bishop Wilkins observes, that there appears a world of difference between natural and artificial things, when viewed with microscopes. The first ever appear adorned with all imaginable elegance and beauty; the latter, though the most curious in their kind, infinitely rude and unhewn: the finest needle appears a rough bar of iron; and the most accurate engraving or emblazonment, as if done with a mattock or a trowel.

**Natural Beauty,** or the beauty of natural objects, is that quality or those qualities in the works of nature, or more properly of God, which are calculated to excite pleasing sensations in the minds of all such persons of true taste as attentively observe them. It will not, we trust, be deemed improper or impertinent, therefore, to introduce a few observations on this subject, previous to our treating of natural history.—To many, it is hoped, it will appear to be a very proper introduction to that important article. "That sensibility to beauty, which, when cultivated and improved, we term taste, is universally diffused through the human species"; and it is most uniform with respect to those objects, which being out of our power, are not liable to variation from accident, caprice, or fashion. The verdant lawn, the shady grove, the variegated landscape, the boundless ocean, and the stately firmament, are contemplated with pleasure by every attentive beholder. But the emotions of different spectators, though similar in kind, differ widely in degree; and to relish with full delight the enchanting scenes of nature, the mind must be uncorrupted by avarice, sensuality, or ambition; quick in her sensibilities; elevated in her sentiments; and devout in her affections. He who possesses such exalted powers of perception and enjoyment, may almost say, with the poet,

I care not, Fortune! what you me deny
You cannot rob me of free Nature's grace;
You cannot shut the windows of the sky,
Through which Aurora shows her bright'ning face;
You cannot bar my constant feet to trace
The woods and lawns, by living stream, at eve:
Let health my nerves and finer fibres brace,
And I their toys to the great children leave:
Of fancy, reason, virtue, naught can me bereave.

"Perhaps such ardent enthusiasm may not be compatible with the necessary toils and active offices which Providence has assigned to the generality of men. But there are none to whom some portion of it may not prove advantageous: and if it were cherished by each individual, in that degree which is consistent with the indispensable duties of his station, the felicity of human life would be considerably augmented. From this source the refined and vivid pleasures of the imagination are almost entirely derived: and the elegant arts owe their choicest beauties to a taste for the contemplation of nature. Painting and sculpture are expressions of visible objects; and where would be the charm of poetry, if divested of the imagery and embellishments which she borrows from rural scenes? Painters, statuary, and poets, therefore, are always ambitious to acknowledge themselves the pupils of nature; and as their skill increases, they grow more and more delighted with every view of the animal and vegetable world. But the pleasure resulting from admiration is transient; and to cultivate taste, without regard to its influence on the passions and affections, "is to rear a tree for its blossoms, which is capable of yielding the richest and most valuable fruit." Physical and moral beauty bear so intimate a relation to each other, that they may be considered as different gradations in the scale of excellence; and the knowledge and relish of the former should be deemed only a step to the sober and more permanent enjoyments of the latter.

"Whoever has visited the Leasowes, in Warwickshire, must have felt the force and propriety of an inscription which meets the eye at the entrance into those delightful grounds.

Would you then taste the tranquil scene?
Be sure your bosoms be serene:
Devoid of hate, devoid of strife;
Devoid of all that poisons life:
And much it "sails you, in their place, To graft the love of human race."

"Now such scenes contribute powerfully to inspire that serenity which is necessary to enjoy and to brighten their beauties. By a secret contagion, the soul catches the harmony which she contemplates; and the frame within assimilates itself to that which is without. For,

"Who can forbear to smile with Nature? Can the stormy passions in the bosom roll,
While every gale is peace, and every grove
Is melody?"

"In this state of sweet composure, we become susceptible of virtuous impressions, from almost every surrounding object. The patient ox is viewed with generous complacency; the guileless sheep with pity; and the playful lamb raises emotions of tenderness and love. We rejoice with the horse, in his liberty and exemption from toil, while he ranges at large through ensaled pastures; and the frolics of the colt would afford unmix'd delight, did we not recollect the bondage which he is soon to undergo. We are charmed with the song of birds, soothed with the buzz of insects, and pleased with the sportive motions of fishes, because these are expressions of enjoyment; and we exult in the felicity of the whole animated creation. Thus an equal and extensive benevolence is called forth into exertion; and having felt a common interest in the gratifications of inferior beings, we shall be no longer indifferent to their sufferings, or become wantonly instrumental in producing them.

"It seems to be the intention of Providence, that the lower order of animals should be subservient to the comfort, convenience, and sustenance of man. But his right of dominion extends no farther; and if this right be exercised with mildness, humanity, and justice, the subjects of his power will be no less benefici-
ed than himself. For various species of living creatures are annually multiplied by human art, improved in their perceptive powers by human culture, and plentifully fed by human industry. The relation, therefore, is reciprocal between such animals and man; and he may supply his own wants by the use of their labour, the produce of their bodies, and even the sacrifice of their lives, whilst he co-operates with all-gracious Heaven in promoting happiness, the great end of existence.

"But though it be true, that partial evil, with respect to different orders of sensitive beings, may be universal good; and that it is a wise and benevolent institution of nature, to make destruction itself, within certain limitations, the cause of an increase of life and enjoyment; yet a generous person will extend his compassionate regards to every individual that suffers for his sake: and whilst he sighs

Even for the kid or lamb that parts its life
Beneath the bloody knife,
he will naturally be solicitous to mitigate pain, both in duration and degree, by the gentlest modes of inflicting it.

"We are inclined to believe, however, that this sense of humanity would soon be obliterated, and that the heart would grow callous to every soft impression, were it not for the beneficent influence of the smiling face of nature. The count de Lauzon, when imprisoned by Louis XIV. in the castle of Figneroil, amused himself during a long period of time with catching flies, and delivering them to be devoured by a rapacious spider. Such an entertainment was equally singular and cruel: and inconsistent, we believe, with his former character, and his subsequent turn of mind. But his cell had no window, and received only a glimmering light from an aperture in the roof. In less unfavourable circumstances, may we not presume, that instead of sporting with misery, he would have released the agonizing flies, and bid them enjoy that freedom of which he himself was bereaved?

"But the taste for natural beauty is subservient to higher purposes than those which have been enumerated; and the cultivation of it not only refines and humanizes, but dignifies and exalts the affections. It elevates them to the admiration and love of that Being who is the author of all that is fair, sublime, and good in the creation. Skepticism and irreligion are hardly compatible with the sensibility of heart which arises from a just and lively relish of the wisdom, harmony, and order subsisting in the world around us: and emotions of pity must spring up spontaneously in the bosom that is in union with all animated nature. Actuated by this divine inspiration, man finds a fane in every grove; and glowing with devout fervour, he joins his song to the universal chorus, or muses the praise of the Almighty, in more expressive silence. Thus they

"Whom Nature's works can charm, with God himself
I hold conversant; grow familiar, day by day,
With his conceptions; act upon his plan;
And form to his the relish of their souls."

On the whole, then, it certainly appears, that the advantages resulting from a taste for natural beauties are great and important: it is equally certain, that as it is useful, so it is a continual source of real enjoyment; for a more rational pleasure cannot possibly occupy the attention or captivate the affections of mankind, than that which arises from a due consideration of the works of nature. Pleasure, we know, is a necessary ingredient in human life, in order to prevent our measure to counterbalance the pains, the evils, and listlessnesses, which are at times perhaps unavoidable, and in order to render life tolerable. It is the part then of the moralist, and it has been frequently his business, to point out and recommend such pleasures as are highly gratifying, and are yet perfectly innocent. The Spectator, whose works will be admired as long as the language in which they are written is understood, recommends strongly and elegantly the pleasure of a garden; and a later writer, of no common degree of me-Dr. Knowl

rit, and of very considerable fame, has an essay on the same subject, from which we shall select a few observations, and so conclude the article. "Not he a

lone (says this elegant writer) is to be esteemed a benefactor to mankind, who makes an useful discovery; but he also who can point out and recommend an innocent pleasure. Of this kind are the pleasures arising from the observation of nature: and they are highly agreeable to every taste uncorrupted by vicious indulgence. Rural scenes of almost every kind are delight

ful to the mind of man. But the misfortune is, that the greater part are buried on in the career of life with too great rapidity to be able to give attention to that which solicits no passion. The darkest habitation in the dirtiest street of the metropolis, where money can be earned, has greater charms, with many than the groves of Hagley.

"The patron of refined pleasure, the elegant Epicurus, fixed the seat of his enjoyment in a garden. He was of opinion, that a tranquil spot, furnished with the united sweets of art and nature, was the best adapted to delicate repose. And even the severer philosophers of antiquity were wont to discourse in the shade of a spreading tree, in some cultivated plantation. It is obvious, on intuition, that nature often intended solely to please the eye in her vegetable productions. She decorates the floweret that springs beneath our feet in all the perfections of external beauty. She has clothed the garden with a constant succession of various hues. Even the leaves of the tree undergo a pleasing vicissitude. The fresh verdure which they exhibit in the spring, the various shades which they assume in summer, the yellow and russet tinge of autumn, and the nakedness of winter, afford a constant pleasure to a lively imagination. From the snowdrop to the moss rose the flower garden displays an infinite variety of shape and colour. The taste of the florist has been ridiculed as trivial; yet surely without reason. Did nature bring forth the tulip and the lily, the rose and the honeysuckle, to be neglected by the haughty pretender to superior reason? To omit a single social duty for the cultivation of a polyanthus were ridiculous as well as criminal; but to pass by the beauties lavished before us, without observing them, is no less ingratefulness than stupidity. A bad heart finds little amusement but in a communication with the active world, where scope is given for the indulgence of 4K2 malignant
NATURAL HISTORY.

The objects of nature may be considered under two points of view: 1st, With respect to their form, structure, habits, and individual properties when viewed in a state of inactivity; 2dly, With respect to the mutual changes which they produce when made to act on each other. Hence the study of nature may be divided into two parts, Natural History and Natural Science; the former considering bodies in comparatively an inactive state, the latter in a state of mutual action.

Natural History, then, is that part of natural knowledge which teaches us to distinguish and describe the objects of nature, to examine their appearance, structure, properties and uses, and to collect, preserve, and arrange them (A).

I. When we take a general survey of the objects with which we are surrounded, we are bewildered amidst the number and variety that are everywhere presented to our view. The air, the woods, the fields, the waters, teem with myriads of animals; a large proportion of the earth's surface is covered with a green mantle of luxuriant herbsage, interspersed with plants and flowers of a thousand varied tints; and when we search below this, when we explore the cloud-capt mountain, the gloomy mine, the sequestered cavern, or the rocky cliff, we discover a great variety of mineral substances, either piled into irregular masses, or lying in uniform beds or layers, disposed in veins or seams, or scattered at random through the other stony matters.

To the casual observer, the number and variety of these objects would appear almost infinite. He would consider it equally impossible to enumerate them, as to number the stars, or count the sands on the sea shore. This idea, however, arises from his seeing them in confusion and disorder. The naturalist, by separating them into those groups or classes, in which they naturally present themselves, has succeeded not only in distinguishing the several kinds from each other, but even in guessing pretty accurately at the number of species that have hitherto been discovered.

There are two objects which should principally occupy the attention of the naturalist: 1st, To classify natural substances; 2dly, To examine their structure.

The number of natural productions being confusedly very great, it is necessary to find out some means of distinguishing them from each other, and of recognizing them on seeing them anew. These means are the peculiarities, or the assemblages of peculiarities, that exclusively belong to each body. Now there is scarcely any substance that has a simple character, that is, which can be distinguished from every other substance by any one of its properties singly. It is only by the combination of several of these properties that we can distinguish an object from others which resemble it in possessing some one or more of those very properties; and the more numerous the species we compare, the more necessary it becomes to bring their properties together, in order to assign to each a character that may distinguish it from the rest. Hence to distinguish a species, considered independently from all others that exist in nature, it is necessary to express in its character almost the whole of its properties; and the more of these we take into the character, the more complete will be our description of the object. But no man can acquire a sufficiently accurate knowledge of all natural objects to enable him to give a complete description of them; human life is too short to admit of the completion of such a task. All that can be expected from our limited faculties is to acquire a general knowledge of natural objects, confining our principal attention to such as possess some striking qualities, or appear convertible to the useful purposes of life.

To gain this end, two modes of procedure have been adopted by naturalists. According to the first mode, we employ characters that proceed by degrees from particulars to generals. We begin by comparing together a certain number of species, that seem to bear the nearest relation to each other. In drawing the characters of these species, it is requisite to express only those differences, which, on a supposition that they are the most nearly related, form but a small part of their properties; a number of species thus brought together constitutes what is called a genus or tribe.

The

(A) Some writers divide natural history into general and particular, which are thus defined by Cuvier. General natural history considers under a single point of view, all natural bodies, and the common result of all their actions in the great whole of nature. It determines the laws of coexistence of their properties; it establishes the degrees of resemblance that exist between different bodies, and classes them according to these degrees. The Particular natural history of any body, to be perfect, should comprehend, 1st, The description of all the sensible properties of that body, and of all its parts; 2d, The mutual relations of these parts, the motions which they produce, and the changes which they undergo while they remain united; 3d, The active and passive relations of this body with every other body in the universe; and 4th, The explanation of all these phenomena. See Tableau Elémentaire d'Histoire Naturelle.
The remainder of these properties which are common to all the species of the genus combine to form the character, or rather the description, of the genus, distinguishing it from all these which might be formed by bringing together other species; but the number of these common properties being still very considerable, we repeat the same means in order to reduce the characters of the genera to smaller terms. We compare together only those genera which most nearly resemble each other, and the generic characters now employed most only express those differences which form but a small part of their common properties. Those properties, which are common to all the genera, compose a character that distinguishes this assemblage or group from all other groups of genera. Such an assemblage of genera is called an order.

Repeating the same operation, and bringing together such orders as are most nearly allied, we form a more general assemblage, called a class; and again uniting a certain number of classes, we form a higher division, to which naturalists have given the name of kingdom: this chain of divisions in which the higher links comprehend the lower, forms what is called a method. The other mode of procedure is to rise gradually from generals to particulars, beginning with the slightest and most obvious differences, thus forming the first division or kingdom; dividing each kingdom into classes, each class into orders, each order into genera, each genus into species, and each species into varieties. This descending series constitutes what is called a system, and is that which has been generally adopted by naturalists.

To illustrate this systematical classification of natural objects, let us select a familiar example. Among the various creatures that pass under our observation, a great number are possessed of life, of sensation, and voluntary motion; these we call animals, and of these we form the order of the animal kingdom. On examining various groups of animals, we find that many have four extremities, and suckle their young by means of teats; these we call quadrupeds or mammalia. We have thus formed a class of animals. Again we find that of the mammalia some have hoofed feet and blunt fore-teeth, and feed almost entirely on vegetables. These will constitute an order of the class of mammalia, to which Linnaeus has given the name of ruminante. Of this order a certain number of animals agree in having six fore-teeth in both jaws, and form a genus or tribe distinguished by this particular from the other animals of the same order, and commonly called the horse tribe. Lastly, in this tribe we find one species that has solid hoofs, a tail bristly at the end, an upright mane, and a black cross on the shoulder of the mare. This species is the common ass.

In framing an artificial system of natural history, most writers have agreed on the division of natural bodies into kingdoms, proceeding on the supposition that those marks which are to distinguish the objects of one kingdom from those of another are sufficiently fixed and certain.

Let us examine for a little how far this supposition agrees with nature's works as we find them.

The division of natural objects commonly adopted is into three kingdoms: the animal, vegetable, and mineral kingdoms. This division has been almost universally received as perfectly consistent with nature; and is by most persons thought to be so clear and distinct, that they suppose it impossible to mistake in referring any particular object to its proper kingdom. This arises from their having noticed only such objects as bear evident marks of the division to which they belong; but if we draw their attention to a variety of other individuals, they will acknowledge themselves to be incompetent to the decision, or will erroneously refer to one division, what has, after accurate examination, been determined to belong to another.

There is one whole class of productions, called zoophytes by naturalists, which seem to form the connecting links between the different kingdoms. They are animals of the polypus kind, mostly covered with a calcareous crust, differing little in composition from the shells of lobsters, shrimps, and other shell-fish, and formed like them from an exudation or secretion on the surface of their bodies. These polypsi are connected together by thousands, or even millions, and assume a great variety of appearances according to their arrangement: the same species, however, always assuming the same, or very nearly the same appearance. Some are connected together in form of stem and branches, as the fuscus, serulariae, corallines, and others; many of which have their offspring in the egg state attached to them, and so situated as to bear exact resemblance to the seed-vessels of plants. These are altogether so like to many of the sea plants, as to be generally confounded with them, under the title of sea-weeds; but the attentive naturalist may, by examining them in their natural state, perceive the tentacula or feelers of each polypus extended in its search for food, and hastily retracting within its shell upon the least alarm. Many of this description are found attached to oysters or other shell-fish; and often to stones and pebbles which are covered or occasionally wetted by the sea.

Other zoophytes assume less regular figures, and are much more firm and solid, resembling the productions of the mineral kingdom. Madrepores and millepores, called often brainstones, are of this kind. At first sight they look very like stones and pebbles, or like pieces of chalk or marble, but on an accurate inspection, any one may perceive marks of an organic structure; and when they are in a recent state, may detect the inhabitants of their numerous cells.

The above examples will suffice to prove how insufficient is either a hasty examination or the judging by similarity of appearance, for determining to what kingdom of nature any particular object belongs. But there are many other productions to which few persons could without hesitation assign their places: for instance, where would we arrange the green powdery substance so common on paling; the spotted and streaked appearance on stones; the mould on cheese, or the green jelly-like matter that floats on the surface of the stagnant waters? Naturalists in general have assigned these productions to the vegetable kingdom; but Senicour and a few others have maintained that some of them are animals.

According to some writers, the most philosophical notion which we can form on this subject is, that the division of natural objects into kingdoms is artificial, and that Nature, acknowledging no such bonds, passes imperceptibly from the animal to the vegetable, and from the...
the vegetable to the mineral world, without defining where one ceases or where the next begins.

As the appearances of natural productions are insufficient, so are their properties and powers, for determining which are animals or which vegetables, according to the received acceptance of the terms. If locomotion is allowed to be the characteristic of an animal, where shall we place the oyster, or the zoophytes of which we have just been speaking, or where some species of water and aquatic plants that swim and are attached in water? If feeling or sensation be the test, who shall decide, that the sensitive plant (Mimosa pudica) possesses it not? and who determines that the leaves of the fly-trap, (Dionaea muscipula), when they contract, and catch the fly as soon as it alights, do not feel the despoiler that comes to rob it of its honey?

Though these and similar objections may certainly be made to the artificial division of nature's works into kingdoms, yet it is convenient to have such a division; and even the very difficulty of establishing to which kingdom any object belongs, is an additional spur to the genius and industry of the naturalist.

The most natural division of the works of nature is that which distinguishes them into organisms and inorganic bodies; and on the whole, we have seen no attempt to establish the differences between these so successful as that adopted by M. Dumeril in his late scientific work, Traité Élémentaire d'Histoire Naturelle.

Some objects, says he, as animals and plants, have formerly constituted a part of other individuals, similar to themselves, from which they have been separated at a certain period, under the form of eggs, of germs, or of little living creatures; and their existence is evidently owing to this generation; they are born. Others, on the contrary, as stones, salts, water, may be formed by certain circumstances, and even by ourselves at pleasure.

They have not necessarily made a part of other similar bodies; their existence seems to depend on certain fortuitous circumstances, that have produced the approximation of their constituent principles, and their origin might be referred to attraction. These bodies are formed. Vegetables and animals, in increasing their size, only develop themselves. Whatever may be their minuteness, we shall, on a careful examination find them already formed, with their parts requiring only to be evolved. Their increase proceeds from within outwards by intus-susception. Stones, and a great many other bodies, are augmented only by the same matter from which they are produced; their growth takes place always from without, by a sort of aggregation.

As the increase of the bodies which compose these two great subdivisions is not alike in both, a duration very different ought to be the result of these dissimilarities. In fact, minerals are susceptible of indefinite increase, and their end is always indeterminate; it is vague, and depends on the circumstances under which they are placed. Plants and animals ought, from the same circumstances which favoured their development, to stop when their extension has been carried to the highest degree, so that the end or death of these bodies is fixed and necessary.

The masses in which stones and other similar bodies generally present themselves, are angular, insulated, and very variable in their size. The individuals which we call plants and animals, have always, and necessarily, a form that is constant, for the most part rounded and symmetrical, and their extension is limited within certain bounds.

There is this great difference between these bodies; that those which increase by aggregation may be divided into molecules, or parts infinitely small, bearing a very near resemblance to the mass from which they were taken; while in those which develop themselves, no portion can be taken away and exist by itself, at least, unless it develop new parts, which replace those that are wanted.

The bodies which do not develop themselves, are in general composed of fluids or solids which remain constantly in the same points; they are composed of very few elements, which may be separated and again reunited. The bodies which develop themselves, on the contrary, are essentially composed of solids and fluids, which are always changing, and in a state of renewal; they have always, and from necessity, more or less consistence, they are penetrated and augmented by fluids, and after being decomposed they never be reformed again such as they were before.

For the more convenient study of natural history, the division of whole subject may be divided into five great branches, viz. Meteorology, Hydrography, Mineralogy, Botany, and Zoology.

1. Meteorology includes the description of all those phenomena which take place in the atmosphere that surrounds our globe. In the present work it is considered under the articles Meteorology, Meteorology, Atmospheric Electricity, Cloud, Moon, Influence of, &c.

2. Hydrography comprehends the natural history of the sea, of rivers, lakes, and other collections of water that make up so great a part of the earth. Much of this subject will be found treated under the article River, and various parts of it have been discussed under Chemistry and Mineralogy.

3. Mineralogy is that part of the subject which treats of the solid inorganic bodies that are found on the solid surface of the earth. It has been considered under the articles Geology and Mineralogy.

4. Botany comprehends the natural history of vegetables. See Botany.

5. Zoology includes the natural history of all animals, insolated beings, and is subdivided into many subordinate classes.

These classes are different in number and denomination, according to the different systems of naturalists. Linnae, whom we have principally followed in this work, has arranged animals under six classes: viz. 1. Mammalia, or those animals which suckle their young at mammary or mammary; see Man, Mammalia and Cetology. 2. Aves, or birds; see Ornithology. 3. Amphibia, or those animals which can live either on land or in water; see Herpetology and Ophiology. 4. Pisces, or fishes; see Ichthyology. 5. Insecta, or insects; see Entomology. And 6. Vermes, or worms; see Helminthology and Conchology.

Later naturalists have divided animals into a greater number of classes, and have subdivided these differently.
NATURAL HISTORY

631.

of the animal kingdom into nine classes, viz. MAMMIFEROUS animals, Birds, Reptiles, Fishes, Mollusca, Worms, CRUSTACEOUS animals, Insects, and ZOOPHYTES.

We have already given an outline of four of these classes, viz. of the MAMMIFEROUS animals, under Mammalia, and of Mollusca, Worms and ZOOPHYTES, under HELMINTHOLOLOGY. To complete our view of Cuvier's arrangement, we shall here add an outline of the remaining five classes.

Cuvier divides birds into five orders, viz. RAPACIOUS birds or Accipitres, Passerine birds, Climbers or Scansores, Gallinaceous birds, Waders or Grallae, and Anserine birds.

1. The RAPACIOUS birds have short feet, toes furnished with strong claws, and a hooked bill. They are subdivided into three sections; viz. Nidicolles, having the head and part of the neck without feathers; containing the vulture tribe. Planicocoles, having the head covered with feathers and a cere at the base of the bill, containing the falcon tribe; including Griffins, Eagles, Sparrow-hawks, Buzzards, Kites, and Falcons. Nycticolles, having the head flattened backward from the front and the eyes directed forward; containing the owl tribe.

2. The Passerine birds are distinguished by having four toes, three before and one behind, with the external toes wholly or partially united. They are subdivided into seven sections; viz. Cremictacoles, having the bill grooved towards the end of the mandible; containing the Shrikes, Flycatchers, Thrushes, Chatterers, and Tamagers. Dendrocolles, having a bill with notched edges; containing the Plant-clippers, Motmots, and Hornbills. Pleniocolles, having the bill straight, strong, compressed and without a groove; containing the Grackles, Crows, Rollers, and Birds of Paradise. Conirocolles, having the bill conical; containing the Orioles, Starres, Groebaks, Sparrows, and Buntings. Sibulirocolles, having the bill slender like an awl; containing the Tityruses, Manakinus, Larks, and Wagtails. Planirocolles, having the bill short, flattened horizontally, and opening very wide; containing the Swallows and Gnat-suckers. Tenuirocolles, having the bill slender, elongated and solid; containing the Nuthatches, Creepers, Humming birds, Hoopoes, Bee-eaters, King’s-eaters and Todys.

3. The Climbers have two toes before and two behind. They are subdivided into two sections; viz. Canicoles, having a slender bill; containing Jacanas, Wood-peckers, Wry-necks, and Cuckoos. Leirocolles, having the bill thick and light; containing the Anis, Tourocanes, Musophages, Curucuis, Barbets, Toucans, and Parrots.

4. The Gallinaceous birds have the front toes united at their base by a short membrane. They are subdivided into two sections; viz. Electrodes, having common wings fitted for flying; containing the Pigeons, Grouse, Peacocks, Pheasants, Pintados, Turkeys, Curassows, Guans, Bustards. Breuipoecoles, having wings too short for flight; containing the Ostrich, Cassowary and Dodo tribes.

5. The Waders have elevated and naked tarsi and the two outer toes united. They are subdivided into five sections; viz. Breuirocolles, having the bill short and thick; containing the Trumpeters, Screamers, Secretaries, Boat-bills, and Flamingos. Culicirocolles, having the bill long, strong, and like a knife; containing the Herons, Jabirius and Ibises. Latirocolles, having the bill long, weak, and flattened horizontally; containing the Spoonbills. Longirocolles, having the bill slender, long and weak; containing the Avocets, Plovers, Lapwings, Phalaropes, and Woodcocks. Pessirocolles, having the bill middle-sized and compressed, containing the Oystercatchers, Rails, Coots, Geese, and Ducks.

6. Anserine birds have the toes united by broad membranes. They are subdivided into four sections, viz. Penipedes, having all the four toes united; containing the Pelicans, Tropic birds and Darters. Micropteros, having the thumb free, the bill not indented; and very long wings; containing the Terns, Gulls, Skimmers, Petrels, and Albatrosses. Serrirocolles, having the thumb free, the bill broad and serrated, and wings of a moderate size; containing the Ducks and Oldenasers. Brachypterus, having the thumb either free or wanting, the bill not serrated, and the wings very short, containing the Grebes, Ducks, and Manchots.

The Amphibia or Reptiles are divided into two orders of reptiles, as follows.

1. Those that have a heart with two auricles. This order is subdivided into two sections, viz. Chelonia, having a back shell and the jaws invested with horn; containing the Tortoise tribe, including Turtles and Testudines. Squamata, having a scaly body, no feet, and always without branchies; containing the tribes of Anguis, Amphiboloma, Coccuro, Acrocordon, Anguila, Coluber or Snake, Boa, and Crotaulus or Rattle-Snake. Batracia, having a naked skin, feet and branchies in the young animals; containing the Frogs, Salamanders, and (according to Cuvier's original table) the Siren.

The fishes are divided into two orders, Cartilaginous and Bony fishes.

1. Those which have a Cartilaginous skeleton are divided into two sections, viz. Chondropterygi, with fixed branchies; containing the Lampreys, Hags, Rays, Dog-fish and Sea-monsters. Branchiostegi, with free branchies; containing the tribes Batrachus or American Toad-fish, Polyodon, Aconger or Sturgeon, Pegasus, Synagnostus or Pipe-fish, Centurus or Bellows-fish, Balistes or Horned-fish, Ostreacion or Trumpet-fish, Tetraodon or Sun-fish, Oviodes, Mola or Male. Diodon or Porcupine-fish, Lophius or Frog-fish, and Cyclopterus or Lamp-fish.

2. The fishes with a bony skeleton are subdivided into four sections, viz. Apodes, having no ventral fins; containing the tribes of Muraena or Eels, Gymnothorax, Synbranchus, Spaghebranchus, Gymnotus or Electric-eel, Trichirius, Gymneterus, Ophidium, Echidnides, or Sand-eel, Anarrhichas, or Sea-sawwires, and Xiphias or Sword-fish. Jugulares, having the ventral fins situated before the pectoral; containing the Haddock, Bliemna, Hunch-back, Dragonets, Sea-dragons, and Star-gazers. Thoracica, with the ventral fins situated below the pectoral; containing the Bull-heads, Scorpions, Gurnards, Gobys, Surmullets, Mackerel, Stickle-backs, Long-tails, Luni-chirius, Johnes, Scientes, Durecs, Stromateus, Theuthis, Chatodon, Dorades, Bodin,,
NATURAL HISTORY.

Of crustaceans.
The Crustacea are divided into two orders, as follows:

1. Monopods, containing the tribe of Limulus, Calygon, Atus, Cyclops, and Polyphemus.

2. Echinoidea, or Crabs, containing the tribes of Cancer, Inachus, Pagurus, Astacus, Palinurus, Scyllus, and Squilla.

Of insects.
The insects are distributed by Cuvier under two general orders, viz.: Those with jaws, and those without jaws.

1. Insects with jaws are arranged under five sections, viz.: Gnaphaephyra, Neuroptera, Hymenoptera, Coleoptera, and Orthoptera. The Gnaphaephyra, having no wings, and are subdivided into Polygynaea, having several pairs of wings, containing the tribes of Phyllopodes, Oniscus, and Cymothoa; Millepedes, having two jaws and feet at each ring of the body, containing the tribes of Julius and Scolopendre; Araneae, having the head joined to the corset, eight feet, and abdomen without feet; Scolopidea, having the head distinct, six feet, and abdomen terminated by silken threads; Ricinns, with the head distinct, six feet, and the abdomen naked. The Neuroptera have four reticulated wings, and are subdivided into Odonata, having the mouth covered with the lip, and the wings extended during repose; Tephromenes, with the mouth salient, and wings hidden below the body during repose; Acrida, with a very small mouth, and no mandibles. The Hymenoptera have four veined wings, and of these some have the abdomen joined to the thorax by a pedicle; as the Melisae, having the lip prolonged into a trunk; the Daphneidea, having the upper wings folded lengthwise; the Crysidae, having the abdomen bent, and the abdomen below by the Anthophagea, with the antennae bilobed, wings not folded, abdomen round, and lips short; the Tetracera, with antennae of two joints; the Myrmegea, with antennae bent, and a rounded abdomen; the Insectiroy, with antennae of 30 joints, and a prominent sting; Cynips, with filiform antennae and a spiral sting. Others of this section have the abdomen sensibly, as the Uroceri, with palps scarcely apparent, and a very prominent sting, and the Tenthredos with very prominent palps and a serrated sting. The Coleoptera have four wings, the uppermost of which are hard, and the lower fold transversely: they have either six palps, as the Cramnassers, with filiform or setaceous antennae; or four palps; and of these latter some have the tarsi five-jointed, as the Lamellicornes, with elevated antennae, having the club lamellated; the Crici, with the antennae either perforated or solid; the Brachyptera, with moniliform antennae and short elytra; the Woodpiercers, with filiform antennae and hard elytra; and the Apalyters, with bifilament and soft elytra. Others have the tarsi four or five-jointed; as the Lucifugae, with variable antennae and hard elytra; and the Blistering-flies, with variable antennae and soft elytra. Others again have the

variable antennae and soft elytra. Others again have the tarsi four-jointed; as the Rostolecornes, with antennae on the beak; the Wood-piercers, with setiform antennae; the Terebriformes, with elevated antennae, and a body after cylindrical; the club solid; the Phalangemata, with granulated antennae and a flattened body; and the Heribor, with bilobed and a body rising above the corselet; the Mantidae, with a very long corselet; and the Leapers, with cylindrical body and long hinder legs formed for jumping.

2. The Insects without jaws are subdivided into Hemiptera, Lepidoptera, Diptera, and Apidae. The Hemiptera have four wings frequently crossed, and a jointed beak; and include the Frontispes, having the beak rising from the fore part of the head; the Ostracodes, with the beak appearing from the sides; and the Planipennis, with the wings not crossed and spreading. The Lepidoptera have scales under spirals; they include the butterflies, with the antennae terminated by a solid mass; the Hesperia, with the antennae curved at their extremity; the Eusicolines, with the antennae swelling towards the middle, and the Seticornes, with setaceous antennae. The Diptera only have two wings; and include the Hydroptera, with filiform or plume antennae and a trunk; the Dentifer, with a fleshy retractable trunk, terminated by two lips; the Sericostoma, with very short antennae, a horned projecting sucker, but no trunk; and the God flies, with short antennae, and neither sucker nor trunk. The Apidae have no wings: they include the Parasitical insects, or Fleas, Lice, and Flies.

It is not surprising that naturalists of taste and genius, from the gradation of plants that seems to take place among the works of nature, should have been led to form the notion that there exists in nature a regular series or chain of beings, the links of which, if we could discover them all, would be found to resemble each other so nearly, as to exhibit to the superficial observer a few shades of difference. Nature non per saltum movent, has become a sort of axiom in natural history.

The notion of a chain of being is alluring, and does not want arguments in its favour. The Esquimaux, Indian; or the inhabitant of Terra del Fuego, seems scarcely inferior in form, and very little in intellect, to the Oran Gaz; the Platypus, the flying Lemur, flying Squirrels, and, still more, the Bats, appear to form the connecting links between quadrupeds and birds; while the Seals, the Walruses, and the whole order of Cete, connect the former with the fishes. In this latter class, the Flying Fish, in its capability of supporting itself in the air, seems to approach the feathered tribes, while some of these, as the Penguins, in their habits and manner of life, bear some distant resemblance to fishes. Again, the Siren and the Eels so nearly resemble each other, that it has been disputed whether the former should be reckoned among the Amphibia or the Fishes; while one species of Lizard, (Laurus lumbricioides), is so like an earth-worm, as appears to connect the Amphibia and the Verses. Farther, the diminutive Humming-bird (Trochilus emilia), and the Humble
Humble Bee, (*Apis terrestris*), are so nearly alike, both in size and manner of life, as to form no very exceptionable links of union between the birds and insects.

If we compare the vegetable tribes with some of the inferior classes of animals, we shall perceive many points of resemblance, which may seem to indicate a continuance of the same chain. Besides the *Mimosa pudica* and *Dioclea muscipula*, already mentioned, the *Syzygium guineanum*, or moving plant, is a remarkable instance of the mobility of vegetables; the carnation flower (*Strep- 

kia hirta*), and some species of *more*, bear the odour of putrid animal substances; while on the other hand, the *Mantis nocifolia* might be mistaken for a dried leaf; several species of *Pennisetum* (sea Penns) and *Sor- 

toria*, for ferns; the *Madrepora fungii* (mushroom madrepore), for a petrified mushroom; and the *Tabui- 

aria magnifica*, and *Actiniae*, when expanded, for the most beautiful full-blown flowers.

Lastly, in comparing the mineral kingdom with the classes of organized beings, we find several so nearly resembling stones, as scarcely to be distinguished from them.

Though the view which we have given above, of the circumstances that have led naturalists to form the idea of a regular chain of beings, is species; it will not bear the scrutiny of a strict examination. The resemblances which we have pointed out, are more apparent than real; and anatomy and chemistry, added to a more accurate acquaintance with the works of nature, have proved, that those links which, to superficial observers, appear most allied, are yet separated by considerable chasms. In fact, if we were to admit these resemblances as ever so accurate, they would lead us to form, not one chain, but many.

It must be considered as a very difficult, though a very curious problem, to ascertain the number of species at present known throughout the several subdivisions of nature. From the different modes in which different naturalists have distributed the objects of their research, and from the discussions that are perpetually made to our knowledge, it may be impossible to fix the precise number of known species at any given time; but we may make a tolerably near approximation to the truth; and this we shall now attempt, going through the several kingdom, classes, and orders, as they have been treated of in the former parts of this work.

I. IN THE ANIMAL KINGDOM.

A. MAN.

B. MAMMALIA.

1. Primates.
2. Bruta.
3. Ferae.
4. Viviparae.
5. Vertebrata.

7. Cetea.

C. BIRDS.

1. Accipiter.
2. Pica.
3. Anseres.
5. Gallaeae.
6. Passeres.

D. AMPHIBIA.

1. Reptiles.
2. Serpentes.

E. FISHES.

1. Aporides.
2. Jugulares.
3. Thoracici.
4. Abdominales.
5. Branchiostegi.
6. Chondropterygi.

F. INSECTS.

1. Coleoptera.
2. Hemiptera.
3. Leptidae.
5. Hymenoptera.
7. Aptera.

G. WORMS.

1. Intestina.
3. Testacea.
4. Zoophyta.
5. Infusoria.

So that the number of species in this kingdom may be estimated at about 23,924, or in round numbers about 25,000 (9).

II. IN THE VEGETABLE KINGDOM.

A. MONANDRIA.

1. Monogynia.
2. Digynia.

B. DIANDRIA.

1. Monogynia.
2. Digynia.
3. Trigynia.

C. TRIANDRIA.

1. Monogynia.
2. Digynia.
3. Trigynia.

D. TETRANDRIA.

(5) The numbers here given differ in several instances from those which we have seen in some late works on this subject. Thus, M. La Cépède, in a note to the discourse delivered by him at the close of his course of Natural History, states the numbers of some classes as follows: Mammalia, 416 species; Birds, 2354; Reptiles, 125; Serpents, 158; Fishes, 992; in all 4247.

III. IN THE MINERAL KINGDOM.

Minerals are divided into four great classes, viz. EARTHS and STONES, SALTS, COMBUSTIBLES, and METALLIC ORES.

EARTHS and STONES.
1. Diamond genus, - - 1
2. Zircon, - - 2
3. Siliceous, - - 62
4. Argillaceous, - - 29
5. Magnesian, - - 17
6. Calcareous, - - 22
7. Barytic, - - 2
8. Strontian, - - 2

Total, 137 species.

SALTS.
1. Sulphates, - - 6
2. Nitrates, - - 1
3. Muriates, - - 3
4. Carbonates, - - 2
5. Borates, - - 2
6. Fluorates, - - 1

Total, 15 species.

COMBUSTIBLES.
1. Sulphur, - - 1
2. Bituminous, - - 6
3. Graphite, - - 2

Total, 9 species.

METALLIC ORES.
are divided into 24 genera, each metal forming a genus, - - 106

Total, 267 species.

Hence, taking the whole number of known animals at 23,000, that of vegetables at 50,000 and that of minerals 267, the whole number of known species of natural objects will be 73,267.

II. Though the classification of natural bodies is often for the highest importance towards making us acquainted with unknown species, and distinguishing them from those which we already know; this alone is not sufficient to form a naturalist. His principal object should be to learn the habits, manners, and uses of the objects which he is studying; and he may perhaps be assisted in this object by the following observations.

1. In Zoology, or the natural history of the animal kingdom, it is necessary to ascertain both the distinctive characters of each individual animal, and its peculiar habits, properties and uses.

The naturalist first learns that the sheep, for instance, is in the class mammalia, being one of those animals that suckle their young; in the order pecora, because it is hoofed, and has no cutting teeth in the upper jaw; and that it is distinguished from other animals of the same order, by its having several blunt wedge-like incisive fore-teeth in the lower jaw only, hollow reclined horns, and no tusks.

This information would satisfy many, who call themselves naturalists; but it is far from being all that is required; the philosophical investigator of Nature inquires into its habits; as its food, its period of gestation, its season of lambing, the weather and climate most suited to its health and vigour. He endeavours to learn what produces the difference in its fleece, whether climate, food, or some peculiarity in the breed; and is anxious to ascertain what variety is most disposed to fatten, and what food effects this speedily; with many other very useful particulars.

The information of the first kind is of consequence, and even necessary in many cases; but that of the latter is most useful.

If a traveller discovers an animal possessing any useful property, or producing any useful drug, if he has not the first kind of information, he gives so confused and inaccurate a description of it, that others, mistaking the animal, discredit the author’s account, and the world loses the benefit of his discovery.

2. Botany, or the natural history of the vegetable kingdom, in the usual acceptation of the term, implies only...
only the knowledge of the distinctive characters of plants; and he who knows the greatest number, and is most accurate in determining the different species, is accounted the best botanist.

This however constitutes but a small part of the science; there is another distinct department, which may properly be termed the philosophy of botany, which is both more interesting and more useful. This includes the knowledge of the structure, or the anatomy of plants; and the knowledge of the uses, or functions of their various parts, as of the leaves, the bark, the pith, the roots, the juices, &c. which is called the physiology of plants. It includes also an acquaintance with the soil and climate adapted to different vegetables, their mode of propagation, and the various uses to which their several parts or productions may be applied.

Botany, in the first sense, which may be called practical botany, is subservient, and absolutely necessary to the study of the philosophy of botany; for no one that is unacquainted with the classification of plants can either convey to others his own information, or himself receive the benefit of that of others, respecting either the structure and economy or the habits and the uses of such plants, as may have been investigated.

If medical virtues are discovered in any vegetable production; without the accuracy of the practical botanist, to ascertain and describe the particular plant which affords it; the discovery is often lost; or perhaps, what is worse, the virtues are attributed to a different plant, and it is only by repeated failures, and in some cases after much mischief, that the error is detected.

It is evident that the same may happen to the agriculturist, the dyer, or any other artizan, who has discovered in the vegetable kingdom the means of improving his art, but has not botanical knowledge sufficient to give an accurate character of the plant, to which he is indebted for his discovery.

In Mineralogy, or the natural history of the mineral kingdom, almost half the students are of that class, who content themselves with collecting, and being able to arrange systematically the minerals they meet with. But in this department of natural history, as well as the other two, which we have considered, something more than arrangement is required.

It is the man who can analyze, and separate the component parts of mineral productions; who knows the art of assaying, and who knows a priori the probable site of a quarry, or a mine, and can tell the direction of a stratum of coal, or of marble, that we may call a mineralogist.

The natural history of the mineral kingdom includes geology, or the study of the formation of the earth. It includes the knowledge of those facts, upon which the art of mining, and the art of separating and purifying metals, is founded; and its object is to teach likewise the properties of those metals, as well as of the earths, and other mineral productions, when separated and in their simple state.

With respect to the utility of the study of natural history, we have unavoidably given many instances of it, in considering the object of the science. We need therefore add but few others.

The grazier knows the advantage of attending to the habits and distinctive marks of our domestic animals, and especially to that which teaches him what variety of sheep to prefer, by what means to obtain a variety of cows, remarkable for their quantity of milk; how to choose the stock that is best adapted to his land, and what is the best food for them during winter.

Much benefit is likely to accrue from the attention lately paid to the cultivation of what are termed the artificial grasses. Instead of sowing his hay seeds indiscriminately, the grazier may select only such grasses as are, by observation, found to be most suited to his soil and cattle.

The farmer's knowledge of the proper succession of the crops, the best times for sowing them, when to weed them, and with what to manure, as well as how to destroy both weeds and insects, is the knowledge of a naturalist; and surely he who is scientifically acquainted with the growth of plants, knowing what part the soil acts in vegetation, and what is the aliment most required by them, will have great advantage over the mere empirical farmer, who has no better reason for what he does, than that his father did the same before him.

By studying the natural history of insects, we learn the habits of such as are noxious and injurious, and thence derive the means of destroying them.

The mineralogist has often enriched individual proprietors of land, and benefited his country, by the discovery of mines; he is enabled to direct the phrenetic canals by warming them of obstacles; and his knowledge has aided the physician in ascertaining the virtues of minerals, and of mineral waters.

In the arts, a knowledge of natural history prevents that confusion, and those innumerable errors that must be committed, when the natural productions which we employ cannot be accurately discriminated from others.

It is to the naturalist that we are many times indebted for the introduction of foreign animals and foreign plants into our own country. Wheat, oats, barley, and other vegetables, which are now become necessary to our existence, were not originally of British growth. The potato, now so general and so useful, was first introduced into this country by Gerard, a noted botanist, and was for some time cultivated in his garden as a rarity. The sugar-cane, the bread-fruit tree, the farinaceous palms, the flax and hemp, have all been transported by naturalists of the present day, to regions where they never grew before.

Besides the above, and many similar instances of advantage to be derived from studying the different branches of natural history, these two inestimable benefits necessarily arise to the student himself, from attending to the whole, or any part of the science; namely, a power of abstracting the mind, and reasoning methodically; and a habit of contemplating the Creator in his works.

Our limits do not permit us to enter further into the short and fertile topics of the utility and advantages of natural history. Its utility, in a moral and religious point of view, has been ably illustrated by Mr Ray, in his "Wisdom of God," by Mr Bingley, in the introduction.
NATURAL HISTORY.

637

III. We have stated it to be one of the principal objects of natural history, to teach the mode of preserving specimens. This art, called by the French, Taxidermie, is exceedingly curious, and would well deserve a much fuller consideration than we can here allow to it. We shall confine our attention on this subject entirely to the animal kingdom, and even here we must be very brief.

The art of preparing and mounting the skins of animals appears to be pretty old; but it made no great progress before the 17th century, when Ramesaur made some attempts to preserve the specimens from the attacks of insects. In the Journal de Physique for 1773, there is a memoir addressed to the Royal Society of London, by M. Kuckhan, on the methods of preparing birds, which is very curious, but is liable to many objections. In the same volume is a memoir by Mouduit, principally respecting the means of preserving animal specimens from the attacks of insects. His preservatives are of a poisonous nature; and, of course, their use is dangerous, while they do not appear to have been attended with the expected success. The artificial soap of Becqueur, much celebrated about the same time, is liable to similar objections.

The latest, and probably the best work on this subject, is that published a few years ago by M. Nicolas, and from this the following observations are derived.

The instruments employed in the preparation of specimens are much the same as those used by anatomists in their ordinary dissections, consisting of small knives or scalpels, forceps or pincers of various forms; probes, needles, and pins or wires.

The preservatives employed by M. Nicolas to protect the specimens from insects, are principally of two kinds: 1. Sulphur, which he applies to the skins by means of inflammation, thus impregnating them with sulphurous acid; 2. A liquor for macerating the skins, another liquor for rubbing over the hair, and a pomatum for anointing the inside of the skin. The first liquor is prepared by steeping a pound and a half of powdered oak bark, and four ounces of powdered alum, in twenty English pints of cold water, for two days, taking care to shake the mixture from time to time. The pomatum is prepared of a pound of white soap, half a pound of castor oil, four ounces of powdered alum, two English pints of water, four ounces of oil of petrolea, and the same of camphire. The soap, cut into small pieces, is put into an earthen pipkin, over a moderate fire; the water poured over it; and when the whole is formed into a sort of soft paste, the alum and then the oil are added; the whole well stirred together, removed from the fire, and when it is nearly cold the camphire is added; being before hand rubbed down in a mortar with a little spirit of wine. The pomatum, thus prepared, must be kept in glass vessels, well stop'd; and, when used, is to be lowered with water to the consistence of thin cream, and laid out the skins by means of a pen-well brush.

The liquor employed for preserving the fur is prepared by infusing an ounce of white soap, shred very small, two ounces of camphire broken into very small pieces, the same of colocyth or bitter-apple grossly powdered, in two English pints of spirit of wine, for four or five days, shaking the vessel from time to time, after which the liquor is to be filtered through blotting-paper.

M. Nicolas has given directions for preparing and preserving specimens of all the various classes of animals. We shall, as far as our limits permit, briefly follow him through each.

In skinning quadrupeds, he proposes to make an incision along the middle of the back, from the haunches for stuffing to the shoulders, except in those animals whose skin is very thick and hard, or is set with spines, in which the opening must be made at the belly in the usual manner. In detaching the skin from the flesh, we must occasionally employ the knife, and as we proceed, must insert tow between the skin and flesh, to prevent soiling the fur. When the whole body is detached, and the skin drawn down as far as the ankles, the nose, and the tip of the tail, the whole body is to be cut away except the head and extremities, which are left to give a better form and support to the specimen. All the fleshy and fatty parts, the brain, and the eyes, however, must be cut away, and nothing left but the bones, the spaces between which and the skin must be stuffed with tow cut fine, and a little soft clay must be put within the orbits, in order to fix the artificial eyes.

Before stuffing, the skin is to be steeped for several days, from five to fifteen, according to the size of the animal; in the liquor first described, and after steeping, the inside is to be well anointed with the pomatum.

When the legs and head are stuffed, the cavity of the skull filled with very dry moss, and the eyes fixed, wires are to be passed through the inside of the body, the extremities, and the head and tail, in the following manner. Three iron wires of a moderate size, well annealed, at least twice as long as the animal, are to be twisted together for nearly half the length, and while one wire is left straight, the other two are to be bent at each end, so as to form a cross. When the skin is turned, ready for stuffing, these wires are to be placed within it in such a manner as that the straight wire shall pass through the head and tail, and the crossing wires through the extremities, coming out at the ball of each foot; and in this way after the cavity is filled up with tow, and the open part neatly stitched, the specimen may be fixed on a board in its natural position. Nothing remains now but to impregnate the fur with the bitter liquor last described, which is done by means of a sponge, with which the whole outside is to be well washed, then covered with folds of linen, and dried in the shade.

The art of preserving birds is perhaps the most curiously. It is an essential part of the present subject, and it is to which the following most attention has been given. M. Nicolas has described several methods of preparing birds, according as we can procure fresh-killed specimens, wholly dried skins brought from abroad, or detached parts of several birds explained at some length the mode recommended by M. Kuckhan in the Journal de Physique; that by Dr. Lettsom, in the Naturalist's and Traveller's Companion; that of Mouduit, inserted in the fifth number of the Encyclopédie méthodique; and that of Buffon, adopted by M. Daubin, and inserted in his Traité d'Ornithologie; after which he details his own.

He describes three methods of preparing birds, according as we can procure fresh-killed specimens, wholly dried skins brought from abroad, or detached parts of several birds.
Natural History.

The last operation consists in enveloping the bird with bandages of muslin or fine linen, pinned round the neck, breast, body, and rump, as well to secure the feathers in their places during drying, as to allow of their being drenched with the bitter liquor to preserve them from the attacks of insects.

The different orders of insects require different methods of preparation. The following is a summary of our author's mode of preserving each kind.

For the coleoptera and hemiptera.—One of these insects, as soon as it has been carefully pinned up in very fine paper, with the ends of the paper curled round to prevent the animal from moving; and this roll of paper including the insect, is to be put into a little box of pasteboard till the insect-hunter returns home. Each insect is then to be held between the thumb and forefinger of the left hand, the wings to be raised by means of a pin, and held open with the middle finger, while the abdomen of the animal is slit open from the back, and the entrails abstracted by means of an iron wire, and the cavity as well as the edges of the wound are to be washed with the bitter spirituous liquor described in No. 36 by means of a very fine pencil. Then a small cotton plug impregnated with oil of petroleum is to be stuffed into the cavity, with the point of a wire, till the cavity is sufficiently full, when the wings are to be suffered to return to their natural situation, and the insect is ready for mounting. For mounting these insects, M. Nicolas employs little squares of card, through the middle and across which he passes a small iron wire well annealed, and about the size of a harpsicord string. A very fine needle is now to be passed through the animal, as near as possible to the corselet; and after having covered the upright iron wire with a light coating of gum-water, he passes it through the hole made by the needle, and fixes the animal in such a manner that its feet may rest upon the card.

For the lepidoptera.—He recommends them to be put, when caught, into a triangular piece of paper, and afterwards into a pasteboard box of the same form, opening with a hinge. For mounting these insects it is sufficient to perforate their bodies with a fine needle, armed with a double thread impregnated with the bitter spirituous liquor, making the needle enter by the head and come out at the end of the belly, and then cutting the thread with scissors. The insect thus prepared is mounted by means of a card, as directed for the coleoptera, and a piece of wood about an inch long, seven or eight lines broad, and a proper thickness, is placed below the wings on each side very near the body, and the wings are kept down by means of plates of lead.

In the preparation of specimens of fishes, M. Nicolas prefers the method of Mauduit to that given by Dr. Lettsom in the Naturalist's and Traveller's Companion; but as Mauduit's method requires much skill and address, he recommends the following, especially for the flat kinds of fish.

He makes a longitudinal incision with scissors along the belly of the fish from the anus to the lower massæ, and then gradually and carefully separates the skin from the flesh with the assistance of the blade and flat handle of a scalpel, till he has laid bare one side of the animal. He then passes to the other side, proceeding in the same manner to detach the skin from that part, after which he separates the head from the body with a
It will be expected that in this introductory article on natural history, we should say something of its rise and progress. Much of our observations on this subject have been anticipated in preceding articles on the particular branches of natural history, so that little remains for us to do in this place than to give a general sketch of the early history of this branch of physics.

We have reason to believe that the works of the Jewish writers have formed the favourite study among the ingenious and inquisitive from the earliest ages of the world. From the continual allusions to the Creator’s works, and the beautiful metaphors drawn from them, which abound in the inspired writings of the Jewish prophets and poets, especially those of Job, Isaiah, Daniel and David, we know that these sages were well acquainted with natural history, as far at least as observation extended. Solomon, as we are told, was acquainted with all vegetables, from the cedar of Lebanon to the hyssop that springeth out of the wall; and probably so wise a man was well acquainted with the other kingdoms of nature. Some writers have gone so far as to assert that Aristotle and Theophrastus learned natural history from the writings of Solomon, though on what data they ground this assertion, we are at a loss to determine.

The principal writers on natural history among the ancients, whose writings have come down to us, are Aristotle, Theophrastus, and Pliny the elder. Of the Aristotle first we may remark with Haller, that his writings on this subject exhibit a continued chain of physical and anatomical facts, which for the most part appear to have been the result of accurate observation. He relieved less than any of the ancient naturalists on uncertain and fabulous report; he industriously collected and examined natural bodies, and appears to have himself dissected many animals, especially fishes, or at least to have been present at their dissection. There are even to be found in his writings, references by letters to figures which he employed to illustrate his observations.

Theophrastus wrote chiefly on the natural history of Theophrastus plants and fossils, on winds, and on fire. His works on these subjects have been edited by Heinsius, but, except in plants, they do not contain much that is worthy of our observation more than what is to be found in the writings of Aristotle.

The natural history of Pliny is a valuable repository for Pliny of ancient knowledge, which, notwithstanding all its errors and extravagances, we may venture to call after the panegyric of his nephew, a comprehensive and learned work, little less various than nature herself. The author, in the dedication of his work to Vespasian, sensible of the defects with which it abounds, apologizes for them, from the consideration that the path which he took had been in a great measure untrodden, and held forth to the traveller few enticements; while some parts of his subject had been so often handled, that readers were become cloyed with them: that it was an arduous task to give what is old an appearance of novelty; to add weight and authority to what is new; to cast a lustre upon subjects that have been obscured by time; to render acceptable what is become trite and disgusting; to obtain credit to doubtful relations; and, in a word, to represent everything according to nature, and with all its natural properties. His design must be acknowledged to be grand and noble, and when we consider that the work was composed in the midst of important engagements,
engagements, and chiefly at broken periods stolen from sleep, we shall not wonder that it was imperfectly executed.

The ancients had no idea of methodical or systematic distinctions. As they were acquainted with but few bodies in comparison with the moderns, and attended only to those which were useful to man; they distinguished them only by their usual properties, their native country, their habits, and the useful purposes to which they might be applied. From the few productions which they described, they were not led to perceive the necessity of searching among them for distinctive marks or relations, which may prevent their being confounded with each other. They doubtless believed that their descriptions were sufficient, and that the names which they imposed would descend with their customs to posterity, without being affected by the disorders and alterations that have changed the face of countries and the seat of empires. But the revolutions that have desolated the fairest regions of the globe, by instigating or displacing their inhabitants, or by confounding them with one another, and altering their language, have frequently almost extinguished the lamp of science. After many ages of ignorance and barbarity, we find in the few works of the ancient naturalists, which have escaped the ravages of war and the devastations of civil discord, little more than uncertainty and obscurity, with respect to those species which they have described. Notwithstanding the labours of numerous commentators, we do not certainly know what species of plant is the circitum employed by the Greeks for the execution of criminals, and which terminated the life of Socrates. We cannot be sure that the animals, which we find best characterized in the ancient writings, bore the names which we attribute to them; nor are we more certain with respect to the ancient nomenclature of minerals.

As long as studious men cultivated the sciences only through the medium of the writings of the ancients, and attempted nothing beyond the interpretation of these, natural history, like every other branch of physics, remained obscure and confused, and fiction or imagination took the place of facts; but when they perceived the advantage of studying nature herself, and interrogating her by observation, methods were erected, and distinctive characters for the species introduced. This fortunate revolution took place in the 16th century. Cesalpinus first attempted to reduce vegetables to classes, and distinguish them into tribes according to their form. Gesner, besides the fine hints that he first gave of the constant relation between the structure of the seed and that of the other parts of plants, was the first who attempted any systematic and methodical arrangement of animals. In the 17th century, Morison, Ray, and Riuinus, improved on the hints of Cesalpinus respecting the classification of vegetables; and Aldrovandus, Redi, and Swammerdam upon those of Gesner respecting animals; and in a short time this first impulse given to the art of arranging and distinguishing natural bodies by constant characters, was communicated to all those who were employed in the study of nature. Tourntefort, profiting by all the attempts towards method and system in the classification of vegetables that had been made before him, advanced a considerable step in botany, by his beautiful method of distinguishing plants according to the form of their flowers and fruits, which he published towards the end of the 17th century.

The same year of the 18th century (1707) gave birth to two men who have advanced the science of natural history far beyond any of their predecessors. We need scarcely mention the names of Linæus and Buffon. The Swedish naturalist extended his enlarged views through every branch of natural history; he arranged in his Systema Naturae and Systema Vegetabilium all the productions of nature, and distinguished them by characters that were precise and simple; he created a new language for expressing with brevity all these characters, and thus presented to the view, as it were, a compendious picture, all the properties of bodies. Buffon, proceeding in a different road, treated more piously the most important parts of natural history, and of the animals that are most nearly allied to man, in a work which the fire of his genius and the brilliancy of his style have rendered a universal favourite. The works of Aristotle and Pliny, whose genius he seems to have combined in the greatness of his views and extent of his plan, and altogether one of the first writers of his age, he inspired a passion for the study of nature in numbers, who without his works would never have engaged in such a study, and communicated to his countrymen that taste which has ever since survived him.

After what has been given in the particular treatises on natural history in this Encyclopedia, both as to the progress of the science, and the principal works on each department of it, since the time of Linæus and Buffon; it is unnecessary for us to trace its progress beyond the period. The advances made within these few years are immense, our stock of information is prodigiously increased, and the modes of study greatly improved and facilitated. The labours of Cuvier, Geoffroy, Lacépède, Dumont, Dumeril, Lamarck, Duvernois, Sonnini, Bloch, Spallanzani, Cuvier, Jussieu, Wildenow, Werner, Patrin, St. Bond, Brochant, Brongniart, Krieger, Fourcroy, Vauquelin, Shaw, Latham, Bancroft, Celsius, Ellis, Smith, Withering, Woodville, Kirwan, Payfair, Thomson, Jameson, &c., with the assistance of their respective societies, have been derived from the Annales de Muséum National, the Naturalists' Miscellany, the Linnaean Transactions, and the splendid plates of Merian, Schreber, Curtis, Sowerby, Sotheby, E. &c. afford ample proofs of the industry and success with which this delightful field has been cultivated, and of the rich harvest that has been derived from the united efforts of so many men of genius and talents.
Natural Philosophy is commonly defined to be that branch of knowledge which considers the powers and properties of natural bodies, and their mutual actions on one another. The province of moral philosophy is the mind of man; its inquiries and researches are into the intellectual world. Natural philosophy, on the other hand, is only concerned with the material part of the creation. The Moralist's business is to inquire into the nature of virtue, the causes and effects of vice; to propose remedies for it, and to point out the mode of attaining happiness, which only can be the result of virtuous conduct. The Naturalist, on the contrary, has nothing to do with spirit; his business is solely about body or matter; and he ought to have a solid and accurate knowledge of all material substances, together with their affections and properties; and if possible, he is to investigate the reasons of such and such appearances. Indeed, the first and principal part of this science is, to collect all the manifest and sensible appearances of things, and reduce them into a body of natural history. Philosophy has often been said, and is even now very generally thought, to mean an inquiry into all the causes of things; but experience informs us, that though we are acquainted with a good number of effects, we can trace but few of their causes; so that philosophy itself will really be found to be in general but a collection of facts. Still, however, it differs from natural history in its appropriated sense; the business of which is only to observe the appearances of natural bodies separately, and from these appearances to class them with other bodies; natural philosophy goes farther, and separates the action of two or more bodies of the same or different kinds upon one another; and though it can neither investigate nor point out the causes of those effects, whatever they are, yet, from mathematical reasoning combined with experience, it can be demonstrated, that in such circumstances such effects must always take place. There are evidently two ways of making observations on the material world: the first is, when we view things nearly as they happen to occur, without any design or intervention of our own; in which way, indeed, no great improvements can be expected in the art, because chance having the direction, only exhibits occasional or extemporary properties. The other method is, when, after a thorough acquaintance with bodies, we apply them to other bodies equally known, diligently attending to the result, and observing whether any thing new arises. Such seems to be in general the nature of our article; nor is it our intention to be much more particular at present. We must therefore refer our readers respectively to those parts of the subject, respecting which they wish for more satisfaction and minute details. The ancient and modern definitions of the word philosophy, together with its origin, as well as the manner of philosophizing in former times as well as at present, with the gradual improvement of science, particularly natural, we shall introduce, we think, more properly, under the words Philosophy and Physics. We need only add, under the present article, what however is well known, that natural philosophy was till lately divided only into four parts, commonly called the four branches, viz. 1. Mechanics; 2. Hydrostatics; 3. Optics; and, 4. Astronomy; and these are again subdivided into various parts. Modern discoveries have added, however, two more parts to the number, viz. Magnetism and Electricity. It is remarkable, that in the English universities these two latter branches are never taken notice of in lecturing on natural philosophy, the old division being still retained, without any mention of these two important articles. The reason may be, that they are only subject to experiment, and not yet reduced to mathematical reasoning; which is the method of teaching philosophy in one of those celebrated seminaries. Of these branches of this extensive science, it is not our intention to take even a general view in this place. We must therefore refer our readers to each particular article, where they will find them treated at considerable length.

NATURALISATION, in Law, the act of naturalizing an alien, or putting him into the condition of a natural-born subject, and entitling him to the rights and privileges thereof. But none can be naturalized unless they have received the sacrament within one month before the bringing in of the bill, and taken the oaths of allegiance and supremacy in the presence of the parliament. A person who is naturalized may have lands by descent, as heir at law, as well as obtain them by purchase; but he is disabled from being a member of the privy council or parliament; or from holding offices, 7 Jac. I. cap. 2. 12 Will. III. cap. 2. All children born out of the king's dominions, whose fathers were or are subjects of this kingdom at the time of their birth, are adjudged to be natural-born subjects of this realm, except children of parents attainted of treason, or that are in the actual service of a foreign prince at enmity with us, 4 Geo. II. cap. 21. Every foreign seaman, who in time of war serves two years on board an English ship, is ipso facto naturalized, 13 Geo. II. cap. 3. And all foreign Protestants and Jews, upon their residing seven years in any of the British colonies, without being absent above two months at a time, or serving two years in a military capacity there, are upon taking the oaths naturalized to all intents and purposes, as if they had been born in this kingdom; and therefore are admissible to all such privileges, and no other, as Protestants or Jews born in this kingdom are entitled to. See Alien and Deline.

In France before the Revolution, naturalization was the king's prerogative; in England it is only done by act of parliament. In the former of those places, before their government was overthrown, Swiss, Savoyards, and Scots, did not require naturalization, being reputed regicides, or natives.

NATURALS, among physicians, whatever naturally belongs to an animal, in opposition to non-natural. See Non-Naturals.

NATURE, according to Mr. Boyle, has eight different significations; it being used, 1. For the author of nature, whom the schoolmen call Natura Naturans, being the same with God. 2. By the nature of a thing we sometimes mean its essence; that is, the attributes which make it what it is, whether the thing be corporeal or not; as when we attempt to define the nature of a fluid, of a triangle, &c. 3. Sometimes we confound that which a man has by nature with what accrues to him by birth; as when we say, that such a man is noble by nature. 4. Sometimes we take nature for an eternal principle of motion; as when we say, that

Vol. XIV. Part II.
Nature a stone by nature falls to the earth. 5. Sometimes we understand by nature, the established course of things. 6. Sometimes we take nature for an aggregate of powers belonging to a body, especially a living one; in which sense physicians say, that nature is strong, weak, or spent; or that, in such or such diseases, nature left to herself will perform the cure. 7. Sometimes we use the term nature for the universe, or whole system of the corporeal works of God; as when it is said of a phoenix, or chimera, that there is no such thing in nature. 8. Sometimes too, and that most commonly, we express by the word nature, a kind of semi-deity, or other strange kind of being.

If, says the same philosopher, I were to propose a notion of nature, less ambiguous than those already mentioned, and with regard to which many axioms relating to that word may be conveniently understood, I should first distinguish between the universal and the particular nature of things. Universal nature I would define to be the aggregate of the bodies that make up the world in its present state, considered as a principle, by virtue whereof they act and suffer, according to the laws of motion prescribed by the Author of all things. And this makes way for the other subordinate notion; since the particular nature of an individual consists in the general nature applied to a distinct portion of the universe; or, which is the same thing, it is a particular assemblage of the mechanical properties of matter, as figure, motion, &c.

Kingdoms of Nature. See Kingdoms.

Conduct or Operations of Nature. See Natural History.

NAVAN, in Ancient Geography, (Tacitus;) a river of Belgica, which runs north-east into the left or west side of the Rhine. Now the Naha, rising at the village Nabewirte, on the borders of the bishopric of Triers, running through the Lower Palatinate, the duchy of Simmeren, by the small town of Bing, into the Rhine.

NAVAL, something relating to a ship; whence

NAVAL Architecture. See Ship-Building.

NAVAL Camp, in antiquity, a fortification, consisting of a ditch and parapet on the land side, or a wall built in the form of a semicircle, and extended from one point of the sea to another. This was sometimes defended with towers, and beautified with gates, through which they issued forth to attack their enemies. Homer hath left us a remarkable description of the Greek fortifications of this sort, in the Trojan war, beginning at ver. 436. Iliad i.

Then, to secure the naval camp and powers, they rais'd embattled walls with lofty towers: From space to space were ample gates around, For passing chariots; and a trench profound, Of large extent; and deep in earth below Strong piles infix'd stood adverse to the foe.

Pope’s Translat.

Towards the sea, or within it, they fixed great pales of wood, like those in their artificial harbours: before these the vessels of burden were placed in such order as that they might be instead of a wall, and give protection to those within; in which manner Niciais is reported by Thucydides to have encamped himself: but this seems only to have been practised when the enemy was thought superior in strength, and raised great apprehensions of danger in them. When their fortifications were thought strong enough to defend them from the assaults of enemies, it was frequent to drag their ships to shore, which the Greeks called amphoral, the Romans subdurrers. Around the ships the soldiers disposed their tents, as appears everywhere in Homer: but this seems only to have been practised in winter, when their enemy's fleet was laid up and could not assault them; or in long sieges, and when they lay in no danger from their enemies by sea; as in the Trojan war, where the defenders of Troy once attempted to encounter the Grecians in a seafight.

The adjacent places were usually filled with masts and stews, well stocked with females, that prostituted themselves to the mariners, merchants, and artisans of all sorts, who flocked thither in great numbers; this, however, appears to have happened only in times of peace.

NAVAL Crown, among the ancient Romans, a crown adorned with figures of prows of ships, conferred on persons who in sea engagements first boarded the enemy's vessel. See Crown.

NAVAL Engagement. See Tactics, Naval.

NAVAL Stores, comprehend all those particular made use of, not only in the royal navy, but in every other kind of navigation; as timber and iron for shipping, pitch, tar, hemp, cordage, sail cloth, gunpowder, ordnance, and fire arms of every sort, ship chandlery, wares, &c.

NAVAL Tactics, the military operations of fleets. See Tactics, Naval.

NAVAN, a borough town of Ireland, in the county of Meath and province of Leinster; situated about 23 miles north-west of Dublin, on the river Boyne. It consists of two chief streets, which intersect each other at right angles. The tholsel, or town house, is a handsome stone building. This place was formerly a great repuate, and walled in by Hugh de Lacy. As abbey for regular canons, dedicated to the Virgin Mary, was erected here; but whether antecedent to the end of the 12th century is not certain: about that period, however, it was either founded or re-edified by Joceline de Angulo or Nangle. In the burial ground are the remains of many ancient tombs. A barracks for horse is now built on the site of the abbey.

NAVARR, a province of Spain, part of the ancient kingdom of Navarre, erected soon after the invasion of the Moors; and is otherwise called Upper Navarre, to distinguish it from Lower Navarre belonging to the French. It is bounded on the south and east by Arragon, on the north by the Pyrenees, and on the west by Old Castile and Biscay; extending from south to north about 80 miles, and from east to west about 75. It abounds in sheep and cattle; game of all kinds, as boars, stags, and roebucks; and in wild fowl, horses, and hounds; yielding also some grain, wine, oil, and a variety of minerals, medicinal waters, and hot baths. Some of the ancient chief of this country were called Sobrarblers, from the custom, as it is supposed, which prevailed among some of those free nations, of choosing and swearing their
Navarre, Peter, an officer of eminence in the 16th century, and particularly celebrated for his dexterity in the directing and springing of mines. He was a native of Biscay, and of low extraction. According to Paul Jove, who affirms that he had an account of the matter from his own mouth, he was first a sailor; but being disgusted with that employment, he sought his fortune in Italy, where poverty compelled him to become a footman to the cardinal of Arragon. He afterwards enlisted himself a soldier in the Houstine army; and having served there for some time, went to sea again, and distinguished himself by his courage. The reputation of his valour having reached the ears of Gon-salvo de Cordova, this general employed him in the war against Naples, and raised him to the rank of a captain. Having contributed greatly to the taking of that city by very opportunely springing a mine, the emperor rewarded him for this signal service with the cardinal of Alveo, situated in that kingdom, and gave him the title of Count of Navarre. Having the command of a naval expedition against the Moors in Afri-ca, he was at first very successful, and took possession of Oran, Tripoli, and some other places; but being afterwards shipwrecked on the island of Gerbes, the great heats and the Moorish cavalry destroyed a part of his army. Our hero was equally unfortunate in Italy: He was made prisoner at the famous battle of Raven-na in 1512, and languished in France for the space of two years. When finding that the king of Spain, who had been prejudiced against him by his courtiers, would do nothing towards his ransom, he went into the service of Francis I., who gave him the command of 20 companies of infantry, consisting of Gascons, Biscayans, and the inhabitants of the Pyrenean mountains. He distinguished himself in several successful expeditions, until the year 1523, when having been sent to the relief of the Genoese, he was taken by the Imperialists. They conducted him to Naples, where he remained a prisoner for three years in the Castel del Ovo. From this confinement he was released by the treaty of Madrid, and afterwards fought at the siege of Naples under Lautric in 1528: but being again made prisoner at the unfortunate retreat from Aversa, he was conducted a second time to the Castel del Ovo. Here the prince of Orange, having by order of the emperor, caused several persons of the Angevine faction to be beheaded, our hero would undoubtedly have suffered the same fate, if the governor, seeing his distressed situation, and feeling for the misfortunes of so great a man, had not saved him the shame of this last punishment by allowing him to die a natural death. Others pretend that he was strangled in his bed, having arrived at a very advanced age. Paul Jove and Philip Thomasini have written his life. This last informs us, that he was of a tall size, had a swarthy countenance, black eyes, beard, and hair. A duke of Sessa, in the last century, being desirous to honour his memory and that of the marshal de Lautrec, caused a monument to be erected to each of them in the church of Saint-Marie-le-Neuve at Naples, where they had been interred without any funeral honours.

Navarre, Martin, surnamed Aspicucta, because he was born in the kingdom which bears that name, successively professor of jurisprudence at Toulouse, Salamanca, and Coimbra, was consulted from all quarters as the oracle of law. For a part of his knowledge he was indebted to the schools of Cahors and Toulouse, in which he had studied. His friend Barthelemi Cerekwa, a Dominican, and archbishop of Toledo, having been charged with heresy by the court of inquisition at Rome, Navarre set out at the age of 80 years to defend him. Pius V. appointed him assessor to Cardinal Francis Alciat, vice-penitentiary. Gregory XIII. never passed his gate without sending for him, and sometimes would converse with him for an hour together on the street: he was even designed to visit him, accompanied by several cardinals. These honours did not render him more haughty. His character became so eminent, that even in his own time the greatest encomiums that could be paid to a man of learning was to say that he was a Navarre: this name thus included the idea of erudition, as that of Rucius formerly marked an accomplished comedian. Aspicucta was the oracle of the city of Rome, and of the whole Christian world. For the influence which he had acquired, he was indebted not only to his knowledge, but also to his probity and virtue. Faithful to the duties which the church prescribed, his temperance and frugality preserved to him a vigorous constitution; and at a very advanced age his genius was equal to the severest study. His savings enabled him to give liberal assistance to the poor. His charities, indeed, were so great, that his mule, it is said, would stop as soon as she perceived a beggar. He died at Rome in 1586, at the age of 92. His works were collected and printed in 6 vols. folio at Lyons in 1597, and at Venice in 1652. They displayed more learning than judgement, and are now very seldom consulted. Navarre was uncle by the mother's side to St Francis of Sales.

Naucrari, among the Athenians, was the name given to the chief magistrates of the Δαμα, "boroughs or townships," called Ναυκρατιαί; because each was obliged, besides two horsemen, to furnish out one ship for the public service.

Naucrates, a Greek poet, who was employed by Artemisia to write a panegyric upon Mausolus,—An orator who endeavoured to alienate the cities of Lycia from the interests of Brutus.

Naucratia, a city of Egypt on the left side of the Canopic mouth of the Nile. It was celebrated for its commerce, and no ship was permitted to land at any other place, but was obliged to sail directly to the city, there to deposit its cargo. It gave birth to Athenaeus.

Naucratites Nomos, in Ancient Geography, (Pliny); a division of the Delta, so called from that town Naucratia; though Plutemy comprises it under the Nomos Saites.

Naucydes, a statue, which lived about four centuries before the Christian era.

Nave, in Architecture, the body of a church, where the people are disposed, reaching from the baluster, or rail of the door, to the chief choir. Some derived
NAVEL [ 644 ]

NAVEL, in Anatomy, the centre of the lower part of the abdomen; being that part where the umbilical vessels passed out of the placenta of the mother. See Anatomy Index.

NAVEL-WORT. See Cotyledon, Botany Index.

NAVEW. See Brassica, Botany Index.

NAVIGATION

Is the art of conducting or carrying a ship from one port to another.

HISTORY.

The poets refer the invention of the art of navigation to Neptune, some to Bacchus, others to Hercules, others to Jason, and others to Janus, who is said to have made the first ship. Historians ascribe it to the Egyptians, the Phoenicians, Tyrians, and the ancient inhabitants of Britain. Some suppose, that the first hint was taken from the flight of the kite; others, as Oppian (De Dei, lib. 7), from the fish called nautilus; others ascribe it to accident.—Scripture refers the origin of so useful an invention to God himself, who gave the first specimen thereof in the ark built by Noah under his direction. For the rivalry which the good man underwent on account of his enterprise shows evidently enough that the world was then ignorant of any thing like navigation, and that they even thought it impossible.

However, profane history represents the Phoenicians, especially those of their capital Tyre, as the first navigators; being urged to seek a foreign commerce by the narrowness and poverty of a slip of ground they possessed along the coasts; as well as by the convenience of two or three good ports, and by their natural genius for traffic. Accordingly, Lebanon, and the other neighboring mountains, furnishing them with excellent wood for ship-building, in a short time they were masters of a numerous fleet; and constantly hazardizing new navigations, and settling new trades, they soon arrived at an incredible height of opulence and populoseness: insomuch as to be in a condition to send out colonies, the principal of which was that of Carthage; which, keeping up their Phoenician spirit of commerce, in time not only equaled Tyre itself, but vastly surpassed it; sending its merchant fleets through Hercules's Pillars, now the straits of Gibraltar, along the western coasts of Africa and Europe; and even, if we believe some authors, to America itself.

Tyre, whose immense riches and power are represented in such lofty terms both by sacred and profane authors, being destroyed by Alexander the Great, its navigation and commerce were transferred by the conqueror to Alexandria, a new city admirably situated for those purposes; proposed for the capital of the empire of Asia, which Alexander then meditated. And thus arose the navigation of the Egyptians; which was afterwards so much cultivated by the Ptolemies, that Tyre and Carthage were quite forgotten.

Egypt being reduced into a Roman province after the battle of Actium, its trade and navigation fell into the hands of Augustus; in whose time Alexandria was only inferior to Rome; and the magazines of the capital of the world were wholly supplied with merchandises from the capital of Egypt.

At length, Alexandria itself underwent the fate of Tyre and Carthage; being surprised by the Saracens, who in spite of the emperor Heraclius, overspread the northern coasts of Africa, &c. whence the merchants being driven, Alexandria has ever since been in a languishing state, though it still has a considerable part of the commerce of the Christian merchants trading to the Levant.

The fall of Rome and its empire drew along with it not only that of learning and the polite arts, but that of navigation; the barbarians into whose hands it fell, contenting themselves with the spoils of the industry of their predecessors.

But no sooner were the more brave among those nations well settled in their new provinces, some in Gaul, as the Franks; others in Spain, as the Goths; and others in Italy, as the Lombards; but they began to learn the advantages of navigation and commerce, and the methods of managing them, from the people they subdued; and this with so much success, that in a little time some of them became able to give new lessons, and set on foot new institutions for its advantage. Thus it is to the Lombards we usually ascribe the invention and use of banks, book-keeping, exchanges, rechanges, &c.

It does not appear which of the European people, after the settlement of their new masters, first betook themselves to navigation and commerce. Some think it began with the French; though the Italians seem to have the justest title to it; and are accordingly regarded as the restorers thereof, as well as of the polite arts, which had been banished together from the time the empire was torn a sunder. It is the people of Italy then, and particularly those of Venice and Genoa, who have the glory of this restoration; and it is to their advantageous situation for navigation they in great measure owe their glory. In the bottom of the Adriatic were a great number of marshy islands, only separated by narrow channels, but those well screened, and almost inaccessible, the residence of some fishermen, who here supported themselves by a little trade in fish and salt, which they found in some of these islands. Thither the Veneti, a people inhabiting that part of Italy along the coasts of the gulf, retired, when Alaric king of the Goths, and afterwards Attila king of the Huns, ravaged Italy.

These new islanders, little imagining that this was to be their fixed residence, did not think of composing any body politic; but each of the 72 islands of this little archipelago continued a long time under its several masters, and each made a distinct commonwealth. When their commerce was become considerable enough to give jealousy to their neighbours, they began to think...
think of uniting into a body. And it was this union, first begun in the sixth century, but not completed till the eighth, that laid the sure foundation of the future grandeur of the state of Venice. From the time of this union, their fleets of merchantmen were sent to all the ports of the Mediterranean; and at last to those of Egypt, particularly Cairo, a new city built by the Saracen princes on the eastern banks of the Nile, where they traded for the spices and other products of the Indies. Thus they flourished, increased their commerce, their navigation, and their conquests on the terra firma, till the league of Cambrai in 1508, when a number of jealous princes conspired to their ruin; which was the more easily effected by the diminution of their East India commerce, of which the Portuguese had got one part and the French another. Genoa, which had applied itself to navigation at the same time with Venice, and that with equal success, was a long time its dangerous rival, disputed with it the empire of the sea, and shared with it the trade of Egypt and other parts both of the east and west.

Jealousy soon began to break out; and the two republics coming to blows, there was almost continual war for three centuries before the superiority was ascertained; when, towards the end of the 14th century, the battle of Chiozza ended the strife; the Genoese, who till then had usually the advantage, having now lost all; and the Venetians, almost become desperate, at one happy blow, beyond all expectation, secured to themselves the empire of the sea, and superiority in commerce.

About the same time that navigation was retrieved in the southern parts of Europe, a new society of merchants was formed in the north, which not only carried commerce to the greatest perfection it was capable of till the discovery of the East and West Indies, but also formed a new scheme of laws for the regulation therefore, which still obtain under the names of Uses and Customs of the Sea. This society is that famous league of the Hanse towns, commonly supposed to have begun about the year 1164. See Hanse Towns.

For the modern state of navigation in England, Holland, France, Spain, Portugal, &c. see Commerce, Company, &c.

We shall only add, that in examining the causes of commerce passing successively from the Venetians, Genoese, and Hanse towns, to the Portuguese and Spaniards, and from these again to the English and Dutch, it may be established as a maxim, that the relation between commerce and navigation, or if we may be allowed to say it, their union, is so intimate, that the fall of the one inevitably draws after it that of the other; and that they will always either flourish or dwindle together. Hence so many laws, ordinances, statutes, &c. for its regulation; and hence particularly that celebrated act of navigation, which an eminent foreign author calls the palladium or tutelar deity of the commerce of England; which is the standing rule, not only of the British among themselves, but also of other nations with whom they traffic.

The art of navigation has been exceedingly improved in all sorts of times; both with regard to the form of the vessels themselves, and with regard to the methods of working them. The use of oars is now entirely superseded by the improvements made in the formation of the sails, rigging, &c. by which means ships can not only sail much faster than formerly, but can tack in any direction with the greatest facility. It is also very probable that the ancients were neither so well skilled in finding the latitudes, nor in steering their vessels in places of difficult navigation, as the moderns. But the greatest advantage which the moderns have over the ancients is from the mariner's compass, by which they are enabled to find their way with as great facility in the midst of an immeasurable ocean, as the ancients could have done by creeping along the coast, and never going out of sight of land. Some people indeed contend, that this is no new invention, but that the ancients were acquainted with it. They say, that it was impossible for Solomon to have sent ships to Ophir, Tarshish, and Parvaim, which last they will have to be Peru, without this useful instrument. They insist, that it was impossible for the ancients to be acquainted with the attractive virtue of the magnet, and to be ignorant of its polarity. Nay, they affirm, that this property of the magnet is plainly mentioned in the book of Job, where the loadstone is mentioned by the name of topaz, or the stone that turns itself.

But it is certain, that the Romans, who conquered Judea, were ignorant of this instrument; and it is very improbable, that such an useful invention, if once it had been commonly known to any nation, would have been forgot, or perfectly concealed from such a prudent people as the Romans, who were so much interested in the discovery of it.

Among those who admit that the mariner's compass is a modern invention, it has been much disputed who was the inventor. Some give the honour of it to Flavio Gioia of Amalfi in Campania, who lived * See Mariner's Compass. about the beginning of the 14th century; while others say that it came from the east, and was earlier known in Europe. But, at whatever time it was invented, it is certain, that the mariner's compass was not commonly used in navigation before the year 1420. In that year the science was considerably improved under the auspices of Henry duke ofViscon, brother to the king of Portugal. In the year 1485, Hoderick and Joseph, physicians to John II. king of Portugal, together with one Martin de Bohemin, a Portuguese, native of the island of Fayal, and scholar to Rogemontanus, calculated tables of the sun's declination for the use of sailors, and recommended the astrolabe for taking observations at sea. Of the instructions of Martin, the celebrated Christopher Columbus is said to have availed himself, and to have improved the Spaniards in the knowledge of the art; for the farther progress of which a lecture was afterwards founded at Seville by the emperor Charles V.

The discovery of the variation is claimed by Columbus, and by Sebastian Cabot. The former certainly did observe this variation without having heard of it from any other person, on the 14th of September 1492, and it is very probable that Cabot might do the same. At that time it was found that there was no variation at the Azores, where some geographers have thought proper to place the first meridian; though it hath since been observed that the variation alters in time. The use of the cross staff now begins, to be introduced among sailors. This ancient instrument is described by John Werner of Nuremberg, in
his annotations on the first book of Ptolemy's Geography, printed in 1514. He recommends it for observing the distance between the moon and some star, in order thence to determine the longitude.

At this time the art of navigation was very imperfect, on account of the inaccuracies of the plane chart, which was the only one then known, and which, by its gross errors, must have greatly misled the mariner, especially in voyages far distant from the equator. Its precepts were probably at first only set down on the sea charts, as is the custom at this day: but at length there were two Spanish treatises published in 1545: one by Pedro de Medina; the other by Martin Cortes, which contained a complete system of the art, as far as it was then known. These seem to have been the oldest writers who fully handled the art; for Medina, in his dedication to Philip prince of Spain, laments that multitudes of ships daily perished at sea, because there were neither teachers of the art, nor books by which it might be learned; and Cortes, in his dedication, boasts to the emperor that he was the first who had reduced navigation into a compendium, valuing himself much on what he had performed. Medina defended the plane chart; but he was opposed by Cortes, who showed its errors, and endeavoured to account for the variation of the compass, by supposing the needle to be influenced by a magnetic pole (which he called the point attractive), different from that of the world; which notion hath been farther prosecuted by others. Medina's book was soon translated into Italian, French, and Flemish, and served for a long time as a guide to foreign navigators. However, Cortes was the favourite author of the English nation, and was translated in 1561; while Medina's work was entirely neglected, though translated also within a short time of the other. At that time the system of navigation consisted of the following particulars, and others similar: An account of the Ptolemaic hypothesis, and the circles of the sphere; of the roundness of the earth, the longitudes, latitudes, climates, &c., and eclipses of the luminaries; a calendar; the method of finding the prime, epect, moon's age, and tides; a description of the compass, an account of its variation, for the discovering of which Cortes said an instrument might easily be contrived; tables of the sun's declination for four years, in order to find the latitude from his meridian altitude; directions to find the same by certain stars, of the course of the sun and moon; the length of the days; of time and its divisions; the method of finding the hour of the day and night; and lastly, a description of the sea chart, on which to discover where the ship is, they made use of a small table, that showed, upon an alteration of one degree of the latitude, how many leagues were run in each rhumb, together with the departure from the meridian. Besides, some instruments were described, especially by Cortes; such as one to find the place and declination of the sun, with the days, and place of the moon; certain dials, the astrolabe, and cross staff; with a complex machine to discovery the hour and latitude at once.

About the same time were made proposals for finding the longitude by observations of the moon. In 1534, Gemma Frisius advised the keeping of the time by means of small clocks or watches, then, as the says, newly invented. He also contrived a new sort of cross staff, and an instrument called the navicular quadrant, which last was much praised by William Cunningham, in his Astronomical Glass, printed in the year 1559.

In 1537 Pedro Nunez, or Nonius, published a book in the Portuguese language, to explain a difficulty in navigation proposed to him by the commander Don Martin Alphonso de Susa. In this he exposes the errors of the plane chart, and likewise gives the solution of several curious astronomical problems; amongst which is that of determining the latitude from two observations of the sun's altitude and intermediate azimuth being given. He observed, that though the rhumbs are spiral lines, yet the direct course of a ship will always be in the arch of a great circle, whereby the angle with the meridians will continually change: all that the steersman can here do for the preserving of the original rhumb, is to correct these deviations as soon as they appear sensible. But though the ship will in reality describe a course without the rhumb line intended; and therefore his calculations for assigning the latitude, where any rhumb line crosses the several meridians, will be in some measure erroneous. He invented a method of dividing a quadrant by means of concentric circles, which, after being much improved by Dr Halley, is used at present, and is called a rector.

In 1577, Mr William Bourne published a treatise, in which, by considering the irregularities in the moon's motion, he shows the errors of the sailors in finding her age by the epect, and also in determining the hour from observing on what point of the compass the sun and moon appeared. He advises, in sailing towards the high latitudes, to keep the reckoning by the globe, as there the plane chart is most erroneous. He desires of our ever being able to find the longitude, unless the variation of the compass should be occasioned by some such attractive point as Cortes had imagined; if which, however, he doubts: but as he had shown how to find the variation at all times, he advises to keep an account of the observations, as he uses for finding the place of the ship, which advice was presented at large by Simon Stevin, in a treatise published at Leyden in 1599; the substance of which was the same year printed at London in English by Mr Edward Wright, entitled the Haven-finding Art. In this ancient tract also is described the way by which our sailors estimate the rate of a ship in her course, by an instrument called the log. This was so named from the piece of wood or log that floats in the water while the time is reckoned during which the line that is fastened to it is veering out. The author of this contrivance is not known; neither was it taken notice of till 1607, in an East India voyage published by Purchas; but from this time it became famous, and was much taken notice of by almost all writers on navigation in every country; and it still continues to be used at first, though many attempts have been made to improve it, and contrivances proposed to supply its place; many of which have succeeded in quiet water, but proved useless in a stormy sea.

In 1581 Michael Coignet, a native of Antwerp, published a treatise, in which he animadvert on Medina. In this he showed, that as the rhumbs are
NAKATION.

ral, making endless revolutions about the poles, numerous errors must arise from their being represented by straight lines on the sea charts; but though he hoped to find a remedy for these errors, he was of opinion that the proposals of Nonius were scarcely practicable, and therefore in a great measure useless. In treating of the sun's declination, he took notice of the gradual decrease in the obliquity of the ecliptic; he also described the cross staff with three transverse pieces, as it is at present made, and which he owned to have been in common use among the sailors. He likewise gave some instruments of his own invention; but all of them are now laid aside, excepting perhaps his nocturnal. He constructed a sea table to be used by such as sailed beyond the 60th degree of latitude; and at the end of the book is delivered a method of sailing on a parallel of latitude by means of a ring dial and a 24 hour glass. The same year the discovery of the dipping needle was made by Mr Robert Norman. In his publication on that art he maintains, in opposition to Cortes, that the variation of the compass was caused by some point on the surface of the earth, and not in the heavens; he also made considerable improvements in the construction of compasses themselves; showing especially the danger of not fixing, on account of the variation, the wire directly under the fleur de luce; as compasses made in different countries have it placed differently. To this performance of Norman's is always prefixed a discourse on the variation of the magnetic needle, by Mr William Burrough, in which he shows how to determine the variation in many different ways. He also points out many errors in the practice of navigation at that time, and speaks in very severe terms concerning those who had published upon it.

All this time the Spaniards continued to publish treatises on the art. In 1585 an excellent compendium was published by Roderico Zamoranes, which contributed greatly towards the improvement of the art, particularly in the sea charts. Globes of an improved kind, and of a much larger size than those formerly used, were now constructed, and many improvements were made in other instruments; however, the plane chart continued still to be followed, though its errors were frequently complained of. Methods of removing these errors had indeed been sought after; and Gerard Mercator seems to have been the first who found the true method of doing this, so as to answer the purposes of seamen. His method was to represent the parallels both of latitude and longitude by parallel straight lines, but gradually to augment the former as they approached the pole. Thus the rhumbs, which otherwise ought to have been curves, were now also extended into straight lines; and thus a straight line drawn between any two places marked upon the chart would make an angle with the meridians, expressing the rhumb leading from the one to the other. But though, in 1569, Mercator published an universal map constructed in this manner, it doth not appear that he was acquainted with the principles on which this proceeded; and it is now generally believed, that the true principles on which the construction of what is called Mercator's chart depends, were first discovered by an Englishman, Mr Edward Wright.

Mr Wright supposes, but, according to the general opinion, without sufficient grounds, that this enlarge-
NAVIGATION.

latitude by the height of the pole star, when not upon the meridian. To this edition was subjoined a translation of Zamoraso’s Compendium above mentioned, in which he corrected some mistakes in the original; adding a large table of the variation of the compass observed in very different parts of the world, to show that it was not occasional by any magntetical pole.

These improvements soon became known abroad.

In 1624, a treatise entitled, Hypomnemata Mathematica, was published by Simon Stevin, for the use of Prince Maurice. In that part relating to navigation, the author having treated of sailing on a great circle, and shown how to draw the rhumbs on a globe mechanically, sets down Wright’s two tables of latitudes and of rhumbs, in order to describe these lines more accurately, pretending even to have discovered an error in Wright’s table. But all Stevin’s objections were fully answered by the author himself, who showed that they arose from the gross way of calculating made use of by the former.

In 1624, the learned Wellesbrodus Snellius, professor of mathematics at Leyden, published a treatise on navigation on Wright’s plan, but somewhat obscurely: and as he did not particularly mention all the discoveries of Wright, the latter was thought by some to have taken the hint of all his discoveries from Snellius. But this supposition is long ago refuted: and Wright enjoys the honour of those discoveries which is justly due.

Mr Wright having shown how to find the place of the ship on his chart, observed that the same might be performed more accurately by calculation: but considering, as he says, that the latitudes, and especially the courses at sea, could not be determined so precisely, he forbore setting down particular examples; as the mariner may be allowed to save himself this trouble, and only mark out upon his chart the ship’s way, after the manner then usually practised. However, in 1614, Mr Rapha Handson, among his nautical questions subjoined to a translation of Pitiscus’s trigonometry, solved very distinctly every case of navigation, by applying arithmetical calculations to Wright’s table of latitudes, or of meridional parts, as it hath since been called. Though the method discovered by Wright for finding the change of longitude by a ship sailing on a rhumb is the proper way of performing it, Handson also proposes two ways of approximation to it without the assistance of Wright’s division of the meridian line. The first was computed by the arithmetical mean between the cosines of both latitudes; the other by the same mean between the secants as an alternative, when Wright’s book was not at hand; though this latter is wider from the truth than the first.

By the same calculations also he showed how much each of these compendiums deviates from the truth, and also how widely the computations on the erroneous principles of the plane chart differ from them all. The method, however, commonly used by our sailors is commonly called the middle latitude; which, though it errs more than that by the arithmetical mean between the two cosines, is preferred on account of its being less operose: yet in high latitudes it is more eligible to use that of the arithmetical mean between the logarithmic cosines, equivalent to the geometrical mean between the cosines themselves; a method since proposed by Mr John Bassat. The computation by the middle latitude will always fall short of the true change of longitude; that by the geometrical mean will always exceed; but that by the arithmetical mean falls short in latitudes above 35 degrees, and exceeds in lesser latitudes. However, none of these methods will differ much from the truth when the change of latitude is sufficiently small.

About this time logarithms were invented by John Napier, baron of Merchiston in Scotland, and proved of the utmost service to the art of navigation. From which Mr Edmund Gunter constructed a table of logarithmic sines and tangents to very minute of the quadrant, which he published in 1620. In this work he applied to navigation, and other branches of mathematics, his admirable ruler known by the name of Gunter’s scale; on which are described lines of logarithms, of logarithmic sines and tangents, of meridional parts, &c. He greatly improved the sector for the same purposes. He showed also how to take a back observation by the cross staff, whereby the error arising from the eccentricity of the eye is avoided. He described likewise another instrument, of his own invention called the cross bow, for taking altitudes of the sun or stars, with some contrivances for the more readily collecting the latitude from the observation. The discoveries concerning logarithms were carried to France in 1624 by Mr Edmund Wingate, who published two small tracts in that year at Paris. In one of these he taught the use of Gunter’s scale; and in the other, of the tables of artificial sines and tangents, as modelled according to Napier’s last form, erroneously attributed by Wingate to Briggs.

Gunter’s rule was projected into a circular arch by the Reverend Mr William Oughtred in 1633, and its uses fully shown in a pamphlet entitled, The Circles of Proportion, where, in an appendix, are well treated several important points in navigation. It has also been made in the form of a sliding ruler.

The logarithmic tables were first applied to the different cases of sailing by Mr Thomas Addis, in his treatise entitled, Arithmetical Navigation, printed in 1625. He also gives two traverse tables, with their uses; the one to quarter points of the compass, the other to degrees. Mr Henry Geilibrand published his discovery of the changes of the variation of the compass, in a small quarto pamphlet, entitled, A discourse mathematical on the variation of the magnetic needle, printed in 1633. This extraordinary phenomenon he found out by comparing the observations made at different times near the same place by Mr Burrough, Mr Gunter, and himself, all persons of great skill and experience in these matters. This discovery was likewise soon known abroad; for Father Athanasius Kircher, in his treatise entitled, Magnum, first printed at Rome in 1641, informs us, that he had been told it by Mr John Greaves; and then gives a letter of the famous Marinus Mercator, containing a very distinct account of the same.

As altitudes of the sun are taken on board by observing his elevation above the visible horizon; to obtain from hence the sun’s true altitude with correctness, Wright observes it to be necessary that the dip of the visible horizon below the horizontal plane passing through the observer’s eye should be brought into the account,
account, which cannot be calculated without knowing the magnitude of the earth. Hence he was induced to propose different methods for finding this; but complained that the most effectual was out of his power to execute; and therefore contented himself with a rude attempt, in some measure sufficient for his purpose: and the dimensions of the earth deduced by him corresponded very well with the usual divisions of the log line; however, as he wrote not an express treatise on navigation, but only for the correcting such errors as prevailed in general practice, the log line did not fall under his notice. Mr Richard Norwood, however, put in execution the method recommended by Mr Wright as the most perfect for measuring the dimensions of the earth, with the true length of the degrees of a great circle upon it; and, in 1635, he actually measured the distance between London and York; from whence, and the summer solstitial altitudes of the sun observed on the meridian at both places, he found a degree on a great circle of the earth to contain 567,196 English feet, equal to 57,300 French Attoms or tacks, which is very nearly the same from most measures that have been made since that time. Of all this Mr Norwood gave a full account in his treatise called The Seaman's Practice, published in 1659. He there shows the reason why Snellius had failed in his attempt: he points out various kinds of his discovery, particularly for correcting the gross errors hitherto committed in the divisions of the log line. But necessary amendments have been little attended to by sailors, whose obstinacy in adhering to established errors has been complained of by the best writers on navigation. This improvement has at length, however, made its way into practice, and few navigators of reputation now make use of the old measure of 42 feet to a knot. In that treatise also Mr Norwood describes his own excellent method of setting down and perfecting a sea reckoning, by using a traverse table; which method he had followed and taught for many years. He shows also how to rectify the course by the variation of the compass being considered; as also how to discover improvements, and to make proper allowance on their account. This treatise, and another on trigonometry, were continually reprinted, as the principal books for learning scientifically the art of navigation. What he had delivered, especially in the latter of them, concerning this subject, was contrasted as a manual for sailors, in a very small piece called his Epitome; which useful performance has gone through a great number of editions. No alterations were ever made in the Seaman's Practice till the 12th edition in 1676, when the following paragraph was inserted in a smaller character: "About the year 1672, Maneuver Picart has published an account in French, concerning the measure of the earth, a breviate whereof may be seen in the Philosophical Transactions, N° 112, where he concludes one degree to contain 305,184 English feet, nearly agreeing with Mr Norwood's experiment;" and this advertisement is continued through the subsequent editions as late as the year 1732.

About the year 1643, Mr Bond published in Norwood's Epitome a very great improvement in Wright's method, by a proper method his meridian line, whereby its divisions are more scientifically assigned than the author himself was able to effect; which was from this theorem, that those divisions are analogous to the excesses of the logarithmic tangents of half the respective latitudes augmented by 45 degrees above the logarithm of the radius. This he afterwards explained more fully in the third edition of Gunter's works, printed in 1653; where, after observing that the logarithmic tangents from 45° upwards increase in the same manner that the secants added together do, if every half degree be accounted as a whole degree of Mercator's meridional line. His rule for computing the meridional parts belonging to any two latitudes, supposed on the same side of the equator, is to the following effect: "Take the logarithmic tangent, rejecting the radius, of half each latitude, augmented by 45 degrees; divide the difference of these numbers by the logarithmic tangent of 45° 30', the radius being likewise rejected; and the quotient will be the meridional parts required, expressed in degrees." This rule is the immediate consequence from the general theorem, That the degrees of latitude bear to one degree (or 60 minutes, which in Wright's table stands for the meridional parts of one degree), the same proportion, with the logarithmic tangent of half any latitude augmented by 45° 30', and the radius neglected, to the like tangents of half a degree augmented by 45 degrees, with the radius likewise rejected. But here was farther wanting the demonstration of this general theorem, which was at length supplied by Mr James Gregory of Aberdeen in his Exercitaciones Geometricae, printed at London in 1668; and afterwards more concisely demonstrated, together with a scientific determination of the divisor, by Dr Halley in the Philosophical Transactions for 1695, N° 219, from the consideration of the spirals into which the rhumbs are transformed in the stereographic projection of the sphere upon the plane of the equinoctial; and which is rendered still more simple by Mr Roger Cotes, in his Logometria, first published in the Philosophical Transactions for 1714, N° 388. It is moreover added in Gunter's book, that if 4½° of this division, which does not sensitively differ from the logarithmic tangent of 45° 1' 30" (with the radius subtracted from it), be used, the error will exhibit the meridional parts expressed in leagues, and this is the divisor set down in Norwood's Epitome. After the same manner the meridional parts will be found in minutes, if the like logarithmic tangent of 45° 1' 30", diminished by the radius, be taken; that is, the number used by others being 2633, when the logarithmic tables consist of eight places of figures besides the index.

In an edition of the Seaman's Kalender, Mr Bond declared, that he had discovered the longitude by having found out the true theory of the magnetic variation; and to gain credit to his assertions, he foretold, that at London in 1657 there would be no variation of the compass, and from that time it would gradually increase the other way; which happened accordingly. Again, In the Philosophical Transactions for 1668, N° 49, he published a table of the variation for 49 years to come. Thus be acquired such reputation, that his treatise, entitled, The Longitude Found, was in 1676 published by the special command of Charles II. and approved by many celebrated mathematicians. It was not long, however, before it met with opposition; and in 1678 another treatise, entitled, The Longitude not Found, made its appearance; and as Mr Bond's hy-
NAVIGATION.

The motion of a ship in the water is well known to depend on the action of the wind upon its sails, regulated by the direction of the helm. The water is a resisting medium and the bulk of the ship very considerable; it thence follows that there is always a great resistance on her fore-part; and when this resistance becomes sufficient to balance the moving force of the wind upon the sails, the ship attains her utmost degree of velocity, and her motion is no longer accelerated. This velocity is different according to the different strength of the wind; but the stronger the wind, the greater resistance is made to the ship's passage through the water: and hence, though the wind should blow ever so strong, there is also a limit to the velocity of the ship: for the sails and ropes can bear but a certain force of air; and when the resistance on the fore-part becomes more than equivalent to their strength, the velocity can be no longer increased, and the rigging gives way.

The direction of a ship's motion depends on the position of her sails with regard to the wind, combined with the action of the rudder. The most natural direction of the ship is, when she runs directly before the wind, the sails are then disposed, so as to be at right angles thereto. But this is not always the case, on account of the variable nature of the winds, and the situation of the intended port, or of intermediate headlands or islands. When the wind therefore happens not to be favourable, the sails are placed so as to make an oblique angle both with the direction of the ship and with the wind; and the sails, together with the rudder, must be managed in such a manner, that the direction of the ship may make an acute angle with that of the wind; and the ship, making boards on different tacks, will by this means arrive at the intended port.

The reason of the ship's motion in this case is, that the water resists the side more than the fore-part, and that in the same proportion as her length exceeds her breadth. This proportion is so considerable, that the ship continually flies off where the resistance is least, and that sometimes with great swiftness. In this way of sailing, however, there is a great limitation: for if the angle made by the keel with the direction of the wind be too acute, the ship cannot be kept in that position; neither is it possible for a large ship to make a more acute angle with the wind than about 6 points; though small sloops, it is said, may make an angle of about 5 points with it. In all these cases, however, the velocity of the ship is greatly retarded; and that not only on account of the obliquity of her motion, but by reason of what is called her lee-side. This is occasioned by the yielding of the water on the lee-side of the ship, by which means the vessel acquires a compound motion, partly in the direction of the wind, and partly in that which is necessary for attaining the desired port.

It is perhaps impossible to lay down any mathematical principles on which the lee-way of a ship could be properly calculated; only we may see in general that it depends on the strength of the wind, the roughness of the sea, and the velocity of the ship. When the wind is not very strong, the resistance of the water on the lee-side bears a very great proportion to that of the current of air; and therefore it will yield but very little; however, supposing the ship to remain
remain in the same place, it is evident, that the water having once begun to yield, will continue to do so for some time, even though no additional force was applied to it; but as the wind continually applies the same force as at first, the lee-way of the ship must go on constantly increasing till the resistance of the water on the lee-side balances the force applied on the other, when it will become uniform, as doth the motion of a ship sailing before the wind. If the ship changes her place with any degree of velocity, then every time she moves her own length, a new quantity of water is to be put in motion, which hath not yet received any momentum, and which of consequence will make a greater resistance than it can do when the ship remains in the same place. In proportion to the swiftness of the ship, then, the lee-way will be the less: but if the wind is very strong, the velocity of the ship bears but a small proportion to that of the current of air; and the same effects must follow as though the ship moved slowly, and the wind gentle; as then the ship must make a great deal of lee-way.—The same thing happens when the sea rises high, whether the wind is strong or not; for then the whole water of the ocean, as far as the swell reaches, has acquired a motion in a certain direction, and that to a very considerable depth. The mountainous waves will not fail to carry the ship very much out of her course; and this deviation will certainly be according to their velocity and magnitude. In all cases of a rough sea, therefore, a great deal of lee-way is made.—Another circumstance also makes a variation in the quantity of the lee-way; namely, the lightness or heaviness of the ship; it being evident, that when the ship sinks deep in the water, a much greater quantity of that element is to be put in motion before she can make any lee-way, than when she swims on the surface. As therefore it is impossible to calculate all these things with mathematical exactness, it is plain that the real course of a ship is exceedingly difficult to be found, and frequent errors must be made, which can only be corrected by celestial observations.

In many places of the ocean there are currents, or places where the water, instead of remaining at rest, runs with a very considerable velocity for a great way in some particular direction, and which will certainly carry the ship greatly out of her course. This occasions an error of the same nature with the lee-way: and therefore, whenever a current is perceived, its direction and velocity ought to be determined, and the proper allowances made.

Another source of error in reckoning the course of a ship proceeds from the variation of the compass.

There are few parts of the world where the needle points exactly north; and in those where the variation is known, it is subject to very considerable alterations. By these means the course of the ship is mistaken; for as the sailors have no other standard to direct them than the compass, if the needle, instead of pointing due north, should point northeast, a prodigious error would be occasioned during the course of the voyage, and the ship would not come near the port to which she was bound. To avoid errors of this kind, the only method is, to observe the sun’s altitude and azimuth as frequently as possible, by which the variation of the compass will be perceived, and the proper allowances can then be made for errors in the course which this may have occasioned.

Errors will arise in the reckoning of a ship, especially when she sails in high latitudes, from the spherical figure of the earth; for as the polar diameter of our globe is found to be considerably shorter than the equatorial one, it thence follows, that the farther we remove from the equator, the longer are the degrees of latitude. Of consequence, if a navigator assigns any certain number of miles for the length of a degree of latitude near the equator, he must vary that measure as he approaches towards the poles, otherwise he will imagine that he hath not sailed so far as he actually hath done. It would therefore be necessary to have a table containing the length of a degree of latitude in every different parallel from the equator to either pole; as without this a troublesome calculation must be made at every time the navigator makes a reckoning of his course. Such a table, however, hath not yet appeared; but that is, that there may be an easy matter to make it, on account of the difficulty of measuring the length even of one or two degrees of latitude in different parts of the world. Sir Isaac Newton first discovered this spheroidal figure of the earth; and showed, from experiments on pendulums, that the polar diameter was to the equatorial one as 229 to 230. This proportion, however, hath not been admitted by succeeding calculators. The French mathematicians, who measured a degree on the meridian in Lapland, made the proportion between the equatorial and polar diameters to be as 1 to 0.99581. Those who measured a degree at Quito in Peru, made the proportion 1 to 0.99624, or 265 to 265. M. Bouguer makes the proportion to be as 179 to 178; and M. Buffon, in one part of his theory of the earth, makes the equatorial diameter exceed the polar one by 2 $\frac{1}{2}$. According to M. du Jour, this proportion is as 321 to 320; and M. de la Place, in his Memoir upon the Figure of Sphered, has deduced the same proportion. From these variations it appears that the point is not exactly determined, and consequently that any corrections which can be made with regard to the spheroidal figure of the earth must be very uncertain.

It is of consequence to navigators in a long voyage to take the nearest way to their port; but this is scarcely possible to be done. The shortest distance between any two points on the surface of a sphere is measured by an arch of a great circle intercepted between them; and therefore it is advisable to direct the ship along a great circle of the earth’s surface. But this is a matter of considerable difficulty, because there are no fixed marks by which it can be readily known whether the ship sails in the direction of a great circle or not. For this reason the sailors commonly choose to direct their course by the rhumbs, or the bearing of the place by the compass. These bearings do not point out the shortest distance between places; because, on a globe, the rhumbs are spirals, and not arches of great circles. However, when the places lie directly under the equator, or exactly under the same meridian, the rhumb then coincides with the arch of a great circle, and of consequence shows the nearest way. The sailing on the arch of a great circle is called great circle sailing; and the cases of it depend all on the solution of problems in spherical trigonometry.
BOOK I.

Containing the Various Methods of Sailing.

INTRODUCTION.

The art of navigation depends upon astronomical and mathematical principles. The places of the sun and fixed stars are deduced from observation and calculation, and arranged in tables, the use of which is absolutely necessary in reducing observations taken at sea, for the purpose of ascertaining the latitude and longitude of the ship, and the variation of the compass. The problems in the various sailings are resolved either by trigonometrical calculation, or by tables or rules formed by the assistance of trigonometry. By mathematics, the necessary tables are constructed, and rules investigated for performing the more difficult parts of navigation. For these several branches of science, and for logarithmic tables, the reader is referred to the respective articles in this work. A few tables are given at the end of this article; but as the other tables necessary for the practice of navigation are to be found in almost every treatise on that subject, it therefore seems unnecessary to insert them in this place.

CHAP. I. Preliminary Principles.

SECT. I. Of the Latitude and Longitude of a Place.

The situation of a place on the surface of the earth is estimated by its distance from two imaginary lines intersecting each other at right angles: The one of these is called the equator, and the other the first meridian. The situation of the equator is fixed, but that of the first meridian is arbitrary, and therefore different nations assume different first meridians. In Britain, we esteem that to be the first meridian which passes through the royal observatory at Greenwich.

The equator divides the earth into two equal parts, called the northern and southern hemispheres; and the latitude of a place is its distance from the equator, reckoned on a meridian in degrees and parts of a degree, and is either north or south, according as it is in the northern or southern hemisphere.

The first meridian being continued round the globe, divides it into two equal parts, called the eastern and western hemispheres; and the longitude of a place is that portion of the equator contained between the first meridian and the meridian of the given place, and is either east or west; according as it is in the eastern or western hemisphere, respectively to the first meridian.

PROB. I. The latitudes of two places being given, to find the difference of latitude.

RULE. Subtract the less latitude from the greater, if the latitudes be of the same name, but add them if of contrary; and the remainder or sum will be the difference of latitude.

Example 1. Required the difference of latitude between the Lizard, in latitude 49° 57' N. and Cape St. Vincent, in latitude 35° 2' N.

Latitude of the Lizard 49° 57' N.
Latitude of Cape St. Vincent. 35° 2' N.

Difference of latitude 14° 55' = 775 miles.

Ex. 2. What is the difference of latitude between Funchal, in latitude 36° 30' N., and the Cape of Good Hope, in latitude 34° 29' S.?

Latitude of Funchal 36° 30' N.
Lat. of Cape of Good Hope 34° 29' S.

Difference of latitude 1° 2' 30" = 69 7/14 miles.

PROB. II. Given the latitude of one place, and the difference of latitude between it and another place, to find the latitude of that place.

RULE. If the given latitude and the difference of latitude be of the same name, add them; but if of different names, subtract them, and the sum or remainder will be the latitude required of the same name with the greater.

Ex. 1. A ship from latitude 39° 22' N. sailed due north 360 miles.—Required the latitude come to?

Latitude sailed from 39° 22' N.
Difference of latitude 56° 17' S. 7° 20' N.

Latitude come to. 38° 42' N.

Ex. 2. A ship from latitude 7° 19' S. sailed 854 miles south.—Required the latitude come to?

Latitude sailed from 7° 19' S.
Difference of latitude 8° 54' S. 14° 14' N.

Latitude come to. 6° 55' N.

PROB. III. The longitudes of two places being given, to find their difference of longitude.

RULE. If the longitudes of the given places are of the same name, subtract the less from the greater, and the remainder is the difference of longitude: but if the longitudes are of contrary names, their sum is the difference of longitude. If this exceeds 180°, subtract it from 360°, and the remainder is the difference of longitude.

Ex. 1. Required the difference of longitude between Edinburgh and New York, their longitudes being 3° 34' W. and 74° 10' W. respectively?

Longitude of New York 74° 10' W.
Longitude of Edinburgh 3° 34' W.

Difference of longitude. 70° 36' W.

Ex. 2. What is the difference of longitude between Missy, in longitude 16° 15' E. and Ohio, in longitude 35° 5' W.?
NA\_VI\_GATION.

| Longitude of Maskallya's Isles | 167° 59' E. |
| Long. of Salonique to time | 35° 5 W. |

Sum - 203 4
Subtract from - 360 0
Difference of longitude - 156 56

**Prob. IV.** Given the longitude of a place, and the difference of longitude between it and another place, to find the longitude of that place.

**Rule.** If the given longitude and the difference of longitude be of a contrary name, subtract the less from the greater, and the remainder is the longitude required of the same name with the greater quantity; but if they are of the same name, add them, and the sum is the longitude sought, of the same name with that given. If this sum exceeds 180°, subtract it from 360°, the remainder is the required longitude of a contrary name to that given.

**Ex. 1.** A ship from longitude 5° 54' E. sailed westerly till the difference of longitude was 23° 18'. Required the longitude come to?
Longitude sailed from: - 9° 54' E.
Difference of longitude: - 23° 18' W.

| Longitude come to | 13° 24' W. |
| Ex. 2. The longitude sailed from is 21° 5' W. and difference of longitude 18° 46' W. Required the longitude come to? | |

| Longitude | 21° 5' W. |
| Difference of longitude | 18° 46' W. |

| Longitude in | 43° 55' W. |

**Sect. II. Of the Tides.**

The theory of the tides has been explained under the article Astronomy, and will again be farther illustrated under that of Tides. In this place, therefore, it remains only to explain the method of calculating the time of high water at a given place.

As the tides depend upon the joint actions of the sun and moon, and therefore upon the distance of these objects from the earth and from each other; and as, in the method generally employed to find the time of high water, whether by the mean time of new moon, or by the epacts, or tables deduced therefrom, the moon is supposed to be the sole agent, and to have an uniform motion in the periphery of a circle, whose centre is that of the earth; it is hence obvious that method cannot be accurate, and by observation the error is sometimes found to exceed two hours. That method is therefore rejected, and another given, in which the error will seldom exceed a few minutes, unless the tides are greatly influenced by the winds.

**Prob. I.** To reduce the times of the moon's phases as given in the Nautical Almanac to the meridian of a known place.

**Rule.** To the time of the proposed phase, as given in the Nautical Almanac, apply the longitude of the place in time, by addition or subtraction, according as it is east or west, and it will give the time of the phase at the given place.

**Ex. 1.** Required the time of new moon at Salonique in May 1793?

**Ex. 2.** What is the time of the last quarter of the moon at Resolution bay in October 1793?

**Time of new moon per Naut. Alm.** 9° 15' 31" 17 E.

| Long. of Salonique in time | 0° 1 33 E. |

| Time of new moon required, in May | 9° 17 4 |
| Ex. 2. What is the time of the last quarter of the moon at Resolution bay in October 1793? | 26° 5' 47" |
| Long. in time | 0° 9 17 E. |
| Time at Resolution bay of last quarter, October | 25 20 30, or 26th day at 8° 30' A.M. |

**Prob. II.** To find the time of high water at a known place.

**Rule.** In the Nautical Almanac seek in the given month, or in that immediately preceding or following it, for the time of that phase which happens nearest to the given day: reduce the time of this phase to the meridian of the given place by Prob. I, and take the difference between the reduced time and the noon of the given day.

Find the equation answering to this difference in Table VII. which applied to the time of high water on the day of new or full moon at the given place, according to the table directs, will give the approximate time of high water in the afternoon.

Now, take the interval between the reduced time of the phase and the approximate time of high water; find the corresponding equation, which applied as before to the syzygy time of high water, will give the time of the afternoon high water.

If the time of the morning high water is required, increase the last interval by one-half hours, if the given day falls before the phase, or diminish it by one-half hours when after that phase; and the equation to this time, applied to the syzygy time, gives the morning time of high water.

**Ex. 1.** Required the morning and afternoon times of high water at Leith, 17th December 1793?

**Nearest phase to 17th Dec. is 1st quart.** 9° 20' 30' |
| Long. of Leith in time | 0° 0 13 |

| Time at Leith of 1st quarter | 9° 20 16 |
| Given day | 11 0 0 |

| Difference | 1 3 44 |
| Time of H. W. at Leith-pier on syz. | 0 2 60 |
| Equat. from Tab. to 1° 3° 44' | 6 32 |

| Approximate time of high water | 11 8 52 |
| Reduced time of 1st quarter | 9 20 16 |

| Interval | 1 12 36 |
| Time of high water at Leith on syz. | 2 20 |
| Equat. from the Tab. to 1° 12° 36' | 6 22 |

| Time of high water at Leith | 9 20 P.M. |
| Time of H. W. at Leith at full & change | 2 20 |
| Equat. to 1° 12° 36'—12° 1° 6 ch | 0 |

| Time of high water at Leith | 9 20 P.M. |
| High water at Leith, Dec. 17th, at 8 42 A.M. |

The time of high water found by the common method is about an hour and a half sooner.

**Ex. 2.** Required the time of high water at Funchal, 15th November 1793?

The.
NAVIGATION.

Tides. The nearest phase to 15th November is that of full moon, longitude of Funchal in time, 17° 8h 46'.

Time of full moon at Funchal, 17 7 38.

Given day, November, 15 0 0.

Difference, 2 7 38.

Time of high water at Funchal at full and change, 0 12 4.

Equation from the table to 2d 7h 38' before full moon, 0 1 35.

Approx. time of high water, Nov. 15 10 29.

Reduced time of full moon, 17 7 38.

Interval, 1 11 9.

Time of high water at full and change, 12 4.

Equation to 1d 11h before full moon, 0 56.

Time of high water, 11 8P.M.

Equation to 1d 11h + 12h = 1d 23h 15h 49', and 12h 45' = 1h 15' = 5h 49' = time of high water in the forenoon.

Ex. 3. Required the time of high water at Duskey Bay, 24th October 1793?
The nearest phase to the 24th October is the last quarter, 26d 5h 47'.

Longitude of Duskey Bay in time, 40 11 5 E.

Reduced time of first quarter of moon, 26 16 52.

Given day, 24 0 0.

Difference, 2 16 52.

Time of high water at full and change, 10 57.

Equation to 2d 16h 52' before last quarter, 2 52.

Approximate time of high water, 1 49.

Change of equation to app. time 1h 49', 3.

Time of high water in the afternoon, 1 52.

Change of equation to 12 hours, 20.

Time of high water in the morning, 1 32.

SECT. III. Of measuring a Ship's Run in a given Time.

The method commonly used at sea to find the distance sailed in a given time, is by means of a log-line and half-minute glass. A description of these is given under the articles Log and Log-Line; which see.

It has been already observed, that the interval between each knot on the line ought to be 50 feet, in order to adapt it to a glass that runs 30 seconds. But although the line and glass be at any time perfectly adjusted to each other, yet as the line shrinks after being wet, and as the weather has a considerable effect upon the glass, it will therefore be necessary to examine them from time to time; and the distance given by them must be corrected accordingly. The distance sailed may, therefore, be affected by an error in the glass, or in the line, or in both. The true distance may, however, be found as follows.

PROB. I. The distance sailed by the log, and the seconds run by the glass, being given, to find the true distance, the line being supposed right.

Rule. Multiply the distance given by the log by 30, and divide the product by the seconds run by the glass, the quotient will be the true distance.

Ex. 1. The hourly rate of sailing by the log is nine knots, and the glass is found to run out in 35 seconds.

Required the true rate of sailing?

9

30

37.270(7.7 = true rate of sailing.

Ex. 2. The distance sailed by the log is 73 miles, and the glass runs out in 26 seconds. Sought the true distance?

73

30

26.2109(8.2 = the true distance.

PROB. II. Given the distance sailed by the log, and the measured interval between two adjacent knots on the line; to find the true distance, the glass running exactly 30 seconds.

Rule. Multiply twice the distance, sailed by the measured length of a knot, point off two figures to the right, and the remainder will be the true distance.

Ex. 1. The hourly rate of sailing by the log is five knots, and the interval between knot and knot measures 53 feet. Required the true rate of sailing?

Measured interval = 53.

Twice hourly rate = 10.

True rate of sailing = 5.30.

Ex. 2. The distance sailed is 64 miles, by a log-line which measures 42 feet to a knot. Required the true distance?

Twice given distance, 120.

Measured interval, 42.

256

512

True distance, 53.76.

PROB. III. Given the length of a knot, the number of seconds run by the glass in half a minute, and the distance sailed by the log: to find the true distance.

Rule. Multiply the distance sailed by the log by six times the measured length of a knot, and divide the product by the seconds run by the glass; the quotient, pointing off one figure to the right, will be the true distance.

Ex. The distance sailed by the log is 159 miles, the measured length of a knot is 42 feet, and the glass runs 53 seconds in half a minute. Required the true distance?

Distance by the log, 159.

Six times length of a knot = 42 x 6 = 252.

318

795

318

Seconds run by the glass = 33.40068 (121.4 = true distance.

CHAIR.
NAVIGATION.

CHAP. II. Plane Sailing.

Plane sailing is the art of navigating a ship upon principles deduced from the notion of the earth’s being an extended plane. On this supposition the meridians are esteemed as parallel right lines. The parallels of latitude are at right angles to the meridians; the lengths of the degrees on the meridians, equator, and parallels of latitude, are everywhere equal; and the degrees of longitude are reckoned on the parallels of latitude as well as on the equator. In this sailing four things are principally concerned, namely, the course, distance, difference of latitude, and departure.

The course is the angle contained between the meridian and the line described by the ship, and is usually expressed in points of the compass.

The distance is the number of miles a ship has sailed on a direct course in a given time.

The difference of latitude is the portion of a meridian contained between the parallels of latitude sailed from and come to; and is reckoned either north or south, according as the course is in the northern or southern hemisphere.

The departure is the distance of the ship from the meridian of the place she left, reckoned on a parallel of latitude. In this sailing, the departure and difference of longitude are esteemed equal.

In order to illustrate the above, let $A$ (fig. 1.) represent the position of any given place, and $AB$ the meridian passing through that place; also let $AC$ represent the line described by a ship, and $C$ the point arrived at. From $C$ draw $CB$ perpendicular to $AB$. Now in the triangle $ABC$, the angle $BAC$ represents the course, the side $AC$ the distance, $AB$ the difference of latitude, and $BC$ the departure.

In constructing a figure relating to a ship’s course, let the upper part of what the figure is to be drawn on represent the north, then the lower part will be south, the right-hand side east, and the left-hand side west.

A north and south line is to be drawn to represent the meridian of the place from which the ship sailed; and the upper or lower part of this line, according as the course is southerly or northerly, is to be marked as the position of that place. From this point as a centre, with the chord of $60^\circ$, an arch is to be described from the meridian towards the right or left, according as the course is easterly or westerly; and the course, taken from the line of chords if given in degrees, but from the line of rhumbs if expressed in points of the compass, is to be laid upon this arch, beginning at the meridian. A line drawn through this point and that sailed from, will represent the distance, which if given must be laid thereon, beginning at the point sailed from. A line is to be drawn from the extremity of the distance perpendicular to the meridian; and hence the difference of latitude and departure will be obtained.

If the difference of latitude is given, it is to be laid upon the meridian, beginning at the point representing the place the ship left; and a line drawn from the extremity of the difference of latitude perpendicular to the meridian, till it meets the distance produced, will limit the figure.

If the departure is given, it is to be laid off on a parallel, and a line drawn through its extremity will limit the distance. When either the distance and difference of latitude, distance and departure, or difference of latitude and departure, are given, the measure of each is to be taken from a scale of equal parts, and laid off on its respective line, and the extremities connected. Hence the figure will be formed.

PROB. I. Given the course and distance, to find the difference of latitude and departure.

Example. A ship from St. Helena, in latitude $15^\circ 55'$ S. sailed S. W. by S. 158 miles. Required the latitude come to, and departure.

By Construction.

Draw the meridian $AB$ (fig. 2.), and with the chord of $60^\circ$ describe the arch $m$, and make it equal to the rhumb of 3 points, and through $m$ draw $AC$ equal to 158 miles; from $C$, draw $CB$ perpendicular to $AB$; then $AB$ applied to the scale from which $AC$ was taken, will be found to measure 151.4 and $BC$ 87.8.

By Calculation.

To find the difference of latitude.

As radius $-$ $-$ $-10.00000$

is to the cosine of the course $-$ $-3$ points $9.91985$

so is the distance $-$ $-158$ miles $-$ $-2.19866$

To the difference of latitude $-$ $-131.4$ points $-$ $-2.11851$

To find the departure.

As radius $-$ $-$ $-10.00000$

is to the sine of the course $-$ $-3$ points $9.74474$

so is the distance $-$ $-158$ miles $-$ $-2.19866$

To the departure $-$ $-87.8$ points $-$ $-1.94340$

By Inspection.

In the traverse table, the difference of latitude answering to the course 3 points, and distance 158 miles, in a distance column is 131.4, and departure 87.8.

By Gunter’s Scale.

The extent from 8 points to 5 points, the complement of the course on the line of sine rhumbs (marked S.R.) will reach from the distance 158 to 131.4, the difference of latitude on the line of numbers; and the extent from 8 points to 3 points on sine rhumbs, will reach from 158 to 87.8, the departure on numbers (A).

Latitude St. Helena $= 15^\circ 55'$ S.

Difference of latitude $-$ $-2$ 11 S.

Latitude come to $-$ $-18$ 6 S.

PROB. II. Given the course and difference of latitude, to find the distance and departure.

Example.

(A) For the method of resolving the various problems in navigation, by the sliding gunter, the reader is referred to Dr. Mackay’s Treatise on the Description and Use of that Instrument.
By Construction.

Draw the portion of the meridian AB (fig. 3.) equal to 218 m.: from the centre A with the chord of 60° describe the arch mn, which make equal to the rhumb of 3 ½ points; through A and draw the line AC, and from B draw BC perpendicular to AB, and let it be produced till it meets AC in C. Then the distance AC being applied to the scale, will measure 282 m. and the departure BC 179 miles.

By Calculation.

To find the distance.

As the sine of the course is radius = 5 points = 9.0654
so is the departure = 192 = 2.3738

To find the difference of altitude.

As the tangent of the course is radius = 5 points
so is the departure = 192 = 2.2130

By Inspection.

Find the departure 192 m. in its proper column above the given course 5 points; and opposite there to is the distance 231 m. and difference of latitude 13°3, in their respective columns.

By Gunter’s Scale.

The extent from 5 points to 8 points on the line of nine rhumbs, being laid from the departure 192 m. numbers, will reach to the distance 231 on the same line; and the extent from 5 points to 4 points on the line of tangent rhumbs, will reach from the departure 192, to the difference of latitude 128.3 m. numbers.

Latitude of Palma = 28° 37’ N
Difference of latitude = 2° 8’ N

By Construction.

Draw the portion of the meridian AB (fig. 5.) equal to 198 miles; from B draw BC perpendicular to AB: then take the distance 285 miles from the scale, and with one foot of the compass in A describe an arch intersecting BC in C, and join AC. With the chord of 60° describe the arch mn, which make equal to the rhumb of 3 points, the complement of the course; draw a line through C n, which produce till it meets BA in A: then the distance AC being measured, will be equal to 251 m. and the difference of latitude AB will be 128.3 miles.

By Calculation.

To find the course.

As the distance is to the cosine of the course
so is the radius = 285 = 9.84174

To find the departure.

As the tangent of the course is radius = 285
so is the departure = 192 = 2.20660

To find the difference of latitude.

As the sine of the course is radius = 285
so is the departure = 192 = 2.10679
NAVIGATION.

By Gunter's Scale.

The extent of the compass, from the distance 260 to the departure 190 on the line of numbers, will reach from 90° to 47°, the course on the line of sines; and the extent from 90° to 43°, the complement of the course on sines, will reach from the distance 260 to the difference of latitude 177\(\frac{1}{2}\) on the line of numbers.

Latitude Fort Royal - - 12° 9' N.
Difference of latitude - 177 - = 2 57 S.

Latitude in - - 9 12 N.

Prob. VI. Given difference of latitude and departure, sought course and distance.

Example. A ship from a port in latitude 7° 36' S., sailed between the south and cast, till her departure is 132 miles; and is then by observation found to be in latitude 12° 3' S. Required the course and distance?

Latitude sailed from - 7° 36' S.
Latitude in by observation 12 3 8.

Difference of latitude - 4 7 = 247.

By Construction.

Draw the portion of the meridian AB (fig. 7.) equal to the difference of latitude 247 miles; from B draw BC perpendicular to AB, and equal to the given departure 132 miles, and join AC; then with the chord of 60° describe an arc from the centre A; and the portion m a of this arc being applied to the line of chords, will measure about 28°; and the distance AC, measured on the line of equal parts, will be 280 miles.

By Calculation.

To find the course.

As the difference of latitude - 247 2.39297
is to the departure - 132 2.12057
so is radius - - 10.00000

to the tangent of the course 28° 7' 9.72587
To find the distance.

As radius - - 10.00000

is to the secant of the course 28° 7' 10.54544
so is the difference of latitude 247 - 2.39297

to the distance - 280 - 2.44724

By Inspection.

Seek in the table till the given difference of latitude and departure, or the nearest thereto, are found together in their respective columns, which will be under 28°, the required course; and the distance answering thereto is 280 miles.

By Gunter's Scale.

The extent from the given difference of latitude 247 to the departure 132 on the line of numbers, will reach from 45° to 28°, the course on the line of tangents; and the extent from 62°, the complement of the course, to 90° on sines, will reach from the difference of latitude 247, to the distance 280 on numbers.

Chap. III. Of Traverse Sailing.

If a ship sail upon two or more courses in a given time, the irregular track she describes is called a traverse; and to resolve a traverse, is the method of reducing these several courses, and the distances run, in-

By Construction.

With the chord of 60° describe the circle NE, SW (fig. 8.), the centre of which represents the position the ship sailed from: draw two diameters NS, EW at right angles to each other; the one representing the meridian, and the other the parallel of latitude of the place sailed from. Take each course from the line of rhumbs, lay it off on the circumference from its proper meridian, and number it in order 1, 2, 3, 4. Upon the first rhumb C1, lay off the first distance 163 miles from C to A; through it draw the second distance AB parallel to C2, and equal to 110 miles; through B draw BD equal to 180 miles, and parallel to C3; and draw DE parallel to C4, and equal to 68 miles. Now CE being joined, will represent the distance made good; which applied to the scale will measure 281 miles. The arch S w, which represents the course, being measured on the line of chords, will be found equal to 41°. From E draw EF perpendicular to CS produced; then CF will be the difference of latitude, and FE the departure made good; which applied to the scale will be found to measure 210 and 186 miles respectively.

As the method by construction is scarcely ever practised at sea, it, therefore, seems unnecessary to apply it to the solution of the following examples.

II. A ship from latitude 1° 38° S. sailed as under. Required her present latitude, course, and distance made good.

Hence the course per compass is nearly S 1° W, and distance 702 4 miles.

Chapter IV. Of Parallel Sailing.

The figure of the earth is spherical, and the meridians gradually approach each other, and meet at the poles. The difference of longitude between any two places is the angle at the pole contained between the meridians of those places; or it is the arch of the equator intercepted between the meridians of the given places; and the meridian distance between two places in the same parallel, is the arch thereof contained between their meridians. It hence follows, that the meridian distance, answering to the same difference of longitude, will be variable with the latitude of the parallel upon which it is reckoned; and the same difference of longitude will not answer to a given meridian distance when reckoned upon different parallels.

Parallel sailing is, therefore, the method of finding the distance between two places lying in the same parallel whose longitudes are known; or, to find the difference of longitude answering to a given distance, run in an east or west direction. This sailing is particularly useful in making low or small islands.

In order to illustrate the principles of parallel sailing, let CABP (fig. 9) represent a section of one fourth part of the earth, the arch ABP being part of a meridian; CA the equatorial, and CP the polar semi-axis. Also let B be the situation of any given place on the earth; and join BC, which will be equal to CA or CP (c). The arch AB, or angle ACB, is the measure of the latitude of the place B; and the arch BP, or angle BCP, is that of its complement. If BD be drawn from B perpendicular to CP, it will represent the cosine of latitude to the radius BC of CA.

Now since circles and similar portions of circles are in the direct ratio of their radii; therefore,

As radius
Is to the cosine of latitude;
So is any given portion of the equator
To a similar portion of the given parallel.

But the difference of longitude is an arch of the equator; and the distance between any two places under the same parallel, is a similar portion of that parallel.

Hence R : cosine latitude :: Diff. longitude : Distance.

And by inversion,

Cosine latitude : R :: Distance : Diff. of longitude.

Also,

Diff. of longitude : Distance :: R : cos. latitude.

Prob. I. Given the latitude of a parallel, and the number of miles contained in a portion of the equator, to find the miles contained in a similar portion of that parallel.

Ex. 1. Required the number of miles contained in a degree of longitude in latitude 55° 58'?

By Construction.

Draw the indefinite right line AB (fig. 10); make the angle BAC equal to the given latitude 55° 58' and AC equal to the number of miles contained in a degree of longitude at the equator, namely 60: from C draw CB perpendicular to AB; and AB being measured on the line of equal parts, will be found equal to 33:5, the miles required.

4 0 2

(b) Greigness is about 2 1/2 miles distant from Aberdeen, in nearly a SSE 1/4 E direction.

(c) This is not strictly true, as the figure of the earth is that of an oblate spheroid; and therefore the radius of curvature is variable with the latitude. The difference between CA and CE, according to Sir Isaac Newton's hypothesis, is about 17 miles.
NAVIGATION.

By Calculation.

As radius

so is miles in a deg. of long. at eq.

so is miles in a deg. in the given par.

By Inspection.

To 56°, the nearest degree to the given latitude, and distance 60 miles, the corresponding difference of latitude is 33.6, which is the miles required.

By Gunter's Scale.

The extent from 50° to 34°, the complement of latitude to 50° on the line of sines, being laid the same way from the distance 342, will reach the difference of longitude 466½ on the line of numbers.

Longitude Cape Finisterre

Difference of longitude

Longitude equin to

Prob. III. Given the number of miles contained in any portion of the equator, and the miles in a similar portion of a parallel; to find the latitude of that parallel.

Example. A ship sailed due east 338 miles, and was found by observation to have differed her longitude 8° 42'. Required the latitude of the parallel?

By Construction.

Make the line AB (fig. 11.) equal to the given distance; to which let BC be drawn perpendicular, with an extent equal to 522°, the difference of longitude; describe an arc from the centre A, cutting BC in C; then the angle BAC being measured by means of the line of chords, will be found equal to 46° 42°, the required latitude.

By Calculation.

As the distance

is to the difference of longitude,

so is radius

to the secant of the latitude,

By Inspection.

As the difference of longitude and distance exceed the limits of the table, let therefore the half of each be taken; these are 261 and 179 respectively. Now, by entering the table with these quantities, the latitude will be found to be between 46° and 47°. Therefore, to latitude 46°, and distance 261 miles, the corresponding difference of latitude is 181°.3, which exceeds the half of the given distance by 22.3. Again, to latitude 47°, and distance 261, the difference of latitude is 170.0, being 1° less than the half of that given: therefore the change of distance answering to a change of 1° of latitude is 3.3.

Now, as 3.3: 2.3 :: 1°: 42°.

Hence the latitude required is 46° 42°.

By Gunter's Scale.

The extent from 522 to 338 on the line of numbers, will reach from 50° to about 43° 47', the complement of which 46° is the latitude required.

Prob. IV. Given the number of miles contained in the portion of a known parallel, to find the length of a similar portion of another known parallel.

Example. From two ports in latitude 33° 48' N., distance 348 miles, two ships sail directly north till they are in latitude 48° 23' N. Required their distance?

By Construction.

Draw the line CB, CE (fig. 13.), making angles Fig 19

with
NAVIGATION

With CP equal to the complements of the given latitudes, namely, 56° 2' and 41° 37' respectively: make BD equal to the given distance 348 miles, perpendicular to CP; now from the centre C, with the radius CB, describe an arc intersecting CE in E; then EF drawn from the point E, perpendicular to CP, will represent the distance required; which being applied to the scale, will measure 278.6 miles.

By Calculation.

As the cosine of the latitude left

33° 58' 9.01874

is to the cosine of the lat. come to

48 23 9.83226

so is the given distance

348 2.54158

to the distance required

278.6 2.44510

By Inspection.

Under 34°, and opposite to 174, half the given distance in a latitude column is 210 in a distance column; being half the difference of longitude answering thereto. Now, find the difference of latitude to distance 210 miles over 48° of latitude, which is 140'.55; from which 1/2 (the proportional part answering to 23 minutes of latitude) being subtracted, gives 139.4 which doubled in 278.6, the distance required.

By Gunter's Scale.

The extent from 36° 2', the complement of the latitude left, to 41° 37', the complement of that same, on the line of sines, being laid the same way from 348, will reach to 278.3, the distance sought on the line of numbers.

Prob. V. Given a certain portion of a known parallel, together with a similar portion of an unknown parallel; to find the latitude of that parallel.

Example. Two ships, in latitude 56° of N, distant 180 miles, sail due south; and having come to the same parallel, are now 322 miles distant. The latitude of that parallel is required?

By Construction.

Make DB (fig. 14.) equal to the first distance 180 miles, DM equal to the second 232, and the angle DBC equal to the given latitude 56°; from the centre C, with the radius CB, describe the arch BE; and through M draw ME parallel to CD, intersecting the arch BE in E; join EC and draw EF perpendicular to CD: then the angle FEC will be the latitude required; which being measured, will be found equal to 43° 53'.

By Calculation.

As the distance on the known parallel 180 2.25527

is to the distance on that required 232 2.36549

so is the cosine of the latitude left 56° 9.74756

to the cosine of the latitude come to 43 53 9.83778

By Inspection.

To latitude 56°, and half the first distance 90 in a latitude column, the corresponding distance is 161, which is half the difference of longitude. Now 161, and 116, half the second distance, are found to agree between 43 and 44 degrees; therefore, to latitude 43° and distance 161, the corresponding difference of latitude is 117.7; the excess of which above 116° is 1.7; and to latitude 44°, and distance 161, the difference of latitude is 115.8; hence 117.7 - 115.8 = 1.9, the change answering to a difference of 1° of latitude.

Therefore, 1.9: 1.7 :: 1°: 53'.

Hence, the latitude is 43° 53'.

By Gunter's Scale.

The extent from 180 to 232 on the line of numbers, being laid in the same direction on the line of sines, from 34°, the complement of the latitude sailed from, will reach to 46° 7', the complement of the latitude come to.

Chap. V. Of Middle Latitude Sailing.

The earth is a sphere, and the meridians meet at the poles; and since a rhumb-line makes equal angles with every meridian, the line a ship describes is, therefore, that kind of a curve called a spiral.

Let AB (fig. 15.) be any given distance sailed upon fig. 15., an oblique rhumb, PBN, PAM the extreme meridians, MN a portion of the equator, and PCK, PEL two meridians intersecting the distance AB in the points CE infinitely near each other. If the arches BS, CD, and AR be described parallel to the equator, it is hence evident, that AS is the difference of latitude, and the arch MN of the equator, the difference of longitude, answering to the given distance AB and course PAB.

Now, since CE represents a very small portion of the distance AB, DE will be the correspondent portion of a meridian: hence the triangle EDC may be considered as rectilineal. If the distance be supposed to be divided into an infinite number of parts, each equal to CE, and upon those, triangles be constructed whose sides are portions of a meridian and parallel, it is evident these triangles will be equal and similar; for, besides the right angle, and hypotenuse which is the same in each, the course or angle CED is also the same. Hence, by the 12th of V. Euc. the sum of all the hypothenuses CE, or the distance AB, is to the sum of all the sides DE, or the difference of latitude AS, as one of the hypothenuses CE is to the corresponding side DE. Now, let the triangle GHI (fig. 16.) be constructed similar to the triangle CDE, having the angle G equal to the course: then as GH: GI :: CE: DC :: AB: AS.

Hence, if GH be made equal to the given distance AB, then GI will be the corresponding difference of latitude.

In like manner, the sum of all the hypothenuses CE, or the distance AB, is to the sum of all the sides CD, as CE is to CD, or as GH to HI, because of the similar triangles.

The several parts of the same rectilineal triangle will, therefore, represent the course, distance, difference of latitude, and departure.

Although the parts HG, GI, and angle G of the rectilineal triangle GHI, are equal to the corresponding parts AB, AS, and angle A, of the triangle ABB upon the surface of the sphere; yet HI is not equal to BS, for HI is the sum of all the arcs CD; but CD is greater than OQ, and less than ZX: therefore HI is greater than BS, and less than AR. Hence the difference of longitude MN cannot be inferred from the departure reckoned either upon the parallel sailed from, or on that come to, but on some intermediate parallel TV.
NAVIGATION.

By Calculation.

To find the course ($\beta$):

As the difference of latitude $- 98^\circ$ = $1.00123$

is to the difference of longitude $624^\prime$ = $2.78124$

so is the cosine of middle latitude $57^\circ 1^\prime$ = $9.73591$

to the tangent of the cosine $- 73^\circ 24^\prime$ = $12.35727$

To find the distance.

As radius $- 10.00022$

to the secant of the course $73^\circ 24^\prime$ = $12.34411$

so is the difference of latitude $98^\circ$ = $1.00123$

to the distance $- 343 = 2.33334$

By Inspection.

To middle latitude $57^\circ$, and $151$ one-fourth of the
difference of longitude in a distance column, the cor-
responding difference of latitude is $82.2$

Now $24.5$, one fourth of the difference of latitude, and $82.2$, taken in a departure column, are found to
agree nearest in table marked $65$ points at the bottom,
which is the course; and the corresponding distance
$8.5$ multiplied by $4$ gives $343$ miles, the distance re-
quired.

By Gunter's Scale.

The extent from $98$ the difference of latitude, is
$604$ the difference of longitude on numbers, being laid
the same way from $33^\circ$, the complement of the middle
latitude on sines, will reach to a certain point beyond
the termination of the line on the scale. Now the ex-
tent between this point and $90^\circ$ on sines, will reach
from $45^\circ$ to $73^\circ 24^\prime$, the course on the line of tangents.
And the extent from $73^\circ 24^\prime$ the course, to $33^\circ$ the
complement of the middle latitude on the line of sines,
being laid the same way from $604$ the difference of
longitude, will reach to $343$ the distance on the line of
numbers.

The true course, therefore, from the island of Man
to the Naze of Norway is $N 73^\circ 24^\prime$ $E$, ENE near; but as the variation at the May is $25$ points
west, therefore, the course per compass from the May is
$E 68^\circ$.

PROB. II. Given one latitude, course, and distance
sailed, to find the other latitude and difference of
longitude.

Example. A ship from Brest, in latitude $48^\circ 23^\prime$ N,
and longitude $4^\circ 30^\prime$ W, sailed SW $238$ miles. Re-
quired the latitude and longitude come to ?

By Construction.

With the course and distance construct the triangle
ABC (fig. 17.), and the difference of latitude $AB$, $C$,
being measured, will be found equal to $124$ miles:
hence the latitude come to is $46^\circ 1^\prime$ $N$, and the middle
latitude $47^\circ 12^\prime$. Now make the angle DBC equal
to...
ATTITUDE.

to 47° 12' 1' and DC being measured, will be 281, the difference of longitude: hence the longitude come to is

\[ 9° 11' W. \]

**By Calculation.**

| Longitude come to | 9° 11' W. |

**By Inspection.**

To the course 42 points, and distance 238 miles, the difference of latitude 141.8, and the departure 191.1. Hence the latitude come to 46° 1' N, and middle latitude 47° 12'. Then to middle latitude 47° 12', and departure 191.1 in a latitude column, the corresponding distance is 281, which is the difference of longitude.

**By Gunter's Scale.**

The extent from 8 points to 32 points, the complement of the course, on sine rhumbs, being laid the same way from the distance 238, will reach to the difference of latitude 142 on the line of numbers; the extent from 42° 48' the complement of the middle latitude, to 23° 26', the course on the line of sines, will reach from the distance 238 to the difference of longitude 281 on numbers.

**Prob. III.** Given both latitudes and course, required the distance and difference of longitude?

**Example.** A ship from St Antonio, in latitude 17° 0' N, and longitude 24° 25' W, sailed NW 4/4 N. Required the distance sailed, and longitude come to?

| Latitude St Antonio | 17° 0' N |
| Latitude by observation | 28 34' N |
| Difference of lat. | 41 34' 6044 |

**By Construction.**

Construct the triangle ABC (fig. 19.), with the given course and difference of latitude, and make the angle BCD equal to the middle latitude. Now the distance AC and difference of longitude DC being measured, will be found equal to 864 and 558 respectively.

**By Calculation.**

To find the distance.

| As radius | 1000000 |
| is to the secant of the course | 32 |
| so is the difference of lat. | 64 |
| To the distance | 864 |

To the difference of longitude.

| As the cosine of middle latitude | 22° 47' |
| is to the tangent of the course | 32 |
| so is the difference of latitude | 64 |
| To the difference of longitude | 558 |

| Longitude of St Antonio | 24° 25' W |
| Difference of longitude | 9° 18' W |

| Longitude come to | 33° 43' W |

**By Inspection.**

To course 32 points, and difference of latitude 231.3 one third of that given, the departure is 171.6 and distance 288, which multiplied by 3 is 864 miles. Again to the middle latitude 22° 47', or 23°, and departure 271.6 in a latitude column, the distance is 186, which multiplied by 3 is 558, the difference of longitude.

**By Gunter's Scale.**

The extent from 42 points, the complement of the course, to 8 points on the line of sine rhumbs, will reach from the difference of latitude 694 to the distance 864 on numbers; and the extent from the course 36° 34' to 67° 13', the complement of middle latitude on sines, will reach from the distance 864 to the difference of longitude 558 on numbers.

**Prob. IV.** Given one latitude, course, and departure, to find the other latitude, distance, and difference of longitude.

Example. A ship from latitude 26° 30' N, and longitude 45° 30' W, sailed NE 4/4 N till her departure is 216 miles. Required the distance run, and latitude and longitude come to?

**By Construction.**

With the course and departure construct the triangle ABC (fig. 20.), and the distance and difference of latitude being measured, will be found equal to 340 and 263 respectively. Hence the latitude come to is 30° 53', and middle latitude 28° 42'. Now make the angle BCD equal to the middle latitude, and the difference of longitude DC applied to the scale will measure 246°.

**By Calculation.**

To find the distance.

| As the sine of the course | 32 |
| is to radius | 1000000 |
| so is the departure | 216 |
| To the distance | 340 5 |

| To | 2 33445 |

*(e) This proportion is obvious, by considering the whole figure as an oblique-angled plane triangle.*
NAVIGATION.

To find the difference of latitude.

As the tangent of the course 34 points is to radius 216 so is the departure 216 to the difference of lat. 263.2 2.42028
Latitude sailed from 26° 30' N 26° 32' N
Difference of latitude 4 23N half 2 12N

Latitude come to 30 53 N Mid lat. 28 42
To find the difference of longitude.

As radius 10 0000 is to the secant of the mid. lat. 28° 42' so is the departure 216 2.33445
to the difference of longitude 246.2 2.39139
Longitude left 45° 30' W
Difference of longitude 4 6 E
Longitude come to 41 24 W

By Inspection.

Under the course 34 points, and opposite to 108, half the departure, the distance is 179, and difference of latitude 131.4; which doubled, give 340 and 263 for the distance and difference of latitude respectively.

Again, to middle latitude 28° 42', and depart 108, the distance is 123.1 which doubled is 246, the difference of longitude.

By Gunter's Scale.

The extent from the course 34 points, on sine rhumbs, to the departure 216 on numbers, will reach from 8 points on sine rhumbs to about 340, the distance on numbers; and the same extent will reach from 40 points, the complement of the course, to 263, the difference of latitude on numbers; and the extent from 61° 18' the complement of the middle latitude, to 90° on sines, will reach from the departure 216 to the difference of longitude 246 on numbers.

PROB. V. Given both latitudes and distance; to find the course and difference of longitude.

Example. From Cape Sable, in latitude 43° 24' N and longitude 65° 39' W, a ship sailed 246 miles on a direct course between the south and east, and is then by observation in latitude 40° 48' N. Required the course and longitude in?

Latitude Cape Sable, 43° 24' N
Latitude by observation, 40° 48' N
Difference of latitude, 2 36 = 2 46; sum 24 12
Middle latitude 42 6

By Construction.

Make AB (fig. 21) equal to 136 miles; draw BC perpendicular to AB, and make AC equal to 246 miles. Draw CD, making with CB an angle of 43° 6' the middle latitude. Now DC will be found to measure 256, and the course or angle A will measure 50° 39'.

By Calculation.

To find the distance.

As the distance 246 2.39093
so is radius 156 2.19372
so is radius of the course 50° 39' 9.82129

To find the difference of longitude.

As the cosine of middle latitude 42° 6' 9.87339
so is the distance 246 2.39093
to the difference of longitude 256.4 2.46888
Longitude Cape Sable, - - 65° 39' W
Difference of longitude 4 16 E
Longitude come to - - 61 23 W

By Inspection.

The distance 246, and difference of latitude 156, are found to correspond above 40 points, and the departure is 190.1. Now, to the middle latitude 42°, and departure 190.1 in a latitude column, the corresponding distance is 256, which is the difference of longitude required.

By Gunter's Scale.

The extent from 246 miles, the distance, to 156, the difference of latitude on numbers, will reach from 9° to about 39°, the complement of the course on the line of sines: and the extent from 48°, the complement of the middle latitude, to 50°, the course on sine, will reach from the distance 246 m. to the difference of longitude 56° on numbers.

PROB. VI. Given both latitudes and distance; sought the course, distance, and difference of longitude.

Example. A ship from Cape St. Vincent, in latitude 37° 2' N, longitude 5° 2' W, sailed between the south and west; the latitude come to is 18° 16' N, and departure 838 miles. Required the course and distance run, and longitude come to?

Latitude Cape St. Vincent, 37° 2' N
Latitude come to - - 18 16 N
Difference of latitude 18 46 = 2126 sum 55 18
Middle latitude 17 39

By Construction.

Make AB (fig. 22) equal to 1126 miles, and BC equal to the departure 838, and join AC; draw CD so as to make an angle with CB equal to the middle latitude 37° 39'. Then the course being measured on chords is about 36° 39', and the distance and difference of longitude, measured on the line of equal parts, will be found to be 1403 and 546 respectively.

By Calculation.

To find the course.

As the difference of latitude 1126 3.0574
so is the departure 838 2.9324
so is radius 10 0000

to the tangent of the course 36° 39' 9.87170
To find the distance.

As radius 10 0000
so is the secant of the course 36° 39' 10.0958
so is the difference of latitude 1126 3.0574

to the distance 1403 3.1472
NAVI GATION.

To find the difference of longitude.

| As radius | 10.00000 |
| is to the secant of mid. lat. | 47° 25' | 10.10583 |
| so is the departure | - | 210 |
| to the difference of longitude | 310.3 | 249185 |
| Longitude of Bourdeaux | - | 0° 35'W |
| Difference of longitude | 5 | 10 W |
| Longitude in | - | 5 45 W |

By Inspection.

The half of the distance 187, and of the departure 105, are found to agree nearest under 34°, and the difference of latitude answering thereto is 155; which doubled is 310 miles.

Again, to middle latitude 49° 25', and departure 105 in the latitude column, the corresponding distance is 155 miles, which doubled is 310 miles, the difference of longitude.

By Gunter's Scale.

The extent from the distance 374 miles to the departure 210 miles on the line of numbers, will reach from 90° to 34° 10', the course on the line of sines; and the extent from 90° to 50° 50', the complement of the course on sines, will reach from the distance 374 to the difference of latitude 309 miles on numbers.

Again, the extent from 42° 35', the complement of the middle latitude, to 90° on sines, will reach from the departure 210 to the difference of longitude 310 on numbers.

| As radius | 10.00000 |
| is to the secant of mid. lat. | 47° 25' | 10.10583 |
| so is the departure | - | 210 |
| to the difference of longitude | 310.3 | 249185 |
| Longitude of Bourdeaux | - | 0° 35'W |
| Difference of longitude | 5 | 10 W |
| Longitude in | - | 5 45 W |

PROB. VIII. Given one latitude, departure, and difference of longitude.

Example. A ship from Bourdeaux, in latitude 49° 50' N, and longitude 0° 35' W, sailed between the north and west 374 miles, and made 210 miles of westing. Required the course, and the latitude and longitude come to?

By Construction.

With the given distance and departure make the triangle ABC (fig. 23). Now the course being measured on the line of chords is about 34° 10', and the difference of latitude on the line of numbers is 309 miles: hence the latitude come to, is 49° 59' N, and middle latitude 47° 25'. Then make the angle BCD equal to 47° 25', and DC being measured will be 310 miles, the difference of longitude.

By Calculation.

To find the course.

| As the distance | - | 374 |
| is to the departure | - | 210 |
| so is the course | - | 2.57287 |
| to the sine of the course | - | 974.935 |

To find the difference of latitude.

| As radius | - | 10.00000 |
| is to the cosine of the course | - | 34° 10' |
| so is the distance | - | 374 |
| to the difference of latitude | - | 2.57287 |
| Latitude of Bourdeaux | - | 49° 50' N |
| Difference of latitude | - | 5° 30' |
| Latitude come to | - | 49° 59' N |

Vol. XIV. Part II.

| Diff. of latitude | - | 2 38 = 158 miles |

By Calculation.

To find the middle latitude.

| As the departure | - | 220 |
| is to the diff. of longitude | - | 396 |
| so is radius | - | 10.00000 |
| To the secant of mid. lat. | - | 56° 15' |
| Double, mid. lat. | - | 112 30' |
| Latitude left | - | 54 56' |
| Latitude come to | - | 57 34' |
NAVIGATION.

To find the course.

As the difference of latitude \(15^\circ\) 2.19866
is to the departure \(220\) 2.34242
so is radius \(10.00000\)
to the tangent of the course \(54^\circ 19'\) 10.14376
To find the distance.

As radius \(10.00000\)
is to the secant of the course \(54^\circ 19'\) 10.23410
so is the difference of latitude \(15^\circ\) 2.19866
to the distance \(270.9\) 2.43276

By Inspection.

As the differences of longitude and departure exceed the limits of the tables, let, therefore, their halves be taken; these are 198 and 110 respectively. Now these are found to agree exactly in the page marked 5 points at the bottom. Whence the middle latitude is \(56^\circ 15'\), and difference of latitude \(15^\circ 8\) miles.

Again, the difference of latitude 158 and departure 220 will be found to agree nearly above \(54^\circ\) the course, and the distance on the same line is 271 miles.

By Gunter's Scale.

The extent from the difference of longitude 306 to the departure 220 on numbers, will reach from \(90^\circ\) to \(33^\circ 45'\), the complement of the middle latitude on sines; and hence the difference of latitude is \(158\) miles. Now the extent from \(158\) to 220 on numbers, will reach from \(45^\circ\) to \(54^\circ\) on tangents; and the extent from the complement of the course \(35^\circ 45'\) to \(90^\circ\) on sines, will reach from the difference of latitude \(158\) to the distance \(271\) on numbers.

PROB. IX. Given the course and distance sailed, and difference of longitude; to find both latitudes.

Example. A ship from a port in north latitude, sailed S E 24 438 miles, and differed her longitude 7° 28'. Required the latitude sailed from, and that come to?

By Construction.

With the course and distance construct the triangle ABC (fig. 25.), and make DC equal to 448 the given difference of longitude. Now the middle latitude BCD will measure \(48^\circ 58'\), and the latitude of AB 324 miles: hence the latitude left is \(51^\circ 40'\), and that come to \(46^\circ 16'\).

By Calculation.

To find the difference of latitude.

As radius \(10.00000\)
is to the cosine of the course \(324\)\footnote{pts.} 986979
so is the distance \(2.64147\)
to the difference of latitude \(324.5\) 2.51126
To find the middle latitude.

As the difference of longitude \(448\)
is to the distance \(438\)
so is the sine of the course \(34\)\footnote{pts.} 9.82788
to the cosine of mid. latitude \(48^\circ 58'\) 9.81727
half difference of latitude \(2.42\)

Latitude sailed from \(51^\circ 40'\)
Latitude come to \(46^\circ 16'\)

By Inspection.

To the course 34 points, and half the distance 219 miles, the departure is 147,2; and difference of latitude 162.2; which doubled is 324.4. Again, to half the difference of longitude 224 in a distance column, the difference of latitude is 149.9 above 45°; and 146.9 over 45°.

Now, as 39 : 29 :: 60' : 38'.

Hence the middle latitude is 48° 58': the latitude sailed from is therefore 51° 40', and latitude come to 46° 16'.

By Gunter's Scale.

The extent from 8 points to 45 points, the complement of the course on sine columns, will reach from the distance 438 miles to the difference of latitude 324 in numbers. And the extent from the difference of longitude 448, to the distance 438 on numbers, will reach from the course 42° 11' to the complement of the middle latitude 41° 2' on sines. Hence the latitude left is 51° 40', and that come to 46° 16'.

PROB. X. To determine the difference of longitude made good upon compound courses, by middle latitude sailing.

RULE I. With the several courses and distances find the difference of latitude and departure made good, and the ship's present latitude, as in traverse sailing.

Now enter the traverse table with the given middle latitude, and the departure in a latitude column, the corresponding distance will be the difference of longitude, of the same name with the departure.

Example. A ship from Cape Clear, in latitude 38° 18' N, longitude 9° 46' W, sailed as follows:—SW 34 miles, W N 63 miles, NNW 48 miles, and NE 85 miles. Required the latitude and longitude come to?

<table>
<thead>
<tr>
<th>Courses</th>

<td>18.4</td>
</tr>
<tr>
<td>NE 85</td>
<td>85</td>
<td>53.9</td>
<td>65.7</td>
</tr>
</tbody>
</table>

Latitude of Cape Clear 51° 18' N

Latitude come to 52° 24' N

Sum 103° 42'

Middle latitude 51° 51'

Now, to middle latitude 51° 51', or 52°, and departure 44.5 in a latitude column, the difference of longitude is 72 in a distance column.

Longitude of Cape Clear 9° 46' W

Difference of longitude 1° 13' W

Longitude come to 10° 59' W

The above method is not always practised to find the difference of longitude made good in the course of
chapter.

**NAVIGATION.**

Theorem might be investigated for computing the Mercator's
errors to which the above method is liable. These cor-
rections may, however, be avoided, by using the follow-
ing method.

**Rule II.** Complete the traverse table as before, to
which annex five columns; the first column is to con-
tain the several latitudes the ship is at the end of
each course and distance; the second, the sums of each
following pair of latitude; the third, half the sums, or
middle latitudes; and the fourth and fifth columns are
to contain the differences of longitude.

Now find the difference of longitude answering to
each middle latitude and its corresponding departure,
and put them in the cast or west difference of longi-
tude columns, according to the name of the departure.
Then the difference of the sums of the east and west
columns will be the difference of longitude made good,
of the same name with the greater.

**Example.** A ship from Halliford in Iceland, in lat. 64° 36' N, long. 27° 15' W, sailed as follows: SSW 46
miles, SW 61 miles, S&W 59 miles, S&E 86 miles, S'E 79 miles. Required the lat. and long. come to?

Difference of longitude 34.1
Longitude Halliford 27.15 W
Longitude in 26.41 W

**Chap. VI. Of Mercator's Sailing.**

It was observed in Middle Latitude Sailing, that the
difference of longitude made upon an oblique rhumb
could not be exactly determined by using the middle
latitude. In Mercator's sailing, the difference of lon-
gitude is very easily found, and the several problems of
sailing resolved with the utmost accuracy, by the assist-
ance of Mercator's chart or equivalent tables.

In Mercator's chart, the meridians are straight lines
parallel to each other; and the degrees of latitude,
which at the equator are equal to those of longitude,
increase with the distance of the parallel from the equa-
tor. The parts of the meridian thus increased are call-
ed meridional parts. A table of these parts was first
constructed by Mr Edward Wright, by the continual
addition of the secants of each minute of latitude.

For by parallel sailing,

R : cos. of lat. :: part of equat. : similar part of parallel.

And
And because the equator and meridian on the globe are equal; therefore,

\[ R : \text{cos. lat.} : : \text{part of meridian} : \text{similar part of parallel.} \]

Or sec. lat. : \( R \) : : part of merid. : similar part of parallel.

Hence, part of meridian = part of parallel.

But in Mercator's chart the parallels of latitude are equal, and radius is a constant quantity. If, therefore, the latitude be assumed successively equal to \( 1^\circ, 2^\circ, 3^\circ \), &c. and the corresponding parts of the enlarged meridian be represented by \( a, b, c, \) &c.; then,

\[ \text{secant } 1' : \text{secant } 2' : \text{secant } 3' : \text{part of mer. } a : \text{part of mer. } b : \text{part of mer. } c, \] &c.

Hence secant \( 1' \) : part of mer. \( a \) :: secant \( 2' \) : part of mer. \( b \) :: secant \( 3' \) : part of mer. \( c \), &c.

Therefore by 12th V. Euclid.

Secant \( 1' \) of part of mer. \( a \) :: secant \( 1' + \text{secant } 2' + \text{secant } 3' \), &c.; parts of \( a + b + c \) of mer. \( c \), &c.

That is, the meridional parts of any given latitude are equal to the sum of the secants of the minutes in that latitude (\( \varepsilon \)).

Since \( CD : LK : R \) : \( \text{secant } LD \), fig. 15.

And in the triangle \( CED \),

\[ \text{ED} : \text{CD} : : R \text{ tangent } CED \]

Therefore, \( ED : \text{LK} : : R \text{ tangent } CED \)

Hence \( \text{ED} \times \frac{\text{secant } LD}{R} \times \text{tangent } CED \)

\[ \text{ED} \times \text{secant } LD = \frac{R \times \text{tangent } CED}{R} \]

But \( \frac{\text{ED} \times \text{secant } LD}{R} \) is the enlarged portion of the meridian answering to \( ED \). Now the sum of all the quantities \( \frac{\text{ED} \times \text{secant } LD}{R} \) corresponding to the sum of all the \( ED \)'s contained in \( AS \), will be the meridional parts answering to the difference of latitude \( AS \); and \( MN \) is the sum of all the corresponding portions of the equator \( LK \).

Whence \( MN = \text{mer. diff. of lat.} \times \text{tangent } \frac{CED}{R} \)

That is, the difference of longitude is equal to the meridional difference of latitude multiplied by the tangent of the course, and divided by the radius.

This equation answers to a right-angled rectilinear triangle, having an angle equal to the course; the adjacent side equal to the meridional difference of latitude, and the opposite side the difference of longitude. This triangle is, therefore, similar to a triangle constructed, with the course and difference of latitude, according to the principles of plane sailing, and the homologous sides will be proportional. Hence, if, in fig. 26. the angle \( A \) represents the course, \( AB \) the difference of latitude, and if \( AD \) be made equal to the meridional difference of latitude; then \( DE \), drawn perpendicular to \( AD \), meeting the distance produced to \( E \), will be the difference of longitude.

It is scarcely necessary to observe, that the meridional difference of latitude is found by the same rules as the proper difference of latitude; that is, if the given latitudes be of the same name, the difference of the secants referring to the corresponding meridional parts will be the meridional difference of latitude; but if the latitudes are of a contrary denomination, the sum of these parts will be the meridional difference of latitude.

Prob. I. Given the latitudes and longitudes of two places, to find the course and distance between them.

Ex. Required the course and distance between Cape Finisterre, in latitude \( 42^\circ 52' \) N., longitude \( 9^\circ 17' \) W., and Port Praya in the island of St. Jago, in latitude \( 14^\circ 54' \) N., and longitude \( 23^\circ 29' \) W.

Cape Finisterre \( 42^\circ 52' \) N., Mer. parts \( 28^\circ 32' \)

Port Praya \( 14^\circ 54' \) N., Mer. parts \( 92^\circ 42' \)

Difference of lat. \( = 27^\circ 35' \) Mer. diff. lat. \( 19^\circ 18' \)

Longitude Cape Finisterre \( 9^\circ 17' \) W.
Longitude Port Praya \( 23^\circ 29' \) W.

Diff. longitude \( = 14^\circ 12' = 852 \)

By Construction.

Draw the straight line \( AD \) (fig. 26.) to represent the meridian of Cape Finisterre, upon which lay off \( AB \), equal to \( 1678 \), and \( 1948 \), the proper and meridional differences of latitude; from \( D \) draw \( DE \) perpendicular to \( AD \), and equal to the difference of longitude \( 852 \), join \( AE \), and draw \( BC \) parallel to \( DE \); then the difference \( AC \) will measure \( 1831 \) miles, and the course \( 23^\circ 37' \).

By Calculation.

To find the course.

As the meridian difference of lat. \( 1948 \) is to the difference of longitude \( 852 \), so is radius \( 100000 \)

To the tangent of the course \( 23^\circ 37' \) is to the difference of latitude \( 1831 \), so is radius \( 100000 \)

To find the distance.

As radius \( 100000 \) is to the secant of the course \( 23^\circ 37' \), so is the difference of latitude \( 1678 \), to the distance \( 100000 \), so is the difference of latitude \( 1678 \), to the distance \( 3847 \)

By Inspection.

As the meridian difference of latitude and difference of longitude are too large to be found in the tables, let the tenth of each be taken; these are \( 194.8 \) and \( 8.1 \) respectively. Now these are found to agree nearest under \( 24^\circ \); and to \( 167.8 \), one-tenth of the proper difference of latitude, the distance is about \( 183 \) miles, which multiplied by 10 is \( 1830 \) miles.

By Gunter's Scale.

The extent \( 1948 \), the meridional difference of latitude, to \( 852 \), the difference of longitude on the bar of numbers, will reach from \( 45^\circ \) to \( 23^\circ 37' \), the course

\( \varepsilon \) This is not strictly true; for instead of taking the sum of the secants of every minute in the distance of the given parallel from the equator, the sum of the secants of every point of latitude should be taken.
NA 

VIGATION.

Prob. II. Given the course and distance, sailed from a place whose situation is known, to find the latitude and longitude of the place come to.

Example. A ship from Cape Hinlopen in Virginia, in latitude 38° 47' N., longitude 75° 4' W., sailed 267 miles NE by N. Required the ship's present place?

By Construction.
With the course and distance sailed, construct the triangle ABC (fig. 27.); and the difference of latitude AB being measured, is 222 miles; hence the latitude come to is 42° 20' N., and the meridional difference of latitude 293. Make AD equal to 293; and draw DE perpendicular to AD, and meeting AC produced in E; then, the difference of longitude DE being applied to the scale of equal parts will measure 196; the longitude come to is therefore 71° 48' W.

By Calculation.
To find the difference of latitude.

As radius
is to the cosine of the course, - 3 points
so is the distance

\[
\frac{10,00000}{9.91985} = 2.42651
\]

to the difference of latitude - 222
Lat. Cape Hinlopen = 38° 47' N. Mer. parts 2528
Difference of lat. - 3 42 N.
Latitude come to - 42 29 N. Mer. parts 2821

Meridional difference of latitude
To find the difference of longitude.

As radius
is to tangent of the course, - 3 points
so is the mer. diff. of latitude

\[
\frac{10,00000}{9.92489} = 1.26872
\]

to the difference of longitude - 195 8
Longitude Cape Hinlopen
Difference of longitude - 3 16 E
Longitude come to - 71 48 W.

By Inspection.
To the course 3 points, and distance 267 miles, the difference of latitude is 222 miles: hence the latitude in is 42° 20', and the meridional difference of latitude 293. Again, to course three points, and 146.5 half the mer. difference of latitude, the departure is 97.9, which doubled is 195.8, the difference of longitude.

By Gunter's Scale.
The extent from 8 points to the complement of the course 7 points, on sine rhumbs, will reach from the distance 267 to the difference of latitude 222 on numbers; and the extent from 4 points to 3 points on tangent rhumbs, will reach from the meridional difference of latitude 293 to the difference of longitude 196 on numbers.

Prob. III. Given the latitudes and bearing of two places; to find their distance and difference of longitude.

Example. A ship from Port Canso in Nova Scotia, Mercator's in latitude 45° 20' N., longitude 60° 55' W., sailed SE. Sailing 14° 14' N. Required the distance sailed, and longitude come to?
Lat. Port Canso - 45° 20' N. Mer. parts - 3058
Lat. in by observation - 41° 14' N. Mer. parts - 2720
Difference of lat. - 4 6 = 246 Mer. diff. lat. 338

By Construction.
Make AB (fig. 28.) equal to 246, and AD equal Fig. 28. to 338; draw AE, making an angle with AD equal to 33 points, and draw BC, DE perpendicular to AD. Now AC being applied to the scale, will measure 332, and DE 306.

By Calculation.
To find the distance.
As radius
is to the secant of the course, - 3 points
so is the difference of latitude

\[
\frac{10,00000}{10.13021} = 2.39093
\]

to the distance - 332
Long. Port Canso - 60° 55' W.
Difference of longitude - 5 6 E
Longitude in - 53 49 W.

By Inspection.
Under the course 33 points, and opposite to half the difference of latitude 123 in a latitude column is 166 in a distance column, which doubled is 332 the distance; and opposite to 169, half the meridional difference of latitude in a latitude column, is 153 in a departure column, which doubled is 306, the difference of longitude.

By Gunter's Scale.
The extent from the complement of the course 43 points to 8 points on sine rhumbs, will reach from the difference of latitude 246 m. to the distance 352 on numbers; and the extent from 4 points, to the course 34 points on tangent rhumbs, will reach from the meridional difference of latitude 338 to the difference of longitude 356 on numbers.

Prob. IV. Given the latitude and longitude of the place sailed from, the course and departure; to find the distance, and the latitude and longitude of the place come to.
Example. A ship sailed from Sallee in latitude 33° 58' N., longitude 6° 20' W., the corrected course was NW by W, and departure 430 miles. Required the distance run, and the latitude and longitude come to?

By Construction.
With the course and departure construct the triangle ABC (fig. 29.); now AC and AB being measured, Fig. 19. will be found to be equal to 476 and 224 respectively; hence
NAVIGATION.

Lat. of St Mary's, \(36^\circ 57'\) N. Mer. parts 3470 Mer. 
Lat. come to \(49^\circ 57'\) N. Mer. parts 2380 Bart. 

Difference of lat. 13 0 Mer. diff. lat. 1081 

780

By Construction.

Make AB (fig. 30.) equal to 782, and AD equal \(56^\circ\) to 1081; draw BC, DE perpendicular to AD; make AC equal to 1162, and through AC draw ACE. Then the course or angle A being measured, will be found equal to \(47^\circ 50'\), and the difference of longitude DE will be 1194.

By Calculation.

To find the course.

As the distance \(1162\) \(3.06521\) 
is to the difference of longitude, \(780\) \(2.84299\) 
so is radius \(10.00000\) \(10.00000\) 

to the cosine of the course \(47^\circ 50'\) \(9.82653\) 

To find the difference of longitude.

As radius \(10.00000\) 
is to the tangent of the course, \(47^\circ 50'\) \(10.04312\) 
so is the mer. diff. of latitude \(1081\) \(3.3333\) 

to the difference of longitude \(1194\) \(3.0783\) 

Longitude of St Mary's \(23^\circ 9'\) W. 

Longitude of difference \(19^\circ 54'\) W. 

Longitude in \(5^\circ 15'\) W.

By Inspection.

Because the distance and difference of latitude exceed the limits of the table, take the tenth of each; these are 116.2 and 78.0: Now these are found to agree nearest above 45 points, which is therefore the course; and to this course, and opposite to 108.1, one tenth of the meridional difference of latitude, in a latitude column, is 119.3 in a departure column, which multiplied by 10 is 1193, the difference of longitude.

By Gunter's Scale.

The extent from the distance 1162 m. to the difference of latitude 780 m. on numbers, will reach from \(90^\circ\) to \(43^\circ 10'\) in the line of sines. And the extent \(47^\circ\) to the course \(47^\circ 50'\) on the line of tangents, will reach from the meridional difference of latitude 1081 to the difference of longitude 1194 on numbers.

PROB. VI. Given the latitudes of two places, and the departure, to find the course, distance, and difference of longitude.

Example. From Aberdeen, in latitude \(57^\circ 9'\) N. longitude \(20^\circ 8'\) W., a ship sailed between the south and east till her departure is 146 miles, and latitude come to \(53^\circ 32'\) N. Required the course and distance run, and longitude come to?

Latitude Aberdeen \(57^\circ 9'\) N. Mer. parts 4199 
Latitude come to \(53^\circ 32'\) N. Mer. parts 3917 

Difference of latitude \(3^\circ 37'\) = 217' Mer. diff. lat. 382 

By Construction.

With the difference of latitude 217 m. and departure 146 m. construct the triangle ABC (fig. 31.), make AD.
NAVIGATION.

By Calculation:

To find the course.

As the difference of latitude 217 - 2.33646
so is radius - 146 - 2.16435

so is the tangent of the course - 33° 56' - 9.8279
To find the distance.

As radius - 10.0000
so is the secant of the course - 33° 56' - 10.08109
so is the difference of latitude 217 - 2.33646

to the distance - 261.5 - 2.41755
To find the difference of longitude.

As the difference of latitude 217 - 2.33646
so is the mer. diff. of latitude 382 - 2.58206
so is the departure - 146 - 2.16435

to the difference of longitude 227 - 2.40995
Longitude of Aberdeen - 2° 8' W
Difference of longitude - 4° 17' E

Longitude come to - 2° 9' E

By Inspection.

The difference of latitude 217, and departure 146, are found to agree nearest under 34°, and the corresponding distance is 262 miles. To the same course, and opposite to 190.7, the nearest to 191, half the meridional difference of latitude, is 128.6 in a departure column, which doubled is 257, the difference of longitude.

By Gunter's Scale.

The extent from the difference of latitude 217, to the departure 146 on numbers, will reach from 43° to about 34°, the course on the line of tangents; and the same extent will reach from the meridional difference of latitude 382 to 257, the difference of longitude on numbers.—Again, the extent from the course 34° to 90° on sines, will reach from the departure 146 to the distance 261 on numbers.

PROB. VII. Given one latitude, distance and departure; to find the other latitude, course, and difference of longitude.

Example. A ship from Naples, in latitude 45° 51' N., longitude 12° 14' W., sailed 272 miles on a direct course between the south and west, and made 173 miles of westing. Required the course made good, and the latitude and longitude come to?

By Construction.

With the distance and departure make the triangle ABC (fig. 32.) as formerly.—Now the course BAC being measured by means of a line of chords will be found equal to 43° 21', and the difference of latitude applied to the scale of equal parts will measure 183': hence the latitude come to is 37° 48' N., and meridional difference of latitude 237.—Make AD equal to 237, and complete the figure, and the difference of longitude DE will measure 224': hence the longitude in is 10° 30' E.

By Calculation:

To find the course.

As the distance - 252 - 2.40140
so is radius - 173 - 2.23805

so is the cosine of the course - 43° 21' - 9.86164
To find the distance, 252 - 2.40140

so is the distance - 183.2 - 2.63202
Latitude of Naples - 43° 51' N. Mer. parts 2693
Difference of latitude - 3° 3' S.

Latitude come to - 37° 48' N. Mer. parts 2453

Meridional difference of latitude - 237
To find the difference of longitude.

As radius - 10.0000
so is the tangent of the course - 43° 21' - 9.97497
so is the mer. diff. of latitude - 237 - 2.37475

to the difference of longitude - 223.7 - 2.34972
Longitude of Naples - - 14° 14' E
Difference of longitude - 3° 44' W.

Longitude in - 10° 30' E

By Inspection.

Under 43° and opposite to the distance 252 m. the departure is 171.8, and under 44°, and opposite to the same distance, the departure is 175.0.

Then as 3.2 : 1.2 : : 60' : 22'.
Hence the course is 43° 22'.

Again, under 43° and opposite to 118.5, half the meridional difference of latitude in a departure column, is 110.5 in a departure column; also under 44° and opposite to 118.5 is 114.4.

Then as 3.2 : 1.2 : : 3.9 : 1.5.
And 110.5+1.5=112, which doubled is 224, the difference of longitude.

By Gunter's Scale.

The extent from the distance 252 on numbers, to 90° on sines, will reach from the departure 173 on numbers, to the course 43° on sines; and the same extent that will reach from the complement of the course 43° on sines will reach to the difference of latitude 183 on numbers.—Again, the extent from 43° to 43° on tangents will reach from the meridional difference of latitude 237, to the difference of longitude 224, on numbers.

PROB. VIII. Given one latitude, course, and difference of longitude: to find the other latitude and distance.

Example. A ship from Tercera, in latitude 38° 45' N., longitude 27° 6' W., sailed on a direct course, which, when corrected, was N 32° E, and is found by observation to be in longitude 18° 24' W. Required the latitude come to, and distance sailed?

Longitude
By Construction.

Make the right-angled triangle ADE (Fig. 23,) having the angle A equal to the course 32°, and the side DE equal to the difference of latitude 522; then AD will measure 835, which added to the meridional parts of the latitude left, will give those of the latitude come to 48° 46'. Hence, the difference of latitude is 601: make AB equal thereto, to which let BC be drawn perpendicular; then AC applied to the scale will measure 708 miles.

By Calculation.

To find the meridional difference of latitude.

As radius is to the co-tangent of the course 32° 32. 10.00000
so is the difference of longitude 5 22 2.71767

To the mer. difference of latitude 835 2.92188

Latitude of Tercera 30° 45' N. Mer. parts 526
Mer. diff. of lat. 835

Latitude come to 48° 46' N Mer. parts 3361

Difference of latitude 10 1 = 601 miles.

To find the distance.

As radius is to the secant of the course 32° 32. 10.07158
so is the difference of latitude 601 2.77887

to the distance 707.7 2.85045

By Inspection.

To course 32°, and opposite to 130.5, one fourth of the given difference of longitude in a departure column, the difference of latitude 208.8, which multiplied by 4 is 835, the meridional difference of latitude; hence the latitude in is 48° 46' N, and difference of latitude 601.

Again, to the same course, and opposite to 200, one third of the difference of latitude, the distance is 236, which multiplied by 3 gives 708 miles.

By Gunter's Scale.

The extent from the course 32°, to 45° on tangents, will reach from the difference of longitude 522 to the meridional difference of longitude 835 on numbers. And the extent from the complement of the course 58° to 90° on sines, will reach from the difference of latitude 601, to the distance 708 miles on numbers.

Prob. IX. To find the difference of longitude made good upon compound courses.

Rule. With the several courses and distances, complete the Traverse Table, and find the difference of latitude, departure, and course made good, and the latitude come to as in Traverse Sailing. Find also the meridional difference of latitude.

Now to the course and meridional difference of latitude, in a latitude column, the corresponding departure will be the difference of longitude, which applied to the longitude left will give the ship's present longitude.

Example. A ship from port St Julian, in latitude 49° 10' S, longitude 68° 44' W, sailed as follows: 1st ESE 53 miles, SE by E 74 miles, E by N 68 m. SE by E 47 miles, and E 84 miles. Required the ship's present place?

</table>

Although the above method is that usually employed at sea to find the difference of longitude, yet as it has been already observed, it is not to be depended on, especially in high latitudes, long distances, and considerable variation in the courses, in which case the following method becomes necessary.

Rule II. Complete the Traverse Table as before, to which annex five columns. Now with the latitude left, and the several differences of latitude, find the successive latitudes, which are to be placed in the first of the annexed columns; in the second, the meridional parts corresponding to each latitude is to be put; and in the third, the meridional differences of latitude. Then to each course, and corresponding meridional difference of latitude, find the difference of longitude, by Prob. VI, which place in the fourth or fifth columns, according as the coast is easterly or westerly; and the difference between the sums of these columns will be the difference of longitude made good upon the whole, of the same name with the greater.

Remarks.

1. When the course is north or south, there is no difference of longitude.

2. When the course is east or west, the difference of longitude cannot be found by Mercator's Sailing; in this case the following rule is to be used.

To the nearest degree to the given latitude taken as a course, find the distance answering to the departure in a latitude column; this distance will be the difference of longitude.
**NAVIGATION.**

**Ex. 1.** Four days ago we took our departure from Faro-head, in latitude $58^\circ 40^\prime$ N, and longitude $4^\circ 50^\prime$ W, Mercator's arg. and since have sailed as follows: NW 32 miles, W 69 miles, WNW 93 miles, W8 77 miles, SW 58 miles, Sailing and W S 49 miles.—Required our present latitude and longitude?

The error of this method, in the present example, is therefore $1^\circ 23^\prime$.

Now to 78.5 half the meridional difference of latitude, and 185.0 half the difference of longitude, the course 67°, and opposite to the difference of latitude 27, the distance is 69 miles.—Hence Hacluit's headland bears S 67° E, distant 69 miles.
Method of resolving the Problems of Mercator's Sailing.

Chap. VII. Containing the Method of resolving the several Problems of Mercator's Sailing, by the Assistance of a Table of Logarithmic Tangents.

Prob. I. Given one latitude, distance, and difference of longitude; to find the course, and other latitude.

Rule. To the arithmetical complement of the logarithm of the distance, add the logarithm of the difference of longitude in minutes, and the log. cosine of the given latitude; the sum rejecting radius will be the log. sine of the approximate course.

To the given latitude taken as a course in the traverse table, add half the difference of longitude in a distance column; the corresponding departure will be the first correction of the course, which is subtractive if the given latitude is the least of the two; otherwise, additive.

In Table A, under the complement of the course, and opposite to the first correction in the side column, is the second correction. In the same table find the number answering to the course at the top, and difference of longitude in the side column; and such part of this number being taken as is found in Table B opposite to the given latitude, will be the third correction. Now these two corrections, subtracted from the course corrected by the first correction, will give the true course.

Now the course and distance being known, the difference of latitude is found as formerly.

Example. From latitude 50° N., a ship sailed 290 miles between the south and west, and differed her longitude 5°. Required the course, and latitude come to?

Distance = 290. ar. co. log. 7.53760
Diff. of longitude = 300 log. 2.47712
Latitude = 50° c. co. = 9.80807

Approximate course = 41 41 sine = 9.82279
To lat. 50°, and half diff. long. 150 in a dist.

The first cor. in a dep. co. is 115 = +1 55

Approximate course = 41 41
Cor. = 1 55

It the table A to co. course 45° and 1st corr. = 0 2

To course 41° and diff. long. 5°, the number is 15, of which 1 (Tab. B) being

taken, gives

True course = 8, 43 31 W.

To find the difference of latitude.

As radius = 10,00000
is to the cosine of the course = 43° 33' = 9.3630
so is the distance = 290 = 2.46240

to the difference of latitude = 210.2 = 2.33260
Latitude left = 58° 30' N.
Difference of latitude = 3 30 S.

Latitude come to = 46° 30' N.

This problem was proposed, and resolved, by Mr. Robert Hues in his Treatise on the Globes, printed at London in the year 1639, p. 181.

It was afterwards proposed by Dr. Halley, in the second volume of the Miscellanea Curiosa, p. 34, in the following words:

A ship sails from a given latitude, and, having run a certain number of leagues, has altered her longitude by a given angle; it is required to find the course steered.

And he then adds—The solution hereof would be very acceptable, if not to the public, at least to the author of this tract, being likely to open some further light into the mysteries of geometry.

Since that time, this problem has been solved in an indirect manner, by several writers on navigation, and others,—As Monsieur Bouger, in his Nouveau Traité de Navigation; Mr. Robertson, in the second volume of his Elements of Navigation; Mr. Emerson, in his Theory of Navigation, which accompanies his Mathematical Principles of Geography; Mr. Israel Lyons, in the Nautical Almanack for 1772; and Monsieur Bezout, in his Traité de Navigation; and lately, Baron Masereis, with the assistance of Mr. Attwood, has given the first direct solution of this problem. For a comparison of the various solutions which have hitherto been made of this problem, the reader is referred to that by Dr. Mackay, in the fourth and sixth volumes of Baron Masereis's Scriptores Logarithmici.

It was intended in this place to have given rules, to make allowance for the spheroidal figure of the earth: but as the ratio of the polar to the equatorial semi-axis is not as yet determined with sufficient accuracy, neither is it known if both hemispheres be similar figures; therefore these rules would be grounded on assumption only, and might probably err more from the truth.

By Calculation.

In the triangle BIF are given BI and BF equal to 30 miles, and 26 miles respectively; and the angle BFI equal to 7 points: To find the side FI, and angle FBI.

To find the angle BIF.

As the distance BI - 30 - 1.59106
so is the distance BF - 26 - 1.41497

so is the sine of BFI - 78° 45' - 0.999157

to the sine of BIF - 40 50 - 0.81548

Sum - - 119 35

Angle FBI - - 60 25

Difference, or EBI - - 33 45

Bearing of Jersey from Brehaut N 63° 20 E.

To find the distance FI.

As the sine of BFI - 78° 45' - 0.999157
so is the distance BF - 30 - 0.999157
so is the distance BI - 39 miles - 1.59106

to the distance FI - 34° 58' - 1.53883

Ex. 3. At noon Dungeness bore N 63° 20 E.

To find the bearing of Dungeness from Beachyhead.

By Calculation.

Describe a circle (fig. 36.) to represent the horizon: from the centre C draw the N6W line CD equal to 15 miles; and the NW6W line CB equal to 35 miles: Join DB, which applied to the scale will measure about 26° 48'; and the inclination of DB to the meridian will be found equal to N 79° 28 W.

By Construction.

In the triangle DCB are given the distances CD, CB equal to 15 and 35 miles respectively; and the angle BCD equal to 4 points; to find the angles B and D, and the distance BD.

To find the angles.

Distance CB=35, sum of the ang. 16 points.
CD=15, angle C = 4

Sum - 50, angles B and D 12

Difference 20, half sum - 6 pts. = 67° 32'
As the sum of the distances - 50 - 1.69897
is to their difference - 20 - 1.03013
so is the tang. of half sum angles 67° 30' - 10.38378

to the tangent of half their diff. 44 0 - 9.98484

Angle CDB - - 111 39

Supplement - - 68 30

Angle, NCD - - 11 15

Magnetic bearing - N 79° 45 W. Or by allowing 2° points of westerly variation, the true bearing of Beachyhead from Dungeness will be W4S nearly.

Ex. 4. Running up Channel E8s per compass at the rate of 5 knots an hour. At 11h A. M. the Eddistone lighthouse bore NEE4E, and the Start point NE6E; and at 4 P. M. the Eddistone bore NW6N, and the Start N4E. Required the distance and bearing of the Start from the Eddistone, the variation being 2° points being allowed to the left of compass.

**By Construction.**

Let the point C (fig. 37.) represent the first station, from which draw the NEE4E line CA, the NEAE4E line CB, and the E8s line CD, which make equal to 25 miles the distance run in the elapsed time; then from D draw the NEAN line DA intersecting CA in A, which represents the Eddistone; and from the same point draw the N4E line DB cutting CB in B, which therefore represents the Start. Now the distance AB applied to the scale will measure 22.8, and the bearing per compass BAF will measure 73°.

**By Calculation.**

In the triangle CAD are given CD equal to 25 miles, the angle CAD equal to 42° points, the distance between NEE4E and NW6N; and the angle ADC equal to 4 points, the distance between the NW6N and W4N points; to find the distance CA.

As the sine of CAD | 42° points | 9.86979 |
| is to the sine of CDA | 4 points | 9.84948 |
| so is the distance CD | 25 miles | 1.39794 |

to the distance CA

23.86 | 1.37753 |

In the triangle BCD, are given the distance CD 25 miles, the angle CBD 45° points the interval between NEAE4E and N4E; and CDB 72° points, the distance between W4N and N4E; to find the distance CD.

As the sine of CBD | 45° points | 9.89819 |
| is to the sine CDB | 72° points | 9.99947 |
| so is the distance CD | 25 miles | 1.39794 |

to the distance CB

32.3 | 1.50922 |

In the triangle CAB, the. distances CA, CB, are given, together with the included angle ACB, equal to 4 points, the distance between NEE4E and NEAE4E; to find the angle CAB and distance AB.

Distance AB 32.3 | Angle ACB = 45°

Distance CA 23.86 | Sum of CAB and ABC 135°

Sum 56.16 | Half 69 30

Difference 8.44 |

As the sum of the distances 56.16 | 1.74943 |
| is to their difference 8.44 | 0.92834 |
| so is the tangent of half sum angles 67 30 | 10.38278 |
| to the tangent of half diff. angles | 19 56 | 9.55969 |

Angle CAB | 87 26 |
Angle CAN | 14 4 |

Bearing per compass S 73 22° E or E8E4E, and

the variation 2° points being allowed to the left of compass, gives E4N, the true bearing of the Start from the Eddistone.

By Construction.

With the meridional difference of latitude, the difference of longitude, and difference of latitude, construct the triangles ADE, ABC (fig. 38.) as in Mer. Fegrator's Sailing, then A will represent the northermost, and C the southernmost port. The distance AC applied to the scale will measure 53 miles, and the bearing BCA will be 25°5. From the points A and C, with distances equal to 82 and 100 miles respectively, describe arches intersecting each other in M, which will therefore be the place of meeting.—Now the angle A, BCA, the ship's course from the southernmost port, will measure N 80° E; and the other ship's course, or angle BAM, will be 67° 48′, or E8E. From M draw the parallel MNP, and AN will be the difference of latitude made by the one ship, and CP that by the other ship: hence either of these being measured and applied to its correspondent latitude, will give 30° 38′, the latitude in. Make AF equal to 57, the meridional difference of latitude between the northermost port and latitude in: from F draw FG perpendicular to AF, and produce AM to G, then FG will be the difference of longitude, which applied to the scale will measure 139° hence the longitude in is 80° 16′ E.

By Calculation.

In the triangle ADE, ABC, are given AD equal to 87, DE equal to 41, and AB equal to 48; to find the angle BAC and distance AC.

To find the bearing of the ports.

As the meridional diff. of lat. 87 | 1.3931 |
| is to the diff. of long. | 41 | 0.61278 |
| so is radius | - | 10.00000 |

to the tangent of the bearing 25° 14′ | 9.67256 |

To find the distance of the ports.

As radius | 10.00000 |
| is to the secant of the bearing | 25° 14′ | 0.04355 |
| so is the diff. of latitude | 48 | 1.68244 |

to the distance | 53.06 | 1.72459 |

In the triangle AMC, the three sides are given to find the angles.
NAVIGATION.

\[ 1.75487 \]

to the diff. of long. = 139.8

Longitude left = 2° 9' W

Longitude in = 0° 11'

CHAP. IX. Of Windsward Sailing.

Windsward sailing is, when a ship by reason of a contrary wind is obliged to sail on different tacks in order to gain her intended port; and the object of this sailing is to find the proper course and distance to be sailed on each tack.

Ex. 1. A ship is bound to a port 48 miles directly to the windward, the wind being SSW, which it is intended to reach on two boards; and the ship can lie within six points of the wind. Required the course and distance on each tack?

By Construction.

Draw the SSW line CB (fig. 39) equal to 48 miles. Make the angles ACB, ABC, each equal to 6 points. Hence the first course will be W, and the second SE; also the distance CA, or AB, applied to the scale, will measure 62½ miles, the distance to be sailed on each board.

By Calculation.

From A draw AD perpendicular to BC; then in the triangle ADC are given CD equal to 24 miles, and the angle ACD, equal to 6 points, to find the distance AC. As radius

\[ 10.00000 \]

Is to the secant of C = 6 points

\[ 10.47116 \]

So is CD = 24 miles

\[ 1.38021 \]

to CA = 62.7

\[ 1.79737 \]

Ex. 2. The wind at NW, a ship bound to a port 64 miles to the windward, proposes to reach it on three boards; two on the starboard, and one on the larboard tack, and each within 5 points of the wind. Required the course and distance on each tack?

By Construction.

Draw the NW line CA (fig. 40) equal to 64 miles; Fig. 40; from C draw CB WBS, and from A draw AD parallel thereto, and in an opposite direction; bisect AC in E, and draw BED parallel to the NEE rhumb, meeting CB, AD in the points B and D; then CB = AD applied to the scale will measure 36½ miles, and BD = 2CB = 73½ miles.

By Calculation.

From B draw BF perpendicular to AC; then, in the triangle BFC are given the angle BCF equal to 5 points, and CF equal to one-fourth of CA = 16 m. to find CB.

As radius

\[ 10.00000 \]

Is to the secant of BCF = 5 points

\[ 10.25526 \]

So is CF = 16 m.

\[ 1.20412 \]

to CB = 36.25

\[ 1.55938 \]

Ex. 3. A ship which can lie within 5½ points of the wind, is bound to a port 36 miles to the windward, the wind being NE of N, which it is intended to reach on four boards, the first being on the larboard tack. Required the course and distance on each tack?

By Construction.

Draw the NE line 6A (fig. 41) equal to 36 Fig. 41; miles, and bisect it in B; from C and B draw lines parallel to the ENE rhumb, and from A and B draw lines parallel to the SSW line, meeting the former in the points D and E. Now the distances AD, BD, BE, and CE, are equal; and any one of them applied to the scale will measure 19.1 miles.

By Calculation.

From E draw EF perpendicular to AC; and in the triangle EFE are given CF = 9 m., and the angle FCE = 5½ points, to find CE.
NAVIGATION.

To find CB, the distance on the larboard tack.

As the sine of B is to the sine of E, so is the distance CE to the distance BC.

Ex. 4. A ship bound to a port bearing N\(\overset{-}{\text{W}}\) distant 40 miles, with the wind at N\(\overset{-}{\text{E}}\)\(\overset{-}{\text{W}}\), intends to reach it on two boards. Required the course and distance on each tack, the ship lying within 52° points of the wind?

By Construction.

Draw the N\(\overset{-}{\text{E}}\)\(\overset{-}{\text{W}}\) line CA (fig. 42.) equal to 40 miles; and because the wind is N\(\overset{-}{\text{E}}\)\(\overset{-}{\text{W}}\), and the ship can lie within 52° points of the wind, the course on the larboard tack will be E\(\overset{-}{\text{S}}\)\(\overset{-}{\text{W}}\), and on the starboard NW. Therefore, from the centre C draw the E\(\overset{-}{\text{S}}\)\(\overset{-}{\text{W}}\) line CB, and from it draw the NW line AB, meeting CB in B; then CB and AB applied to the scale will measure 26.7 and 48.1 miles respectively.

By Calculation.

In the triangle ACB, given AC=40 miles, and the angles A, B, and C, equal to 3, 5, and 8 points respectively, to find AB and BC.

To find the distance CB.

As the sine of B is to the sine of A, so is the distance CA to the distance CB.

Ex. 5. A ship close hauled within 5 points of the wind, and making one point of leeway, is bound to a port bearing SSW distant 54 miles, the wind being S\(\overset{-}{\text{S}}\)\(\overset{-}{\text{E}}\): It is intended to make the port at three boards, the first of which must be on the larboard tack in order to avoid a reef of rocks. Required the course and distance on each tack?

By Construction.

Draw the SSW line CA (fig. 43.) equal to 54 m., and as the wind is S\(\overset{-}{\text{S}}\)\(\overset{-}{\text{E}}\), the ship makes her course good within 6 points of the wind, therefore the course on the larboard tack will be SW\(\overset{-}{\text{S}}\)\(\overset{-}{\text{W}}\), and on the starboard E\(\overset{-}{\text{E}}\)\(\overset{-}{\text{S}}\)\(\overset{-}{\text{W}}\): hence from C draw the SW\(\overset{-}{\text{S}}\)\(\overset{-}{\text{W}}\) line CB, and from A draw AD parallel thereto; bisect CA in E, and draw BED parallel to the E\(\overset{-}{\text{E}}\)\(\overset{-}{\text{S}}\)\(\overset{-}{\text{W}}\) line; then will CB and AD be the distances on the larboard tack, which applied to the scale, each will be found to measure 37.4; and the distance on the starboard tack BD will measure 42.4 miles.

By Calculation.

The triangles CBE, EAD are equal and similar; hence in the first of these are given CE, equal to 27 miles, half the distance between the ship and port; the angles C, B, and E, equal to 3, 4, and 9 points respectively, to find CB and BE.
NAVIGATION

Ex. 1. A ship sailed NNE at the rate of 8 knots an hour, during 18 hours, in a current setting NW8W2\degree
miles an hour. Required the course and distance made
good?

By Construction.

Draw the NNE line CA (fig. 45.) equal to 18 x 8
144 miles; and from A draw AB parallel to the
NW8W rhumb, and equal to 18 x 25 = 45 miles: now
BC being joined will be the distance, and NCB the
course. The first of these will measure 159 miles, and
the second 6\degree 23\'.

By Calculation.

In the triangle ACB, are given AC=144 miles,
AB=45 miles, and the angle CAB=9 points, to find
BAC and BC.

To find the course made good.

\[
\begin{align*}
\text{Dist. AC} & = 144 \\
\text{Dist. AB} & = 45 \\
\text{Sum} & = 189 \\
\text{Diff.} & = 99
\end{align*}
\]

\[
\begin{align*}
\text{As the sum of the sides} & = 189 \quad \text{is to the difference of the sides} & = 99 \quad \text{so is the tan. of half sum angles} & = 39 \frac{22}{2} \quad \text{tan. of half diff. angles} = 23 \frac{15}{7} \\
\text{Angle ACB} & = 16 \quad 7 \\
\text{Angle ACD} & = 22 \quad 30
\end{align*}
\]

Course made good N 6 23

To find the distance.

\[
\begin{align*}
\text{As the sine of ACB} & = 16 \quad 7 \quad 9.44341 \\
\text{is to the sine of CAB} & = 101 \quad 15 \quad 9.99157 \\
\text{so is the distance AB} & = 45 \quad 1.65321
\end{align*}
\]

to the distance CB

Ex. 2. A ship from a port in latitude 42\degree 52' N, sailed S8W4W 17 miles in 7 hours, in a current setting
between the north and west; and then the same
port bore ENE, and the ship's latitude by observation
was 42\degree 42' N. Required the setting and drift of the
current?

By Construction.

Draw the S8W4W line CA (fig. 46.) equal to 17
miles, and make CB equal to 10 miles, the difference
of latitude: through B draw the parallel of latitude
BD, and draw the WSW line CD, intersecting BD
in D: AD being joined, will represent the drift of the
current, which applied to the scale will measure 20.2,
and the angle DAE will be its setting, and will be
found equal to 72\degree.

By Calculation.

In the triangle CBD, given CB=10 miles, and the
angle BCD=6 points; to find the distance CD.

As radius -- -- -- -- 10.0000
is to the secant of BCD -- 6 points 10.41710
so is the diff. of lat. CB -- 10 miles 2.0000

to the distance CD 26.13 1.41710

Again, In the triangle ACD are given the distance
AC=17 miles, CD=26.13, and the angle ACD 47\degree
points; to find the remaining parts.

To find the setting of the current.

\[
\begin{align*}
\text{Distance DC} & = 26.13 \\
\text{Angle ACD} & = 47 \text{ points}
\end{align*}
\]

\[
\begin{align*}
\text{Sum} & = 43.13 \\
\text{CAD} & = 114 \text{ points}
\end{align*}
\]

\[
\begin{align*}
\text{Difference} & = 9.13 \\
\text{As the sum of the sides} & = 43.13 \quad 1.63478 \\
\text{is to the differ. of the sides} & = 9.13 \quad 0.96074 \\
\text{so is tang. half sum angles} & = 64 41' \quad 10.32509 \\
\text{to tang. half diff. angles} & = 24 6 \quad 9.65078
\end{align*}
\]

Angle CAD -- 88 47
Angle CAE = ACD = 114 \text{ points} = 16 62

Setting of the current EAD = 71 55

To find the drift of the current.

As the sine of CAD -- 88 47' 9.00990
is to the sine of ACD -- 47 24' 9.88819
so is the distance CD -- 26.13 1.41710

to the drift of current AD 20 2 1.30359

Hence the hourly rate of the current is 19.2, and 50.5 respectively:
and the angle DCE will be 41\degree 42/2.

Ex. 3. A ship, from latitude 38\degree 20' N, sailed 24
hours in a current setting NW8N, and by account is in
latitude 58\degree 42' N, having made 44 miles of casting;
but the latitude by observation is 38\degree 08' N. Required
the course and distance made good, and the drift of the
current.

By Construction.

Make CE (fig. 47.) equal to 22 miles, the difference
of latitude by D, R, and EA=54 miles, the departure,
and join CA; make CD=38 miles, the difference
of latitude by observation; draw the parallel of
latitude DB, and from A draw the NW8N line AB,
intersecting DB in B, and AB will be the drift of the
current in 24 hours: CB being joined, will be the
distance made good, and the angle DBC the true course.
Now, AB and CB applied to the scale, will measure
19.2 and 50.5 respectively: and the angle DBC will be
41\degree 42/2.

By Calculation.

From B draw BF perpendicular to AE, then in the
triangle AFB are given BF=16 miles, and the angle
ABF=3 points; to find AB and AF.

To find the drift of the current AB.

As radius -- -- -- -- 10.0000
is to the secant of ABF -- 3 points 10.8015
so is BF -- -- 16 miles 1.20412

to the drift of the current AB 19.24 1.28427

Hence the hourly rate -- 19.24 0.8.

To find AF.

As radius -- -- -- -- 10.0000
is to the tangent of ABF -- 3 points 9.82489
so is BF -- -- 16 miles 1.20412

to AF -- -- 10.69 1.02901

True departure EF=DB=33.31

Now,
NAVIGATION.

In the position of the SESE line, draw DC = 21 miles (fig. 49); draw DE NE=24 miles, from E with 6 miles cut DC in F; draw DF parallel to EF, meeting CB drawn parallel to DF: then the distance DB applied to the scale will measure 19.4 and 8, the course SDB will be SE8S.

By Calculation.

In the triangle DBF, given DB=24 miles, EF =6 miles and the angle EDF=6 points; to find the angle DFE=CBD.

As the hourly rate of sailing 6m. is to the hourly rate of current 2m. so is the sine of EDF=6 point 67° 30' 9.99811 to the sine of DFE 22 38 9.3481

Angle 66 52 8611 2 11 52

Course SDB 39 14=SE8S.

In the triangle DBE, given DC=21 miles, the angle BDC=DFE=22° 39', and the angle DBC=6 points; to find the distance DB.

As the sine of DBC 89° 52' 9.99999 is to the sine of DCB 67 30 9.9881 so is the true distance DC 21 m. 1.21211 to the distance by the log DB 21 m. 1.2375

CHAP. XI. Instruments proposed to solve the various Problems in Sailing, independent of Calculation.

VARIOUS methods, besides those already given, have been proposed to save the trouble of calculation.

One of these methods is by means of an instrument composed of rulers, so disposed as to form a right-angled triangle, having numbers in a regular progression marked on their sides. These instruments are made of different materials, such as paper, wood, bone, &c. and are differently constructed, according to the fancy of the inventor. Among instruments of the kind, that by John Cooke, Esq. seems to be the best. A number of other instruments, very differently constructed, have been proposed for the same purpose; of these, however, we shall only take notice of the rectangular instrument, by A. Mackay, LL.D. F.R.S. &c.

Description. The stock a b c d (fig. 50) is a parallelepiped: The length from a to b is two feet, the breadth from a to d two inches, and the depth is one inch and a half. The stock is perforated longitudinally, so as to be capable of containing within it a cylinder of wood one inch diameter; g h is an aperture on the surface of the stock above a quarter of an inch wide, which discloses one-twelfth part of the surface of the cylinder contained; the edge c d is divided into twelve parts, each of these is divided into six parts, and the space between each of these again into ten parts. The surface of the cylinder is divided longitudinally into twelve parts, and on each of them is engraved a
NAVIGATION.

Prob. II. Both latitudes and course given, to find the distance and departure.

Example. Let the latitude sailed from be 43° 50' N, and that come to 47° 8' N, and the course NNE. Required the distance and departure?

Move the centre of the semicircle to the latitude left 43° 50', and the edge of the box to the latitude come to 47° 8'; fix the index at the given course 2 points: then at the point of intersection of the index and perpendicular is the distance 214 miles on the index, and the departure 82 miles on the perpendicular.

Prob. III. Given the course and departure, to find the distance and difference of latitude.

Example. Let the latitude sailed from be 32° 38' N, the course SWS, and the departure 200 miles. Required the distance and latitude come to?

Move the centre of the semicircle to the latitude left 32° 38', set the index to the given course 3 points, and move the perpendicular till the given departure 200 cuts the index; at this point on the index is 360 miles, and the edge of the box will cut the latitude come to 27° 39' N.

Prob. IV. Given the difference of latitude and distance, to find the course and departure.

Example. Let the latitude left be 17° 10' N, the latitude come to 21° 40' N, and the distance sailed on a direct course between the north and west 300 miles. Required the course and departure?

Move the semicircle and box to the given latitudes, and the index until the distance found thereon meets the perpendicular; then at the point of contact on the perpendicular is 130.8, the departure, and on the semicircle by the index is 23° 50', the course.

Prob. V. The distance and departure given, to find the course and difference of latitude.

Example. The distance sailed is 246 miles between the south and east, the departure is 138 miles, and the latitude left 51° 10' N. Required the course and latitude come to?

Set the centre of the semicircle to 51° 10', the latitude sailed from; find the distance 246 on the index, and the departure 138 on the perpendicular; then move both till these points meet, and the course 34° 10' will be found on the semicircle by the index, and the latitude in 47° 47' N, by the edge of the box.

Prob. VI. Both latitudes and departure given, to find the course and distance.

Example. A ship from latitude 43° 10' N, sailed between the north and west till she was in latitude 47° 14' N, and has made 170 miles of departure. Required the course and distance?

Move the centre of the semicircle over 43° 10', and the edge of the box to 47° 14'; find the departure on the perpendicular, and bring the edge of the index thereeto; now at the point of intersection is the distance 297.4 miles on the index, and the course 34° 52' on the semicircle.

Traverse Sailing.

Example. A ship from latitude 46° 48' N, sailed SSW 24 miles, SSW 36 miles, and S'E 40 miles.
NA V I G A T I O N.

Instruments to solve Problems in Sailing, without Calculation.

Miles. Required the latitude in, together with the direct course and distance.
Set the semicircle to the latitude sailed from 46° 48', and the index to the course SSW 36° W; mark the distance 24 on the index, and bring the perpendicular to meet it; then the index will cut the departure 11.3 on the perpendicular, and the perpendicular will cut the latitude 46° 27' N on the base. For the next course and distance, bring the semicircle to the latitude marked by the perpendicular, and lay down the course 56° W: if it be towards the first meridian, move the last marked departure until it meets the index, and the limb of the box will mark the present departure; but if the course be from the first meridian, bring the last departure 11.3 to the limb of the box, the index will mark the departure made good 18.3 on the perpendicular, and the latitude arrived at 45° 32' will be marked on the base by the perpendicular; proceed in the same manner with all the courses of which the traverse consists, then the difference of latitude 1° 36' will be intercepted between the latitude sailed from 46° 48', and the latitude come to 45° 12' last marked by the perpendicular; and also the departure made good will be intercepted between that point on the perpendicular where the first departure commenced, and that where the last terminated.
Now, with the difference of latitude 1° 36' and the departure, the course will be S 8° 30' W, and distance 97 miles, by last problem in Plane Sailing.

Parallel Sailing.
PROB. I. The difference of longitude between two places in one parallel of latitude given, to find the distance between them.

Example. Let the common latitude be 49° 30' N, and the difference of longitude 3° 30'. Required the distance?
Set the index to 40° 30', the complement of the latitude on the semicircle; mark the difference of longitude in miles on the index, then move the perpendicular until it meets the termination of the difference of longitude on the index, and the part of the perpendicular intercepted between the limb of the box and the point of intersection will be the distance 136.4 miles.

PROB. II. The distance between two places in one parallel of latitude given, to find the difference of longitude between them.

Example. Let the latitude of the given parallel be 49° 30' N, the distance sailed 136.4 E. Required the difference of longitude?
Set the index to the complement of the latitude 45° 30', and mark the distance sailed on the perpendicular; then move it until it meets the index, and the point of intersection will show the difference of longitude 210° or 3° 30' on the index.

PROB. III. Given the distance sailed on a parallel, and the difference of longitude, to find the latitude of that parallel.

Example. The distance sailed due east is 136.4, and the difference of longitude 3° 30'. Required the latitude of the parallel?
Find the difference of longitude 210° on the index, and the distance 136.4 on the perpendicular, and move both until these numbers meet, and the complement of the latitude 4° 30' will be shown by the index on the semicircle.

Mercator's and Middle Latitude Sailing.

PROB. I. The latitudes and longitudes of two places given, to find the direct course and distance between them.

Example. Required the course and distance between two places whose latitudes and longitudes are 50° 30' N, 15° 0' W, and 54° 30' N, 15° 30' W, respectively?

By Mercator's Sailing.
To find the course.
Move the centre of the semicircle perpendicular over the meridional degree answering to latitude 50° 30' N, then move the box until the edge of the perpendicular cuts the meridional parts of the other latitude 54° 30' N, and move the index until it cuts the difference of longitude 4° 30' on the perpendicular, and the index will mark the course 30° 10', or NNE E actually the semicircle.

To find the distance.
Screw the index to this course, and move the centre of the semicircle to the latitude 50° 50' N, and the edge of the perpendicular to the latitude 54° 30' N, then the perpendicular will cut the distance 2347 on the index.

By Middle Latitude Sailing.
To find the departure.
Move the centre of the semicircle to the latitude 50° 50', and the edge of the index to the complement of the middle latitude 37° 20' on the semicircle; then move the box until the edge of the perpendicular intersects the termination of the difference of longitude 210° on the index, which point of intersection will mark the departure 128 on the perpendicular.

To find the course and distance.
Move the edge of the perpendicular to the other latitude 54° 30', and the index until it cuts the departure 128 on the perpendicular; then will the perpendicular mark the course on the index 234.7 miles, and the index will mark the course on the semicircle 30° 10', or NNE E nearly.

PROB. II. Both latitudes and course given, to find the distance and difference of longitude.

Example. A ship from latitude 50° 30' N, longitude 15° 0' W, sailed N 30° 10' E, until she is in latitude 54° 30' N. Required the distance and difference of longitude?

By Mercator's Sailing.
To find the difference of longitude.
Move the box and semicircle as in the former problem to the meridional parts of the given latitudes, then set the index to the course, and it will mark the difference of longitude 3° 30' on the perpendicular; hence the longitude in is 15° 30' W.

To find the distance.
Move the perpendicular and semicircle to the given latitudes, and put the index to the given course; then the perpendicular will cut the distance 234.7 miles on the index.
NAVI
GATI
ON.

By Middle Latitude Sailing.

To find the distance and departure.

Move the semicircle and perpendicular to the given latitudes, and the index to the course; then the perpendicular will show the departure 128 miles, and the index the distance 254.7 miles at the point of intersection.

To find the difference of longitude.

Set the index to the complement of the middle latitude on the semicircle, and move the box until the termination of the departure on the perpendicular meets the index, which will mark the difference of longitude thereon 210 min. or 3° 30'.

Prob. III. Both latitudes and distance given, to find the course and difference of longitude.

Example. From latitude 50° 50' N, longitude 10° 0' W, a ship sailed 254.7 miles between the north and east, and by observation is in latitude 54° 30' N. Required the course and difference of longitude?

By Mercator's Sailing.

To find the course.

Move the perpendicular and semicircle to the given latitudes, and the index until the distance sailed marked on it meets the perpendicular; then the index will mark the course N 30° 10' E on the semicircle.

To find the difference of longitude.

Screw the index to the course, move the perpendicular and semicircle to the meridional parts of the given latitudes, and the space intercepted between the limb of the box and the index will be the difference of longitude 3° 30'.

By Middle Latitude Sailing.

To find the departure and course.

Move the semicircle and perpendicular to the given latitudes, and the index until the distance sailed on it cuts the perpendicular; then the perpendicular will show the departure 128 miles, and the semicircle the course N 30° 10' E.

To find the difference of longitude.

Set the index to 37° 20', the complement of the middle latitude on the semicircle, and move the perpendicular until the termination of the departure on it cuts the index; then the point of intersection will mark the difference of longitude 210 miles on the index.

Prob. IV. Both latitudes and departure given, to find the course, distance, and difference of longitude.

Example. Let the latitude and longitude sailed from be 56° 40' S and 28° 55' E respectively, the latitude come to 61° 20' S, and departure 172 miles. Required the course, distance, and difference of longitude?

By Mercator's Sailing.

To find the course and distance.

Move the perpendicular and semicircle to the given latitude (H); then move the index till it meets the extremity of the departure on the perpendicular; the distance will be marked on the index 329, and the course S 31° 35' E, or SSE 4° E nearly, on the semicircle.

To find the difference of longitude.

Move the perpendicular and semicircle to the meridional parts of the given latitudes, and the index will cut the difference of longitude on the perpendicular 5° 35'.

By Middle Latitude Sailing.

The course and distance are found as before.

To find the difference of longitude.

Set the index to 31°, the complement of the middle latitude on the semicircle, and move the perpendicular until the departure marked on it cuts the index, and this point of intersection will mark the difference of longitude on the index 335 m. or 5° 35'.

Prob. V. One latitude, course, and distance given, to find the difference of latitude and difference of longitude.

Example. Let the latitude left be 56° 40' S, longitude 28° 55' E, the course S 31° 35' E, and distance 329 m. Required the latitude and longitude come to?

By Mercator's Sailing.

To find the latitude come to.

Set the semicircle to the latitude sailed from, and the index to the course, and bring the perpendicular to the distance, which at the same time will mark the latitude come to 61° 20' S.

To find the difference of longitude.

Screw the index to the course, and move the semicircle and perpendicular to the meridional parts of both latitudes; then the index will cut the difference of longitude on the perpendicular 5° 35'.

By Middle Latitude Sailing.

The latitude arrived at is found as above.

To find the departure.

The semicircle and perpendicular being set to both latitudes, and the index to the course, it will show the departure 172.7 on the perpendicular.

To find the difference of longitude.

Set the index to 31° the complement of the middle latitude on the semicircle, and move the perpendicular until the departure marked on it cuts the index, and the division on the index at the point of intersection will be the difference of longitude 335.

Prob. VI. One latitude, course, and departure given, to find the distance, difference of latitude, and difference of longitude.

Example. Let the latitude sailed from be 56° 40' N, longitude 28° 35' W, the course N 31° 35' W, and departure 172.7. Required the distance, and the latitude and longitude come to?

By Mercator's Sailing.

To find the distance and latitude come to.

Move the semicircle to the latitude left, and the index to the course; mark the departure on the perpendicular.

(H) In southern latitudes, the end of the cylinder where the numbers begin must be turned towards the north pointed out by the semicircle; and in northern latitudes, it must be reversed.
NAVI GAT I ON.

is evident that any triangle whatever may be formed on it. In applying to nautical problems, the course is to be found at top, or right-hand side, in the column of degrees or points, according as it is expressed; the distance is to be found on the index, the difference of latitude at either side column, and the departure at the head or foot of the instrument. The numbers in these columns may represent miles, leagues, &c.; but when used in conjunction with the enlarged meridional line, then 10 is to be accounted 100 miles, 20 is to be esteemed 200 miles, and so on, each number being increased in a tenfold ratio; and the intermediate numbers are to be reckoned accordingly.

Plane Sailing.

PROB. I. The course and distance sailed given, to find the difference of latitude and departure.

Example. Let the course be NE 45° N, distance 44 miles. Required the difference of latitude and departure?

Move the index until the graduated edge be over 35 points, and find the given distance 44 miles on the index: this distance will be found to cut the parallel of 34 miles, the difference of latitude in the side column, and that of 28 miles, the departure at the top.

PROB. II. Given the course and difference of latitude, to find the distance and departure.

Example. Required the distance and departure answering to the course 28°, and difference of latitude 60 miles?

Lay the index over the given course 28°: find the difference of latitude 60 miles in the side column; its parallel will cut the index at 58 miles, the distance and the corresponding departure at the top is 32 miles.

PROB. III. The course and departure given, to find the distance and difference of latitude.

Example. Let the course be SSW and the departure 36 miles. Required the distance and difference of latitude?

Lay the index over two points; find the departure at the top, and its parallel will cut the index at 54 miles the distance, and the difference of latitude on the side column is 87 miles.

PROB. IV. Given the distance and difference of latitude, to find the course and departure.

Example. The distance is 35 leagues, and the difference of latitude 30 leagues. Required the course and departure?

Bring 35 leagues on the index to the parallel of 30 leagues in the side; then the departure at the top is 18 leagues, and the course by the edge of the index on the line of rhumbs is 24 points.

PROB. V. Given the distance and departure, to find the course and difference of latitude.

Example. Let the distance be 58 miles, and the departure
NAVIGATION.

Prob. VI. The difference of latitude and departure being given, to find the course and distance.

Example. Let the difference of latitude be 30 miles, and the departure 28 miles. Required the course and distance?

Bring the index to the intersection of the parallels of 30 and 28; then the distance on the index is 41 miles, and the course by its edge is 43°.

 Traverse Sailing.

Find the difference of latitude and departure answering to each course and distance by Prob. I. of Plane Sailing, and from thence find the difference of latitude and departure made good; with which find the course and distance by the last problem.

An example is unnecessary.

Parallel Sailing.

Prob. I. Given the difference of longitude between two places on the same parallel, to find the distance between them.

Example. Let the latitude of a parallel be 48°, and the difference of longitude between two places on it 3° 40'. Required their distance?

Put the index to 48°, the given latitude, and find the difference of longitude 220 on the index, and the corresponding parallel from the side will be 147; the distance required.

Prob. II. The latitude of a parallel, and the distance between two places on that parallel, being given, to find the difference of longitude between them.

Example. The latitude of a parallel is 56°, and the distance between two places on it 200 miles. Required their difference of longitude?

Put the index to the given latitude, and find the distance in the side column, and the intersection of its parallel with the index will give 358, the difference of longitude sought.

Prob. III. Given the distance and difference of longitude between two places on the same parallel, to find the latitude of that parallel.

Example. The number of miles in a degree of longitude is 46.5. Required the latitude of the parallel?

Bring 60 on the index to cut the parallel of 46.5 from the side, then the edge of the index will give 39° 11', the latitude required.

Middle Latitude and Mercator's Sailing.

Prob. I. The latitudes and longitudes of two places being given, to find the course and distance between them.

Example. Required the course and distance between Genoa, in latitude 44° 2' N, longitude 8° 36' E, and Palermo, in latitude 38° 10' N, longitude 13° 38' E?

By Mercator's Sailing.

Take the interval between 38° 10' and 44° 2' on the enlarged meridian, which laid off from C upwards will reach to 500; now find the difference of longitude 302 at the top, and bring the divided edge of the index to the intersection of the corresponding parallels, and the index will show the course 31° 8' on the line of degrees; then find the difference of the latitude 375 on the side column, and its parallel will intersect the index at 438, the distance.

By Middle Latitude Sailing.

Put the index to 41° 18', the complement of the middle latitude on degrees, and the difference of longitude 302 on the index will intersect the parallel of 227, the departure, in the side column. Now move the index to the intersection of the parallels of 375 and 227, the first being found in the side column, and the other at top or bottom; then the distance answering thereto on the index will be 438, and the course on the scale of degrees is 41° 10'.

Prob. II. Given one latitude, course, and distance, to find the other latitude and difference of longitude.

Example. Let the latitude and longitude sailed from be 30° 22' N, and 12° 8' W respectively, the course NNW4 W, and distance 500 miles. Required the latitude and longitude come to?

By Mercator's Sailing.

Put the index to the course 25 points, and find the distance 500 miles thereon; then the corresponding difference of latitude will be 441 miles, and the departure 2315 miles, hence the latitude in is 46° 43' N. Now take the interval between the latitudes of 39° 22', and 46° 43' on the enlarged meridian, which laid off from C will reach to about 605, the parallel of which will intersect the vertical parallel of the difference of longitude 323 at the edge of the index: hence the longitude in is 17° 31' W.

By Middle Latitude Sailing.

Find the difference of latitude and departure before, and hence the latitude in is 46° 43' N, and the middle latitude 43° 3'. Now put the index to 43° 3', and the horizontal parallel of the departure 2315 will intersect the index at 322, the difference of longitude.

Prob. III. Both latitudes and course given, to find the distance and difference of longitude.

Example. The latitude sailed from is 22° 54' S, and longitude 42° 40' W, the course is SE by E, and latitude come to 26° 8' S. Required the distance sailed, and longitude in?

By Mercator's Sailing.

Bring the index to 5 points, the given course, and the parallel of 194, the difference of latitude found in the side column, will intersect the index at 349, the distance; and it will cut the vertical parallel of 200, the departure.

Take the interval between the given latitudes 22° 54' and 26° 8' on the enlarged meridian; lay off that extent from the centre on the side column, and it will reach to 213: the parallel of this number will intersect the vertical parallel of 319, the difference of longitude. Hence the longitude in is 37° 21' W.
By Middle Latitude Sailing.

With the given course and difference of latitude find the distance and departure as before; then bring the index to the middle latitude 24° 31’; find the departure 200 in the side column, and its parallel will intersect the index at 319, the difference of longitude.

Prob. IV. One latitude, course, and departure, given, to find the other latitude, distance, and difference of longitude.

Example. The latitude and longitude left are 20° 30’ N. and 49° 17’ W. respectively; the course is NE1N, and departure 212 miles. Required the latitude and longitude come to, and distance sailed?

By Mercator’s Sailing.

Put the index to the given course 34, and the vertical parallel of 212 will cut the index at 356, the distance, and the horizontal parallel of 286, the difference of latitude; the latitude come to is therefore 23° 16’ N.

Now take the interval between the latitudes 20° 30’, and 23° 16’, on the enlarged meridian, which laid off from the centre, C will reach to 311; and this parallel will intersect the vertical parallel of the difference of longitude 230, at the edge of the index. Hence the longitude in is 45° 27’ W.

By Middle Latitude Sailing.

Find the distance and difference of latitude as directed above; then bring the index to 22° 53’, the middle latitude, and the horizontal parallel of 212, the departure, will intersect the index at 230, the difference of longitude.

Prob. V. Both latitudes and distance given, to find the course and difference of longitude.

Example. The distance sailed is 500 miles between the north and west; the latitude and longitude left are 40° 11’ N. and 6° 20’ W. respectively; and the latitude in is 46° 40’ N. Required the course and longitude in?

By Mercator’s Sailing.

Bring the distance 500 on the index to intersect the horizontal parallel of the difference of latitude 390; then the course 38° 44’ is found on the line of degrees by the edge of the index, and the vertical parallel of the above point of intersection is that answering to 313, the departure.

Take the interval between the latitudes 40° 11’ and 46° 40’, which laid off from the centre, C, and its horizontal parallel will intersect the vertical parallel of 431, the difference of longitude, by the edge of the index, it being in the same position as before. Hence the longitude in is 16° 31’ W.

By Middle Latitude Sailing.

The course and departure are found as formerly, and the middle latitude is 43° 25’, to which bring the edge of the index, and the horizontal parallel of 313, the departure, will intersect the index at 431, the difference of longitude.

Prob. VI. Both latitudes and departure given, to find the course, distance, and difference of longitude.

Example. Let the latitude sailed from be 42° 32’ N. long. 9° 17’ W., the departure 250 miles W., and the sea chart latitude come to 36° 18’ N. Required the course and distance sailed, and the longitude come to?

By Mercator’s Sailing.

Find the point of intersection of the horizontal parallel of 304, the difference of latitude, and the vertical parallel of 250, the departure; to this point bring the index, and the corresponding division thereof will be 467 miles, and the course on the scale of degrees by the edge of the index will be 32° 25’.

Take the interval between the latitudes on the enlarged meridian; which being laid off from the centre will reach to 412: now the horizontal parallel of 312 will cut the vertical parallel of 325, the difference of longitude, at the edge of the index. The longitude come to is therefore 14° 42’ W.

By Middle Latitude Sailing.

The course and distance are to be found in the same manner as above. Then bring the index to 39° 35’, the middle latitude, and the horizontal parallel of 250 will intersect the edge of the index at 3245, the difference of longitude.

Prob. VII. Given one latitude, distance, and departure, to find the other latitude, course, and difference of longitude.

Example. A ship from latitude 32° 38’ N., longitude 17° 6’ W., sailed 586 miles between the south and west, and made 336 miles of departure:—Required the course, and the latitude and longitude come to?

By Mercator’s Sailing.

Move the index till the distance 386 intersects the vertical parallel of the departure 336; then the corresponding horizontal parallel will be 480, the difference of latitude, and the course 35°. Hence the latitude in is 24° 38’ N.

Now take the interval between the latitudes on the enlarged meridian, which laid off from the centre will reach to 547, the horizontal parallel of which will cut the vertical parallel of 383, the difference of longitude. The longitude in is therefore 23° 29’ W.

By Middle Latitude Sailing.

Find the course and difference of latitude as before, and hence the middle latitude is 28° 38’, to which bring the index, and the horizontal parallel of 336, the departure, will intersect the index at 383, the difference of longitude.

It seems unnecessary to enlarge any further on the use of this instrument, as the above will make it sufficiently understood.

Chap. XII. Of Sea-Charts.

The charts usually employed in the practice of navigation, are of two kinds, namely, Plane and Mercator’s Charts. The first of these is adapted to represent a portion of the earth’s surface near the equator; and the last for all portions of the earth’s surface. For a particular description of these, reference has already been made from the article Chart, to those of Plane and Mercator and as these charts are particularly described under the above articles, it is therefore sufficient in this place to describe their use.
NAVIGATION.

Use of the Plane Chart.

Prob. I. To find the latitude of a place on the chart.

Rule. Take the least distance between the given place and the nearest parallel of latitude; now this distance applied the same way on the graduated meridian, from the extremity of the parallel, will give the latitude of the proposed place.

Thus the distance between Bonavista and the parallel of 15 degrees, being laid off from that parallel upon the graduated meridian, will reach to 16° 5', the latitude required.

Prob. II. To find the course and distance between two given places on the chart.

Rule. Lay a ruler over the given places, and take the nearest distance between the centre of any of the compasses on the chart and the edge of the ruler; move this extent along, so as one point of the compass may touch the edge of the ruler, and the straight line joining their points may be perpendicular thereto; then will the other point show the course: the interval between the places, being applied to the scale, will give the required distance.

Thus the course from Palma to St. Vincent will be found to be about SSW 1/4 W, and the distance 13° 3/2 or 795 m.

Prob. III. The course and distance sailed from a known place being given, to find the ship's place on the chart.

Rule. Lay a ruler over the place sailed from, parallel to the rhumb, expressing the given course; take the distance from the scale, and lay it off from the given place by the edge of the ruler; and it will give the point representing the ship's present place.

Thus, suppose a ship had sailed SSW 1/4 W 160 miles from Cape Palmas; then by proceeding as above, it will be found that she is in latitude 27° 57' N.

The various other problems that may be resolved by means of this chart require no further explanation, being only the construction of the remaining problems in Plane Sailing on the chart.

Use of Mercator's Chart.

The method of finding the latitude and longitude of a place, and the course of bearing between two given places by this chart, is performed exactly in the manner as in the Plane Chart, which see.

Prob. I. To find the distance between two given places on the chart.

Case I. When the given places are on the same meridian.

Rule. The difference or sum of their latitudes, according as they are on the same or on opposite sides of the equator, will be the distance required.

Case II. When the given places are on the same parallel.

Rule. If that parallel be the equator, the difference or sum of their longitudes is the distance; otherwise, take half the interval between the places, lay it off upwards and downwards on the meridian from the given parallel, and the intercepted degrees will be the distance between the places.

Or, take an equal extent of a few degrees from the meridian on each side of the parallel, and the number of extents, and parts of an extent, contained between the places, being multiplied by the length of an extent, will give the required distance.

Case III. When the given places differ both in latitude and longitude.

Rule. Find the difference of latitude between the given places, and take it from the equator or graduated parallel; then lay a ruler over the two places, and move one point of the compass along the edge of the ruler until the other point just touches a parallel; then the distance between the place where the point of the compass rested by the edge of the ruler, and the point of intersection of the ruler and parallel, being applied to the equator, will give the distance between the places in degrees and parts of a degree, which multiplied by 60 will reduce it to miles.

Prob. II. Given the latitude and longitude in, to find the ship's place on the chart.

Rule. Lay a ruler over the given latitude, and lay off the given longitude from the first meridian by the edge of the ruler, and the ship's present place will be obtained.

Prob. III. Given the course sailed from a known place, and the latitude in, to find the ship's present place on the chart.

Rule. Lay a ruler over the place sailed from, in the direction of the given course, and its intersection with the parallel of latitude arrived at will be the ship's present place.

Prob. IV. Given the latitude of the place left and the course and distance sailed, to find the ship's present place on the chart.

Rule. The ruler being laid over the place sailed from, and in the direction of the given course, take the distance sailed from the equator, put one point of the compass at the intersection of any parallel with the ruler, and the other point of the compass will reach to a certain place by the edge of the ruler. Now this point remaining in the same position, draw in the other point of the compass until it just touch the above parallel when swept round: apply this extent to the equator, and it will give the difference of latitude. Hence the latitude in will be known, and the intersection of the corresponding parallel with the edge of the ruler will be the ship's present place.

The other problems of Mercator's Sailing may be very easily resolved by this chart; but as they are of less use than those given, they are, therefore, omitted, and may serve as an exercise to the student.

BOOK II.

Containing the method of finding the Latitude and Longitude of a Ship at Sea, and the Variation of the Compass.

Chap. I. Of Hadley's Quadrant.

Hadley's quadrant is the chief instrument in use at present for observing altitudes at sea. The form of this instrument, according to the present mode of construction,
NAVIGATION.

Method of finding the Latitude and Longitude at Sea.

Plate CCLXVII

Fig. 54.

Construction, is an octagonal sector of a circle, and therefore contains 45 degrees; but because of the double reflection, the limb is divided into 90 degrees.

See Astronomy and Quadrant. Fig. 54, represents a quadrant of the common construction, of which the following are the principal parts.

1. ABC, the frame of the quadrant.
2. BC, the arch or limb.
3. D, the index; a b, the subdividing scale.
4. E, the index-glass.
5. F, the fore horizon-glass.
6. G, the back horizon-glass.
7. K, the coloured or dark glasses.
8. H, the vanes or sights.

Of the Frame of the Quadrant.

The frame of the quadrant consists of an arch BC, firmly attached to the two radii AB, AC, which are bound together by the braces LM, in order to strengthen it, and prevent it from warping.

Of the Index D.

The index is a flat bar of brass, and turns on the centre of the octant: at the lower end of the index there is an oblong opening; to one side of this opening the vernier scale is fixed, to subdivide the divisions of the arch; at the end of the index there is a piece of brass, which bends under the arch, carrying a spring to make the subdividing scale lie close to the divisions. It is also furnished with a screw to fix the index in any desired position. The best instruments have an adjusting screw fitted to the index, that it may be moved more slowly, and with greater regularity and accuracy, than by the hand. It is proper, however, to observe, that the index must be previously fixed near its right position by the above-mentioned screw.

Of the Index Glass E.

Upon the index, and near its axis of motion, is fixed a plane speculum, or mirror of glass quicksilvered. It is set in a brass frame, and is placed so that its face is perpendicular to the plane of the instrument. This mirror being fixed to the index moves along with it, and has its direction changed by the motion thereof; and the intention of this glass is to receive the image of the sun, or any other object, and reflect it upon either of the two horizon-glasses, according to the nature of the observation.

The brass frame with the glass is fixed to the index by the screw e; the other screw serves to replace it in a perpendicular position, if by any accident it has been deranged.

Of the Horizon-Glasses F, G.

On the radius AB of the octant are two small speculums: the surface of the upper one is parallel to the index-glass, and that of the lower one perpendicular there to, when o on the index coincides with o on the limb. These mirrors receive the reflected rays, and transmit them to the observer.

The horizon-glasses are not entirely quicksilvered; the upper one F is only silvered on its lower half, or that next the plane of the quadrant, the other half being left transparent, and the back part of the frame cut away, that nothing may impede the sight through the unsilvered part of the glass. The edge of the foil of this glass is nearly parallel to the plane of the instrument, and ought to be very sharp, and without a flaw. The other horizon-glass is silvered at both ends. In the middle there is a transparent slit through which the horizon may be seen.

Each of these glasses is set in a brass frame, to which there is an axis passing through the wood work, and is fitted to a lever on the under side of the quadrant, by which the glass may be turned a few degrees on its axis, in order to set it parallel to the index-glass. The lever has a contrivance to turn it slowly, and a button is in it. To set the glasses perpendicular to the plane of the instrument, there are two sunk screws, one before and one behind each glass: these screws pass through the plate on which the frame is fixed into another plate; so that by loosening one and tightening the other of these screws, the direction of the frame with its mirror may be altered, and set perpendicular to the plane of the instrument.

Of the Coloured Glasses K.

There are usually three coloured glasses, two of which are tinged red and the other green. They are used to prevent the solar rays from hurting the eye at the time of observation. These glasses are set in a frame, which turns on a centre, so that they may be used separately or together as the brightness of the sun may require. The green glass is particularly useful in observations of the moon; it may be also used in observations of the sun, if that object be very bright. In the fore-observation, these glasses are fixed as in Fig. 54; but when the back observation is used, they are removed to N.

Of the two Sight Vanes, H, I.

Each of these vanes is a perforated piece of brass, designed to direct the sight parallel to the plane of the quadrant. That which is fixed at I is used for the fore, and the other for the back, observation. The vane has two holes, one exactly at the height of the silvered part of the horizon-glass, the other a little higher, to direct the sight to the middle of the transparent part of the mirror.

Of the divisions on the Limb of the Quadrant.

The limb of the quadrant is divided from right to left into 90 primary divisions, which are to be considered as degrees, and each degree is subdivided into three equal parts, which are therefore of 20 minutes each: the intermediate minutes are obtained by means of the scale of divisions at the end of the index.

Of the Vernier, or Subdividing Scale.

The dividing scale contains a space equal to 113 divisions of the limb, and is divided into 20 equal parts. Hence the difference between a division on the dividing scale and a division on the limb is one-twentieth of a division on the limb, or one minute. The degree and minute pointed out by the dividing scale may be easily found thus.

Observe what minute on the dividing scale coincides with a division on the limb: this division being added to the degree and part of a degree on the limb, immediately

ton.

Methods of Hadley's Quadrant.

The adjustments of the quadrant consist in placing the mirrors perpendicular to the plane of the instrument. The fore horizon-glass must be set parallel to the speculum, and the planes of the speculum and back horizon-glass produced must be perpendicular to each other when the index is at o.

Adjustment I. To set the index-glass perpendicular to the plane of the quadrant.

Method 1. Set the index towards the middle of the limb, and hold the quadrant so that its plane may be nearly parallel to the horizon; then look into the index-glass; and if the portion of the limb seen by reflection appears in the same plane with that seen directly, the speculum is perpendicular to the plane of the instrument. If they do not appear in the same plane, the error is to be rectified by altering the position of the screws behind the frame of the glass.

Method 2. This is performed by means of the two adjusting too's, fig. 55, 56, which are two wooden frames, having two lines on each, exactly at the same distance from the bottom.

Place the quadrant in a horizontal position on a table; put the index about the middle of the arch; turn back the dark glasses; place one of the above-mentioned tools near one end of the arch, and the other at the opposite end, the side with the lines being towards the index-glass; then look into the index-glass, directing the sight parallel to the plane of the instrument, and one of the tools will be seen by direct vision, and the other by reflection. By moving the index a little, they may be brought exactly together. If the lines coincide, the position of the mirror is right; if not, they must be made to coincide by altering the screws behind the frame, as before.

Adjustment II. To set the fore horizon-glass perpendicular to the plane of the instrument.

Set the index to o; hold the plane of the quadrant parallel to the horizon; direct the sight to the horizon, and if the horizons seen directly and by reflection are apparently in the same straight line, the fore horizon-glass is perpendicular to the plane of the instrument; if not, one of the horizons will appear higher than the other. Now if the horizon seen by reflection is higher than that seen directly, release the nearest screw in the pedestal of the glass, and screw up that on the farther side, till the direct and reflected horizons appear to make one continued straight line. But if the reflected horizon is lower than that seen directly, unscrew the farthest, and screw up the nearest screw till the coincidence of the horizons is perfect, observing to leave both screws equally tight, and the fore horizon-glass will be perpendicular to the plane of the quadrant.

Adjustment III. To set the fore horizon-glass parallel to the index-glass, the index being at o.

Vol. XIV. Part II.

Set o on the index exactly to o on the limb, and fix it in that position by the screw at the under side; hold the plane of the quadrant in a vertical position, and direct the sight to a well-defined part of the horizon; then if the horizon seen in the silvered part coincides with that seen through the transparent part, the horizon-glass is adjusted; but if the horizons do not coincide, unscrew the milled screw in the middle of the lever on the other side of the quadrant, and turn the nut at the end of the lever until both horizons coincide, and fix the lever in this position by tightening the milled screw.

As the position of the glass is liable to be altered by fixing the lever, it will therefore be necessary to re-examine it, and if the horizons do not coincide, it will be necessary either to repeat the adjustment, or rather to find the error of adjustment, or, as it is usually called, the index-error; which may be done thus:

Direct the sight to the horizon, and move the index until the reflected horizon coincides with that seen directly; then the difference between o on the limb and o on the vernier is the index error; which is additive when the beginning of the vernier is to the right of o on the limb, otherwise subtractive.

Adjustment IV. To set the back horizon-glass perpendicular to the plane of the instrument.

Put the index to o; hold the plane of the quadrant parallel to the horizon, and direct the sight to the horizon through the back sight vane. Now if the reflected horizon is in the same straight line with that seen through the transparent part, the glass is perpendicular to the plane of the instrument. If the horizons do not unite, turn the sunk screws in the pedestal of the glass until they are apparently in the same straight line.

Adjustment V. To set the back horizon-glass perpendicular to the plane of the index-glass produced, the index being at o.

Let the index be put as much to the right of o as twice the dip of the horizon amounts to; hold the quadrant in a vertical position, and apply the eye to the back vane; then if the reflected horizon coincides with that seen directly, the glass is adjusted; if they do not coincide, the screw in the middle of the lever on the other side of the quadrant must be released, and the nut at the extremity turned till both horizons coincide. It may be observed, that the reflected horizon will be inverted; that is, the sea will be apparently uppermost, and the sky lowest.

As this method of adjustment is esteemed troublesome, and is often found to be very difficult to perform at sea, various contrivances have therefore been proposed to render this adjustment more simple. Some of these are the following.

1. Mr. Dollond's method of adjusting the back horizon-glass.

In this method an index is applied to the back horizon-glass, by which it may be moved so as to be parallel to the index-glass, when o on the vernier coincides with o on the limb. When this is effected, the index of the back horizon-glass is to be moved exactly go° from its former position, which is known by means of a divided arch for that purpose; and then the plane of the back horizon-glass will be perpendicular to the plane of the index-glass produced.
NAVIGATION.

2. Mr. Blair's method of adjusting the back horizon-glass.

All that is required in this method is to polish the lower edge of the index-glass, and expose it to view. The back horizon-glass is adjusted by means of a reflection from this polished edge, in the very same method as the fore horizon-glass is adjusted by the common method.

In order to illustrate this, let RHIE (fig. 57.) represent a pencil of rays emitted from the object R, incident on the index-glass I, from which it is reflected to the fore horizon-glass H, and thence to the eye at E. By this double reflection, an image of the object is formed at r. RHE represents another pencil from the same object R, coming directly through the fore horizon-glass to the eye at E; so that the double reflected image r appears coincident with the object R itself, seen directly.

When this coincidence is perfect, and the object R so very distant as to make the angle IRH insensible, the position of the speculum I and H will differ insensibly from parallelism; that is, the quadrant will be adjusted for the fore observation. Now it is from the ease and accuracy with which this adjustment can at any time be made, that the fore-observation derives its superiority over the back observation. But by grinding the edge of the index-glass perpendicular to its reflecting surface, and polishing it, the observation is rendered capable of an adjustment equally easy and accurate as the fore horizon-glass: for by a pencil of rays emitted from the object S, incident on the reflecting edge of the index-glass D, thence reflected to the back horizon-glass B, and from that to the eye at e, an image will be formed at s; which image being made to coincide with the object S itself, seen directly, ascertains the position of the back horizon-glass relative to the index-glass, with the same precision, and in a manner equally direct, as the former operation does that of the fore horizon-glass.

Directions for adjusting the Back Horizon-Glass.

The method of adjusting the quadrant for the back-observation is this. If it is to be done without making use of the telescope, place the index at o, and, applying the eye to the hole in the sight-vane (k), or tube for directing the sight, direct it through the back horizon-glass to the horizon, if that is the object to be used for adjusting. The two horizons are then to be made to coincide, holding the quadrant first in a vertical and then in a horizontal position; by which means both adjustments will be effected as in the fore-observation.

There will be no difficulty in finding the reflected horizon, if the observer first directs his eye to that part of the horizon-glass where he observes the image of the polished edge of the index-glass, which will appear double. When the direct horizon is made to appear in this case, the reflected one will be seen closely by it, unless the instrument wants a great adjustment. In this case, a little motion of the back horizon-glass backwards and forwards will presently bring it into view.

When the horizon, or any obscure terrestrial object, is to be made use of for adjusting by means of the reflecting edge, there is a precaution to be taken, without which the observer will sometimes meet with what will appear an unaccountable difficulty; for if the sky, or other object behind him, should happen to be very bright, he will not be able to discern the horizon at all. This arises from the image of the object behind him, which is reflected from the silvered surface of the index-glass, appearing to coincide with the horizon; in which case, the bright picture of the former, which is formed in the bottom of the eye, prevents the fainter impression of the latter from being perceived. This will be avoided either by applying a black screen over the silvered surface of the index-glass, or, without being at this trouble, by standing at a door or window, so that only the dark objects within can be reflected from the index-glass; but if the observation is to be made in the open air, a hat, or any such dark obstacle, held before the silvered surface of the index-glass, will very effectually remove this inconvenience.

It may be remarked, that some observers, instead of making the principal adjustment, place the speculum parallel, by moving the index without altering the position of the horizon-glass: and the difference between o on the vernier and o on the limb is the index error, which must be subtracted from all angles measured by the back-observation, when o on the index is to the right of o on the limb, and added when to the left.

3. Mr. Wright's method of adjusting the back horizon-glass of his improved patent quadrant.

Fig. 58. Is a representation of the quadrant complete in all its parts for use. A, is the reflecting surface of the index-glass, which is made of the usual length, and \( \frac{1}{2} \) of an inch broad. The bottom part is covered in front by the brass frame, and the reflecting surface is \( \frac{1}{4} \) on the back. B, the fore horizon-glass, placed as usual: O, the back horizon-glass, now placed under the fore sight-vane on the first radius of the quadrant I: C, the sight-vane of the fore horizon-glass: D, the sight-vane of the back horizon-glass: E, the coloured glasses in a brass frame, in the proper place for the fore observation: F, a hole in the frame to receive the coloured glasses when an observation is to be taken with the back horizon-glass in the common way, by turning the back to the sun: G, a hole in the frame of the farthest radius K, to receive the coloured glasses when an observation is to be taken by the new method; which is by looking through the lower hole in the sight-vane of the back horizon-glass, directly...
NAVI GATION.

The sun in the line of sight DN; the horizon from behind will then be reflected from the back of the index-glass to the horizon-glass, and from thence to the eye. (See fig. 62.) H, a brass clamp on the upper end of the index, having a milled screw underneath, which fastens the round plate to the index when required. (See fig. 59.) K, the graduated arch of the quadrant divided into 90 degrees: L, the brass index which moves over the graduated arch: M, the vernier to subdivide the divisions on the arch into single minutes of a degree.

Fig. 59 shows the upper part of the index L on a larger scale, with part of the brass frame that fastens the index-glass, and the three adjusting screws D to adjust its axis vertical to the plane of the quadrant: B, the centre on which the milled plate O moves over the index: The dotted line BF is the distance it is required to move: K, the adjusting screw to stop it in its proper place for adjusting the back observation-glass G, a piece of brass fastened to the index opposite to the clamp H, to keep the plate O always close to the index L.

Fig. 60 represents the parallel position of the index and horizon glasses after adjustment by the sun: BC, a ray from the sun incident on the index-glass C, and from thence reflected to the fore horizon-glass D, and again to the eye at E, in the line DE, where the eye sees the sun at A by direct vision, and the image by reflection, in one; the parallel lines AE and BC being so near to each other, that no apparent angle can be observed in the planes of the index and horizon-glass, when adjusted by a distant object.

In fig. 61. the index-glass is removed 45 degrees from the plane of the fore horizon-glass, and fixed in its proper place for adjusting the back horizon-glass parallel to its plane, in the same manner as the fore horizon-glass is adjusted.

In fig. 62. the index-glass (after the adjustment of the fore and back horizon glasses) is carried forward by the index on the arch 90 degrees, and makes an angle of 45° with the plane of the fore horizon-glass, and is at right angles to the plane of the back horizon-glass. The eye at E now sees the sun in the horizon at H, reflected by the index and horizon glasses from the zenith at Z, the image and object being 90 degrees distant. The back horizon K is now reflected from the back surface of the index-glass C to the horizon-glass M, and from thence to the eye at D, in a right line with the fore horizon F. In order to make an exact contact of the fore and back horizons at F, the index must be advanced beyond the 90th degree on the arch, by a quantity equal to twice the dip of the horizon.

The quadrant is adjusted for the fore observation as usual, having previously fixed the index-glass in its proper place by the milled screw at H, as represented in fig. 59.

To adjust the Quadrant for the Back-observation.

Fasten the index to 90° on the limb; loosen the screw II (fig. 59), and turn the plate O by the milled edge until the end of the adjusting screw K touches the edge of the clamp M; and by means of a distant object observe if the glasses are then parallel, as at fig. 60: if they are, fasten the screw H; if not, with a screw-driver turn the screw K gently to the right or left to make them perfect, and then fasten the screw. Now remove the index back to O on the limb, and the index-glass will be parallel to the back horizon glass E, fig. 61; if not, make them so by turning the adjusting screw of the glass E, the eye being at the upper hole in the sight-vane D, and the sight directed to the horizon, or any distant object in the direction DN (fig. 58).

Now the index remaining in this position, the index-glass is to returned, to stop at the pin E, and it will be parallel to the fore horizon-glass as at first: then the quadrant will be adjusted for both methods of observation.

To observe the Sun's Altitude by the Back-observation.

Remove the coloured glasses to G (fig. 58.), and look through the lower hole in the sight-vane D, in the line of direction DN, directly to the sun, and move the index forward on the arch exactly in the same manner as in the fore-observation: make the contact of the sun's limb and the back horizon exact, and the degrees and minutes shown by the index on the limb is the sun's zenith distance. It may be observed, that the horizon will be inverted. If the sun's lower limb be observed, the semidiameter is to be subtracted from the zenith distance; but if the upper limb is observed, the semidiameter is to be added.

The observation may be made in the usual manner, by turning the back to the sun. In this case the coloured glasses are to be shifted to F, and proceed according to the directions formerly given.

Use of Hadley's Quadrant.

The altitude of any object is determined by the position of the index on the limb, when by reflection that object appears to be in contact with the horizon.

If the object whose altitude is to be observed be the sun, and it so bright that its image may be seen in the transparent part of the fore and back glasses, the eye is to be applied to the upper hole in the sight vane; otherwise, to the lower hole: and in this case, the quadrant is to be held so that the sun may be bisected by the line of separation of the silvered and transparent parts of the glass. The moon is to be kept as nearly as possible in the same position; and the image of the star is to be observed in the silvered part of the glass adjacent to the line of separation of the two parts.

There are two different methods of taking observations with the quadrant. In the first of these the face of the observer is directed towards that part of the horizon immediately under the sun, and is therefore called the fore-observation. In the other method, the observer's back is to the sun, and it is hence called the back-observation. This last method of observation is to be used only when the horizon under the sun is obscured, or rendered indistinct by fog or any other impediment.

In taking the sun's altitude, whether by the fore or back observation, the observer must turn the quadrant about upon the axis of vision, and at the same time turn himself about upon his heel, so as to keep the sun always in that part of the horizon-glass which is at the same distance as the eye from the plane of the quadrant. In this way the reflected sun will describe an arch of a parallel circle round the true sun, whose convex side will
NAVIGATION.

Method of finding the Latitude and Longitude at Sea.

will be downwards in the fore-observation and upwards in the back; and consequently, when by moving the index, the lowest point of the arch in the fore-observation, or highest in the back, is made to touch the horizon, the quadrant will stand in a vertical plane, and the altitude above the visible horizon will be properly observed. The reason of these operations may be thus explained: The image of the sun being always kept in the axis of vision, the index will always show on the quadrant the distance between the sun and any object seen directly which its image appears to touch; therefore, as long as the index remains unmoved, the image of the sun will describe an arc everywhere equidistant from the sun in the heavens, and consequently a parallel circle about the sun, as a pole. Such a translation of the sun's image can only be produced by the quadrant's being turned about upon a line drawn from the eye to the sun, as an axis. A motion of rotation upon this line may be resolved into two, one upon the axis of vision, and the other upon a line on the quadrant perpendicular to the axis of vision; and consequently a proper combination of these two motions will keep the image of the sun constantly in the axis of vision, and cause both jointly to run over a parallel circle about the sun in the heavens: but when the quadrant is not vertical, a line through it perpendicular to the axis of vision will become a vertical axis; and a small motion of the quadrant is all that is wanted, it will never differ much in practice from a vertical axis. The observer is directed to perform two motions rather than the single one equivalent to them on a line drawn from the eye to the sun: because we are not capable, while looking towards the horizon, of judging how to turn the quadrant about upon the elevated line going to the sun as an axis, by any other means than by combining the two motions above mentioned, so as to keep the sun's image always in the proper part of the horizon-glass. When the sun is near the horizon, the line going from the eye to the sun will not be far removed from the axis of vision; and consequently the principal motion of the quadrant will be performed on the axis of vision, and the part of motion made on the vertical axis will be but small. On the contrary, when the sun is near the zenith, the line going to the sun is not far removed from a vertical line, and consequently the principal motion of the quadrant will be performed on a vertical axis, by the observer turning himself about, and the part of the motion made on the axis of vision will be but small. In intermediate altitudes of the sun, the motions of the quadrant on the axis of vision, and on the vertical axis, will be more equally divided.

Observations taken with the quadrant are liable to errors, arising from the bending and elasticity of the index, and the resistance it meets with in turning round its centre: whence the extremity of the index, on being pushed along the arch, will sensibly advance before the index-glass begins to move, and may be seen to recoil when the force acting on it is removed. Mr Hadley seems to have been apprehensive that his instrument would be liable to errors from this cause; and in order to avoid them, gives particular directions that the index be made broad at the end next the centre, and that the centre, or axis itself, have as easy a motion as is consistent with steadiness; that is, an easy freedom from looseness, or shake, at the vertex of the index. The error in question may indeed be greatly diminished; but so far, perhaps, as to render it nearly inapparent, were the index made strong, and the proper median between the two extremes of a shake at the centre on one hand, and too much stiffness there on the other, entirely hit; but it cannot be entirely corrected. For to more or less of bending the index will always be subject; and some degree of resistance will remain at the centre, unless the friction there could be totally removed, which is impossible.

Of the reality of the error to which he is liable from this cause, the observer, if he is provided with a quadrant furnished with a screw for moving the index gradually, may thus satisfy himself. After finishing the observation, lay the quadrant on a table, and move the angle; then cautiously loosen the screw which fastens the index, and it will immediately, if the quadrant is not remarkably well constructed, be seen to start from its former situation, more or less according to the perfection of the joint and the strength of the index. This starting, which is owing to the index recoiling after being released from the confined state it was in during the observation, will sometimes amount to several minutes; and its direction will be opposite to that in which the index was moved by the screw at the time of finishing the observation. But how far it affects the truth of the observation, depends on the manner in which the index was moved in setting it to o, for adjusting the instrument; or in finishing the observations necessary for finding the index error.

The easiest and best rule to avoid these errors seems to be this: In all observations made by Hadley's quadrant, let the observer take notice constantly to fasten his observations, by moving the index in the same direction which was used in setting it to o for adjusting; or in the observations necessary for finding the index error. If this rule is observed, the error arising from the spring of the index will be obviated. For as the index was bent the same way, and in the same degree in adjusting as in observing, the truth of the observations will not be affected by this bending.

To take Altitudes by the Fore-observation.

I. Of the Sun.

Turn down either of the coloured glasses before the horizon-glass, according to the brightness of the sun; direct the sight to that part of the horizon which is under the sun, and move the index until the coloured image of the sun appear in the horizon-glass; then give the quadrant a slow vibratory motion about the axis of vision; move the index until the lower or upper limb of the sun is in contact with the horizon, at the lowest part of the arch described by this motion; and the degrees and minutes shown by the index on the limb will be the altitude of the sun.

II. Of the Moon.

Put the index to o, turn down the green glass, place the eye at the lower hole in the sight-case, and observe the moon in the silvered part of the horizon-glass; move the index gradually, and follow the moon's reflected image until the enlightened limb is in contact with
NAVIGATION.

III. Of a Star or Planet.

The index being put to $\theta$, direct the sight to the star through the lower hole in the sight-vane and transparent part of the horizon-glass; move the plane of the quadrant a very little to the left, and the image of the star will be seen in the silvered part of the glass. Now move the index, and the image of the star will appear to descend; continue moving the index gradually until the star is in contact with the horizon at the lowest part of the arch described; and the degrees and minutes shown by the index on the limb will be the altitude of the star.

To take Altitudes by the Back-observation.

I. Of the Sun.

Put the stem of the coloured glasses into the perforation between the horizon-glasses, turn down either according to the brightness of the sun, and hold the quadrant vertically; then direct the sight through the hole in the back sight-vane, and the transparent slit in the horizon-glass to that part of the horizon which is opposite to the sun; now move the index till the sun is in the silvered part of the glass, and by giving the quadrant a vibratory motion, the axis of which is that of vision, the image of the sun will describe an arch whose convex side is upwards; bring the limb of the sun, when in the upper part of this arch, in contact with the horizon; and the index will show the altitude of the other limb of the sun.

II. Of the Moon.

The altitude of the moon is observed in the same manner as that of the sun, with this difference only, that the use of the coloured glass is unnecessary unless the moon is very bright; and that the enlightened limb, whether it be the upper or lower, is to be brought in contact with the horizon.

III. Of a Star or Planet.

Look directly to the star through the vane and transparent slit in the horizon-glass; move the index until the opposite horizon, with respect to the star, is seen in the silvered part of the glass; and make the contact perfect as formerly. If the altitude of the star is known nearly, the index may be set to that altitude; the sight directed to the opposite horizon, and the observation made as before.

SECT. II. Of finding the Latitude of a Place.

The observation necessary for ascertaining the latitude of a place, is that of the meridional altitude of a known celestial object; or two altitudes when the object is out of the meridian. The latitude is deduced with more certainty and with less trouble from the first of these methods, than from the second; and the sun, for various reasons, is the object most proper for this purpose at sea. It, however, frequently happens, that by the interposition of clouds, the sun is obscured at noon; and by this means the meridian altitude is lost. In this case, therefore, the method by double altitudes becomes necessary. The latitude may be deduced from three altitudes of an unknown object, or from double altitudes, the apparent times of observation being given.

The altitude of the limb of an object observed at sea, requires four separate corrections in order to obtain the true altitude of its centre: these are for semidiameter, dip, refraction, and parallax. (See ASTRONOMY, and the respective articles). The first and last of these corrections vanish when the observed object is a fixed star.

When the altitude of the lower limb of any object is observed, its semidiameter is to be added thereto in order to obtain the central altitude; but if the upper limb be observed, the semidiameter is to be subtracted. If the altitude be taken by the back-observation, the contrary rule is to be applied. The dip is to be subtracted from, or added to, the observed altitude, according as the fore or back observation is used. The refraction is always to be subtracted from, and the parallax added to, the observed altitude.

PROB. I. To reduce the sun’s declination to any given meridian.

RULE. Find the number in Table IX. answering to the longitude in the table nearest to that given, and to the nearest day of the month. Now, if the longitude is west, and the declination increasing, that is, from the 20th of March to the 22d of June, and from the 22d of September to the 22d of December, the above number is to be added to the declination. During the other part of the year, or while the declination is decreasing, this number is to be subtracted. In east longitude, the contrary rule is to be applied.

Ex. 1. Required the sun’s declination at noon 16th April 1810, in longitude 84° W?

Sun’s declination at noon at Greenwich 0° 59.2’ N.
Number from Table IX. 4 50

Reduced declination 10 4.2

Ex. 2. Required the sun’s declination at noon 22d March 1793, in longitude 151° E?

Sun’s declination at noon at Greenwich 0° 53 N.
Equation from Table X. 10

Reduced declination 0 43 N

PROB. II. Given the sun’s meridional altitude, to find the latitude of the place of observation.

RULE. The sun’s semidiameter is to be added to, or subtracted from, the observed altitude, according as the lower or upper limb is observed; the dip answering to the height from Table V. is to be subtracted if the fore-observation is used; otherwise, it is to be added; and the refraction answering to the altitude from Table IV. is to be subtracted: hence the true altitude of the sun’s centre will be obtained. Call the altitude south or north, according as the sun is south or north at the time of observation; which subtracted from 90°, will give the zenith distance of a contrary denomination.

Reduce the sun’s declination to the meridian of the place of observation, by Prob. I.; then the sun or difference
NAVI GAT ION.

Ex. 1. October 19, 1810, in longitude 32° E, the meridian altitude of the sun’s lower limb was 48° 53′ S, height of the eye 18 feet. Required the latitude?

Obs. alt. sun’s lower limb 48° 53′ S. Sun’s dec. 19 Oct. noon. 0° 51′ S.
Semidiameter + 1 6
Dip and refract. — 0 5 Reduced decl. 9 49 S

True alt. sun’s centre 49 48 S Zenith distance - 40 56 N
Latitude 31 7 N

Ex. 2. November 16, 1812, in longitude 158° W, the meridian altitude of the sun’s lower limb was 87° 37′ N, height of the eye 10 feet. Required the latitude?

Obs. alt. sun’s lower limb 87° 37′ N. Sun’s dec. noon. 18° 49′ S.
Semidiameter + 0 16 Equation tab. + 0 8
Dip and refract. — 0 3 Reduced decl. 19 38 N

True alt. sun’s centre 87 50 N. Zenith distance 21 10 S
Latitude 21 6 S

Ex. 3. December 19, 1811, being nearly under the meridian of Greenwich, the altitude of the sun’s upper limb at noon was 4° 30′ S, height of the eye 20 feet. Required the latitude?

Observed altitude of the sun’s upper limb 4° 30′ S
Sun’s semidiameter — 0 16
Dip and refract. — 0 15

True altitude of the sun’s centre
Zenith distance — 86 25 N
Declination — 23 25 S
Latitude — 62 36 N

Ex. 4. August 23, 1812, in longitude 107° E, the meridian altitude of the sun’s lower limb by the back observation was 61° 8′ N, and the height of the eye 14 feet. Required the latitude?

Observed altitude sun’s upper limb 61° 8′ N
Sun’s semidiameter — 0 16
Dip — 0 34
Refraction — 0 4

True altitude of sun’s centre
Zenith distance — 60 55 N
Reduced declination — 29 5 S

Latitude — 17 39 S

The dip in Table V. answers to an entirely open and unobstructed horizon. It, however, frequently happens, that the sun is over the land at the time of observation, and the ship nearer to the land than the visible horizon would be if unconfined. In this case, the dip will be different from what it would otherwise have been, and is to be taken from Table VI. in which the height is expressed at the top, and the distance from the land in the side column in nautical miles. — Seamen, in general, can estimate the distance of any object from the ship with sufficient exactness for this purpose, especially when that distance is not greater than six miles; which is the greatest distance of the visible horizon from an observer on the deck of any ship.

PROB. III. Given the meridian altitude of a fixed star, to find the latitude of the place of observation.

RULE. Correct the altitude of the star by dip and refraction, and find the zenith distance of the star formerly; take the declination of the star from Table XI. and reduce it to the time of observation. Now, the sum or difference of the zenith distance and declination of the star, according as they are of the same or of a contrary name, will be the latitude of the place of observation.

Ex. 1. December 1, 1810, the meridian altitude of Sirius was 59° 52′ S, height of the eye 14 feet. Required the latitude?

Observed altitude of Sirius — 59 52 S
Dip and refract. — 0 4

True altitude — 59 48 S
Zenith distance — 30 14 N
Declination — 16 38 S

Latitude — 13 46 N

Ex. 2. February 17, 1797, the meridian altitude of Procyon was 71° 15′ N, the height of the eye 10 feet. Required the latitude?

Observed altitude of Procyon — 71 15 N
Dip and refract. — 0 3

True altitude — 71 12 N
Zenith distance — 18 48 S
Declination — 5 43 N

Latitude — 13 58 N

PROB. IV. Given the meridian altitude of a planet, to find the latitude of the place of observation.

RULE. Compute the true altitude of the planet as directed in last problem (which is sufficiently accurate for altitudes taken at sea); take its declination from the Nautical Almanac, p. iv. of the month, and reduce it to the time and meridian of the place of observation; then the sum or difference of the zenith distance and declination of the planet will be the latitude as before.

Ex. 1. August 7, 1812, the meridian altitude of Saturn was 68° 42′ N, and height of the eye 15 feet. Required the latitude?

Observed altitude of Saturn — 68 42 N
Dip and refract. — 0 4

True altitude — 68 38 N
Zenith distance — 21 28 S
Declination — 22 43 S

Latitude — 44 68 N

Ex. 2. October 15, 1812, the meridian altitude of Jupiter was 81° 5′ S, height of the eye 18 feet. Required the latitude?

Observed
NAVIGATION.

Observed altitude of the moon's lower limb 81° 15' N
Semidiameter          + 0 15
Dip                   + 0 3
Apparent altitude of the moon's centre 81° 27' N
Correction            + 0 8

True altitude of moon's centre 81° 33' N
Zenith distance       8 25' S
Declination           14 49' N

Latitude              6 42' N

Remark. If the object be on the meridian below the pole at the time of observation, then the sum of the true altitude and the complement of the declination is the latitude, of the same name as the declination or altitude.

Ex. 1. July 2, 1812, in longitude 1° 5' W, the altitude of the sun's lower limb at midnight was 8° 58', height of the eye 18 feet. Required the latitude?

Observed altitude sun's lower limb 8° 58' N
Semidiameter          + 0 16
Dip and refraction    + 0 10

True altitude of sun's centre 9 4' N
Compl. decl. reduced to time and place 66° 37' N

Latitude              76° 1' N

Prob. VI. Given the latitude by account, the declination and two observed altitudes of the sun, and the interval of time between them, to find the true latitude.

Rule. To the log. secant of the latitude by account, add the log. secant of the sun's declination; the sum, rejecting 20 from the index, is the logarithm ratio. To this add the log. of difference of the natural sines of the two altitudes, and the log. of the half elapsed time from its proper column.

Find this sum in column of middle time, and take out the time answering thereto; the difference between which and the half elapsed time will be the time from noon when the greater altitude was observed.

Take the log. answering to this time from column of rising, from which subtract the log. ratio, the remainder is the logarithm of a natural number; which being added to the natural sine of the greater altitude, the sum is the natural cosine of the meridian-zenith distance; from which and the sun's declination the latitude is obtained as formerly.

If the latitude thus found differs considerably from that by account, the operation is to be repeated, using the computed latitude in place of that by account (1).

Example 1.

(1) This method is only an approximation, and ought to be used under certain restrictions; namely,

The observations must be taken between nine o'clock in the forenoon and three in the afternoon. If both observations be in the forenoon, or both in the afternoon, the interval must not be less than the distance of the time of observation of the greatest altitude from noon. If one observation be in the forenoon and the other in the afternoon, the interval must not exceed four hours and a half; and in all cases, the nearer the greater altitude is to noon the better.

If the sun's meridian zenith distance be less than the latitude, the limitations are still more contracted. If the latitude be double the meridian zenith distance, the observations must be taken between half past nine in the morning and half past two in the afternoon, and the interval must not exceed three hours and a half. The observations must be taken still nearer to noon, if the latitude exceed the zenith distance in a greater proportion. See Maskelyne's British Mariner's Guide, Dr Mackay's Treatises on the Longitude and Navigation, &c. and Requisite Tables, 2d edit.

Declination 9 37

Latitude 51 10

As this latitude differs only 5' from that used in the computation, it may therefore be depended upon as the true latitude.

PROB. VII. Given the latitude by account, the sun's declination, two observed altitudes, the elapsed time, and the course and distance run between the observations; to find the ship's latitude at the time of observation of the greater altitude.

Rule. Find the angle contained between the ship's course and the sun's bearing at the time of observation of the least altitude, with which enter the Traverse Table as a course, and the difference of latitude answering to the distance made good will be the reduction of altitude.

Now, if the least latitude be observed in the afternoon, the reduction of altitude is to be applied there to by addition or subtraction, according as the angle between the ship's course and the sun's bearing is less or more than eight points. If the least altitude be observed in the afternoon, the contrary rule is to be used.

The difference of longitude in time between the observations is to be applied to the elapsed time by addition or subtraction, according as it is east or west. This is, however, in many cases so inconsiderable as to be neglected.

With the corrected altitudes and interval, the latitude by account and sun's declination at the time of observation of the greater altitude, the computation is to be performed by the last problem.

Ex. 1. July 6. 1793, in latitude 58° 14' N by account, and longitude 16° E, at 10h 54' A. M. per watch, the altitude of the sun's lower limb was 53° 17', and at 11h 17' P. M. the altitude was 52° 51', and bearing per compass 85W8'. the ship's course during the elapsed time was 86W7W, and the hourly rate of making 8 knots, the height of the eye 16 feet. Required the true latitude at the time of observation of the greater altitude?

Sun's bear at 2d. ob. 85W8. Interval bet. observ. 2h 23'.

Ship's course 86W7W Dist. run = 2h 23x8 = 198'.

Contained angle 3° 10' points.

**Natural number:**

| Greatest altitude      | 53° 29' N. sine 80368             |                        |                  |
| Mer. zenith dist.      | 34 29 N. cos. 82436               |                        |                  |
| Declination            | 22 40 N.                         |                        |                  |
| Latitude               | 57° 9 N.                         |                        |                  |

As this latitude differs only 4 miles from that used in the computation, it may therefore be depended on as the true latitude.

**Remark.** If the sun come very near the zenith, the sines of the altitude will vary so little as to make it uncertain which ought to be taken as that belonging to the natural sine of the meridian altitude. In this case, the following method will be found preferable.

To the log. rising of the time from noon found as before, add the log. secant of half the sum of the estimated meridian altitude, and greatest observed altitude; from which subtract the log. ratio, its index being increased by 10, and the remainder will be the log. sine.

Vol. XIV. Part II.
PROB. VIII. Given the altitudes of two known stars, observed at the same or at different times; and if at different times, the interval between the observations; to find the latitude.

RULE. If both altitudes be observed at the same time, call the difference between their right ascensions the reduced interval.

But if the altitudes be taken at different times, reduce the interval between the observations to sidereal time, by adding thereto the proportional part answering to the interval, and 3° 30', the daily acceleration of the fixed stars. Now to the right ascension of the first observed star, add the interval in sidereal time, and the difference between this sum and the right ascension of the other star will be the reduced interval.

To the logarithm rising of the reduced interval, add the logarithmic cosines of the stars declinations; subtract the natural number answering to the sum of these logarithms from the natural cosine of the difference or sum of the stars declinations, according as they are of the same or of a contrary name, and the remainder will be the natural sine of arch first.

To the logarithmic cosine of arch first add the logarithmic secant of declination of the star having the least polar distance, and the logarithm half elapsed time of the reduced interval, the sum will be the logarithm half elapsed time of arch second.

From the natural cosine of the difference between arch first and the altitude of the star having the greatest polar distance, subtract the natural sine of the altitude of the other star, and find the logarithm of the remainder; to which add the logarithm secant of arch first, and the logarithmic secant of the altitude of the star having the greatest polar distance, the sum will be the logarithm rising of arch third. The difference between arches second and third is arch fourth.

To the logarithm rising of arch fourth add the logarithmic cosines of the declination and altitude of the star having the greatest polar distance; subtract the corresponding natural number from the natural cosine of the difference between the altitude and declination, the polar distance being less than 90°; otherwise, from their sum, and the remainder will be the natural sine of the altitude.

Ex. January 1st 1793, the true altitude of Capella was 69° 23', and at that time instant the true altitude of Sirius was 16° 15'. Required the latitude?

Right ascension of Capella 1° 27' 25"
Right ascension of Sirius 6° 36' 1"

Interval 1° 34' 36"
Capella's decl. 45° 45' N cosine 0.9536
Sirius's decl. 16° 27' 5 cosine 0.9638

CHAP. II. Containing the Method of finding the Longitude at Sea by Lunar Observations.

SECT. I. Introduction.

The observations necessary to determine the longitude by this method are, the distance between the sun and moon, or the moon and a fixed star near the ecliptic, together with the altitude of each. The stars used in the Nautical Almanack for this purpose are the following: namely, α Arietis, Aldebaran, Polus, Regulus, Spica Virginis, Antares, α Aquilæ, Fomalhaut, and α Pegasi; and the distances of the moon’s center from the sun, and from one or more of these stars, are contained in the viii. Ex. x. and xi. pages of the month, at the beginning of every third hour apparent time, by the meridian of Greenwich. The distance between the moon and the sun, or one of these stars, is observed with a sextant; and the altitudes of the objects are taken as usual with a Hadley’s quadrant.

In the practice of this method, it will be found convenient to be provided with three assistants: two of these are to take the altitudes of the sun and moon, or moon and star, at the same time the principal observer is taking the distance between the objects; and the third assistant is to observe the time, and write down
NAViGAITION.

Ring down the observations. In order to obtain accuracy, it will be necessary to observe several distances, and the corresponding altitudes; the intervals of time between them being as short as possible; and the sum of each divided by the number will give the mean distance and mean altitudes; from which the time of observation at Greenwich is to be computed by the rules to be explained.

If the sun or star from which the moon's distance is observed be at a proper distance from the meridian, the time at the ship may be inferred from the altitude observed at the same time with the distance: in this case, the watch is not necessary; but if that object be near the meridian, the watch is absolutely necessary, in order to connect the observations for ascertaining the apparent time at the ship and at Greenwich with each other.

An observer without any assistants may very easily take all the observations, by first taking the altitudes of the objects, then the distance to gain their altitudes, and reduce the altitudes to the time of observation of the distance; or, by a single observation of the distance, the apparent time being known, the longitude may be determined.

A set of observations of the distances between the moon and a star, and their altitudes, may be taken with accuracy during the time of the evening or morning twilight; and the observer, though not much acquainted with the stars, will not find it difficult to distinguish the star from which the moon's distance is to be observed. For the time of observation nearly, and the ship's longitude by account being known, the estimated time at Greenwich may be found; and by entering the Nautical Almanac with the reduced time, the distance between the moon and given star will be found nearly. Now set the index of the sextant to this distance, and hold the plane of the instrument so as to be nearly at right angles to the line joining the moon's cusps, direct the sight to the moon, and by giving the sextant a slow vibratory motion, the axis of which being that of vision, the star, which is usually one of the brightest in that part of the heavens, will be seen in the transparent part of the horizon glass.

SECT. II. Of the Sextant.

This instrument is constructed for the express purpose of measuring with accuracy the angular distance between the sun and moon, or between the moon and a fixed star, in order to ascertain the longitude of a place by lunar observations. It is, therefore, made with more care than the quadrant, and has some additional appendages that are wanting in that instrument.

Fig. 63. represents the sextant, so framed as not to be liable to bend. The arch AA is divided into 120 degrees; each degree is divided into three parts; each of these parts, therefore, contains 20 minutes, which are again subdivided by the vernier into every half minute or 30 seconds. The vernier is numbered at every fifth of the longer divisions, from the right towards the left, with 5, 10, 15, and 20; the first division to the right being the beginning of the scale.

In order to observe with accuracy, and make the images come precisely in contact, an adjusting screw B is added to the index, which may thereby be moved with greater accuracy than it can be by hand; the longitude, but this screw does not act until the index is fixed by the finger screw C. Care should be taken not to force the adjusting screw when it arrives at either extremity of its adjustment. When the index is to be moved any considerable quantity, the screw C at the back of the sextant must be loosened; but when the index is brought nearly to the division required, this back screw should be tightened, and then the index may be moved gradually by the adjusting screw.

There are four tined glasses D, each of which is set in a separate frame that turns on a centre. They are used to defend the eye from the brightness of the solar image and the glare of the moon, and may be used separately or together as occasion requires.

There are three or more such glasses placed behind the horizon glass at E, to weaken the rays of the sun or moon when they are viewed directly through the horizon. The paler glass is sometimes used in observing altitudes at sea, to take off the strong glare of the horizon.

The frame of the index glass I is firmly fixed by a strong cock to the centre plate of the index. The horizon glass F is fixed in a frame that turns on the axes or pivots, which move in an exterior frame; the holes in which the pivots move may be tightened by four screws in the exterior frame. G is a screw by which the horizon glass may be set perpendicular to the plane of the instrument: should this screw become loose, or move too easy, it may be easily tightened by turning the capstan head screw H, which is on one side of the socket through which the stem of the finger screw passes.

The sextant is furnished with a plain tube (fig. 64.) Fig. 64. without any glasses; and to render the objects still more distinct, it has two telescopes, one (fig. 65.) re-presenting the objects erect, or in their natural position; the other (fig. 66.) shows them inverted; fig. 66. it has a large field of vision, and a little use will soon accustom the observer to the inverted position, and the instrument will be as readily managed by it as by the plain tube alone. By a telescope the contact of the images is more perfectly distinguished; and by the place of the images in the field of the telescope, it is easy to perceive whether the sextant is held in the proper place for observation. By sliding the tube that contains the eye-glasses in the inside of the other tube, the object is suited to different eyes, and made to appear perfectly distinct and well defined.

The telescopes are to be screwed into a circular ring at K; this ring rests on two points against an exterior ring, and is held thereto by two screws: by turning one or other of these screws, and tightening the other, the axis of the telescope may be set parallel to the plane of the sextant. The exterior ring is fixed on a triangular brass stem that slides on a socket, and by means of a screw at the back of the quadrant may be raised or lowered so as to move the centre of the telescope to point to that part of the horizon glass which shall be judged the most fit for observation. Fig. 67. is a circular head, with tined glasses to screw Fig. 67. on the eye end of either of the telescopes or the plain tube. The glasses are contained in a circular plate which...
NAVIGATION.

Use of the Sextant.

When the distance between the moon and the sun, or a star is to be observed, the sextant must be held so that its plane may pass through the eye of the observer and both objects; and the reflected image of the most luminous of the two is to be brought in contact with the other seen directly. To effect this, therefore, it is evident, that when the brightest object is to the right of the other, the face of the sextant must be held upwards; but if to the left, downwards. When the face of the sextant is held upwards, the instrument should be supported with the right hand, and the index moved with the left hand. But when the face of the sextant is from the observer, it should be held with the left hand, and the motion of the index regulated by the right hand.

Sometimes a sitting posture will be found very convenient for the observer, particularly when the reflected object is to the right of the direct one; in this case, the instrument is supported by the right hand, the elbow may rest on the right knee, the right leg at the same time resting on the left knee.

If the sextant is provided with a ball and socket, and a staff, one of whose ends is attached thereto, and the other rests in a belt fastened round the body of the observer, the greater part of the weight of the instrument will by this means be supported by his body.

To observe the Distance between the Moon and any Celestial Object.

1. Between the Sun and Moon.

Put the telescope in its place, and the wires parallel to the plane of the instrument; and if the sun is very bright, raise the plate before the silvered part of the speculum, direct the telescope to the transparent part of the horizon glass, or to the line of separation of the silvered and transparent parts according to the brightness of the sun, and turn down one of the coloured glasses; then hold the sextant so that its plane produced may pass through the sun and moon, having its face either upwards or downwards according as the sun is to the right or left of the moon; direct the sight through the telescope to the moon, and move the index till the limb of the sun is nearly in contact with the enlightened limb of the moon; now fasten the index, and by a gentle motion of the instrument make the image of the sun move alternately past the moon; and, when in that position where the limbs are nearest each other, make the coincidence of the limbs perfect by means of the adjusting screw: this being effected, read off the degrees and parts of a degree shown by the index on the limb, using the magnifying glass; and thus the angular distance between the nearest limbs of the sun and moon is obtained.

2. Between the Moon and a Star.

Direct the middle of the field of the telescope to the line of separation of the silvered and transparent part of the horizon glass; if the moon is very bright, turn down the lightest coloured glass; and hold the sextant so that its plane may be parallel to that passing through the eye of the observer and both objects; its face bent upwards if the moon is to the right of the star, but if to the left, the face is to be held from the observer; now direct the sight through the telescope to the star, and

Adjustments of the Sextant.

The adjustments of a sextant are, to set the mirrors perpendicular to its plane and parallel to each other when the index is at zero, and to set the axis of the telescope parallel to the plane of the instrument. The three first of these adjustments are performed nearly in the same manner as directed in the section on the quadrant: as however the sextant is provided with a set of coloured glasses placed behind the horizon glass, the index error may be more accurately determined by measuring the sun's diameter twice, with the index placed alternately before and behind the beginning of the divisions: half the difference of these two measures will be the index error, which must be added to, or subtracted from, all observations, according as the diameter measured with the index to the left of zero is less or greater than the diameter measured with the index to the right of the beginning of the divisions.

Adjustment IV. To set the Axis of the Telescope parallel to the Plane of the Instrument.

Turn the eye end of the telescope until the two wires are parallel to the plane of the instrument; and let two distant objects be selected, as two stars of the first magnitude, whose distance is not less than 90° or 100°: make the contact of these objects as perfect as possible at the wire nearest the plane of the instrument; fix the index in this position; move the sextant till the objects are seen at the other wire, and if the same points are in contact, the axis of the telescope is parallel to the plane of the sextant; but if the objects are apparently separated, or do partly cover each other, correct half the error by the screws in the circular part of the support, one of which is above and the other between the telescope and sextant; turn the adjusting screw at the end of the index till the limbs are in contact; then bring the objects to the wire next the instrument; and if the limbs are in contact, the axis of the telescope is adjusted; if not, proceed as at the other wire, and continue till no error remains.

It is sometimes necessary to know the angular distance between the wires of the telescope; to find which, place the wires perpendicular to the plane of the sextant, hold the instrument vertical, direct the sight to the horizon, and move the sextant in its own plane till the horizon and upper wire coincide; keep the sextant in this position, and move the index till the reflected horizon is covered by the lower wire: and the division shown by the index of the limb, corrected by the index error, will be the angular distance between the wires. Other and better methods will readily occur to the observer at land.
NAVIGATION.

The glasses of the larger set, which belongs to the central mirror, should have each about half the degree of the shade with which the correspondent glass of the set belonging to the horizon mirror is tinged. These glasses are kept tight in their places by small screws, and make an angle of about 9° with the plane of the instrument; by which means the image from the coloured glass is not reflected to the telescope. When the angle to be measured is between 5° and 35°, one of the glasses of the largest set is to be placed before the horizon glass.

The handle is of wood, and is screwed to the back of the instrument, immediately under the centre, with which it is to be held at the time of observation.

Fig. 70, is a plan of the instrument, wherein the limb is represented by the divided circular plate; A is the central mirror; a a, the places which receive the stems of the glass, fig. 73; E F, the first or central index with its scale and adjusting screw; MN, the second or horizon index; G H, the telescope; I K, the screws for moving it towards or from the plane of the instrument; C, the plane of the coloured glass, fig. 72; and D, its place in certain observations.

Fig. 71, is a section of the instrument, wherein the several parts are referred to by the same letters as in fig. 20. Fig. 72, represents one of the horizon coloured glasses; and fig. 73, one of the central coloured glasses: Fig. 74, is the key for turning the adjusting screws of the mirrors: Fig. 75, is the handle: Fig. 76, a section of one of the radii towards its middle: Fig. 77, is used in some terrestrial observations for diminishing the light of the direct object, whose place at the time of observation is D: Fig. 78, is the tool for adjusting the central mirror; and for rectifying the position of the telescope with regard to the plane of the instrument, there is another tool exactly of the same size. The height of these is nearly equal to that of the middle of the central mirror.

Adjustments of the Circular Instrument.

I. To set the horizon glass so that none of the rays from the central mirror shall be reflected to the telescope from the horizon mirror, without passing through the coloured glass belonging to this last mirror. — Place the coloured glass before the horizon mirror; direct the telescope to the silvered part of that mirror, and make it nearly parallel to the plane of the instrument; move the first index; and if the rays from the central mirror to the horizon glass, and from thence to the telescope, have all the same degree of shade with that of the coloured glass used, the horizon glass is in its proper position; otherwise the pedestal of the glass must be turned until the uncoloured images disappear.

II. Place the two adjusting tools on the limb, about 35° of the instrument distant, one on each side of the division on the left, answering to the plane of the central mirror produced: then the eye being placed at the upper edge of the nearest tool, move the central index till one half only of the reflected image of this tool is seen in the central mirror towards the left, and move the other tool till its half to the right is hid by the same edge of the mirror; then, if the upper edges of both tools are apparently in the same straight line,
Of finding the Longitude at Sea by Lunar Observations.

III. To set the horizon mirror perpendicular to the plane of the instrument.—The central mirror being previously adjusted, direct the sight through the telescope to any well-defined distant object; then, if, by moving the central index, the reflected image passes exactly over the direct object, the mirror is perpendicular; if not, its position must be rectified by means of the screws in the pedestal of the glass.

A planet, or star of the first magnitude, will be found a very proper object for this purpose.

IV. To make the line of collimation parallel to the plane of the instrument.—Lay the instrument horizontally on a table; place the two adjusting tools on the limb, towards the extremities of one of the diameters of the instrument, and at about 15 or 20 feet distant let a well-defined mark be placed, so as to be in the same straight line with the tops of the tools; then raise or lower the telescope till the plane, passing through its axis and the tops of the tools, is parallel to the plane of the instrument, and direct it to the fixed objects; turn either or both of the screws of the telescope till the mark is apparently in the middle between the wires; then is the telescope adjusted; and the difference, if any, between the divisions pointed out by the indices of the screws will be the error of the indices. Hence this adjustment may in future be easily made.

In this process the eye tube must be so placed as to obtain distinct vision.

V. To find that division to which the second index being placed the mirrors will be parallel, the central index being at zero.—Having placed the first index exactly to 0, direct the telescope to the horizon mirror, so that its field may be bisected by the line of separation of the silvered and transparent parts of that mirror; hold the instrument vertically, and move the second index until the direct and reflected horizons agree; and the division shown by the index will be that required.

This adjustment may be performed by measuring the sun’s diameter in contrary directions, or by making the reflected and direct images of a star or planet to coincide.

Use of the Circular Instrument.

To observe the Distance between the Sun and Moon.

I. The sun being to the right of the moon.

Set a proper coloured glass before the central mirror, if the distance between the objects is less than 33°; but if above that quantity, place a coloured glass before the horizon mirror: make the mirrors parallel, the first index being at 0, and hold the instrument so that its plane may be directed to the objects, with its face downwards, or from the observer: direct the sight through the telescope to the moon; move the second index, according to the order of the divisions on the limb, till the nearest limbs of the sun and moon are almost in contact: fasten that index, and make the coincidence of the limbs perfect by the adjusting screw belonging thereto; then invert the instrument, and move the central index towards the second by a quantity equal to twice the arch passed over by that index: direct the plane of the instrument to the objects: look directly to the moon, and the sun will be seen in the opposite field of the telescope: fasten the central index, and the long make the contact of the same two limbs exactly equal by moving back or forth the adjusting screw: then half the angle shown by the central index will be the distance between the nearest limbs of the sun and moon.

II. The sun being to the left of the moon.

Hold the instrument with its face downwards, so that its plane may pass through both objects: direct the telescope to the moon, and make its limb coincide with the nearest limb of the sun’s reflected image, by moving the second index; now put the instrument in an opposite position; direct its plane to the objects, and the sight to the moon, the central index being previously moved towards the second by a quantity equal to twice the measured distance; and make the same two limbs that were before observed coincide exactly, by turning the adjusting screw of the first index: then half the angle shown by the first index will be the angular distance between the observed limbs of the sun and moon. This instrument has of late been greatly improved by Captain Mendoza.

To observe the Angular Distance between the Moon and a Fixed Star or Planet.

I. The star being to the right of the moon.

In this case the star is to be considered as the direct object; and the enlightened limb of the moon’s reflected image is to be brought in contact with the star or planet, both by a direct and inverted position of the instrument, exactly in the same manner as described in the last article. If the moon’s image is very bright, the lightest tinted glass is to be used.

II. The star being to the left of the moon.

Proceed in the same manner as directed for observing the distance between the sun and moon, the sun being to the right of the moon, using the lightest tinted glass, if necessary.

SECTION IV. Of the Method of determining the Longitude from Observation.

PROB. I. To convert degrees or parts of the equator into time.

RULE. Multiply the degrees and parts of a degree by 4, beginning at the lowest denomination, and the product will be the corresponding time. Observing that minutes multiplied by 4 produce seconds of time, and degrees multiplied by 4 give minutes.

Ex. 1. Let 26° 45’ be reduced to time.

26° 45’

\[ \frac{26}{4} \]

1b 47’ = time required.

Ex. 2. Reduce 83° 37’ to time.

83° 37’

\[ \frac{83}{4} \]

Corresponding time = 5 34 28

PROB. II. To convert time into degrees.

RULE. Multiply the given time by 10, to which add the half of the product. The sum will be the corresponding degrees.

Ex.
NAVI\GATION.

Example. Let the latitude of the place of observation be $57^\circ \text{g}' \text{N}$, the interval of time between the observations of the equal altitudes $5h 47'$, the sun's declination $17^\circ 48' \text{S}$, and the daily change of declination $16^h 19' \text{W}$: Required the equation of equal altitudes?

\[
\text{Half the interval} = 2h 38\frac{1}{2} = 39^\circ 37'.

Prob. VIII. Given the latitude of a place, the altitude of a known fixed star, and the sun's right ascension, to find the apparent time of observation and error of the watch.

Rule. Correct the observed altitude of the star, and reduce its right ascension and declination to the time of observation.

With the latitude of the place, the true altitude and declination of the star, compute its horary distance from the meridian by last problem; which being added to, or subtracted from, its right ascension, according as it was observed in the western or eastern hemisphere, the sum or remainder will be the right ascension of the meridian.

From the right ascension of the meridian subtract the sun's right ascension, as given in the Nautical Almanack.

Moon's right ascension at Greenwich — 7° 22' 54"

Prob. IX. Given the altitude of the moon, the
latitude of a place, and the apparent time at Greenwich;
and a place, to find the apparent time at the place of
observation.

Rule. Correct the altitude of the moon's limb by
Problem V. p. 731, and reduce its right ascension and
deposition, and the sun's right ascension, to the Green-
wich time of observation. Now with the latitude of
the place, the declination and altitude of the moon,
compute its meridian distance as before: Which being
applied to its right ascension by addition or subtraction,
according as it is in the western or eastern hemisphere,
will give the right ascension of the meridian. Then
the sun's right ascension subtracted from the right as-
cension of the meridian, will give the apparent time of
observation.

Example. March 3, 1792, in latitude 51° 38' N, at 11° 29' 37" F. M. per watch, the altitude of the moon's
lower limb was 37° 31', the height of the eye being 15 feet, and the time at Greenwich 13° 43'. Required the
error of the watch?

Altitude of the moon's lower limb — 37° 31'
Semidiameter — + 15
Dip — — 3
Correction — + 42
Corrected alt. of moon's centre — 38 25
Latitude — 51 38 N — secant
Declination — 17 0 N — secant
Difference — 34 38
Moon's altitude — 38 25

Moon's meridian distance
Right ascension — 3° 14' 36"
Sun's right ascension — 23° 2' 54"
Apparent time at ship — 11 35 30
Time per watch — 11 29 7
Watch slow — 4.53064

Prob.

**NAVIGATION.**

**Rule.** To the logarithmic difference answering to the moon's apparent altitude and horizontal parallax, add the logarithmic sines of half the sum, and half the difference of the apparent distance and difference of time between the apparent altitudes; half the sum will be the logarithmic cosine of an arch; now add the logarithmic sine of half of the sum and difference of this arch, and half the difference of the true altitudes, and half the sum will be the logarithmic cosine of half the true distance.

**Example.** Let the apparent altitude of the moon's centre be 48° 22', that of the sun's 27° 43', the apparent central distance 31° 23' 40", and the moon's horizontal parallax 58° 45'. Required the true distance?

| Apparent altitude sun's centre | 27° 43' 00" | Correction | - | 1 40
| Sun's true altitude | 27 41 20
| Sun's apparent altitude | 27 43
| Moon's apparent altitude | 48 22
| Difference | 20 39
| Apparent distance | 81 23 40
| Sum | 102 2 40
| Difference | 60 44 40
| Half difference true altitudes | 10 39 33
| Arch | 51 27 29
| Sum | 62 7 2
| Difference | 40 47 36
| 40 32 16

**True distance** 81 4 32

**Prob. XI.** To find the time at Greenwich answering to a given distance between the moon and the sun, or one of the stars, used in the Nautical Almanac.

**Rule.** If the given distance is found in the Nautical Almanac opposite to the given day of the month, or to that which immediately precedes or follows it, the time is found at the top of the page. But if this distance is not found exactly in the ephemeris, subtract the prop. log. of the difference between the distances which immediately precede and follow the given distance from the prop. log. of the difference between the given and preceding distances; the remainder will be the prop. log. of the excess of the time corresponding to the given distance, above that answering to the preceding distance: And hence the apparent time at Greenwich is known.

**Example.** September 21, 1793, the true distance between the centres of the sun and moon was 68° 15' 8". Required the apparent time at Greenwich?

| Given distance | 68° 15' 8"
| Dist. at 6 h. | 67 53 27
| Dist. at 9 h. 30 6 | Diff. 1 39 30 P. log. 691
| Excess | 0 36 39 P. log. 691
| Preceding time | 9 0 0
| App. time at Greenwich | 9 36 39

**Prob. XII.** The latitude of a place and its longitude by account being given, together with the distance between, and the altitude of the moon and the sun, one of the stars in the Nautical Almanac; to find the true longitude of the place of observation.

**Rule.** Reduce the estimate time of observation to the meridian of Greenwich by Problem III. Find the apparent time at Greenwich by Problem X, and find the apparent time at the ship answering thereto by the last problem.

If the sun or star be at a proper distance from the meridian at the time of observation of the distance, compute the apparent time at the ship. If not, the error of the watch, may be found from observations taken either before or after that of the distance; or the apparent time may be inferred from the moon's altitude taken with the distance, by Problem IX.

The difference between the apparent times of observation at the ship and Greenwich, will be the longitude of the ship in time; which is east or west according as the time at the ship is later or earlier than the Greenwich time.

**Ex. 1.** March 17, 1792, in latitude 34° 53' N, and longitude by account 20° W, about 9h. A. M. the distance between the nearest limbs of the sun and moon was 60° 34'; the altitude of the sun's lower limb 33° 18'; that

For various other methods of determining the longitude of a place, the reader is referred to Dr. Mackay's Treatise on the Theory and Practice of finding the Longitude at Sea or Land.
chap. iii. of the variation of the compass.

the variation of the compass is the deviation of the points of the mariner's compass from the corresponding points of the horizon; and is denominated east or west variation, according as the north point of the compass is to the east or west of the true north point of the horizon.

a particular account of the variation, and of the several instruments used for determining it from observation, may be seen under the articles azimuth, compass, and variation: and for the method of communicating magnetism to compass needles, see magnetism.

prob. i. given the latitude of a place, and the sun's magnetic amplitude, to find the variation of the compass.

rule. to the log. secant of the latitude, add the log. sign of the sun's declination, and the sum will be the log. cosine of the true amplitude; to be reckoned from the north or south according as the declination is north or south.

the difference between the true and observed amplitudes, reckoned from the same point, and if of the same name, is the variation; but if of a different name, their sum is the variation.

if the observation be made in the eastern hemisphere, the variation will be east or west according as the observed amplitude is nearer to or more remote from the north than the true amplitude. the contrary rule holds good in observations taken in the western hemisphere.

ex. 1. may 15. 1794, in latitude 33° 10' n, longitude 18° w, about 5h a.m. the sun was observed to rise e®n. required the variation?

sun's dec. may 15. at noon 18° 58' n.

equation to 7h from noon o 4

--- to 18° w o 1

reduced declination 18 55 sine 9.51080
latitude 33 10 secant 0.8723

true amplitude n 67 13 e cosine 9.85803

ex. 2. december 20. 1793, in latitude 31° 38' s, longitude 83° w, the sun was observed to set s®w. required the variation?

latitude 31° 38' secant 0.6585
declination 23 28 sine 9.60012

true amplitude s 62 7 w cosine 9.66997
observed ampl. s 45 o w

variation 17 7; which is east, as the observed amplitude is farther from the south than the true amplitude, the observation being made at sunset.

it may be remarked, that the sun's amplitude ought to be observed at the instant the altitude of its lower limb is equal to the sum of 15 minutes and the dip of the horizon. thus, if an observer be elevated 18 feet above the surface of the sea, the amplitude should be taken at the instant the altitude of the sun's lower limb is 19 minutes.

prob. ii. given the magnetic azimuth, the altitude and declination of the sun, together with the latitude of the place of observation; to find the variation of the compass.

rule. reduce the sun's declination to the time and place of observation, and compute the true altitude of the sun's centre.

find the sum of the sun's polar distance and altitude and the latitude of the place, take the difference between the half of this sum and the polar distance.

to the log. secant of the altitude add the log. secant of the latitude, the log. cosine of the half sum, and the log. cosine of the difference; half the sum of these shall be the log. sine of half the sun's true azimuth, to be reckoned from the south in north latitude, but from the north in south latitude.

the difference between the true and observed azimuth will be the variation as formerly.

ex. 1. november 18. 1793, in latitude 50° 22' n, longitude 24° 30' w, about three quarters past eight a.m. the altitude of the sun's lower limb was 8° 10', and bearing per compass s, 23° 18' e: height of the eye 20 feet. required the variation of the compass?

Chap. IV. Of a Ship's Journal.

A JOURNAL is a regular and exact register of all the various transactions that happen aboard a ship whether at sea or land, and more particularly that which concerns a ship's way, from whence her place at noon or any other time may be justly ascertained.

That part of the account which is kept at sea is called sea work; and the remarks taken down while the ship is in port are called harbour work.

At sea, the day begins at noon, and ends at the noon of the following day: the first 12 hours, or those contained between noon and midnight, are denoted by P.M. signifying after midday; and the other 12 hours, or those from midnight to noon, are denoted by A.M. signifying before midday. A day's work marked Wednesday March 6. began on Tuesday at noon, and ended on Wednesday at noon. The days of the week are usually represented by astronomical characters. Thus Σ represents Sunday; Π Monday; Ξ Tuesday; ζ Wednesday; ζ Thursday; ζ Friday; and ζ Saturday.

When a ship is bound to a port so situated that she will be out of sight of land, the bearing and distance of the port must be found. This may be done by Mercator's or Middle-latitude Sailing; but the most expeditious method is by a chart. If islands, capes, or headlands intervene, it will be necessary to find the several courses and distances between each successively. The true course between the places must be reduced to the course per compass, by allowing the variation to the right or left of the true course, according as it is west or east.

At the time of leaving the land, the bearing of some known place is to be observed, and its distance is usually found by estimation. As perhaps the distance thus found will be liable to some error, particularly in misty or foggy weather, or when that distance is considerable, it will therefore be proper to use the following method for this purpose.

Let the bearing be observed of the place from which the departure is to be taken; and the ship having run a certain distance on a direct course, the bearing of the same place is to be again observed. Now having one side of a plain triangle, namely the distance sailed, and all the angles, the other distances may be found by Prob. I. of Oblique Sailing.

The method of finding the course and distance sailed in a given time is by the compass, the log-line, and half-minute-glass. These have already been described. In the royal navy, and in ships in the service of the East India Company, the log is hove once every hour; but in most other trading vessels only every two hours.

The several courses and distances sailed in the course of 24 hours, or between noon and noon, and whatever remarks are thought worthy of notice, are set down with chalk on a board painted black, called the log-board, which is usually divided into six columns: the first column on the left hand contains the hours from noon to noon; the second and third the knots and parts of a knot sailed every hour; or every two hours, according as the log is marked; the fourth column contains the courses steered; the fifth the winds; and in the sixth the various
Practice.

various remarks and phenomena are written. The
log-board is transcribed every day at noon into the
log-book, which is ruled and divided after the same
manner.

The courses steered must be corrected by the varia-
tion of the compass and leeway. If the variation is
west, it must be allowed to the left hand of the course
steered; but if east, to the right hand, in order to ob-
tain the true course. The leeway is to be allowed to
the right or left of the course steered, according as the
ship is on the larboard or starboard tack. The method
of finding the variation, which should be determined
daily if possible, is given in the preceding chapter; and
the leeway may be understood from what follows.

When a ship is close hauled, that part of the wind
which acts upon the hull and rigging, together with a
considerable part of the force which is exerted on the
sails, tends to drive her to the leeward. But since the
bow of a ship exposes less surface to the water than her
side, the resistance will be less in the first case than in
the second; the velocity in the direction of her head
will therefore in most cases be greater than the velocity
in the direction of her side; and the ship's real course
will be between the two directions. The angle formed
between the line of her apparent course and the line she
really describes through the water is called the angle of
leeway, or simply the leeway.

There are many circumstances which prevent the lay-
ing down rules for the allowance of the leeway. The con-
struction of different vessels, their trim with regard to
the nature and quantity of their cargo, the position and
magnitude of the sail set, and the velocity of the ship,
together with the swell of the sea, are all susceptible of
great variation, and very much affect the leeway. The
following rules, are, however, usually given for this
purpose.

1. When a ship is close hauled, has all her sails set,
the water smooth, with a light breeze of wind, she is
then supposed to make little or no leeway.
2. Allow one point when the top-gallant sails are
handed.
3. Allow two points when under close reefed topsails.
4. Allow two points and a half when one top-sail is
handed.
5. Allow three points and a half when both top-sails
are handed.
6. Allow four points when the fore course is handed.
7. Allow five points when under the main-sail only.
8. Allow six points when under balanced mizen.
9. Allow seven points when under bare poles.

These allowances may be of some use to work up the
day's work of a journal which has been neglected; but
a prudent navigator will never be guilty of this neglect.
A very good method of estimating the leeway is to ob-
serve the bearing of the ship's wake as frequently as
may be judged necessary; which may be conveniently
done by drawing a small semicircle on the taffarel,
with its diameter at right angles to the ship's length,
and dividing its circumference into points and quarters.
The angle contained between the semidiameter which
points right aft, and that which points in the direction
of the wake, is the leeway. But the best and most ra-
tional way of bringing the leeway into the day's log is

described, with a low crutch or swivel in its centre; af-
ter heaving the log, the line may be slipped into the
crutch just before it is drawn in, and the angle it makes
on the limb with the line drawn right aft will show the
leeway very accurately; which as a necessary article,
ought to be entered into a separate column against the
hourly distance on the log-board.

In hard blowing weather, with a contrary wind and
a high sea, it is impossible to gain any advantage by
sailing. In such cases, therefore, the object is to avoid
as much as possible being driven back. With this in-
tention it is usual to lie to under no more sail than is
sufficient to prevent the violent rolling which the vessel
would otherwise acquire, to the endangering her masts,
and straining her timbers, &c. When a ship is brought
to, the tiller is put close over to the leeward, which
brings her head round to the wind. The wind having
then very little power on the sails, the ship loses her
way through the water; which ceasing to act on the
rudder, her head falls off from the wind, the sail which
she has set fills, and gives her fresh power through the
water; which acting on the rudder brings her head again
to the wind. Thus the ship has a kind of vibratory
motion, coming up to the wind and falling off from it
alternately. Now the middle point between those
upon which she comes up and falls off is taken for her
apparent course; and the leeway and variation is to be
allowed from thence, to find the true course.

The setting and drift of currents, and the heave of
the sea are to be marked down. These are to be cor-
corrected by variation only.

The computation made from the several courses
corrected as above, and their corresponding distances,
is called a day's work; and the ship's place, as deduced
therefrom, is called her place by account, or dead rec-
koning.

It is almost constantly found that the latitude by ac-
count does not agree with that by observation. From
an attentive consideration of the nature and form of the
common legs, that its place is alterable by the weight of
the line, by currents, and other causes, and also the en-
ronment to which the course is liable, from the very often
wrong position of the compass in the binnacle, the varia-
tion not being well ascertained, an exact agreement of
the latitudes cannot be expected.

When the difference of longitude is to be found by
dead reckoning, if then the latitudes by account and
observation disagree, several writers on navigation have
proposed to apply a conjectural correction to the depar-
ture or difference of longitude. Thus, if the course be
near the meridian, the error is wholly attributed to the
distance, and the departure is to be increased or diminis-
ed accordingly: if near the parallel, the course only is
supposed to be erroneous; and if the course is towards
the middle of the quadrant, the course and distance are
both assumed wrong. This last correction will, accord-
ing to different authors, place the ship upon opposite
sides of her meridian by account. As these corrections
are, therefore, no better than guessing, they should be
absolutely rejected.

If the latitudes are not found to agree, the navigator
ought to examine his log-line and half-minute glass, and
correct the distance accordingly. He is then to consi-
der if the variation and leeway have been properly
ascertained; if not, the courses are again to be corrected,
NAVIGATION.

and no other alteration whatever is to be made on them. He is next to observe if the ship's place has been affected by a current or heave of the sea, and to allow for them according to the best of his judgment. By applying these corrections, the latitudes will generally be found to agree tolerably well; and the longitude is not to receive any further alteration.

It will be proper, however, for the navigator to determine the longitude of the ship from observation as often as possible; and the reckoning is to be carried forward in the usual manner from the last good observation; yet it will perhaps be very satisfactory to keep a separate account of the longitude by dead reckoning.

General Rules for working a Day's Work.

Correct the several courses for variation and leeway; place them, and the corresponding distances, in a table prepared for that purpose. From whence, by Traverse Sailing, find the difference of latitude and departure made good; hence the corresponding course and distance, and the ship's present latitude, will be known.

Find the middle latitude at the top or bottom of the Traverse Table, and the distance, answering to the departure found in a latitude column, will be the difference of longitude: Or, the departure answering to the course made good, and the meridional difference of latitude in a latitude column, is the difference of longitude. The sum, or difference of which, and the longitude left, according as they are of the same or of a contrary name, will be the ship's present longitude of the same name with the greater.

Compute the difference of latitude between the ship and the intended port, or any other place whose bearing and distance may be required: find also the meridional difference of latitude and the difference of longitude. Now the course answering the meridional difference of latitude found in a latitude column, and the difference of longitude in a departure column, will be the bearing of the place, and the distance answering to the difference of latitude will be the distance of the ship from the proposed place. If these numbers exceed the limits of the Table, it will be necessary to take aliquot parts of them; and the distance is to be multiplied by the number by which the difference of latitude is divided.

It will sometimes be necessary to keep an account of the meridian distance, especially in the Baltic or Mediterranean trade, where charts are used in which the longitude is not marked. The meridian distance on the first day is that day's departure; and any other day it is equal to the sum or difference of the preceding day's meridian distance and the day's departure, according as they are of the same or of a contrary denomination.

</table>

As there is no land in sight this day at noon, and from the course and distance run since the last bearing of the Eddystone light was taken, it is not to be supposed that any part of England will be seen, the departure is therefore taken from the Eddystone; and the distance of the ship from that place is found by resolving an oblique-angled plane triangle, in which all the angles are given, and one side, namely, the distance run (16 miles) between the observations. Hence the distance of the Eddystone at the time the last bearing of the light was taken will be found equal to 18 miles; and as the bearing of the Eddystone from the ship at that time was NE, the ship's bearing from the Eddystone was SE. Now the variation 2° points W, being allowed to the left of SW, gives S 52° 4' W, the true course. The other courses are in like manner to be corrected, and inserted in the following table, together with their respective distances, beginning at 10 o'clock A. M. the time when the last bearing of the Eddystone was taken. The difference of latitude, departure, course, and distance made good, are to be found by Traverse Sailing.

### Traverse Table

#### Courses

<table>
<thead>
<tr>
<th>Courses</th>
<th>Dist.</th>
<th>Diff. of Lat.</th>
<th>Departure</th>

<td>61.6</td>
</tr>
</tbody>
</table>

Yesterday's lat. by obsr. = 49° 9' N
Latitude by account = 47° 51' N
Sum = 97° 0'
Middle latitude = 48° 30'
To middle latitude 48° 30', and departure 61.6 in a latitude column, the corresponding difference of longitude in a distance column is 93° = 1° 33' W.
Yesterday's longitude = 9° 18' W.
Longitude in by account = 7° 51' W.

It is now necessary to find the bearing and distance of the intended port, namely, Funchal; but as that place is on the opposite side of the island with respect to the ship, it is therefore more proper to find the bearing of the east or west end of Madeira; the east end is, however, preferable. But as the small island of Porto Sancto lies a little to the NE of the east end of Madeira, it therefore seems more eligible to find the bearing and distance of that island.

To find the bearing and distance of Porto Sancto.

Latitude of ship = 47° 51' N.
Lat. of Porto Sancto = 32° 38' N.
Difference of latitude = 14° 13' = 893'.
M. D. Lat. = 1181'.
Difference of long. = 8° 34' = 514'.
The course answering to the meridional difference of latitude and difference of longitude is about 23° 4', and the distance corresponding to the difference of latitude is 974 miles. Now as Porto Sancto lies to the southward and westward of the ship, the course is therefore S 23° 4' W: and the variation, because W, being allowed to the right end, gives SW 1/2 W nearly, the bearing per compass; and which is the course that ought to be steered.

Yesterday's latitude: 47° 51'.

Longitude in by account: 58° 58'.

To find the bearing and distance of Porto Santo.

Latitude of ship: 47° 28' N. Mer. parts: 3444. Longitude: 8° 58' W.

Lat. of Porto Santo: 32° 58' N. Mer. parts: 2097. Longitude: 16° 25' W.

Hence the bearing of Porto Santo is S 21° W, and distance 932 miles. The course per compass is therefore S 8° W nearly.

<td>12° 31′</td>
<td>2 Points</td>
<td>S 12° W</td>
<td>870 m.</td>
</tr>
</tbody>
</table>

Two points leeway are allowed on the first course, one on the second; and as the ship is 7 points from the wind on the third course, there is no leeway allowed on it. The opposite point to NW, that from which the swell set, with the variation allowed upon it, is the last course in the Traverse Table.

### Traverse Table

</table>

Yesterday's latitude 47° 39′ 6.5
Latitude by account 47° 9′ 103°.6
Sum 48
Middle latitude 47° 24′
To middle latitude 47° 24′ and departure 103°.6, the difference of longitude is 153° = 2° 33′ W.
Yesterday's longitude - 9° 59′ W.

12° 32′ W.

To find the bearing and distance of Porto Sanote.

Latitude of ship - 47° 9′ Mer. parts - 3216 Longitude - 12° 32′ W
Lat. Porto Sanote - 32° 58′ Mer. parts - 2097 Longitude - 16° 25′ W

Difference of latitude 14° 11′ = 851′ M. D. lat. 1119 D. Longitude 3° 53′ = 233
Hence the bearing of Porto Sanote is S 12° W, and distance 870 miles; the course per compass is therefore about SW6W.

<td>13° 13'</td>
<td>12° 59'</td>
<td>21°</td>
<td>S 12° W. 737 miles</td>
<td></td>
</tr>
</tbody>
</table>

The observed variation 21° being allowed to the left of SW6S gives S 12° 45' W, the corrected course, and the distance summed up is 127,9, or 128 miles. Hence the difference of latitude is 124.8, and the departure 28.2. The latitude by account is therefore 45° 4' N, and the middle latitude 46° 6', to which, and the departure 28.2 in a latitude column, the difference of longitude in a distance column is 41° W; which being added to 12° 32' W, the yesterday's longitude gives 13° 13' W, the longitude in by account. But the longitude by observation was 12° 28' W at half past 8 P. M.; since that time the ship has run 96 miles; hence the departure in that interval is 21.2 m. Now half the difference of latitude 47 m. added to 44° 59', the latitude by observation at noon, the sum 45° 46' is the middle latitude; with which and the departure 21.2, the difference of longitude is found to be 31° W; which, therefore, added to 12° 28', the longitude observed, the sum is 12° 59' W, the longitude by observation reduced to noon.

To find the bearing and distance of Porto Sancto.

Latitude ship - 44° 59' N. Mer. parts - 3028 Longitude - 12° 59' W
Lat. Porto Sancto - 32° 18' N. Mer. parts - 2097 Longitude - 16° 25' W

Difference of latitude - 12° 1=721 M. D. lat. 931 D. Longitude - 3 26=206'

Hence the bearing of Porto Sancto is S 12° W, and distance 737 miles. The course to be steered is therefore S 33° W, or SW6S nearly.

</thead>
<tbody>
<tr>
<td>S 13° 51' W.</td>
<td>183</td>
<td>178</td>
<td>43</td>
<td>42° 1'</td>
<td>59° W.</td>
<td>14° 12' 10° 13' 58'</td>
<td>20° 14'</td>
<td>S 1° 21' 14' 555 m</td>
</tr>
</tbody>
</table>

The course corrected by variation is S 23° 31' W, and the distance run is 183 miles; hence the difference of latitude is 177.9, and the departure 42.8.

Yesterday's latitude by observation 44° 59' N. Mar. parts - - 3028
Difference of latitude 2° 59' S. 42° 1 N. Mar. parts - - 3783
Meridional difference of latitude - - 245

Now to course 13° 51', and meridional difference of latitude 245 in a latitude column, the difference of longitude in a departure column is 59° W; hence the longitudes of yesterday by account and observation, reduced to the noon of this day, will be 14° 12' W and 13° 58' respectively.

To find the bearing and distance of Porto Sancto.

<table>
<thead>
<tr>
<th>Lat. ship</th>
<th>42° 1' N.</th>
<th>Mer. parts</th>
<th>2783</th>

<th>13° 58' W</th>
</tr>
</thead>
</table>

Difference of latitude 9° 3 = 543 M. D. latitude 696° D. Longitude 2° 27 = 147.

The meridional difference of latitude and difference of longitude will be found to agree nearest under 12, the correct bearing of Porto Sancto; and the variation being allowed to the right hand of S 12° W, gives S 32° W, the bearing per compass; and the distance answering to the difference of latitude 543, under 12 degrees, is 555 miles.

<tbody>
<tr>
<td>SWS</td>
<td>184</td>
<td>178</td>
<td>45</td>
<td>39° 3'</td>
<td></td>
<td>59° W.</td>
<td>1° 10'</td>
<td>14° 52'</td>
<td>1½ pts.</td>
<td></td>
</tr>
</tbody>
</table>

The mean of the variation is about 1½ points W: hence the course corrected is SWS; with which and the distance run 184 miles, the difference of latitude is 178.5, and the departure 44.7.

Yesterday's latitude - - - 42° 1' N. Mer. parts - - 2783

Difference of latitude - - 2° 58' S.

Latitude in by account - - 39° 3' N. Mer. parts - - 2549

Meridional difference of latitude - - 234

Now, to course 1½ points, and meridional difference of latitude 234, the difference of longitude is about 59 m.; which, added to the yesterday's latitude by account 14° 12' W, the sum 15° 11' W is the longitude in by account at noon. The longitudes by observation are reduced to noon as follow:

The distance run between noon and 3h 34' P. M. is 29 miles; to which, and the course 1½ points, the difference of latitude is 28'.

Yesteray's latitude at noon - - 42° 1' N.

Latitude at time of observation - - 41° 33' N. Mer. parts - - 2746

Latitude at noon - - 39° 3' N. Mer. parts - - 2549

Meridional difference of latitude - - 197

Then, to course 1½ points, and meridional difference of latitude 197 in a latitude column, the difference of longitude in a departure column is 49 W; which added to 14° 1' W, the longitude by observation, the sum 14° 50' W is the longitude reduced to noon.

Again, the distance run between the preceding noon and 9h 22' P. M. is 75 miles; hence the corresponding difference of latitude is 72.8, or 73 miles; the ship's latitude at that time is therefore 40° 48' N.

Latitude at time of observation - 40° 48' N. Mer. parts - - 2686

Latitude at noon - - 39° 3' N. Mer. parts - - 2549

Meridional difference of latitude - - 137

Now, with the corrected course, and meridional difference of latitude, the difference of longitude is 34' W; which added to 40° 20' W, the sum is 14° 54' W, the reduced longitude. The mean of which and the former reduced longitude is 14° 52' W, the correct longitude.

VOL. XIV. Part II. + 4 Y A Journal
A Journal from England towards Madeira.

<td>32</td>
<td>37° 12'</td>
<td>41° 8'</td>
<td>15° 52'</td>
<td>15° 33'</td>
</tr>
</tbody>
</table>

The latitude by observation at 11h 10' A.M. is 37° 10', and from that time till noon the ship has run about 4 miles. Hence the corresponding difference of latitude is two miles, which subtracted from the latitude observed gives 37° 8', the latitude reduced to noon.

To find the bearing and distance of Porto Santo.

Latitude of ship - 37° 9' N. - Mer. parts. 2403 - Longitude - 15° 33' W
Latitude of Porto Santo - 32° 58' N. - Mer. parts. 2097 - Longitude - 16° 25' W
Difference of latitude - 4 10 = 250 - M. D. lat. - 306 - Diff. longitude - 52

Hence the bearing of Porto Santo is S 10° W, or SSW 2W nearly, per compass, and the distance is 254 miles.

Half a point of leeway is allowed on each course; but as the variation is expressed in degrees, it will be more convenient and accurate to reduce the several courses into one, leeway only being allowed upon them. The course thus found is then to be corrected for variation, with which and the distance made good the difference of latitude and departure are to be found.

Yesterday's latitude - 36° 41' N.
Latitude by account - 33° 42' N.
Sum - 70° 0' 29"
Middle latitude - 35° 15' 29"

To middle latitude and the departure, the difference of longitude in a distance column is 31° E.
Yesterday's long. by acc. 16° 57' W. by obs. 16° 38' W.
Difference of long. - 0 31 E. - 0 31 E.

Longitude in 16° 26' W. 16° 7' W.

To find the bearing and distance of Porto Sancto:

Latitude of ship - 33° 46' N. 21° 55' Longitude - 16° 7' W.
Lat. Porto Sancto - 32° 58' N. Mer. parts - 20° 97' Longitude - 16° 25' W.

Difference of latitude 48 Mer. diff. lat. 58 Diff. long. - 18

Hence the bearing of Porto Sancto is S 17° W, distance 30 miles.

Found here his majesty's ship Venus, and 7 English merchants.</td>
</tr>
</tbody>
</table>

This journal is performed by inspection agreeable to the precepts given. Other methods might have been used for the same purpose; for which the two instruments described and explained seem well adapted. We cannot, however, omit recommending the sliding guarter, which will be found very expeditious, not only in performing a day's work, but also in resolving most other nautical problems. See Sliding-Gunter.

It will be found very satisfactory to lay down the ship's place on a chart at the noon of each day, and her situation with respect to the place bound to, and the nearest land, will be obvious. The bearing and distance of the intended or any other port, and other requisites, may be easily found by the chart as already explained; and indeed, every day's work may be performed on the chart; and thus the use of tables superceded.

EXPLANATION OF THE TABLES.

TABLE I. To reduce points of the compass to degrees, and conversely.

The two first and two last columns of this table contain the several points and quarter-points of the compass; the third column contains the corresponding number of points and quarters; and the fourth, the degrees &c. answering thereto. The manner of using this table is obvious.

TABLE II. The miles and parts of a mile in a degree of longitude at every degree of latitude.

The first column contains degrees of latitude, and the second the corresponding miles in a degree of longitude; the other columns are a continuation of the first and second. If the given latitude consists of degrees and minutes, a proportional part of the difference between the miles answering to the given and following degrees of latitude is to be subtracted from the miles answering to the given degree.

Example. Required the number of miles in a degree of longitude, in latitude 57°9'.

The difference between the miles answering to the latitudes of 57° and 58° is 0.80.

Then as 60' : 9' :: 0.80 : 0.13

Miles answering to 57°32.68

Miles answering to 57°9' 32.55

This table may be used in Parallel and Middle Latitude Sailing.

TABLE III. Of the Sun's Semidiameter.

This table contains the angle subtended by the sun's semidiameter at the earth, for every sixth day of the year. The months and days are contained in the first column, and the semidiameter expressed in minutes and seconds in the second column. It is useful in correcting altitudes of the sun's limb, and distances between the sun's limb and the moon.

TABLE.
TABLE IV. Of the Refraction in Altitude.

The refraction is necessary for correcting altitudes and distances observed at sea; it is always to be subtracted from the observed altitude, or added to the zenith distance. This table is adapted to a mean state of the atmosphere in Britain, namely, to 29.6 inches of the barometer, and 50° of the thermometer. If the height of the mercury in these instruments be different from the mean, a correction is necessary to reduce the tabular to the true refraction. See Refraction.

TABLES V. VI. Of the Dip of the Horizon.

The first of these tables contains the dip answering to a free or unobstructed horizon; and the numbers therein, as well as in the other table, are to be subtracted from the observed altitude when the fore-observation is used; but added, in the back-observation.

When the sun is over the land, and the ship nearer it than the visible horizon when unconfined; in this case, the sun's limb is to be brought in contact with the line of separation of the sea and land; the distance of that place from the ship is to be found by estimation or otherwise; and the dip answering thereto, and the height of eye, is to be taken from Table VI.

TABLE VII. Of the Correction to be applied to the time of high water at full and change of the moon, to find the time of high water on any other day of the month.

The use of this table is fully explained at Section II. Chap. I. Book I. of this article.

TABLES VIII. IX. X. Of the Sun's Declination, &c.

The first of these tables contains the sun's declination, expressed in degrees, minutes, and tenths of a minute, for four successive years, namely, 1793, 1794, 1795, and 1796: and by means of Table X. may easily be reduced to a future period; observing that, after the 28th of February 1800, the declination answering to the day preceding that given is to be taken.

Ex. 1. Required the sun's declination May 1. 1816?

May 1. 1812 is four years after the same day in 1812.
Sun's declination May 1. 1812 = 15° 6'.7 N
Equation from Table X. = +0 0.6
Sun's declination May 1. 1799 = 15° 7'.3 N

Ex. II. Required the sun's declination August 20. 1805?

The given year is 12 years after 1793, and the time is after the end of February 1800.
Now, Sun's dec. August 19. 1793 = 17° 36'.6
Equation from Table X. to 12 years = +0 1.9

Sun's declination August 20. 1805 = 17° 38'.5

The declination in Table VIII. is adapted to the meridian of Greenwich, and Table IX. is intended to reduce it to any other meridian, and to any given line of the day under that meridian. The titles at the top and bottom of this table direct when the reduction is to be added or subtracted.

TABLE XI. Of the Right Ascensions and Declinations of Fixed Stars.

This table contains the right ascensions and declinations of 60 principal fixed stars, adapted to the beginning of the year 1793. Columns fourth and sixth contain the annual variation arising from the precession of the equinoxes, and the proper motion of the stars; which serves to reduce the place of a star to a period of 17 years after the epoch of the table with sufficient accuracy. When the place of a star is wanted, after the beginning of 1793, the variation in right ascension is additive; and that in declination is to be applied according to its sign. The contrary rule is to be used when the given time is before 1793.

Example. Required the right ascension and declination of Bellatrix, May 1. 1798?

Right ascension January 1. 1793 = 3h 14' 3"
Variation = 3°.21 X 5° 7.1
Right Ascension, May 1. 1798 = 6h 14' 20"
Declination = 6° 8'.55 N
Variation = 4° X 5° 7.1
Declination May 1. 1798 = 6° 9'.14 N

The various other tables necessary in the practice of navigation are to be found in most treatises on the subject. Those used in this article are in Mackay's Treatises on the Longitude and Navigation.

Navigation of the Ancients. See Phoenixia and TRADE.

Inland Navigation, the method of conveying commodities from one part of a country to another by means of rivers, lakes, canals, or arms of the sea. See Canal.

We have already, under Canal, taken notice of a method proposed by Dr. Anderson of raising and lowering vessels by means of mechanical powers, instead of dams and locks. We shall describe another mechanical contrivance proposed by Mr. Leach for the same purpose. This machinery is compounded of an inclined plane and wheel in axis. The inclined plane is a parallelogram whose length reaches from the end of one canal to the beginning of another, or to the sea or navigable river, to which the vessel is next to be conveyed; the breadth ought to be 22½ feet. It may be made of good oak or deal plank, and sufficiently strong to bear the weight to be laid upon it; and it must be very strongly supported by beams of oak or other wood. It ought to be divided in the middle by a ledge or rib of 12 inches square, the side ribs being nine by 12 inches. The elevation must depend upon particular circumstances. Fig. 1. shows the inclined part of the machine; AB being the wooden part just described, placed between the side of the hill W and the navigable river F. According to the dimensions already given, the two paths A and B on which the vessels move are exactly ten feet wide. G represents the canal, brought perhaps from the distance of several miles to the top of the precipice WW. At the end of the canal, and quite across from R to B, must be built a very strong wall; in which are two sluices with flood-gates at K and L, to let out the water occasionally. Between the head of the plane, AB, and the end of the canal G, is a horizontal platform divided into two parts, as is represented in the figure by the letters H H. At the end of the canal are six rollers M. and N, of use in carrying the boats and lighters in and out of the canal. Near the end of the canal, at S, and T, are two other sluices, with their flood-gates, for letting out a quantity of fluid to drive the other part of the machine. O and P represent the two ends of the towing paths, one on each side of the canal.

Fig. 2. shows the vehicle by which the lighters are conveyed up and down the inclined plane, by the two paths A and B, fig. 1. AA (fig. 2.) represents part of the inclined plane, B the vehicle in the position in which it rolls up and down the two paths. C is the body of the vehicle, which is made hollow, to contain a quantity of wood occasionally used as a counterbalance for its corresponding vehicle. DDD are three rollers between the bottom of the vehicle and the plane, for the purpose of rolling the boats up and down. HHH are six rollers; four by the horizontal part of the vehicle on which the boat E is to rest in its passage up and down the plane; the other two rollers are in a moveable part, which is fastened to the body of the vehicle with a pair of very strong hinges: and in the passage of the vehicle up and down the plane, it turns up between the head of the boat and the plane, preventing the former from rubbing against the plane. When the vehicle gets up to the top, this moveable part falls down on the platform marked HH, Inland Navigation, becoming parallel with the horizontal part of the vehicle; after which it serves for a launch and passage to place the boat upon the rollers MN (fig. 1.) at the end of the canal. This passage part of the vehicle, together with the three rollers at the end of the canal, is likewise of great use in towing a boat out of the canal, in order to place it on the horizontal part. At the bottom of the cavity of the vehicle is a large hole F, with a valve opening inwardly. Through this hole the water enters when the vehicle sinks into the navigable river F, for the purpose of receiving a boat on the top or horizontal part of the vehicle, till it is quite full, and then will sink entirely under water, while the boat is towed in on the horizontal part. A small rope K is fastened to the valve, on purpose to lift it up and to keep it so, while the vehicle and boat are ascending the plane out of the canal; so that the water may discharge itself till as much as is necessary be got out, or till it becomes an equal balance for the corresponding vehicle and its contents, which are descending by the other path. Hence we see, that every machine must have two of these vehicles furnished with rollers as already described, and so constructed that one may be as nearly as possible a counterbalance to the other. As it is necessary that the vehicles should be water tight, the insides of them must be caulked; very tight; and they should be capacious enough to hold as much water as will balance the largest boat with its contents. Here it may be observed, that every vessel will be balanced by as many cubic feet of water as it displaces by being put into the water when loaded.

The quantity may easily be known, by observing how far the boat sinks in the water, and calculating the bulk of the part immersed.

The machine which puts the vehicles in motion, may either be constructed with an under-shot or breast-water wheel: or by an over-shot water wheel: or by two walking-wheels, for men to walk in as in canoes, &c.

Fig. 3. shows a front view of the under-shot water-wheel movement; where A is the end of the axis or cylinder of the cog or spur wheel; the diameter of which axis is four feet, and whose length not less than 22 feet, as it must be extended quite across the canal from one side to the other, and placed on the top of very strong supporting in each side of the canal, about seven feet above the surface of the water, as the loaded boat is to pass backwards and forwards under the cylinder, and at a convenient distance from the wall RR (fig. 1.); and placed between the two sluices S and T; on the end of which cylinder is the cog-wheel B (fig. 3.). The wheel B is supposed to be 20 feet of diameter, having on its edge 120 cogs, and underneath the cog-wheel is the breast-water one C, 24 feet in diameter, from the tip of one aller-board to the tip of its opposite. On the end of the axis of the water-wheel D is a trundle two feet and a half in diameter, with 15 rounds and staves contained therein. This must be placed between the two sluices S and T, to let the water out of the canal; which, falling on the float-boards, will turn the wheel round from the right hand towards the left, when the sluice on the left hand of the wheel is opened; but the contrary way when that of the right is opened. — The water falling...
at the top to receive the boat, the other will be at the bottom to take in water. Let then any of the movements just described be set to work, and it is plain, that as the upper vehicle with its boat descends, the under vehicle will ascend with the water; the valve being in the mean time lifted up till a sufficient quantity of water has flowed out, to make the one nearly a counterbalance to the other; so that the vessel may slide down gently and without any violence.

If it happens that a boat is to go up while none is to come down, one of the vehicles being at the foot of the plane under water, and in readiness to have the boat towed upon its horizontal part, one of the sluices at K or L is to be opened, and a quantity of water let into the cistern of the upper vehicle sufficient to counterbalance the boat with the contents which is to ascend. This being done, the machine is set to work, the valve of the under vehicle kept open till the water is all discharged; and then the boat will roll up to the top of the plane.

From this description of the canal and machinery for raising and lowering the vessels, the reader can be at no loss to understand the principles on which it depends. It would be superfluous to adduce examples, or follow our author through his calculations relative to particular cases. We shall only observe, that the difference of time in which vessels may be raised or lowered by the machinery just described, in comparison with what can be done in the common way by dams and locks, must give a very favourable idea of the new method. According to Mr Leach's computations, a boat with its cargo weighing 10 tons might be raised by the walking machine in 12 or 14 minutes, by the under-shot wheel in 15 minutes, and by the over-shot wheel in 30 minutes; and that through a space of less than 30 fathoms measured on the inclined plane, or 114 feet perpendicular.

NAVIGATORS ISLANDS. See Opoun.

NAULUM, in Roman antiquity, a piece of money put into the mouth of a person deceased, to enable him to pay Charon the ferryman for his passage. It was to be of the current coin of the reigning emperor; so that from this money the time of the person's death may be known. The sum for poor men was a farthing, but the rich in general were very liberal to Charon, as appears from the number of coins often found in the neighbourhood of Rome on opening the graves of great men. Charon was looked upon as a very morose and obstinate old fellow, who would not carry over any man without his fare; and hence the proverbial use of that verse in Juvenal,

_Furor est post omnia perdere naulum._

A similar custom took place among the Greeks: The money put into the mouth of the deceased was by them called _Δηλομακρινή_.

NAUMACHIA, in antiquity, a show or spectacle among the ancient Romans, representing a sea fight. These mock sea-fights are supposed to have originated at the time of the first Punic war, when the Romans first instructed their men in the knowledge of naval affairs. Afterwards they were intended to entertain the populace, as well as to improve the seamen. They were often, like other shows, exhibited at the expense of individuals, to increase their popularity.
In these spectacles they sometimes strove to excel each other in swiftness; and sometimes engaged in a warlike manner. The naumachie of Claudius indeed was a most savage diversion. The combatants used to destroy each other to amuse a tyrant and a cruel mob. As they passed before him, they used this melancholy greeting, "Ave Imperator, moriturui te salutant." The emperor replied, "Acute vos." This they understood as an answer of kindness, and a grant of their lives; but they soon discovered that it proceeded from wanton cruelty, and barbarous insensibility. In the time of the emperor Domitian, such a vast number of vessels engaged as would have nearly formed two regular fleets for a real fight, and the channel of water was equal in magnitude to a natural river. The emperor Heliodorus is reported to have filled the channel where the vessels were to ride with wine instead of water. Tritons and sea monsters were frequently exhibited during the engagement. Suetonius and Dio Cassius state one of these sea fights of Domitian a violent shower fell; the emperor, however, continued till the end of the engagement, often changing his clothes, nor would he suffer any one to depart; and as the rain continued for several hours, many were seized with distempers, and some even died, Suet. cap. 4. Dio. lib. lvii. Naumachie were also places fitted up for these shows, a sort of circi or amphitheatres, with seats and porticoes, &c. There were several of them at Rome; three built by Augustus, one by Claudius, another by Domitian, and another by Nero, which served for the reverse of his medals. Claudius used the lake Fucinus as a naumachie.

NAUMBURG, a town of Germany, in the circle of Upper Saxony, capital of the county of Saxe-NAumburg, situated on the river Salz, in E. Long. 11. 20. N. Lat. 51. 12.

NAUFACTUS, or NAUFACTUM, in Ancient Geography, a city of Αἰτωλία, at the mouth of the Evenus. The word is derived from Ναῦαι and μακήνας, because it was there that the Naupactus built the first ship which carried them to Peloponnesus. It first belonged to the Locrians of Ocloe, and afterwards fell into the hands of the Athenians, who gave it to the Messenians, who had been driven from Peloponnesus by the Lacedaemonians. It became the property of the Lacedaemonians after the battle of Εγέσποτομος, and it was restored to the Locrians. Philip of Macedon afterwards took it, and gave it to the Αἰτωλίας; from which circumstance it has generally been called one of the chief cities of their country. E. Long. 22. 20. N. Lat. 38. 0.

There was on the shore a temple of Neptune, and near it a cave filled with offerings, and dedicated to Venus, where widows resorted to request new husbands of the goddess. Pausan. lib. x. p. 898.

NAUPLIA, in Ancient Geography, a maritime city of Peloponnesus. It was the naval station of the Argives. The fountain Canathos was in its neighbourhood.

NAUPLUS, in fabulous history, a son of Neptune and Anymone, king of Euboea. He was the father of the famous Palamedes, who was so unjustly sacrificed to the artifice and resentment of Ulysses by the Greeks at the Trojan war. The death of Palamedes highly enraged Nautilus; and to revenge the injustice of the Grecian princes, he endeavoured to debauch their wives, and ruin their characters. When the Greeks returned from the Trojan war, Nautilus was pleased to see them distressed in a storm on the coasts of Euboea; and to make their disaster still more universal, he lighted fires on such places as were surrounded with the most dangerous rocks, that the fleet might be shipwrecked upon the coast. This had the desired effect; but Nautilus was so disappointed when he saw Ulysses and Diomedes escape from the general distress, that he threw himself into the sea. According to some mythologists there were two persons of this name: one a native of Argos, who went to Colchis with Jason. He was son of Neptune and Amyone.—The other was king of Euboea, and lived about the time of the Trojan war. He was, as some observe, son of Clytonus, one of the descendants of Nautilus the Argonaut. The Argonaut was remarkable for his knowledge of sea affairs and of astronomy. He built the town of Nauplius, and sold Auge daughter of Aeës to King Teiresias, to screen her from her father's resentment.

NAUPORTUS, or NAUPORTUM, in Ancient Geography, a town on a cognominial river, towards its source, in Pannonia Superior. The reason of the name, according to Pliny, is that the ship Argo, after coming up the Danube, the Save, and the Lausbach, was thence carried on men's shoulders over the Alps into the Adriatic. The river Nauportus rises in the Alps, near Longaticum, at the distance of six miles from the town Nauportum; which was a colony of the Taurisci, a people on the confines of Naricum. Now Upper Lausbach in Carinthia, on the river Lausbach. E. Long. 14. 40. N. Lat. 46. 28.

NAUSCOPY, the art of discovering the approach of ships or the neighbourhood of land at a considerable distance. This pretended art was discovered by M. Bottineau, employed in the king and company's service in the island of France, from the year 1782 to 1784; the account of it is as follows:

"This knowledge is not derived either from the undulation of the waves, or from the subtilest sight, or from any particular sensation; but merely from observation of the horizon, which discovers signs indicating the proximity of ships or of land.

"On the approximation of a ship toward the land, or towards another ship, there appears in the atmosphere a meteor of a particular nature, visible to every one without any painful attention. It is not by any kind of accident that this meteor appears under these circumstances; on the contrary, it is the necessary result of the approximation of one vessel towards another, or towards the land. The existence of the meteor, and the knowledge of its different modifications, are what constitute the certainty and the precision of my information.

"If I am asked, how it is possible that the approach of a ship towards land should give birth to any meteor whatsoever in the atmosphere, and what connexion there can be between two objects at such a distance from each other? I reply, that I am not obliged to give an account of the house and the wharf: for that is sufficient for me to have discovered the fact, without being obliged to account for its principle."

The writer concludes, by desiring to be called on for experimental proofs, and by promising in future a complete treatise of Nauscopy, with maps, plates, &c.
This complete treatise, as far as we know, has not yet been published; nor do we expect ever to see such a treatise on the subject as will satisfy the minds of those who are persuaded that every effect must have an adequate cause. The whole seems to be the work of fancy.

NAUSEA, or SICKNESS; a retching or propensity and endeavour to vomit, arising from something which irritates the stomach.

NAUTILUS, a genus of animals belonging to the order of vermes testacens. See Conchology Index.

NAVY, the fleet or shipping of a prince or state. See Marine.

The management of the British royal navy, under the lord high admiral of Great Britain, is intrusted to principal officers and commissioners of the navy, who hold their places by patent. The principal officers of the navy are four, viz. the treasurers, whose business it is to receive money out of the exchequer, and to pay it at the charges of the navy, by warrant from the principal officers: comptroller, who attends and controls all payment of wages, is to know the rates of stores, to examine and audit all accounts, &c.: surveyor, who is to know the states of all stores, and see what is supplied; to estimate repairs, charge boathouses, &c. with what stores they receive, and at the end of each voyage to state and audit accounts: clerk of the acts, whose business it is to record all orders, contracts, bills, warrants, &c.

The commissioners of the navy are five: The first executes that part of the comptroller's duty which relates to the comptrolling the victualers' accounts; the second, another part of the said comptroller's duty relating to the account of the storekeepers of the yard; the third has the direction of the navy at the port of Portsmouth; the fourth has the same at Chatham; and the fifth at Plymouth. There are also other commissioners at large, the number more or less according to the exigencies of public affairs; and since the increase of the royal navy, these have several clerks under them, with salaries allowed by the king.

The victualling of the royal navy hath formerly been undertaken by contract; but is now managed by commissioners, who hold their office on Tower-hill, London. The navy office is where the whole business concerning the navy is managed by the principal officers and commissioners.

The royal navy of Great Britain is now in a very flourishing state, having been diligently kept up in late reigns, as the natural strength of the kingdom. When it is complete, it is divided into three squadrons, distinguished by the colours of the flags carried by the respective admirals belonging to the same, viz. red, white, and blue; the principal commander of which bears the title of admiral; and each has under him a vice admiral and a rear admiral, who are likewise flag officers.

Navy Exercise. See Exercise.
Navy Discipline, or Regulations. See Maritime State.

NAWORTH CASTLE, in Cumberland, 10 miles from Carlisle, near the Clyde. This castle is still entire and inhabited. It is a large pile, square, and built round a court. On the north it stands over the river Lthing, at a great height, the banks shagged with wood. The whole house is a very irregular building; the rooms numerous, accessible by 16 staircases, with most frequent and sudden ascents and descents, &c.

The great hall has a gallery at one end, adorned with four vast crests carved in wood, viz. a griffin and dolphin, with the scallops; an unicorn, and an ox with a coronet round his neck. In front is a figure in wood of an armed man; two others, perhaps vassals, in short jackets and caps. The top and upper end of the room is painted in squares, representing the Saxon kings and heroes. This castle was built by one of the Dacres about the reign of Henry III. In the garden walls were stones with Roman inscriptions, which the late earl of Carlisle gave to Sir Thomas Robinson, and were by him removed to his museum at Rookby: On one of these stones is this inscription, peditum centum quingentos

NAVIA, or NAXOS, a considerable island of the Archipelago, 25 miles in length, and 88 in circumference. The whole island is covered with orange, olive, lemon, cedar, citron, pomegranate, fig, and mulberry trees; and there are a great many springs and brooks. This island has no harbour; and yet they carry on a considerable trade in barley, wine, figs, cotton, silk, flax, cheese, salt, oxen, sheep, mules, and oil. They burn only oil of mastich, though olive oil is exceedingly cheap. It is inhabited both by Greeks and Latins, who live in great dread of the Turks; for when the meanest of their ships appear here, they always wear red caps like galleyslaves, and tremble before the lowest officer; but as soon as they are gone, they put on their caps of velvet. The ladies are so vain, that when they return out of the country they have 40 women in their train, half on foot and half on asses, one of whom carries a napkin or two, another a pettochet, another a pair of stockings, and so on; which is a very ridiculous sight to strangers. There are four archbishops sees in this island, and a great many villages; but so thin of people, that the whole island does not contain above 8000 inhabitants. The highest mountain is Zio, which signifies “the mountain of Jupiter.” There are but few antiquities, except some small remains of the temple of Bacchus. Some say they have mines of gold and silver; however, there is one of emery, which is so common here and so cheap, that the English often ballast their ships therewith.

NAXOS, or NAXIA, a considerable town, and capital of the isle of Naxos, over against the isle of Paros, with a castle and two archbishops sees, the one Greek and the other Latin. The greatest part of the inhabitants are Greeks. E. Long. 23° 31. N. Lat. 37° 8.

NAXUS, now NAXIA, formerly Strongylus, De, Dionysius, Callipolis, and Little Sicily. It was called Strongylus, from a Greek word, signifying “round;” though in reality it is rather square than round. The names of De or Divine, and Dionysus, were given it as being consecrated in a peculiar manner to the fabulous god Dionysus or Bacchus. The appellations of Callipolis, Pliny and Solinus derive from the metropolis of the island, formerly a most beautiful city, which
NAX

which is the import of the word Callipolis. The great fertility of the country gave rise to the name of Little Sicily, Naxus being the most fruitful of all the Cyclades, as Agatharchus informs us, and no less fertile than Sicily itself. As for the name of Naxos, some assert that it was borrowed from one Naxus, under whose conduct the Carians possessed themselves of the island; others pretend it received its name from Naxos, the son of Endymion, Stephanus, Suidas, and Phavorinus, derive the name of Naxos, from the Greek word naxos, signifying, "to sacrifice," and will have it to have been so called from the many sacrifices offered here to Bacchos. With these Bochart agrees, as to its being called Naxos from the sacrifices performed here in honour of Bacchos, but will have the word naxos to be a corruption of the Phoenician naaqa, or naqa, signifying "a sacrifice, offering." Naxos is, according to Pliny, 75, but reckoned by the present inhabitants 100 miles, in compass. It has Paros to the west, Mykonos and Delos to the north, and Ios to the south. This island is the most fruitful of the Archipelago, and was formerly famed for the excellent wines it produced. Archilocho, as quoted by Athenaeus, compares them to the nectar of the gods; and Aesop, and Hesiod, and Homer, superseded them by Bacchos, and took more delight in Naxos than in any other place whatsoever, having himself taught the inhabitants to cultivate their vines. The wine of Naxos maintains to this day its ancient reputation, being by some deemed the best of the Levant. Besides wine, this island abounds with all sorts of delicious fruits, the plains being covered with orange, olive, lemon, cedar, citron, pomegranate, mulberry, and fig trees. It was formerly famous for quarries of that sort of marble which the Greeks called opisthe, from its being green, and speckled with white spots like the skin of a serpent. The best emerald is found here on the mountains near the western coast, whence the neighbouring cape is called by the Italians capo smaragdus, or the emerald cape. As to the inhabitants of Naxos, Diogoras relates that the island was first peopled by the Thracians. These were in a little time subdued by a body of Thessalians, who, having possessed the island for the space of 200 years and upwards, were compelled to abandon it by a drought and famine.

After the Trojan war, the Carians settled here, and called the island Naxos, from their king, who was the son of Eolus. He was succeeded by his son Leucippus, and Leucippus by his son Smerdis, in whose reign Theseus, coming out of Crete, landed here with Ariadne, whom he was, in his sleep, commanded by Bacchos to leave in this island. In process of time a colony of Cnidians and Rhodians settled here under the conduct of Hippothus and Xuthus: and last of all the Ionians, who, in time, possessed the whole island; and whoso the Naxians are, by Herodotus, called Ionians, and ranged among the Athenian colonies. E. Long. 26. 5. N. Lat. 36. 30. It is about 105 miles in circumference, and about 30 broad.

NAXUS, in Ancient Geography, a town of Crete, famous for its honeys, called lapis Naxus. Another of Sicily, built by the Chalcidians; situated on the south side of Mount Taurus, destroyed by Dionysius the Great; from its ruins Thermopolea, built by Timeus, either arose or was increased, (Plutarch).

NAYRES, the modesty of the Malabar coast. We may with truth affirm that they are the oldest modesty in the world; for the most ancient writers mention them, and quote the law that permits the Nayres ladies to have many husbands; everyone being allowed four. Their houses, which stand single, have as many doors as the lady has husbands. When one of them visits her, he walks round the house, striking with his sabre on his buckler; he then opens his door, and leaves a domestic with his arms in a kind of porch, who serves to inform others that the lady is engaged. It is said, that one day in the week the four doors are all opened, and all her husbands visit her, and dine together with her. Each husband gives a sum of money, or portion, at the time of marriage; and the wife only has the charge of the children. The Nayres, even the Samorins, and the other princes, have no other heirs than the children of their sisters. This law was established, that the Nayres, having no family, might be always ready to march against the enemy. When the nephews are of age to bear arms, they follow their uncles. The name of father is unknown to a Nayre child. He speaks of the husbands of his mother and of his uncles, but never of his father.

NAZARETH, a little city in the tribe of Zebulun, in Lower Galilee, to the west of Tabor, and to the east of Ptolemais. Eusebius says, it is 15 miles from Legion towards the east. This city is much celebrated in the Scriptures, for having been the usual place of the residence of Jesus Christ for the first 33 years of his life, Luke i. 51. It was there our Saviour became incarnate, where he lived in obedience to Joseph and Mary, and from whence he took the name of Nazarene. After he had begun to execute his mission, he preached there sometimes in the synagogue, Id. iv. 16. But because his countrymen had no faith in him, and were offended at the meanness of his original, he did not many miracles there, Matt. xiii. 54. 58. nor would he dwell therein; so he fixed his habitation at Capernaum for the latter part of his life, Id. iv. 13. The city of Nazareth was situated upon an eminence; and on one side there was a precipice, from whence the Nazarenes one day had a design of throwing down our Saviour, because he upbraided them with their incredulity, Luke iv. 29.

St Epiphanius says, that in his time Nazareth was only a village, and that to the reign of Constantine it was inhabited by Jews alone, exclusive of all Christians. Adamnanus, a writer of the seventh age, says, that in his time there were two great stones to be seen at Nazareth, one in the midst of the city, built upon two arches, in the place where our Saviour's house had stood. Under the two arches now mentioned, was a very fine fountain, which furnished water to the whole city, and from whence water was drawn also by the help of a pulley for the use of the church above. The second church of Nazareth was built in a place where the house stood wherein the angel Gabriel revealed to the virgin Mary the mystery of our Lord's incarnation; and we are assured that the church of the Incarnation, which is supported by two arches, is still in being to
Nazareth, this day. Mr. Maundrell tells us, that there is a convent built over what is said to be the place of annunciation; for the chamber where she received the angel’s salutation was about 500 years ago removed from Nazareth, and, according to the Roman legends, transported by angels to Loretto, then a small village in the pope’s dominions, now become a bishop’s see. However, Calmet’s opinion (which is certainly the true one) upon the different translations of this famous house of Loretto, is, that they were no other than so many different buildings made upon the model of the church of Nazareth, just as in several places sepulchres have been built upon the model of that at Jerusalem. Mariti tells us, that in the eastern part of the city stands the church dedicated to the Blessed Virgin: the zeal of the Canobites raised it from the ruins of that which had been destroyed by the Saracens. It is a very handsome building, and consists of three naves; in the middle of which is the principal altar; to which there is an ascent by two magnificent stairs, much admired for their iron ballustrades, the work of an ingenious monk of the convent. The descent to the grotto or annunciation chapel below is by steps of beautiful marble, cut with great taste. Two beautiful columns of oriental granite strike the eye of the observer in the entrance. They appear to have been constructed both to support and ornament the grotto. The altar of this subterranean chapel is extremely elegant; and the different kinds of marble with which it is ornamented, receive an additional lustre from the combined light of several silver lamps presented by Christian princes. On solemn festivals, the walls and the pilasters are ornamented with various pieces of tapestry, representing the mysteries of the virgin; a superb present from the House of Austria. In the western part of the city stands a Christian church, built, as it is said, on the site of the ancient synagogue where Jesus showed the Jews the accomplishment of the prophecies in his person. This place served a long time as a shelter for flocks, but at present it is in good repair. In the neighbourhood may be seen a fountain of excellent water, which is, however, esteemed by the people on another account. They conjecture that it was contiguous to the habitation of the virgin, and that it was used by her. At some distance is a large stone of a round form, called Christ’s Table. It is pretended that he came hither more than once with his disciples to eat. The inhabitants of Nazareth pay it a kind of worship, burning perfumes and incense around it. It is situated in 35° E. Long. and in 32° N. Lat.; and formerly held the third rank under the patriarch of Jerusalem. At present it is part of the domains of the chief of Acre. The ancient city, after the ravages of fanaticism, was reduced to a miserable hamlet, containing only a few Arab huts.—Under the protection of Daher Omar, however, it recovered very considerably, and is now of far more importance.

NAZARITE, or NAZAREAN, or Nazarines, a term which may signify, 1. One that is of Nazareth, or any native of this city. 2. It was given to Jesus Christ and his disciples, and is commonly taken in a sense of derision and contempt in such authors as have written against Christianity. 3. It has been taken for a sect of heretics called Nazarenes. 4. For a Nazarite, a man that has laid himself under the obligation of a vow to observe the rules of Nazaritish, whether it be for his whole life, as Samson and John the Baptist, or only for a time, as those mentioned in Numbers vi. 18, 19, 20. Amos ii. 11, 12. Lastly, The name Nazarene, in some passages of Scripture, denotes a man of particular distinction and great dignity in the court of some prince. But we must speak of these several sorts of Nazarenes something more distinctly.

The name of Nazarene belongs to Jesus Christ, not only because of his having lived the greatest part of his life at Nazareth, and because this city has always been considered as his country, but also because the prophets had foretold that he should be called a Nazarene, Matt. ii. 23. "And he came and dwelt in a city called Nazareth, that it might be fulfilled which was spoken by the prophets, He shall be called a Nazarene." We find no particular place in the prophets in which it is said that the Messiah should be called a Nazarene; and St Matthew only quotes the prophets in general. Perhaps he would insinuate, that the consecration of the Nazarenes, and the great purity of which they made profession, was a type, and a sort of prophecy of those of our Saviour, or else that the name Nazir or Nazaret given to the patriarch Joseph, Gen. xliv. 26. Deut. xxxiii. 16. was a prophecy which was to be fulfilled in the person of Jesus Christ, of whom Joseph was a figure. Lastly, St Jerome was of opinion, that St Matthew here alludes to that passage of Isaiah xi. 1 and lx. 21. "And there shall come forth a rod out of the stem of Jesse, and a branch (in Hebrew Neser) shall grow out of his roots." This branch or Neser, and this rod, are certainly intended to denote Jesus Christ, by the general consent of all the fathers and interpreters.

When the word Nazarite is put for the heretics known by this name, it denotes Christians converted from Judaism, whose chief error consisted in defending the necessity or expediency of the works of the law, and who obstinately adhered to the practice of the Jewish ceremonies. The name of Nazarenes at first had nothing odious in it, and it was often given to the first Christians. The fathers frequently mention the gospel of the Nazarenes, which differs nothing from that of St Matthew, which was either in Hebrew or Syriac, for the use of the first converts, but was afterwards corrupted by the Ebionites. These Nazarenes preserved this first gospel in its primitive purity. Some of them were still in being in the time of St Jerome, who does not reproach them with any error. They were very zealous observers of the law of Moses, but held the traditions of the Pharisees in very great contempt.

Nazarite, when put to signify those under the ancient law who made a vow of observing a more than ordinary degree of purity (Numb. ubi. cit.), denotes a man or woman who engage themselves by a vow to abstain from wine and all intoxicating liquors, to let their hair grow without cutting or shaving, not to enter into any house that was polluted by having a dead corpse in it, nor to be present at any funeral. And if by chance any one should have died in their presence, they began again the whole ceremony of their consecration and Nazaritish. This ceremony generally lasted eight days, sometimes a month, and sometimes their whole lives. When the time of their Nazarite-ship
The ship was accomplished, the priest brought the person to the door of the temple, who there offered to the Lord a he lamb for a burnt-offering, a she lamb for an expiatory sacrifice, and a ram for a peace-offering. They offered likewise loaves and cakes, with wine necessary for the libations. After all this was sacrificed and offered to the Lord, the priest or some other shaved the head of the Nazarite at the door of the tabernacle, and burnt his hair, throwing it upon the fire of the altar. Then the priest put into the hand of the Nazarite the shoulder of the ram roasted, with a loaf and a cake, which the Nazarite returning into the hands of the priest, he offered them to the Lord, lifting them up in the presence of the Nazarite. And from this time he might again drink wine, his Nazarite ship being now accomplished.

As to those that were perpetual Nazarites, as were Samsen and John the Baptist, it appears that they were consecrated to their Nazarite ship by their parents, and continued all their lives in this state without drinking wine or cutting their hair.

Those that made a vow of Nazarite ship out of Palestine, and could not come to the temple when their vow was expired, contented themselves with observing the abstinence required by the law, and after that cutting their hair in the place where they were: as to the offerings and sacrifices prescribed by Moses, which were to be offered at the temple by themselves, or by others for them, they deferred this till they could have a convenient opportunity. Hence it was, that St Paul being at Corinth, and having made the vow of a Nazarite, he had his hair cut off at Cenchrea, and put off fulfilling the rest of his vow till he should arrive at Jerusalem, Acts xviii. 18. When a person found that he was not in a condition to make a vow of Nazarite ship, or had not leisure to perform the ceremonies belonging to it, he contented himself by contributing to the expense of the sacrifice and offerings of those that had made and fulfilled this vow; and by this means he became a partaker in the merit of such Nazarite ship.

When St Paul came to Jerusalem, in the year of Christ 58, the apostle St James the Less, with the other brethren, said to him, Acts xxii. 23, 24, that to quiet the minds of the converted Jews, who had been informed that he everywhere preached up the entire abolition of the law of Moses, he ought to join himself to four of the faithful who had a vow of Nazarite ship upon them, and contribute to the charge of the ceremony at the shaving of their heads; by which the new converts would believe that he continued to keep the law, and that what they had heard of him was not true.

The Hebrew word נזיר, Nazir, which is made use of to express a man exalted to great dignity, as it is said of the patriarch Joseph, Gen. xlix. 26, and Deut. xxxiii. 16, "that he was separated from his brethren," as it is in our translation; or as the Vulgate and others understand the Hebrew, "that he was a Nazarite among his brethren," is variously understood. Some think that the Hebrew word נזיר, Nazir, in these places, signifies one who is crowned, chosen, separated, or distinguished: the word נער, Nazir, signifies a crown. The Septuagint translate this word a chief, or him that is honoured. Calmet thinks that this was a term of dignity in the courts of eastern princes, and that at this day in the court of Persia the word Nazir signifies the superintendent general of the king's household, the chief officer of the crown, the high steward of his family, treasures, and revenues; and that in this sense Joseph was the Nazir of the court of Pharaoh. Le Clerc translates the Nazir, a prince, and calls Joseph "the prince of his brethren," in the two places already quoted. Mr Pool declares in favour of this last translation. See Joseph. Chardin. Chrysost. St Jerome, &c.

Nazi, the lord lieutenant, viceroj., or governor of a province in Hindostan; the same as Subahdar, or Nabob.

Nealized, among seamen, is used when the sounding is deep water close to the shore; as also when the shore is sandy, clayey, oozy, or foul and rocky ground.

Nealizing, or rather Annealing, a term used for the preparing of several matters, by heating or baking them in the oven, or the like.

Nealizing of glass, is the baking of glass, to dry, harden, and give it the due consistence, after it has been blown, and fashioned into the proper works,—This is usually performed in a kind of a tower called the fettor, built over the melting furnace. See Glass.

Nealizing of glass is also used for the art of staining glass with metalline colours. "One fine use of silver (says Mr Boyle) was only discovered since the art of annealing upon glass came to be practised. For prepared silver, or even the crude metal, being burnt on a glass plate, will tinge it of a fine yellow or golden colour. And there are several mineral earths, and other coarse matters, of use in this art, which by means of fire impart transparent colours to glass, and sometimes very different ones from those of the bodies themselves."

Nealizing of steel, is the heating it in the fire to a blood-red heat, and then taking it out, and letting it cool gently of itself. This is done to make it softer, in order to engrave and punch upon it. See Tempering and Engraving.

Nealizing is also used for the art or act of burning or baking earthen or other ware in an oven. The miners at Mendip, when they meet with a rock they cannot cut through, anneal it by laying on wood and coal, and contriving the fire so that they quit the mine before the operation begins, it being dangerous to enter it again before it be quite cleared of the smoke.

Nealizing of tile is used in ancient statutes for the burning of tile. The word is formed of the Saxon onelan, accendere, to light, burn.

Neap or Neep tides, are those tides which happen when the moon is in the sign of the second and fourth quarters. The neap tides are low tides, in respect of their opposites the spring tides. As the highest of the spring tides is three days after the full or change, so the lowest of the neap is four days before the full or change. On which occasion the seamen say that it is deep neap.

Neaped. When a ship wants water, so that she cannot get out of the harbour, off the ground, or out of the dock, the seamen say she is neaped, or beneaped.

Neapolis, in Ancient Geography, a city of the Higher Egypt, in the Nomos Panopolitanus, between Thebe to the south, and Panopolis to the north, on the east side of the Nile; otherwise called Caesarea.
NEC

second Neapolis of Babylonia, situated near the Euphrates on the south side.—A third of Campania, an ancient town and a colony from Cumae. (See Velleius, Pliny, Strabo); accounted a Greek city, and a great stickler for Greek usages. (See Livy, Tacitus). Its hot baths were in nothing inferior to those of Baiae, according to Strabo; at two miles distance from it stands the monument of Virgil, held in religious veneration by learned posterity. The Younger Pliny relates, that Virgil’s birth day was more religiously observed by Silius Italicus than his own, especially at Naples, where he resorted to his tomb as to a temple. The city is washed by the river Seleucus. Virgil feigns the nymph Seleithis to preside over the stream. Now Naples, capital of the kingdom of that name. See NAPLES.—A fourth, Neapolis of Caria, near the Meander, (Ptolemy).—A fifth, an inland town of Crete, situated between Ptolemais and Arsinoe, (Ptolemy); and to be distinguished from the Camopolis, or Neapolis, on the east border of the same province, (id.) A sixth of Ionia, (Strabo); which belonged first to the Ephesians, but afterwards to the Samians, who exchanged Marathonides, a more distant city, for a nearer.—A seventh, Neapolis of Macedonia Adjecta, situated at the distance of 12 miles to the east of Philippi, (Antonine).—An eighth, Neapolis of Pisidia, on the borders of Galatia, situated between Amblyada and Pappa, (Ptolemy).—A ninth of Samaria, the ancient Sichem, which see; so called upon its restoration by the Romans, (Coin, Pliny, Josephus).—A tenth of Sardinia, situated on the south-west side of the island, 30 miles to the north of Matterna; now called Neapoliti.—An eleventh, of the Regio Syrta, called also Lepis.—A twelfth, of Zeugitana on the Mediterranean, to the east of Clypeus, and south of the Promontory of Mount Etna.

NEAT, or Net Weight, the weight of a commodity alone, clear of the cask, bag, case, or even fith. See NET.

NEBEL, or NARLUM, a musical instrument among the Jews. See NABUM.

NEBIO, or NEBBIO, a ruined city, on the north side of the island of Corsica, with a bishop’s see, whose bishop resides at San Fiorenza, from which it is a mile distant.

NEBO, in Ancient Geography, a very high mountain, a part of the mountains of Abarim, and their highest top, whither Moses was ordered to ascend to take a view of the land of Canaan, and there die. Situated in the land of Moab over against Jericho: with a cognominial town at its foot (Isaiah) belonging to the Reubenites, which afterwards returned to the Moabites; in Jerome’s time desolate; eight miles to the south of Heshbon.

NEO, or Nabo. See NABO.

NEBUCHADNEZZAR. See NABUCHADNEZZAR.

NEBULY, or NERULE, in Heraldry, is when a coat is charged with several little figures, in form of words running within one another, or when the outline of a bordure, ordinary, &c. is indented or waved.

NECESSITY, whatever is done by a cause or power that is irresistible; in which sense it is opposed to freedom. Man is a necessary agent, if all his actions be so determined by the causes preceding each action, that not one past action could possibly not have come necessary to pass, or have been otherwise than it hath been; nor one future action can possibly not come to pass, or be otherwise than it shall be. But he is a free agent, if he be able, at any time, under the circumstances and causes he then is, to do different things; or, in other causes, if he be not unavoidably determined in every point of time, by the circumstances he is in, and the causes he is under, to do that one thing he does, and not possibly to do any other thing. Whether man is a necessary or a free agent, is a question which has been debated with much ingenuity by writers of the first eminence, from Hobbes and Clarke, to Priestley and Gregory. See Metaphysics, Part III. chap. v. and Predestination.

NECESSITY, in Mythology, a power superior to all other powers, and equally irresistible by gods and by men. Herodotus, as he is quoted by Codworth, mentions an oracle which declared that “God himself could not shun his destined fate.” And among the fragments of Philemon collected by Le Clerc, is the following sentence:

Ανεδιά βασιλεύς αυτής, ο άριστος το ίδιον, δέν τις αναγκάζει.

“We are subject to kings, kings to the gods, and God to Necessity.” Hence it is that, in the Iliad, we find Jove himself, the sire of gods and men, regretting that he was restrained by Necessity from resuing his favourite son from the sword of Patroclus. Nay to such a height this was impiety carried in the earliest ages of Greece, that we find Hesiod and Homer teaching that the gods themselves were generated by Necessity, of Night and Chaos.

This power, though always represented as blind and unintelligient, was however worshipped as a goddess, bearing in her hand large iron nails, wedges, anchors, and melted lead, &c., as emblems of the inflexible severity of her nature. “In the city of Corinth she had a temple, in which the goddess Violence likewise resided, and into which no person was ever permitted to enter but the priest who officiated in sacrific.”

Learned men have exercised their ingenuity in vain in these attempts to trace this portentous notion to its origin. Some, who wished to interpret it in a pious sense, have supposed that the gods who are subject to Necessity were only those who were the ministers of the supreme person; and that by necessity itself was meant nothing more than divine providence. But this is not consistent with Hesiod and Homer’s Generation of the Gods, or with the epithets serva necessitates, duras necessitates, by which this power was perpetually distinguished. Others, and among them Mosheim, have supposed that this monstrous fable was invented by the Pagan priests, and diligently inculcated upon the minds of the people, in order to excuse the villanies of the objects of their worship. For, says he, who could be indignant at Jupiter’s numberless adulteries, after it was known that in all his actions he was the servant of blind necessity: In the thefts of Mercury, the whoresoms of Venus, and the frequent squabbles of the other gods, there could be no moral turpitude, if they were under the influence of a superior power.

Nimina cum vites duris omnino fatis,

Invidia possit exsorcire deos Ι.

This
Necessity. This account of the matter is at least as plausible as any other which is usually given; but the real case undoubtedly was, that when men "did not like to retain God in their knowledge, God gave them over to a reprobate mind to do those things which are not convenient; when their foolish heart was darkened, and professing themselves to be wise, they became fools." See PAR. E.

Necessity, in Law, as it implies a defect of will, excuses from the guilt of crimes. See Crime.

Compulsion and inevitable necessity are a constraint upon the will, whereby a man is urged to do that which his judgment disapproves; and which, it is to be presumed, his will (if not to itself) would reject. As punishments are therefore only inflicted for the abuse of that free will which God has given to man, it is highly just and equitable that a man should be excused for those acts which are done through unavoidable force and compulsion.

1. Of this nature, in the first place, is the obligation of civil subjection, whereby the inferior is constrained by the superior to act contrary to what his own reason and inclination would suggest: as when a legislator establishes iniquity by a law, and commands the subject to do an act contrary to religion or sound morality. How far this excuse will be admitted in furo conscientiae, or whether the inferior in this case is not bound to obey the divine rather than the human law, it is not our business to decide; though among the casuists, it is believed the question will hardly bear a doubt. But, however that may be, obedience to the laws in being is undoubtedly a sufficient extenuation of civil guilt before the municipal tribunal. The sheriff who burnt Latimer and Ridley, in the bigoted days of Queen Mary, was not liable to punishment from Elizabeth for executing so horrid an office; being justified by the commands of that magistracy which endeavoured to restore Supremacy, under the holy auspices of its merciless sister, Persecution.

As to persons in private relations, the principal case where constraint of a superior is allowed as an excuse for criminal misconduct, is with regard to the matrimonial subjection of the wife to her husband, for neither a son nor a daughter can be excused from the commission of any crime, whether capital or otherwise, by the command or coercion of the parent or master; though in some cases the command or authority of the husband, either express or implied, will privilege the wife from punishment, even from capital offences. And therefore, if a woman commit theft, burglary, or other civil offences against the law of society, by the coercion of her husband, or even in his company, which the law construes a coercion, she is not guilty of any crime; being considered as acting by compulsion, and not of her own will. This doctrine is at least 1000 years old in this kingdom, being to be found among the laws of King Ina the West Sax. And it appears, that among the northern nations on the continent, this privilege extended to any woman transgressing in concert with a man, and to any servant that committed a joint offence with a freeman: the male or freeman only was punished, the female or slave dismissed; procul dubio quod alterum libertas, alterum necessitas impellit. But (besides that, in our law, which is a stranger to slavery, no impunity is given to servants, who are as much free agents as their masters) even with regard to wives, this rule admits of an exception in crimes that are mala in se, and prohibited by the law of nature; as murder, and the like; not only because these are of a deeper dye, but also, since in a state of nature no one is in subjection to another, it would be unreasonable to screen an offender from the punishment due to natural crimes, by the refinements and subordinations of civil society. In treason also (the highest crime which a member of society can, as such, be guilty of), no plea in couverture shall excuse the wife; no presumption of the husband's coercion shall extenuate her guilt; as well because of the odiousness and dangerous consequence of the crime itself, as because the husband, having broken through the most sacred tie of social community by rebellion against the state, has no right to that obedience from a wife, which he himself as a subject has forgotten to pay. In inferior misdemeanours also, we may remark another exception, that a wife may be indicted and set in the pillory with her husband, for keeping a brothel: for this is an offence touching the domestic economy or government of the house, in which the wife has a principal share; and is also such an offence as the law presumes to be generally condoned by the intrigue of the female sex. And in all cases where the wife offends alone, without the company or coercion of her husband, she is responsible for her offence as much as any feminine.

2. Another species of compulsion or necessity is what our law calls duress per minas; or threats and menaces, which induce a fear of death or other bodily harm, and which take away for that reason the guilt of many crimes and misdemeanours, at least before the human tribunal. But then that fear which compels a man to do an unwarrantable action ought to be just and well grounded; such, "qui cadere possit in virum constantem, non timideam et metedeolum," as Bracton expresses it in the words of the civil law. Therefore in time of war or rebellion, a man may be justified in doing many reasonable acts by compulsion of the enemy or rebels, which would admit of no excuse in the time of peace. This, however, seems only, or at least principally, to hold so positive or criminal by the law of society, and which therefore society may excuse; but not as to natural offences, so declared by the law of God, wherein human magistrates are only the executioners of divine punishment. And therefore though a man be violently assaulted, and hath no other possible means of escaping death but by killing an innocent person, this fear and force shall not acquit him of murder; for he ought rather to die himself than escape by the murder of an innocent. But in such case he is permitted to kill the assailant; for there the law of nature, and self-defence its primary cause, have made him his own protector.

3. There is a third species of necessity, which may be distinguished from the actual compulsion of external force or fear; being the result of reason and reflection, which act upon and constrain a man's will, and oblige him to do an action which without such obligation would be criminal. And that is, when a man has his choice of two evils set before him, and being under a necessity of choosing one, he chooses the least pernicious
NEC [ 742 ]

NEC

Necessity, perrissions of the two. Here the will cannot be said freely to exert itself, being rather passive than active; or, if active, it is rather in rejecting the greater evil than in choosing the less. Of this sort is that necessity, where a man by the commandment of the law is bound to arrest another for any capital offence, or to disperse a riot, and resistance is made to his authority: it is here justifiable, and even necessary, to beat, to wound, or perhaps to kill the offenders, rather than permit the murderer to escape, or the riot to continue. For the preservation of the peace of the kingdom, and the apprehending of notorious malefactors, are of the utmost consequence to the public; and therefore excuse the felony, which the killing would otherwise amount to.

4. There is yet another case of necessity, which has occasioned great speculation among the writers upon general law; viz. whether a man in extreme want of food or clothing may justify stealing either, to relieve his present necessities. And this, both Groseius and Puffendorf, together with many other of the foreign jurisists, hold in the affirmative; maintaining by many ingenious, humane, and plausible reasons, that in such cases the community of goods, by a kind of tacit concession of society, is revived. And some even of our lawyers have held the same; though it seems to be an unwarranted doctrine, borrowed from the notions of some civilizers; at least it is now antiquated, the law of England admitting no such excuse at present. And this its doctrine is agreeable not only to the sentiments of many of the wisest ancients, particularly Cicero, who holds, That suum cuique incommodum ferendum est, potius quam de alterius commodia detradendum; but also to the Jewish law, as certified by King Solomon himself: "If a thief steal to satisfy his soul when he is hungry, he shall restore sevenfold, and shall give all the substance of his house" which was the ordinary punishment for theft in that kingdom. And this is founded upon the highest reason: for men's properties would be under a strange insecurity, if liable to be invaded according to the wants of others; of which wants so man can possibly be an adequate judge but the party himself who pleads them. In England especially, there would be a peculiar impropriety in admitting so dubious an abuse: for by the laws such sufficient provison is made for the poor by the power of the civil magistrate, that it is impossible that the most needy stranger should ever be reduced to the necessity of thieving to support nature. The case of a stranger is, by the way, the strongest instance put to Baron Puffendorf, and whereon he builds his principal arguments: which, however they may hold upon the continent, where the parsonimious industry of the natives orders every one to work or starve, yet must lose all their weight and efficacy in England, where charity is reduced to a system, and interwoven in our very constitution. Therefore our laws ought by no means to be taxed with being unmerciful, for denying this privilege to the necessitous; especially when we consider, that the king, on the representation of his ministers of justice, hath a power to soften the law, and to extend mercy in cases of peculiar hardship. An advantage which is wanting in many states, particularly those which are democratical: and these have in its stead introduced and adopted, in the body of

the law itself, a multitude of circumstances tending to alleviate its rigour. But the founders of our constitution thought it better to vest in the crown the power of pardoning particular objects of compassion, than to contemnance and establish theft by one general undistinquishing law.

NECHO, king of Egypt, began his reign 660 B.C. and was killed eight years after by Sabacoen king of Ethiopia. Psammiticus his son succeeded him, and was the father, as Herodotus informs us, of Necho II, who reigned in the 616 B.C. This Necho II. is celebrated in history for attempting, though in vain, to cut a canal from the Nile to the Arabian gulf. He carried his arms as far as the Euphrates, and conquered the city of Carchemish. This prince is not only known in Scripture under the name of Neero, but also in profane history. He no sooner succeeded to the crown than he raised great land armies, and fitted out vast fleets, as well upon the Mediterranean as upon the Red sea: he gave battle to the Syree near the city of Migdol; routed them, and made himself master of the city of Cadysis. The learned, however, are not agreed about this city Cadysis. Some will have it to be Cades in Arabia Petraea, others Jerusalem; and others say it is the city of Cedes, or Cloeish, in Galilee, in the tribe of Naphtali.

The Scriptures acquaint us with the whole expedition of Necho in all its particulars, 2 Kings xxiii. 20. &c. and 2 Chr. xxxv. 20, 21 &c. In the year of the world 3364, this prince having drawn out his army into the field to make war with the Assyrians or Babylonians, and to take the city of Carchemish, otherwise called Ciriaenum, upon the Euphrates, Josiah king of Judah, who was a tributary to the king of Babylon, marched to oppose his passage. Necho, who had no designs against him, sent to tell him, "What have I to do with you, king of Judah? It is not against you that I am come forth, but against another people, against whom the Lord hath commanded me to make war. Leave off therefore to set yourself against me, for fear the Lord should punish you for your resistance." But Josiah would not hearken to the remonstrances of Necho, but gave him battle at Megiddo, where he received the wound of which he died. The people of Jerusalem set up Jehoahaz for king of Judah, and Necho soon passed forward, without making any longer stay in Judea.

But at his return from his expedition, which was very successful, he halted at Riblah in Syria; and sending for Jehoahaz king of the Jews, he deposed him, loaded him with chains, and sent him into Egypt. Then coming to Jerusalem, he set up Eliakim, or Jehoiakim, in his place, and exacted the payment of 100 talents of silver and one talent of gold from the country. Jeremiah (xlvi. 2.) acquaints us that the city of Carchemish was taken from Necho by Nebuchadnezzar king of Babylon, in the fourth year Jehoiakim king of Judah; so that Necho did not enjoy his conquest above four years. Josephus adds, that the king of Babylon pursuing his victory, brought under his dominion all the country which is between the Euphrates and Egypt, excepting Judea. Thus Necho was again reduced within the limits of his own country.

NECK, in Anatomy, is the slender part situated between
NEC [743] NEC

Necromancy, the art of revealing future events by a pretended communication with the dead.

This superstitious and impious imposture appears to have had its origin at a very early period in Egypt, and to have been thence propagated in every nation with the manners of which history has made us acquainted. The conquest of Sesostris might introduce it into India; the Israelites would naturally borrow it from the people among whom they sojourned 400 years; and it would easily find its way into Phenicia, from the vicinity of that country to the land of its nativity. From the Egyptians and Phenicians it was adopted, with the other rites of paganism, by the Greeks; and it was imported into Rome with Grecian literature and Grecian manners. It was not however confined to the pagan nations of antiquity: it spread itself through all the modern nations of Europe, and took such deep root as to be long retained even after those nations were converted to the Christian faith.

Of its early antiquity we have complete evidence in the writings of Moses, where it is severely condemned as an abomination to the Lord; and though it appears to have been even then spread into Phenicia, we might yet conclude its birthplace to have been Egypt, because, at their exody, the Israelites were corrupted only by Egyptian superstitions, and because necromancy seems to be one of those whoredoms which the prophet Ezekiel represents his countrymen as having brought with them from Egypt, and continued to practise till they were carried captives into Babylon.

If from sacred we proceed to consult profane authors, we shall find them not only affirming Egypt to have been the birthplace of necromancy, but in some degree accounting for the origin of so impious a delusion.

From Diodorus the Sicilian we learn that the Grecian fable of Charon the ferryman of hell, of Styx, Co-cytus, the Elysian Fields, Tartarus, the judgment of Minos and Rhadamantus, &c. with the whole scenery of the infernal regions, were imported from Egypt into Greece. The ancient Egyptians, and indeed all the people of the east, made use of caves for burying places, which were well suited to the solemn sadness of the surviving friends, and proper receptacles for those who were never more to behold the light. In Egypt, many of those subterraneous cavities being dug out of the natural rock, still remain, and command the admiration of travellers; and near to the pyramids in particular there are some apartments of a wonderful fabric, which though they extend in length 4400 feet, and are about 30 feet in depth, appear to have been, if not entirely dug at least reduced to form by the chisel or pickaxe of the artist.

From the practice of burying in such caverns sprang the opinion that the Infernal mansions were situated somewhere near the centre of the earth, which by the Egyptians was believed to be not very distant from its surface. In these dreary mansions, it was very easy for such adepts as the priests of Egypt to fabricate Erobus, Tartarus, the Elysian Fields, and all those scenes which were displayed before the initiated (see Mysteries), and by them described to the million of the people. As it was in those dark abodes that necromancy was practised, it would be no difficult matter for such magicians as withstood Moses to impose so far upon the credulous vulgar, as to make them believe, that in consequence of their invocations they actually saw the ghosts of their friends ascend out of the earth. It appears from the book of Exodus, that the Israelitish women were, even in the wilderness, well acquainted with the use of the mirror, which was therefore undoubtedly known to the Egyptians. But a mirror of a particular form and properly illuminated at the instant required, might be easily made to reflect, in a cavern from which all other light was carefully excluded, the image of the deceased, who was called upon by the necromancer; and we can readily conceive, that with respect to the question to be proposed, a person might be concealed, prepared to give such ambiguous answers as would satisfy the inquirer, and at the same time save the credit of the oracle. The terrified imaginations of the spectators would aid the delusion, and make a very slight resemblance pass for the ghost of their departed friend; or the necromancer might assign plausible reasons why a spectre, after having dwelt for some time in the infernal regions, should lose something of its resemblance to the body which it animated. Such juggling tricks, though performed by artists less accomplished than Jannes and Jambres, have gained credit among people much more enlightened than the Egyptians can possibly have been when the science of necromancy was invented by their priests.

That the Israelites, notwithstanding the prohibition of their legislator, continued to practise the rites of necromancy, is apparent from Saul's transaction with the witch of Endor (see Magic). From the same transaction, it is likewise apparent that the witches of Israel, and therefore in all probability the necromancers of Egypt, pretended to evocate the ghosts of the dead by a demon or familiar spirit, which they had at their command to employ upon every emergency. This demon was called ob; and therefore Saul desires his servants to find him a woman who was mistress of an ob (A).

It

(A) The original, or radical, signification of this word occurs, in Job xxxii. ver. 19; where Elihu compares his belly to new bottles, which he calls oboth, the plural of ob. But as bottles were then made of leather, new bottles filled with wine and ready to burst, as Elihu describes them, would of course be of a form nearly globular.
It is probable that those wretched impostors had in their pay some persons who occasionally acted the part of the demon, and when the execution of the plot required their agency, emitted, by means of a cavity dug for that purpose, a low hollow voice from below the ground. Hence we find Israël, in his denunciations against Ariel, saying, "Thou shalt be brought down, and shalt speak out of the ground; and thy speech shall be low out of the dust, and thy voice shall be as of one that hath a familiar spirit (an ob) out of the ground, and thy speech shall whisper out of the dust."

But though the Egyptian priests were undoubtedly the inventors of the whole mystery of necromancy, and though it was from them imported into Greece by the Sacles or priests of Dodona, it does not appear that the Greek necromancers pretended to be masters of one or familiar spirits. Mopsus, Orpheus, Linus, Eumenides, &c., who either travelled into Egypt in quest of knowledge, or were actually natives of that country, inducted the early Greeks in this occult science; but whatever might be the practice of these apostles themselves, their disciples professed to do all the feats of magic by performing certain rites, by offering certain sacrifices, by uttering a certain form of words, by charms, spells, and enchantments. By these they pretended to evoke the dead as certainly as the Egyptians and Jews did by their familiar spirits. By a small display of critical learning this might be easily proved from the popular story of Orpheus and Eurydice, which certainly was founded on one of these necromantic deceptions exhibited in a cave near Dodona, where the priests had a hader or infernal mansion, in humble imitation of those with which the first of them were well acquainted in Egypt. It is indeed evident, without the aid of criticism: no man of any letters is ignorant, that whatever superstitions of this kind prevailed among the Romans were borrowed from the Greeks. But we all know that Virgil makes one of his shepherds, by means of certain herbs, poissons, and senseless charms, raise up ghosts from the bottoms of their graves; and Lucian has fabricated a story of this kind, which may be considered as an exact parallel to the witch of Endor. Just before the battle of Pharsalia he makes young Pompey travel by night to a Thessalian sorceress, and anxiously inquire of her the issue of the war. This female necromancer, by a tedious process of charms and incantations, conjures up the ghost of a soldier who had been lately slain. The phantom, after a long preamble, denounces a prediction much of the same kind with that which the king of Israel received from Samuel at Endor; and though we have elsewhere shown, that nothing but the spirit of God could have foreseen the inevitable destruction of Saul, his sons, and his army, (see MAGIC), it was very easy for any man of tolerable gacitv to foresee the defeat of Pompey's raw and disciplined troops by the hardy veterans of the victorious Caesar.

It would be endless to enumerate all the fallacies of evocations of ghosts, and the ambiguous responses returned by those pretended spirits, of which we have accounts from the poets and historians of the celebrated nations of antiquity. We shall therefore proceed to mention a few which occur in the fabulous history of more modern nations, and then leave the subject to the meditation of our readers. In Mallet's Northern Antiquities, we have the following account of a necromantic exploit, between which, and the descent of the ancient heroes into hell, it is impossible not to remark a striking similitude:

"Odin the sovereign of man arises. He saddles his horse Sleipnir; he mounts, and is conveyed to the subterraneous abode of Helo. The dog which guards the gates of death meets him. His breast and his jaws are stained with blood. He opens his voracious mouth to bite, and barks a long time at the father of magic. Odin pursues his way; and the infernal cavern recoils and trembles under his horse's hoofs. At length he reaches the deep abode of death, and stops near the eastern gate, where stands the tomb of the prophetess. He sings with a voice adapted to call up the dead; he looks towards the world; he engraves Runic characters on her tomb; he utters mysterious words; and he demands an answer, until the prophetess is constrained to arise and thus utter the words of the dead.--" Who is this unknown that dares to disturb my repose, and drag me from the grave, in which I have been dead so long, all covered with snow, and moistened with the rains?" &c.

The Gaelic druids pretended to be masters of the same secret. This is evident from the name of a species of divination, not uncommon among the Scotch Highlanders so lately as in the beginning of the 18th century. By a gentleman excellently versed in the antiquities of that people, and a steady friend to the writer of this article, we have been informed, that not many years ago some of the Highlanders relied implicitly upon certain oracular responses, called in their language taghaim. This word seems to be compounded of t, which in some parts of the Highlands is still used to denote a spirit or ghost, and ghairm, which signifies calling upon or invoking. Taghaim, therefore, in its original import, is necromancy in the most proper sense of that word.

There were different kinds of taghaim, of which we were very lately practised in Skye. The diviner covered himself with a cow's hide, and repaired at night to some deep-sounding cave, whether the person who consulted..."
At the mouth of the cave he proposed aloud the questions of which he wanted solutions; and the man within pronounced the responses in a tone of voice similar to that with which the obs, or pretended demons of antiquity, gave from beneath the ground their oracle answers. That in the latter days of taghaim, the Gaelic diviners pretend to evoke ghosts, and from them to extort solutions of difficulties proposed, we have no positive evidence; but that such was the original pretense there can be little doubt, when we reflect either upon the place where this species of divination was practised, or upon the import of the word by which it was denominated.

As we have been led to mention taghaim, we shall beg leave to make a few observations on another species of it, called taghaim am usge, or "taghaimh by water." This too was last practised in the Isle of Skye, by a man of the name of McCiulain, whose ancestors had long been famous for the art. He lived near a beautiful cascade on a small river; and when consulted on any matter of consequence, he covered his whole body with a cow's hide, that necessary implement of Highland divination, and placed himself between the water of the cascade and the rock over which it flowed. Then another man with a heavy pole gave repeated strokes to the water, and the diviner behind it crying out now and then in Gaelic, "Is this a stock or arm?" This operation was continued till McCiulain was perceived to be frantic or furious, when he was considered as in a condition to answer the most important questions. He was frequently consulted about futurity; and though he could not, in the proper sense of the word, be called a necromancer, his responses were listened to as proceeding from something more than human. A degree of phrenzy, either real or affected, seems to have accompanied the predictions of certain kinds of diviners in all ages; and we cannot help remarking the similarity between the madness of McCiulain and that of the Sibyl in the sixth book of the Æneid; though we cannot suppose the one to have been borrowed from the other.

At Phœbi nondum patiens, immannis in antro
Bacchatur votis, magnum si pectore posit
Excusae Deum: tanto magis ille fatigat
Os rubidum, fera corda domans, fngitque premendo.

Struggling in vain, impatient of her load,
And lab'ring underneath the ponderous god;
The more she strove to shake him from her breast,
With more and far superior force he press'd.

—Dryden.

That all these pretences, whether ancient or modern, to the power of divination by means of familiar spirits, or by the art of necromancy, were groundless as well as impious, it would be affronting the understandings of our readers to offer any proof. Under the article Magic we have said enough on the subject, and perhaps more than enough, to those who know that demons, if they have any existence, and the departed spirits of good and bad men, are all under the control of Him who governs the intellectual as well as material world by fixed and equal laws. These details of superstition, however, will not be useless, if, by showing

Vol. XIV. Part II.†

how poor and wretched a creature man becomes when left to his own inventions, they shall make any one grateful for the benefits of good government, and the blessings of revealed religion.

Necropolis, a suburb of Alexandria in Egypt. It signifies "the City of the Dead;" wherein there were temples, gardens, and superb mausoleums. Here Cleopatra is said to have applied the aspic to her breast, to prevent being led in triumph by Augustus, who endeavoured to save her.

Necrosis, necropsy, in Medicine, a complete mortification of any part; called also sideratio and sphacelus.

Nectanebus, or Nectanabis, a king of Egypt, who defended his country against the Persians. His grandson of the same name made an alliance with Agesilus king of Sparta, and with his assistance he quelled a rebellion of his subjects. Some time after he was joined by the Sidonians, Phocicians, and inhabitants of Cyprus, who had revolted from the king of Persia. This powerful confederacy was soon attacked by Darius the king of Persia, who marched at the head of his troops. Nectanebus, to defend his frontiers against so dangerous an enemy, levied 30,000 mercenary soldiers in Greece, the same number in Libya, and 60,000 were furnished in Egypt. This numerous body was not equal to the Persian forces, and Nectanebus, defeated in a battle, gave up all hopes of resistance, and fled into Ethiopia, where he found a safe asylum. His kingdom of Egypt became from that time tributary to the king of Persia.

Nectar, among ancient poets, the drink of the fabulous deities of the heathens; in contradistinction from their solid food, which was called ambrosia.

Nectarine, a fruit differing in nothing from the common peach, of which it is a species, but in having a smoother rind and a firmer pulp. See Persica.

Nectarium, from nectar, the fabled "drink of the gods!" defined by Linnaeus to be a part of the corolla, or appendage to the petals, appropriated for containing the honey, a species of vegetable salt under a fluid form, that oozes from the plant, and is the principal food of bees and other insects.

Notwithstanding this definition, which seems to consider the nectarium as necessary a part of the corolla as the petals, it is certain that all flowers are not provided with this appendage; neither indeed is it essential to fructification.

There is, besides, a manifest impropriety in terming the nectarium a part of the corolla. Linnaeus might, with equal propriety, have termed it a part or appendage of the stamens, calyx, or point, as the appearance in question is confined to no particular part of the flower, but is as various in point of situation as of form. The truth is, the term nectarium is exceedingly vague; and, if any determinate meaning can be affixed to it, is expressive of all the singularities which are observed in the different parts of flowers.

The tube, or lower part of flowers with one petal, Linnaeus considers as a true nectarium, because it is generally found to contain the sweet liquor formerly mentioned. This liquor Pontedera compares to that called amnios in pregnant animals, which enters the fertile or impregnated seeds: but that this is not at

5 B

least
Nectarium, least its sole use, is evident from this circumstance, that the honey or liquor in question is to be found in flowers where there are either no seeds, or those which, from the want of male organs, cannot be impregnated. Thus the male flowers of nettle and willow, the female flowers of sea-side laurel and black bryony, the male and female flowers of cluita, kiggeilaria, and butcher's broom, all abound with the honey or nectar alluded to.

Vaillant was of opinion, that the nectarium was an essential part of the corolla; for which reason he distinguished the singular appearances in fennel flower and colombine by the name of petals: the coloured leaves which are now termed the petals he denominates the flower cup.

That the nectarium, however, is frequently distinct from the petals, is evident both from the well known examples just mentioned, as likewise from the flowers of monkshood, hellobore, isoypyrum, fennel flower of Crete, barrenwort, grass of Parnassus, chocolate nut, cherelaria, and savagesia.

These general observations being premised, we proceed to take a nearer and more particular view of the principal diversities, both in form and situation, of this striking appendage to the flower. 1. In many flowers the nectarium is shaped like a spur or horn; and that either in flowers of one petal, as valerian, water mignon (strictricularia), butterwort, and calves-anoint; or in such as have more than one, as larkspur, violet, fumitory, balsam, and orchis. 2. In the following plants, the nectarium is properly a part of the corolla, as lying within the substance of the petals: ranunculus, lily, iris, crown imperial, water leaf, mouse tail, anemone, or pine apple, dog's-tooth violet, piperidge bush, walliseria, hermannis, uvularia, and swertia. 3. The nectarium is frequently placed in a series or row within the petals, though entirely unconnected with their substance. In this situation it often resembles a cup, as in narcissus. A nectarium of this kind is said by Linnaeus to crown the corolla. The following are examples: daffodil, sea daffodil, campan, viscous campan, swallow-wort, stapelia, cynanchum, nepenthes, cherelaria, balsam-tree, African spirea, witch-hazel, ola, and passion-flower. 4. In Indian-cress, buckler, mustard, Barbadoes cherry, and monotrope, the nectarium is situated upon or makes part of the calyx. 5. The nectarium in bastard flower-fence is seated upon the anthers or tops of the stamina; whence the name adenanthera, or glandular anthera, which has been given to this genus of plants. In the following list it is placed upon the filaments; bean-caper, bay, fraxinella, marvel of Peru, bellflower, lead-wort, roella, and commelina. 6. In hyacinth, flowering-rush, stock July flower, and rocket, the nectarium is placed upon the seed-bud. 7. In honey-flower, orpine, buckwheat, collinsonia, laurus, mayweed, mercury, cluita, kiggeilaria, sea-side laurel, and African spirea, it is attached to the common receptacle. Lastly, In ginger, nettle, dyer's weed, heart seed, costus, turmeric, graxia, bastard orpine, valerello, show-tree, and willow, the nectarium is of a very singular construction, and cannot properly fall under any of the foregoing heads.

In discriminating the genera, the nectarium often furnishes an essential character.

Plants which have the nectarium distinct from the petals, that is, not lodged within their substance, are Neceus as affirmed by Linnaeus to be generally poisonous. The following are adduced as examples: monkshood, hellobore, colombine, fennel-flower, grass of Parnassus, barren-wort, oleander, marvel of Peru, bean-caper, swallow-wort, fraxinella, and honey-flower.

NECUIA, in Botany, a name given by the ancient Greeks to a species of mullein.

The Greeks and Romans both used the stalks of a peculiar kind of mullein, called erythraia by Nicander, for the making of wicks of lamps. We have a kind of mullein called lychnites, and candle-wick mullein, from the ancients of Dioscorides; but it is not certain that ours is the same plant.

The ancients used the stalks of many different plants for the wicks of their candles and lamps. The rush, stripped of its bark, was as commonly in use with them as with us for that purpose; and they also used the nettle, this mullein, and many other plants, whose stalks were composed of tough filaments, for the same purpose; beating them out like hemp, and when dry dipping them in melted resin, and other such inflammable substances. When thus prepared, they are readily inflammable, like our flambeau; and this mullein, having stalks more long and large, and more firm than all the others, was used to make those lights with which they set fire to the funeral pile, for consuming the ashes of their dead friends.

NECYDALIS, a genus of insects belonging to the order of coleoptera. See Entomology Index.

NEEDHAM, John Tuberville, was born at London the 10th of September in the year 1715. His parents were descended from ancient and noble families. His father, who had once possessed a considerable patrimony at Histon, in the county of Monmouth, was of the younger and Catholic branch of the Needham family: the head of the elder and Protestant branch was Lord Kilmore, and died in the year 1625. The father of Mr Needham died young, and left but a small fortune to his four children. His eldest son, who is the subject of this article, prosecuted his studies under the secular clergy of the English college of Douay, where he took orders, taught rhetoric for several years, gave eminent proofs of sagacity and genius, and surpassed all the other professors of that seminary in the knowledge of experimental philosophy. In 1740, he was engaged by his superiors in the service of the English mission, and was entrusted with the direction of the school erected at Twyford, near Winchester, for the education of the Roman Catholic youth. In 1744, he was appointed professor of philosophy in the English college at Lisbon, where, on account of his bad health, he remained only 15 months. After his return, he passed several years at London and Paris, which were principally employed in microscopic observations, and in other experimental philosophy. The results of these observations, and experiments, were published in the Philosophical Transactions of the Royal Society of London in 1749, and in a volume in 12mo at Paris in 1750; and an account of them was also given by M. de Buffon, in the first volumes of his Natural History. There was an intimate connexion between this illustrious French naturalist and Mr Needham: they made their experiments and observations together;
Needle; though the results and systems which they deduced from the same objects and operations were totally different. Mr Needham was admitted to a place in the Royal Society of London in the year 1747, and in the Antiquarian Society some time after. From the year 1751 to 1767 he was chiefly employed in finishing the education of several English and Irish noblemen, by attending them as tutor in their travels through France, Italy, and other countries. He then retired from this wandering life to the English seminary at Paris, and in 1768 was chosen by the Royal Academy of Sciences in that city a corresponding member.

When the regency of the Austrian Netherlands, in order to the revival of philosophy and literature in that country formed the project of an Imperial academy, which was preceded by the erection of a small literary society to prepare the way for its execution, Mr Needham was invited to Brussels by Count Cobenztel and the president Néo, and was appointed successive chief director of both these foundations. He held this place, together with some ecclesiastical preferments in the Low Countries, until his death, which happened the 30th of December 1781. "His piety, temperance, and purity of manners (we follow the expressions of the abbé Mann) were eminente; his attachment to the doctrines and duties of Christianity was inviolable. His zealous opposition to modern infidels was indefatigable, and even passionate. His probity was unattainted. He was incapable of every species of duplicity; his beneficence was universal, and his unsuspicous candour rendered him often a dupe to pedlary." These and other good qualities the panegyrist attributes to his deceased friend; and the learned authors of the Monthly Review, to whom Mr Needham was known, admit the justness of the panegyric. He was undoubtedly (say they), both an honest man and a worthy citizen; but though his death be a real loss to the literary world, yet he died happily for himself; for he had lived to see Joseph II. and the Great making so free with the paint, patches, and trinkets of the mother church, confiscating her lands, abolishing her convents, suppressing her holidays, introducing common sense into her worship, erecting political conductors to disperse the thunder of the Vatican, and achieving many other things in this style of improvement, it would have vexed full sore his feeling heart. For this honest man was narrow even to superstition and bigotry in his religious system; and we never knew a man in whom there was such an unaccountable mixture of implicit faith and philosophical curiosity as in Mr Needham. He was a keen and judicious observer of nature, had a peculiar dexterity in confirming his observations by experiments, and he was always occupied (sometimes indeed with too much fancy and precipitation) in generalizing facts, and reducing them to his system. "His pen (says Abbé Mann) was neither remarkable for fecundity nor method; his writings are rather the great lines of a tract expressed with energy, and thrown upon paper in a hurry, than finished treatises." His works are well known both in Britain and in France.

Needham, a town in Suffolk, 73 miles from London, stands on the Orwell, 9 miles from Ipswich. Its population in 1811 was 1301.

Needle, a very common little instrument or utensil made of steel, pointed at one end, and pierced at the other, used in sewing, embroidery, tapestry, &c.

Needles make a very considerable article in commerce, though there is scarce any commodity cheaper, the consumption of them being almost incredible. The sizes are from No. 1, the largest, to No. 25, the smallest. In the manufacture of needles, German and Hungarian steel is of most repute.

In the making of them, the first thing is to pass the steel through a coal fire, and under a hammer, to bring it out of its square figure into a cylindrical one. This done, it is drawn through a large hole of a wire-drawing iron, and returned into the fire, and drawn through a second hole of the iron smaller than the first; and thus successively from hole to hole, till it has acquired the degree of fineness required for that species of needles; observing every time it is to be drawn, that it be greased over with lard, to render it more manageable. The steel, thus reduced to a fine wire, is cut in pieces of the length of the needles intended. These pieces are flattened at one end on the anvil, in order to form the head and eye: they are then put into the fire to soften them farther; and thence taken out and pierced at each extreme of the flat part on the anvil, by force of a punchion of well-tempered steel, and laid on a leaden block to bring out, with another punchion, the little piece of steel remaining in the eye. The corners are then filed off the square of the heads, and a little cavity filed on each side of the flat of the head; this done, the point is formed with a file, and the whole filed over: they are then laid to heat red hot on a long narrow iron, crooked at one end, in a charcoal fire; and when taken out thence, are thrown into a bason of cold water to harden. On this operation a good deal depends; too much heat burns them, and too little leaves them soft; the medium is learned by experience. When they are thus hardened, they are laid in an iron shovell, on a fire more or less brisk in proportion to the thickness of the needles; taking care to move them piecemeal time and time again, to temper them, and take off their brittleness; great care here must be taken of the degree of heat. They are then straightened one after another with the hammer, the coldness of the water used in hardening them, having twisted the greatest part of them.

The next process is the polishing them. To do this, they take 12,000 or 15,000 needles, and range them in little heaps against each other on a piece of new buckram sprinkled with emery dust. The needles thus disposed, emery dust is thrown over them, which is again sprinkled with oil of olives; at last the whole is made up into a roll, well bound at both ends. This roll is then laid on a polishing table, and over it a thick plank loaded with stones, which two men work backwards and forwards a day and a half, or two days, successively; by which means the roll thus continually agitated by the weight and motion of the plank over it, the needles within slide being rubbed against each other with oil and emery, are monthly polished. After polishing they are taken out, and the fifth washed off them with hot water and soap: they are then wiped in hot bran, a little moistened, placed with the needles in a round box, suspended in the air by a cord, which is kept stirring till the bran and needles be dry.

The needles thus wiped in two or three different brans,
are taken out and put in wooden vessels, to have the
good separated from those whose points or eyes have
been broken either in polishing or wiping; the points
are then all turned the same way, and smoothed with
an emery stone turned with a wheel. This operation
finishes them, and there remains nothing but to make
them into packets of 250 each. Needles were first
made in England by a native of India, in 1545, but the
art was lost at his death; it was, however, recovered by
Christopher Greening in 1606, who was settled with
his three children, Elizabeth John, and Thomas, by
Mr Damar, ancestor of the present Lord Milton, at
Long Crendon in Bucks, where the manufactory has
been carried on from that time to the present day.

The dipping needle was invented in the year 1577, by
one Robert Norman, a compass-maker at Wapping.
The occasion of the discovery, according to his own
account, was, that it being his custom to finish and hang
the needles of his compasses before he touched them, he
always found, that immediately after the touch, the
north-point would bend or incline downward, under the
horizon; inasmuch that, to balance the needle again,
he was always forced to put a piece of wax on the south
end as a counterpoise. The constancy of this effect
led him at length to observe the precise quantity of the
dip, or to measure the greatest angle which the needle
would make with the horizon; and this at London he
found to be 71° 50′. In 1723 Mr Graham made a
great many observations on the dipping-needle, and
found the angle to be between 74 and 75 degrees.
Mr Nairne, in 1773 found it to be somewhat above
72°. It is not certain whether the dip varies, as well
as the horizontal direction, in the same place. The
trivial difference between Mr Norman and Mr Nairne
would lead us to imagine that the dip was unalterable;
but Mr Graham, who was a very accurate observer,
makes the difference more considerable. It is certain,
however, from a great number of experiments and ob-
servations that the dip is variable in different latitudes,
and that it increases in going northwards. It appears
from a table of observations made with the marine dip-
ing-needle in a voyage towards the north pole in 1733,
that in lat. 60° 18′ the dip was 75°; and in lat. 70° 45′,
it was 77° 52′; in lat. 80° 12′ it was 81° 52′; and in
lat. 80° 27′ it was 82° 24′.

Several authors have endeavoured to apply this dis-
covey of the dip to the finding of the latitude; and
Mr Bond attempted to apply it to the finding of the
longitude also; but for want of observations and ex-
periments he could not make any progress. The af-
fair was farther prosecuted by Mr Whiston, who pub-
lished a treatise on the longitude, and for some time
imagined it was possible to find it exactly by means of
the dip of the needle; but he was at last deserted of it,
for the following reasons: 1. The weakness of the magne-
tic power. 2. The concurrence of the ship, which he
found it exceedingly difficult to avoid so much as was
necessary for the accuracy of the experiments. 3. The
principal objection was an irregularity in the motions
of all magnetic needles, both horizontal and dipping,
by which they, within the compass of about a degree,
very uncertainly backward and forward; even some
times in a few hours time, without any evident cause.
For a particular account of these variations, both of
the horizontal and dipping needle, see the article Va-
riation.

Mr Nairne made a dipping needle in 1772 for the
Board of Longitude, which was used in the voyage
towards the north pole. This is represented at fig. 2, p. 41.
The needle AA is 12 inches long, and its axis, the
ends BB of which are made of gold alloyed with copper,
rests on friction wheels CCC, of four inches
diameter, each end on two friction wheels; which
wheels are balanced with great care. The ends of the
axis of the friction wheels are likewise of gold alloyed
with copper, and moved in small holes made in bell
metal; and opposite to the ends of the axes of the
needle and the friction wheels, are flat agates, set in
DDD, finely polished. The magnetic needle vi-
lates within a circle of bell metal EEE, divided into
degrees and half degrees, and a line passing through
the middle of the needle to the ends, points to the
divisions. The needle of this instrument was balanced
before it was made magnetic; but by means of a cross,
the ends of which are FFFF, (contrived by the rever-
send Mr Mitchell) fixed on the axis of the needle,
on the arms of which are cut very fine screws to receive
small buttons, that may be screwed nearer or farther
from the axis, the needles may be adjusted both ways
to a great nicety, after being made magnetic, by revolv-
ing the poles, and changing the sides of the needle.
GG are two levels, by which the line of o degrees
of the instrument is set horizontal, by means of the fur-
nexting screws LLLL; H is the perpendicular axis,
by which the instrument may be turned, that the di-
vided face of the circle may face the east or west;
to this axis may be fixed an index I, which points to an
opposite line on the horizontal plate K when the in-
strument is turned half round; MMMM are screws
which hold the glass cover to keep the needle from
being disturbed by the wind. When this needle is
constructed for sea, it is suspended by an universal
joint on a triangular stand, and adjusted vertically by
a plumb line and button above the divided circle and
the dovetail work at the upper 90; and the divisions
on the circle are adjusted so as to be perpendicular
to the horizon by the same plumb line, and an adjoin-
ing screw; and when it is adjusted, a pointer annexed to
a screw, which serves to move the divided circle, is
fixed at the lowest 90. Whenever the instrument is used
to find the dip, it must be so placed that the needle may
vibrate exactly in the magnetic meridian.

Magnetic Needle, in Navigation, a needle touched
with a loadstone, and sustained on a pivot or centur;
on which playing at liberty, it directs itself to certain
points in or under the horizon; whence the magne-
tical needle is of two kinds, viz. horizontal or inclinatory.
See the article Magnet.

Horizontal needles are those equally balanced on each
side of the pivot that sustains them, and which, playing
horizontally with their two extremes, point out the north
and south points of the horizon. For their applications
and use, see the article Compass.

In the construction of the horizontal needle, a piece
of pure steel is provided; of a length not exceeding six
inches.
There were of these lofty white rocks formerly three, but about 14 years ago the tallest of them, called Lot's Wife, which rose 120 feet above low water mark, and in its shape resembling a needle, being undermined by the constant efforts of the waves, was thrown down, and totally disappeared.

NEEDS, or St Neots, six miles from Huntingdon, 58 miles from London, so called from the monument of a saint of that name in it, who was burnt by the Danes, is a large well built town, having a handsome strong church, with a very fine steeple, and a stone bridge over the Ouse. Its population in 1811 was 1088.

NEEDWOOD FOREST, in Staffordshire, between the Trent, Dove, and Blythe, and near Uttoxeter, is said to exceed all the forests in England in the excellence of its soil and the fineness of its turf.

NEE EXEAT REGNO, in Law, is a writ to restrain a person from going out of the kingdom without the king's license. F. N. B. 85. It may be directed to the sheriff, to make the party find surety that he will not depart the realm, and on refusal to commit him to prison: or it may be directed to the party himself; and if he then goes, he may be fined. And this writ is granted on a suit being commenced against a man in the chancery, when the plaintiff fears the defendant will fly to some other country; and thereby avoid the justice and equity of the court; which hath been sometimes practised: and when thus granted, the party must give bonds to the master of the rolls, in the penalty of 1000l. or some other large sum, for yielding obedience to it; or satisfy the conty, by answer, affidavit, or otherwise, that he hath no design of leaving the kingdom, and give security.

NEFASIS DIES, in Roman antiquity, an appellation given to those days wherein it was not allowed to administer justice, or hold courts. They were so called because non faci possat, the priest was not allowed to pronounce the three solemn words or formulas of the law, do, dice, addice, I give, I appoint, I adjudge. These days were distinguished in the calendar by the letter N. for nefatus; or N. P. Nefastus Prime, when the day was only nefatus in the forenoon, or first part. The days of a mixed kind were called intericii.

NEGAPO TAN, a town of Asia, in the peninsula on this side the Ganges, and on the coast of Coromandel. It was first a colony of the Portuguese, but was taken from them by the Dutch, and new form part of the British territory. It is situated in E. Long. 79. 10. N. Lat. 11. 15.

NEGATION, in Logic, an act of the mind affirming one thing to be different from another; as that the soul is not matter. See Logic.

NEGATIVE, in general, something that implies a negation: thus we say, negative quantities, negative powers, negative signs, &c.

Negative Sign. The use of the negative sign, in algebra, is attended with several consequences that at first sight are admitted with difficulty, and has sometimes given occasion to notions that seem to have no real foundation. This sign implies, that the real value of the quantity represented by the letter to which it is prefixed is to be subtracted; and it serves, with the positive sign, to keep in view what elements or parts enter into the composition of quantities, and in what...

\[
\text{Negative Signs.}
\]

\[
\begin{align*}
\text{what manner, whether as increments or decrements, (that is, whether by addition or subtraction), which is} \\
\text{of the greatest use in this art.}
\end{align*}
\]

In consequence of this, it serves to express a quantity of an opposite quality to the positive, as a line in a contrary position; a motion with an opposite direction; or a centrifugal force in opposition to gravity; and thus often saves the trouble of distinguishing and demonstrating separately, the various cases of proportions, and preserves their analogy in view. But as the proportions of lines depend on their magnitude only, without regard to their position, and motions and forces are said to be equal or unequal, in any given ratio, without regard to their directions; and, in general, the proportion of quantity relates to their magnitude only, without determining whether they are to be considered as increments or decrements; so there is no ground to imagine any other proportion of \(-b\) and \(+a\) (or of \(-1\) and \(1\)) than that of the real magnitude of the quantities represented by \(b\) and \(a\), whether these quantities are, in any particular case, to be added or subtracted. It is the same thing to subtract the decrement, as to add an equal increment, or to subtract \(-b\) from \(-a\), as to add \(+b\) to it: and because multiplying a quantity by a negative number implies only a repeated subtraction of it, the multiplying \(-b\) by \(-a\), is subtracting \(-b\) as often as there are units in \(-a\); and is therefore equivalent to adding \(+b\) so many times, or the same as adding \(+a\). But, if we infer from this, that \(1\) is \(-\) \(-a\) to \(-b\) to \(a\), according to the rule, that unit is to one of the factors as the other factor is to the product, there is no ground to imagine, that there is any mystery in this, or any other meaning than that the real magnitudes represented by \(1\), \(a\), \(b\), and \(a\) are proportional. For that rule relates only to the magnitude of the factors and product, without determining whether any factor, or the product, is to be added or subtracted. But this likewise must be determined in algebraic computations; and this is the proper use of the rules concerning the signs, without which the operation could not proceed. Because a quantity to be subtracted is never produced in composition by any repeated addition of a positive, or repeated subtraction of a negative, a negative square number is never produced by composition from the root. Hence \(\sqrt{-1}\), or the square root of a negative, implies an imaginary quantity; and in resolution, is a mark or character of the impossible cases of a problem, unless it is compensated by another imaginary symbol or supposition, when the whole expression may have a real significance. Thus \(1 + \sqrt{-1}\) and \(1 - \sqrt{-1}\), taken separately, are imaginary, but their sum is \(2\); as the conditions that separately would render the solution of a problem impossible, in some cases destroy each other's effect when conjoined. In the pursuit of general conclusions, and of simple forms representing them, expressions of this kind must sometimes arise where the imaginary symbol is compensated in a manner that is not always so obvious.

By proper substitutions, however, the expression may be transformed into another, wherein each particular term may have a real significance as well as the whole expression. The theorems that are sometimes briefly discovered by the use of this symbol, may be demonstrated without it by the inverse operation, or some other way; and though such symbols are of some use in the computations by the method of fluxions, its evidence cannot be said to depend upon arts of this kind.

See ALGEBRA and Fluxions.

NEGATIVE Electricity. See the article Electricity, passion. See also Positive Electricity.

NEGIMOTH. This term is read before some of the Psalms, as Psalm lxvii. It signifies string instruments of music, to be played on by the fingers, or women musicians; and the titles of these Psalms where this word is found, may be thus translated, A psalm of David to the master of music, who presides over the string instruments.

NEGOMBO, a sea port town of Asia, on the west coast of Ceylon. It has a fort built by the Portuguese, which was taken from them by the Dutch in 1640. E. Long. 80° 25'. N. Lat. 17° 0'.

NEGRILO POINT, the most westerly promontory of the island of Jamaica.

NEGRO, Homo pelli nigra, a name given to a variety of the human species, who are entirely black, and are found in the torrid zone, especially in that part of Africa which lies within the tropics. In the complexion of Negroes, we meet with many various; but they resemble each other far from other men in all the features of their face. Round cheeks, high cheekbones, a forehead somewhat elevated, a short, broad, flat nose, thick lips, small ears, ugliness, and irregularity of shape, characterize their external appearance. The negro women have the loins greatly depressed, and very large buttocks, which gives the back the shape of a saddle. Vices the most notorious seem to be the portion of this unhappy race; idleness, treachery, revenge, cruelty, impudence, stealing, lying, profanity, debauchery, nastiness, and intemperance, are said to have extinguished the principles of natural law, and to have silenced the reproofs of conscience. They are strangers to every sentiment of compassion, and are an awful example of the corruption of man when left to himself.

The origin of the negroes, and the cause of their remarkable difference from the rest of the human species, has much perplexed the naturalists. Mr Bayly has observed, that it cannot be produced by the heat of the climate: for though the heat of the sun may darken the colour of the skin, yet experience does not show that it is sufficient to produce a new blackness like that of the negroes.

In Africa itself, many nations of Ethiopia are not black; nor were there any blacks originally in the West Indies. In many parts of Asia under the same parallel with the African region inhabited by the blacks, the people are but tawny. He adds, that there are negroes in Africa beyond the southern tropic; and that a river sometimes parts nations, one of which is black, and the other only tawny. Dr Barriere alleges that the gall of negroes is black, and being mixed with their blood is deposited between the skin and scarf-skin. However, Dr Mitchell of Virginia, in the Philosophical Transactions, No 476, has endeavoured by many learned arguments to prove, that the influence of the sun in hot countries, and the manner of life of their inhabitants, are the remote causes of the colour of the negroes, Indians, &c. Lord Kamo
on the other hand, and such philosophers as he, whose
genius and imagination are too lively to submit to a
dry and painful investigation of facts, have contended
that no physical cause is sufficient to change the
colour, and what we call the regular features of white
men, to the dark hue and deformity of the woolly-
headed negro. Their arguments have been examined
with much acuteness and ingenuity by Dr Stanhope
Smith of New Jersey, Dr Hunter, and Professor
Zimmerman, who have made it in a high degree pro-
bable, that the action of the sun is the original and
chief cause of the black colour, as well as distorted
features of the negro. See America, No. 48—51, and
Complexion.

True negroes are found in no quarter of the globe
where the heat of the climate is not very great. They
exist nowhere but in the torrid zone, and only in three
regions situated in that zone, viz. in Senegal, in Guinea,
and on the western shore of Africa, in Nubia, and the
Egyptian land, or what is called New Guinea. In all
these regions the atmosphere is scorching, and the heat
excessive. The inhabitants of the north are whitest;
and as we advance southwards towards the line, and
those countries on which the sun's rays fall more per-
pendicularly, the complexion gradually assumes a daker
shade. And the same men, whose colour has been
rendered black by the powerful action of the sun, if
they remove to the north, gradually become whiter (at
least their posterity), and lose their burnt colour.
Whites when transported into the burning regions of
the torrid zone, are the first subject to fever; the skin
of the face, hands, and feet, becomes burnt, hardens,
and falls off in scales. Hitherto the colour of negroes
appears to be only local, extrinsic, and accidental, and
their short frizzled and sparse hair is to be accounted
far in the same manner.

Climate possesses great and evident influences on
the hair, not only of men, but of all other animals. If in
case these transmutations are acknowledged to be
consistent with identity of kind, they ought not in the
other to be esteemed criterions of different species.
Nature has adapted the pliancy of her work to the situa-
tions in which she may require it to be placed. The
beaver and sheep removed to the warm latitudes ex-
change, the one its fur, and the other its wool, for a
coarse hair that preserves the animal in a more moderate
temperature. The coarse and black shag of the bear is
converted, in the arctic regions, into the finest and
whitest fur. The colour of the hair is likewise changed
by climate. The bear is white under the arctic circle;
and, in high northern latitudes, foxes, hares, and rabbits,
are found white. Similar effects of climate are discern-
able on mankind: the hair of the Danes is generally
red; of the English, fair or brown; and of the French,
commonly black. The hair of all people of colour is
black, and that of the African negroes is likewise sparse
and curled in a manner peculiar to themselves; but this
peculiarity is analogous to the effect which warm cli-
mate has on almost every other animal. Cold, by ob-
structing the perspiration, tends to throw out the per-
meable matter accumulated at the skin in an additional
but of hair. A warm climate, by opening the pores,
vaporates this matter before it can be concreted into
the substance of hair; and the laxness and aperture of
the pores render the hair liable to be easily eradia-
ted by innumerable incidents. Its curl may result
in part from the nature of the secretion by which it is
nourished, and in part from external heat. That it
depends in some degree on the quality of the secretion
is rendered highly probable from its appearance on the
chin and other parts of the human body. Climate is as
much distinguished by the nature and proportion of the
secretions as by the degree of heat. (See Physiolo-
ogy, sect. 6.) Whatever be the nutriment of the hair,
it is evidently combined in the torrid zone of Africa
with some fluid of a highly volatile or ardent quality,
which produces the rank smell of many African nations.
Saline secretions tend to curl and to burn the hair. The
evaporation of any volatile spirit would render its sur-
fce dry and disposed to contract; whilst the centre con-
taining distended by the vital motion, these opposite
dilatations and contractions would necessarily produce a
curve, and make the hair grow involved. External and
internal heat parching the external surface of the hair, tends
likewise to involve it. A hair held near the fire in-
stantly coils itself up. Africa is the hottest country on
the globe; and the influence of its heat, either external
or internal, or both, in giving the peculiar form to the
hair of the natives, appears, not only from its harshness
and its curl, but from its colour. It is not of a shining,
but of an adust black; and its extremities tend to
brown, as if it had been scorched by the fire.

The peculiarities of the negro features and form may
likewise be accounted for. the excessive heat of the cli-
ite and the state of African society. Being sav-
ages, they have no arts to protect them from the rays
of a burning sun. The heat and serenity of the sky
preserving the lives of the children without much care of
the parents, they seem of course to be, in the interior
parts of the country, negligent of their offspring. Able
themselves to endure the extremes of that ardent climate,
they inure their children to it from their most tender
age. They suffer them to roll in the dust and sand be-
side the direct rays of a vertical sun. Their children,
if they be engaged, lay down the infant on the first spot
she finds, and is seldom at the pains to seek the miser-
able shelter of a barren shrub, which is all that the in-
terior country affords. When we reflect on the influ-
ence of a glare of light upon the eye, and on the con-
tortions of countenance produced by our efforts to re-
pel or prevent it, we need not wonder, that the pliant
features of a negro infant should, by constant exposure,
acquire that permanent irregularity which we term their
characteristic ugliness. But besides the climate, food
and clothing and modes of life have prodigious effects
on the human form and features. This is apparent even
in polished societies, where the poor and labouring part
of the community are much more coarse in their features,
and ill-formed in their limbs, than persons of better for-
tune and more liberal means of subsistence. What an
immense difference exists in Scotland, for instance, be-
tween the chiefs and the commonalty of the Highland
clans? If they had been separately fed in different
countries, they would have been ranging by some phi-
losophers under different species. A similar distinction
takes place between the nobility and peasantry of
France, of Spain, of Italy, and of Germany.

That food and clothing, and the different modes of
life, have as great an influence upon the shapes and fea-
tures of the Africans as upon the natives of Europe, is
evident.
to them. If they be, indeed, such as their enemies represent, treacherous, cruel, revengeful, and inexpressibly, by a necessity of nature, they must be a different race from the whites; for though all these vices abound in Europe, it is evident that they proceed not from nature, but from wrong education, which gives to the youthful mind such deep impressions as future exertions can completely eradicate. Let us inquire coolly if the vices of the negroes may not have a similar origin.

In every part of Africa with which the nations of Europe have any commerce, slavery prevails at the worst kind. Three-fourths of the people are slaves to the rest, and the children are born to no other inheritance. "Most parts of the coast differ in their governments; some are absolute monarchies, whilst others draw near to an aristocracy. In both the authority of the civil and military authorities is exercised as often as criminal causes require, unless death is commuted into slavery; in which case the offender is sold, and if the shipping will not buy the criminal, he is immediately put to death. Fathers of free condition have power to sell their children, but this power is very seldom enforced. In Congo, however, a father will sell a son or daughter, or perhaps both, for a piece of cloth, a collar or girdle of coral or beads, or an article of drink. A husband may have as many wives as he pleases, and repudiate or even sell them, though with child, at his pleasure. The wives and concubines, though it be a capital crime for the former to break the conjugal faith, have a way to rid themselves of their husbands, if they have set their affections upon a new gallant, by accusing them of some crime for which the punishment is death. In a word, the bulk of the people in every state of Africa are born slaves to great men, reared as such, held as property, and as property sold (see SLAVERY). There are indeed many circumstances by which a free man may become a slave: such as being in debt, and not the able to pay; and in some of such cases, if the debt be large, not only the debtor, but his family likewise, become the slaves of his creditor, and may be sold. Adultery is commonly punished in the same manner, both the offending parties being sold, and the purchase-money paid to the injured husband. Obi, or pretended witchcraft (in which all the negroes firmly believe, see WITCHCRAFT), is another, and a very common offence, for which slavery is adjudged in the basest punishment; and it extends to all the family of the offender. There are various other crimes which subject the offender and his

(A) 1. A white man with a negro woman, or negro man with a white woman, produce a mulatto, half white and half black, or of a yellow-blackish colour, with black, short frizzled hair. 2. A white man with a mulatto woman, or a negro with a mulatto woman, produce a quadroon, three-fourths white and one-fourth black, or three-fourths black and one-fourth white, or of a lighter yellow than the former. In America, they give the name of cabres to those who are descended from a black man and a mulatto woman, or a mulatto man and a black woman, who are three-fourths black and one-fourth white, and who are not so black as a negro, but blacker than a mulatto. 3. A white man with a quadroon woman, or a negro with a quadroon woman, produce a mestizo, seven-eighths white and one-eighth black, or seven-eighths black and one-eighth white. 4. A white man with a mestizo woman, or a negro with a mestizo woman, produce, the one almost a perfect white, the other almost a perfect black, called a quinteroon. This is the last gradation, there being no visible difference between the fair quinteroons and the whites; and the children of a white and quinteroon consider themselves as free from all taint of the negro race.
NEG [ 753 ]

In such a state of society, what dispositions can be looked for in the people, but cruelty, treachery, and revenge? Even in the civilized nations of Europe, blessed with the lights of law, science, and religion, some of the lower orders of the community consider it as a very trivial crime to defraud their superiors; whilst almost all look up to them with stupid malignity or rancorous envy. That a depressed people, when they get power into their hands, are revengeful and cruel, the present age affords a dreadful proof in the conduct of the demagogues of a neighbouring nation; and is it wonderful that the negroes of Africa, unacquainted with moral principles, blinded by the cruellest and most absurd superstitions, and whose customs tend to eradicate from the mind all natural affection, should sometimes display to their lordly masters of European extraction the same pride that has been so generally displayed by the lower orders of Frenchmen to their ecclesiastics, their nobles, and the family of their murdered sovereign! When we consider that the majority of the negroes groan under the cruellest slavery, both in their own country, and in every other where they are to be found in considerable numbers, it can excite no surprise that they are in general treacherous, cruel, and vindictive. Such are the caprices of their tyrants at home, that they could not preserve their own lives or the lives of their families for any length of time, but by a perpetual vigilance, which must necessarily degenerate, first into cunning, and afterwards into treachery; and it is not conceivable that habits formed in Africa should be instantly thrown off in the West Indies, where they are the property of men whom some of them must consider as a different race of beings.

But the truth is, that the ill qualities of the negroes have been greatly exaggerated. Mr. Edwards, in his valuable History of the West Indies, assures us that the Mandingo negroes display such gentleness of disposition and deportment, as would seem the result of early education and discipline, were it not that, generally speaking, they are more prone to theft than any of the African tribes. It has been supposed that this propensity, among other vices, is natural to a state of slavery, which degrades and corrupts the human mind in a deplorable manner; but why the Mandingoes should have become more vicious in this respect than the rest of the natives of Africa in the same condition of life, is a question he cannot answer.

The circumstances which (according to the same author) distinguish the Koromantyn or Gold Coast negroes from all others, are firmness both of body and mind; a ferociousness of disposition; but withal, activity, courage, and a stubbornness, or what an ancient Roman would have deemed an elevation of soul, which prompts them to enterprises of difficulty and danger, and enables them to meet death, in its most horrid shape, with fortitude or indifference. They are sometimes taken to labour with great promptitude and alacrity, and have constitutions well adapted for it; for many of them have undoubtedly been slaves in Africa. But as the Gold Coast is inhabited by various tribes, which are engaged in perpetual warfare and hostility with each other, there cannot be a doubt that many of the captives taken in battle, and sold in the European settlements, were of free condition in their native country, and perhaps the owners of slaves themselves. It is not wonderful that such men should endeavour, even by means of the most desperate, to regain the freedom of which they have been deprived; nor do I conceive that any further circumstances are necessary to prompt them to action, than that of being sold into captivity in a distant country.

Negro.

Very different from the Koromantyns are the negroes imported from the Bight of Benin, and known by the name of Eboes. So great is their constitutional timidity and dependency of mind, as to occasion them very frequently to seek, in voluntary death, a refuge from their own melancholy reflections. They require therefore the greatest and mildest treatment to reconcile them to their situation; but if their confidence be once obtained, they manifest as great fidelity, affection, and gratitude, as can reasonably be expected from men in a state of slavery. The females of this nation are better labourers than the men, probably from having been more hardly treated in Africa.

"The natives of Whidah, who, in the West Indies, are generally called Papores, are unquestionably the most docile and best disposed slaves that are imported from any part of Africa. Without the fierce and savage manners of the Koromantyn negroes, they are also happily exempt from the timidity and dissembling temper of the Eboes. The cheerful acquiescence with which these people apply to the labours of the field, and their aversion to the thought of such employment, is in itself a proof of a country, not a slave, the result of gentle treatment and agriculture in their native country. Bosman speaks with rupture of the improved state of the soil, the number of villages, and the industry, riches, and obliging manners of the natives. He observes, however, that they are much greater thieves than those of the Gold Coast, and very unlike them in another respect, namely, in the dread of pain, and the apprehension of death. They are, says he, so very apprehensive of death, that they are unwilling to hear it mentioned, for fear that abuse should hasten their end; and no man dares to speak of death in the presence of the King, or any great man, under the penalty of suffering it himself, as a punishment for his presumption. He relates further, that they are addicted to gaming beyond any people of Africa. All these propensities are observable in the character of the Papores in a state of slavery in the West Indies. Their punishment which excites the Koromantyn to rebel, and drives the Ebo negro to suicide, is reconciled by the Papores as the chastisement of legal authority, to which it is their duty to submit patiently. The case seems to be, that the generosity of these people are is a state of absolute slavery in Africa, and, having been habituated to a life of labour, they submit to a change of situation with little reluctance."
Having recited such observations as occurred to him on contemplating the various tribes of negroes from each other, Mr. Edwards thus estimates their general character, influenced as they are by circumstances which soon efface the native and original impressions which distinguish one nation from another when newly imported into the West Indies.

"Notwithstanding what has been related of the firmness and courage of the natives of the Gold Coast, it is certain that the negroes in general in our islands (such of them as have been any length of time in a state of servitude) are of a distrustful and cowardly disposition. So degrading is the nature of slavery, that fortitude of mind is lost as free agency is restrained. To the same cause probably must be imputed their propensity to conceal or violate the truth; which is so general, that the vice of falsehood is one of the most prominent features in their character. If a negro is asked even an indifferent question by his master, he seldom gives an immediate reply; but, affecting not to understand what is said, compels a repetition of the question, that he may have time to consider, not what is the true answer; but what is the most politic one for him to give. The proneness observable in many of them to the vice of theft has already been noticed; and I am afraid (says our author), that evil communication makes it almost general. It is no easy matter, I confess, to discriminate those circumstances which are the result of proximate causes, from those which are the effects of national customs and early habits in savage life; but I am afraid that cowardice and dissimulation have been the properties of slavery in all ages, and will continue so to the end of the world. It is a situation that necessarily suppresses many of the best affections of the human heart.—If it calls forth any latent virtues, they are those of sympathy and compassion towards persons in the same condition of life; and accordingly we find that the negroes in general are strongly attached to their countrymen, but above all, to such of their companions as came in the same ship with them from Africa. This is a striking circumstance: the term shipmate is understood among them as signifying a relationship of the most endearing nature; perhaps as recalling the time when the sufferers were cut off together from their common country and kindred, and awakening reciprocal sympathy from the remembrance of mutual affliction. But their benevolence, with a very few exceptions, extends no further. The softer virtues are seldom found in the bosom of the enslaved African. Give him sufficient authority, and he becomes the most remorseless of tyrants. Of all the degrees of wretchedness endured by the sons of men, the greatest, accordingly, is the misery which is felt by those who are unhappily doomed to be the slaves of slaves; a most unnatural relation, which sometimes takes place in the sugar plantations. The same observation may be made concerning their conduct towards the animal creation. Their treatment of cattle under their direction is brutal beyond belief. Even the useful and social qualities of the dog secure him to no kind usage from an African master. One of the most pleasing traits in their character is the respect and attention which they pay to their aged countrymen. The whole body of negroes on a plantation must be reduced to a deplorable state of wretchedness, if at any time, they suffer their aged companions to want the common necessities of life, or even many of its comforts, as far as they can procure them. They seem to be actuated on these occasions by a kind of involuntary impulse, operating as a primitive law of nature, which scorns to wait the cold dictates of reason: among them, it is the exercise of a common duty, which courts no observation, and looks for no applause."

As the colour and features, and moral qualities of the negroes, may be thus easily accounted for by the influence of climate and the mode of savage life, so there is good reason to believe that their intellectual endowments are equal to those of the whites who have been found in the same circumstances. Of those initiatory arts in which perfection can be attained only in an improved state of society, it is natural to suppose that they have but little knowledge; but the fabric and colour of the Guinea cloths are a proof of their native ingenuity. In the West Indies many of them are expert carpenters, some watchmakers, and one or two have successfully practised physic; while others have figured both in Latin and English poetry, so that we cannot doubt but that "God, who made the world, hath made of one blood all nations of men," and animated them with minds equally rational.

Negroland, or Negroitia, a country of Africa, lying next to Guinea towards the north, and extending from 18° of west to 23° of east longitude, and from 9° to 20° of north latitude. On the north it is bounded by Zaara or the Desert; on the east, by countries unknown; on the south, by the Atlantic ocean; and is watered by the great river Niger or Senegal, which runs through it from east to west. The Europeans have settlements on the coasts of this country, especially near the mouths of the Niger and Gambia, which last is supposed to be a branch of the former. A great many nations inhabit the banks of the rivers; some Parens, some Mohammedans, of different languages, and independent of one another. The country is fruitful, especially along the rivers; abounding in rice, Guinea grain, and Indian corn, where it is cultivated; and with cocoa nuts, plantains, pulse, palm trees, and tropical fruits; nor is it destitute of cattle, and a variety of other animals, particularly such as abound in Guinea. See Guinea.

Negroland is fertilized by the overflowing of its rivers the Senegal and Gambia, as Egypt is by the Nile. It hath not yet been ascertained whether the Gambia is a branch of the Senegal or not. As far as the Europeans have penetrated upon the country, it seems to be distinct; and that Mandingo negroes report that the Gambia has a different origin. The entrance into Senegal river, is narrow and somewhat difficult, by reason of its immovable bar, and sandy shoals, as well as the several islands at the mouth of it, and the several canals and marines that ebb it: but after sailing up eight or ten leagues, it is found broad and deep, and fit to carry large vessels; and, excepting about five or six leagues on each side above the mouth, which is sandy and barren ground, the banks are covered with stately trees and villages, and the country in general is fertile and well watered; for, like the Nile, this river overflows its banks for many leagues, and enriches the land to a great degree.
NEGRIS, the inhabitants do not reap the advantages which they might obtain from its fertility. The people on both sides of the river live as near to it as they can, and feed great herds of cattle, sowing large and small millet, the former of which is called by us Turkey wheat, in great quantities, and with great increase. If the river fails of overflowing at its usual season, a great scarcity ensues in the adjacent country; and, even when it overflows regularly, it breeds such vast flights of grasshoppers and insects, as quite darken the air, and frequently devour the whole produce of the soil: in which case the people kill those insects and eat them; which they do either by pounding in leather bags, and then boiling them in milk, or which is reckoned the more delicious method, by frying or broiling them over a light blaze in a fryingpan full of holes. Thus the legs and wings of the insects are burnt off, and the rest of the body is sufficiently roasted to be eaten as a delicacy, while they look upon it to be very wholesome and nourishing.

To the east, north-east, and south-east of the island of Senegal, the country, as far as it is known, is overrun with woods and marshes: the Senegal, Gambia, and Sherbro, passing through it in their way to the Atlantic ocean. The Niger rises near the Senegal, and runs eastward, but its termination is unknown. During the rainy months, which begin in July, and continue to October, they lay the whole country under water; and indeed the sudden rise of these rivers is incredible to such as are not acquainted with the violent rains that fall between the tropics. At Galam, 900 miles from the mouth of the Senegal, the waters rise 150 feet perpendicular from the bed of the river. At the island of Senegal, the river rises gradually, during the rainy season, above 20 feet perpendicular over part of that flat coast; which of itself, so freshens the water that ships lying at anchor, at the distance of three leagues from its mouth, generally make use of it, and fill their water there for their voyage home. When the rains are at an end, which soon happens in October, the intense heat of the sun makes the waters grow cold, which is also, to the higher parts, and the remainder from lakes and marshes, in which are found all sorts of dead animals. At last, those too are quite dried up; and then the effluvia that arise are almost quite insupportable. At this season the winds blow so hot from the land, that they may be compared to the heat proceeding from the mouth of an oven, and they bring with them an intolerable smell. The wolves, tigers, lions, and other wild beasts, then resort to the river, steeping their bodies under water, and only their snout above it for the sake of breathing. The birds soar to an immense height in the air, and fly a vast way over the sea, where they continue till the wind changes, and comes from the west.

NEGRIS, White. See HELIOPHORI and ALBINO.
NEGROMANCY. See NECROMANCY.
NEGROPI, anciently Eubea, an island of the Archipelago, stretching along the eastern coast of Achaia or Livadia, from which it is separated by a narrow channel called the Euripus. This strait is so narrow, that the island is joined to the continent by a bridge thrown over it; and here, it is thought, there was formerly an isthmus. The irregularity of the tides in the Euripus hath from the remotest antiquity been very remarkable, and this irregularity is found to be connected with the age of the moon. From the three last days of the old moon to the eighth day of the new moon, and from the 14th to the 20th day inclusive, they are regular; but on the other days they are irregular, flowing 12, 13, or 14 times in the space of 24 hours, and ebbing as often. The island is 90 miles long and 25 broad in the widest part; and produces corn, oil, fruit, and cattle, in great abundance. The only place in the island worth notice is the capital, which is called Negropont; and which is walled, and contains about 15,000 inhabitants; but the Christians are said to be much more numerous than the Turks. The captain bashaw, or admiral of Turkey, who is also governor of the city, the island, and the adjacent continent of Greece, resides here: and the harbour, which is very safe and spacious, is seldom without a fleet of galleys, ready to be put to sea against the pirates and the Maltese. A part of the bridge between the two city and the coast of Greece, consists of a draw bridge no longer than just to let a galley pass through.

NEHEMIAH, or NEEMIAS, son of Hachaliah, was born at Babylon during the captivity, (Neh. i. 1, 2, 8c.). He was, according to some, of the race of the priests, but according to others, of the tribe of Judah and the royal family. Those who maintain the first opinion, support it by a passage in Ezra, (x. 10,) where he is called a priest; but those who believe that he was of the race of the kings of Judah, say, 1st, That Nehemiah having governed the republic of the Jews for a considerable time, there is great probability he was of that tribe of which the kings always were. 2dly, Nehemiah mentions his brethren Hanani, and some other Jews, who coming to Babylon during the captivity, acquainted him with the sad condition of their country. 3dly, The office of cupbearer to the king of Persia, to which Nehemiah was promoted, is a further proof that he was of an illustrious family. 4thly, He excuses himself from entering into the inner part of the palace, probably because he was only a laic. (Neh. vi. 11.) "Should such a man as I see? And who is there that, being as I am, would go into the temple to save his life?"

The Scripture (Ezra ii. 63. Nehem vii. 65,) calls him אֲבֹתֵנִי tirshatha, that is to say, "cup-bearer," for he had this employment at the court of Artaxerxes Longimanus. He had an excluding great tenderness for the country of his fathers, though he had never seen it; and one day, as some Jews newly come from Jerusalem acquainted him with the miserable estate of that city, that its walls were burnt down, its gates burnt, and the Jews were become a reproach among all nations; he was sensibly affected with this relation; he fasted, prayed, and humbled himself before the Lord, that he would be favourable to the design he had then conceived of asking the king's permission to rebuild Jerusalem. The course of his attendance at court being come, he presented the cup to the king according to custom; but with a countenance sad and dejected; which the king observing, entertained some suspicion, as if he might have had some bad design; but Nehemiah (i.) discovering the occasion of his disquiet, Artaxerxes gave him leave to go to Jerusalem, and repair its walls and gates; but, however, upon this condition, that he

5 C 2
Nehemiah, should return to court at a time appointed. Letters were made out, directed to the governors beyond the Euphrates, with orders to furnish Nehemiah with timbers necessary for covering the towers and gates of the city, and the house designed for Nehemiah himself, who was now appointed governor of Judea, in the year of the world 3350.

Nehemiah being arrived at Jerusalem with the king's commission, went round the city; and having viewed the condition of the walls, assembled the chief of the people, produced his commission, and exhorted them to undertake the repairation of the gates and walls of the city. He found every person ready to obey him; whereupon he immediately began the work. The enemies of the Jews observing these works in such forwardness, made use of all the means in their power to deter Nehemiah from this undertaking, and made several attempts to surprise him; but finding that their designs were discovered, and that the Jews kept upon their guard, they had recourse to craft and stratagem, endeavouring to draw him into an ambuscade in the fields, where they pretended they would finish the dispute at an amicable conference: but Nehemiah gave them to understand, that the work he had begun required his personal attendance; and therefore he could not come to them. He sent the same answer to four several messages that they sent one after another on the same subject, (Id. iv. and vi.).

Sanballat, the chief of the enemies of the Jews, together with his associates, wrote word, that a report was spread that the Jews were building the walls of Jerusalem only with a design to make it a place of strength, to support them in an intended revolt; that it was said also that Nehemiah had suborned false prophets to favour his designs, and to encourage the people to choose him king; and to stop the course of these rumours, he advised him to come to him, that they might confer together, and take such resolutions as should be found convenient. Nehemiah gave himself no trouble on this account, but returned for answer, that all those accusations were false and made at random. About the same time he discovered, that a false prophet called Shebamiah, had been corrupted by his enemies, and that some of the chief of the city were secretly in confederacy with them. Yet all this did not discourage him; he went on with his work, and happily completed it in two and fifty days after it had been begun.

Then he made a dedication of the walls, of the towers, and of the gates of Jerusalem, with the solemnity and magnificence that such a work required. He separated the priests, the Levites, and the princes of the people, into two companies, one of which walked to the south and the other to the north, on the top of the walls. These two companies were to meet at the temple. The procession was accompanied with music both vocal and instrumental: and when they were come to the temple, they there read the law, offered sacrifices, and made great rejoicings. And as the feast of tabernacles happened at the same time, it was celebrated with great solemnity. (Id. viii.). Nehemiah observing that the compass of the city was too large for its inhabitants, he ordered that the chief of the nation should fix their dwelling in the city; and caused them to draw lots, by which a tenth part of the whole people of Judah were to dwell at Jerusalem, (Id. xi.). Then he applied himself to the reformation of such abuses as had crept into the administration of the public affairs. He curbed the inhumanity of the great ones, who held in a state of slavery the sons and daughters of those who were poor or unfortunate, keeping their lands in possession, which these poor people had been obliged either to mortgage or to sell to the rich. Another abuse there was, which Ezra had in vain attempted to redress, that they had contracted marriages with strange and idolatrous women. Nehemiah undertook to dissolve these marriages, succeeded in it, and sent away all such women as had been taken against the express command of the law, (Id. ix.). Having likewise observed, that the priests and Levites were obliged to take refuge wherever they could, and so the ministry of the temple was not attended or performed with that decency it ought, because they did not receive the revenues that the law had appointed for their subsistence; he obliged the people punctually to pay the ministers of the Lord what was due to them, and enjoined the priests and Levites duly to attend on their respective duties, and to discharge their functions, (Id. xiii. 10, 11, &cc.). He enforced the observance of the sabbath, which had been much neglected at Jerusalem, and would not permit strangers to come in to buy and sell, but kept the gates of the city shut all that day. And, to perpetuate as much as was possible these good regulations which he had newly established, he engaged the chief men of the nation solemnly to renew the covenant with the Lord. This ceremony was performed in the temple, and an instrument was drawn up, which was signed by the principal men, both priests and people (Id. ix. x.), in the year of the world 3551.

We read in the books of Maccabees (2 Macc. i. 19, 20, 21, &cc.), that Nehemiah sent to search for the holy fire, which before the captivity of Babylon the priests had hid in a dry and deep place, but not finding any fire there, but instead thereof a thick and muddy water, he sprinkled this upon the altar; whereupon the wood which had been sprinkled with this water took fire presently as soon as the sun began to appear. Which miracle coming to the knowledge of the king of Persia, he caused the place to be encompassed with walls where the fire had been hid, and granted great favours and privileges to the priests. It is recorded in the same books, (2 Macc. ii. 13, 14.), that Nehemiah erected a library, wherein he placed whatever he could find, either of the books of the prophets, of David, or of such princess as had made presents to the temple. Lastly, he returned to Babylon (Id. v. 14. and xiii. 6.) according to the promise he had made to King Artaxerxes, about the thirty-second year of this prince, in the year 3563. From thence he returned again to Jerusalem, where he died in peace, about the year 3580, having governed the people of Judah for about thirty years.

The book which in the English Bible, as also in the Hebrew, has the name of Nehemiah, in the Latin Bible is called the book of Ezra; and it must be confessed, that though this author speaks in the first person, and though at first reading one would think that he had writ it day by day as the transactions occurred, yet there are some things in this book which could not have been written by Nehemiah himself; for example, memorials are quoted wherein were registered the names
NEHOW, one of the Sandwich islands, discovered by Captain Cook in his last voyage to the Pacific ocean: these islands are eleven in number, and are situated from 18° 44′ to 22° 35′ N. Lat. and from 151° 56′ to 160° 24′ W. Long.

NEIGHBOUR, 1. One who dwells near to another (2 Kings iv. 3.). 2. Every man to whom we have an opportunity of doing good (Matt. xxii. 39.). 3. A fellow labourer of one and the same people (Acts xvi. 37.). 4. A friend (Job. xvi. 21.). At the time of our Saviour, the Pharisees had restrained the word neighbour to signify those of their own nation only, or their own friends; being of opinion that to hate their enemy was not forbidden by their law. But our Saviour informed them, that the whole world were their neighbours; that they ought not to do to another what they would not have done to themselves; and that this charity ought to be extended even to their enemies. (Matt. v. 43. Luke x. 29, &c.).

NEISSE, a town of Silesia, containing 7000 people, and the residence of the bishop of Breslaw, who has a magnificent palace here. The air is very wholesome, and provisions are cheap; the inhabitants carry on a great trade in wine and linen. This place suffered greatly by an inundation and fire in 1790. It was taken by the Prussians in 1741, who augmented the fortifications, and built a citadel to which they gave the name of Prussia. It is seated on a river of the same name, in E. Long. 17° 35′ N. Lat. 50° 32′.

NEUSMOSIS, in Ancient Geography, at the foot of which stood Ithaca, a town of the island of that name. (Homer).

NELSON, The Right Honourable Viscount, one of the most celebrated naval commanders, was the son of the reverend Edmund Nelson, and was born at Burnham Thorpe, in Norfolk, where his father was rector, in the year 1758. He received his education at the school of North Walsham, but we are unacquainted with the particulars relative to his childhood, and whether the progress he made in his studies was in any respect extraordinary. It is certain, however, that he discovered a strong predilection for the naval profession at a very early period, and having quitted school at the age of twelve years, went on board the Raisonable of 64 guns, commanded by his mother’s brother, Captain Maurice Suckling.

In the month of April 1773, a voyage of discovery to the north pole was undertaken by the honourable Constantine John Phipps, afterwards Lord Mulgrave, in consequence of an application by the Royal Society to Lord Sandwich; and although the instructions which were issued, prohibited all boys from being received on board, yet the enterprising spirit of Horatio Nelson earnestly solicited to be appointed cookswain to Captain Latwide, rather than submit to be left behind; and his unsubdued spirit so forcibly struck the captain, that his wish was complied with.

When the ship returned to England in the month of October 1773, Mr Nelson having received information that a squadron was fitting out for the East Indies, employed all his interest to be appointed to one of the ships. It was not long before he was placed in the seashore of 20 guns, commanded by the celebrated Captain Farmer, and stationed in the fore-top to keep watch, but soon after removed to the quarter-deck.

He obtained the professional order of lieutenant on the 8th of April, 1777, and received his commission the next day, as second of the Lowestoffe of 32 guns, Captain William Locker, in which ship he arrived at Jamaica; but feeling that his glowing mind was circumscribed in so small a frigate, he requested the command of a schooner, which acted as tender to the Lowestoffe, thus availing himself of the opportunity of becoming an experienced pilot for every intricate passage through the islands, situated on the northern side of Hispaniola.

When Sir Peter Parker arrived at Jamaica in the year 1778, Lieutenant Nelson was nominated by that gallant admiral to be the third of his own flag ship, the Bristol, and by rotation soon became the first. In this ship his services terminated in the rank of a lieutenant.

On the 11th of June, 1799, he obtained the rank of post-captain; and during the nine years he had been in the service he not only became an able officer by his constant attention to every part of his duty, and his keen observation, but he also laid the foundation of being a pilot of distinguished eminence. The first ship to which he was appointed after being made a post captain, was the Hinchinbroke. On the arrival of Count d’Estaing at Hispaniola, as an attack upon Jamaica was immediately apprehended, Captain Nelson was intrusted with the command of the batteries of Port-Royal, with the concurring approbation of the British admiral and general. In the month of January 1790, it was resolved on to reduce Fort Juan, on the river St John, in the gulf of Mexico, when Captain Nelson was made choice of to command the naval department, and that of the military was committed to Major Polson. In accomplishing the object of this arduous and interesting undertaking, Nelson’s usual intrepidity was again exhibited. Having quitted the ship under his command, he superintended the transporting of the troops in boats, 300 miles up a river, which none but Spaniards had ever navigated since the time of the buccaneers.

His great and vigorous exertions were represented by Major Polson to General Dalling in their true colours,
When Lord Hood left his station in the Mediterranean in the month of October, 1794, the command devolved on Admiral Hotham, who honoured our boys with an equal share of his confidence and esteem. On the 13th and 14th of March, and 13th of July 1795, he again rendered himself conspicuous in the actions which then took place with the French fleet; and soon after he was chosen by Admiral Hotham to cooperate with General De Vins, on the coast of Genoa, in which service he continued so long as Hotham retained the command, who was superseded by Sir John Jervis. This officer so much applauded the conduct of Captain Nelson, that he received the honour of wearing a pendant of distinction; and in the month of May he was removed from the Agamemnon to the Captain of 74 guns. On the 11th of August he had a captain appointed under him.

From April to October 1795, Commodore Nelson was continuously employed in the most active and arduous service, the blockade of Leghorn, the taking of Porto Ferrajo, with the island of Caprea, and finally the evacuation of Bastia. In December 1796 he hoisted his broad pendant on board La Minerve frigate, and was dispatched with that ship, and La Blanche, to Porto Ferrajo, to bring the naval stores left there to Gibraltar, which the fleet was in much want of. While on this service in the night of the 17th December, he fell in with two Spanish frigates, one of which immediately attacked, and ordered the Blanche to bear down to engage the other. About half past ten the commodore brought his ship to close action, which continued without interruption till half past one, when the Spanish frigate of 30 guns, 28 of which were 18 pounders, struck to La Minerve.

After various other active and important services during the three preceding months, Sir Horatio Nelson, in April 1797, hoisted his flag on board the Captain of 74 guns as rear-admiral of the blue, and in the end of May he shifted his flag from the Captain to the Thetis, when he was appointed to the command of the inner squadron at the blockade of Cadiz. While on this service he exhibited another remarkable proof of his undaunted personal courage. In the attack on the Spanish gun-boats in July, he was boarded in his barge, which had only the usual complement of 10 men, and the cockpit. The commander of the Spanish gun-boats, in a barge with 30 men and officers, made a desperate attack on the admiral and his brave companions. The conflict remained long doubtful, but after 18 of the Spaniards were killed, and almost the whole of the remainder wounded, the rear-admiral and his brave crew succeeded in carrying this superior force.

On the 15th of July the same year, Admiral Nelson was detached with a small squadron to attack the town of Santa Cruz in the island of Tenerife. A thousand men, including marines, were landed in the course of a dark night, made themselves masters of the town, and retained possession of it for seven hours; but finding it impossible to storm the citadel, they prepared for their retreat, which the Spaniards allowed them to make unmolested, agreeable to the stipulations which had been entered into. In this unfortunate attack the brave Nelson lost his arm by a cannon shot.

But a more splendid scene of the life of our hero is now opening. On the 13th of April 1798 he was detached...
tached from Earl St Vincent's fleet, in pursuit of the
French to the coast of Egypt, with 12 sail of the line
and one 50 gun ship, while the enemy's fleet consisted
of 13 sail of the line and four frigates, protected by the
batteries on the shore, and several gun-boats. This me-
memorable action commenced at sunset, and terminated
eloquently for the honour of our hero and that of the
British navy. Nine sail of the line fell into the hands
of the conqueror, two were burnt, and two effected
their escape. The brave Nelson was wounded in the
action, believing himself to have been shot through the
head; but after his wound was examined by the sur-
genous, it was luckily found not to be mortal, a cir-
tical glory. Let us do him the most lively satisfaction
that we are indebted for the victory of Copenhagen,
and the annihilation of that formidable northern confed-
ecacy which menaced the prosperity, the commerce, the
very existence of the rest of Europe.

One of the most important services which Lord Nel-
sen performed, was the pursuit of the combined fleets
of France and Spain to the West Indies. This fleet
had sailed from Cadiz on the 10th of April, and it was
at first conjectured that Egypt was the place of their
destination. In consequence of this conjecture, Lord
Nelson sailed in pursuit of the enemy for the coast of
Egypt; and, having missed his object, after reconnoi-
ttering that coast, he passed the straits of Gibraltar,
and anchored in Lagos bay on the 30th of May; soon after
which he sailed for the West Indies with ten ships of
the line; arrived off Barbadoes on the 4th of June; and
having touched at Tobago, Trinidad, and Grenada, at
the latter of which places he was informed that the
combined fleet had been seen near off Dominica; he
reached Antigua on the 12th, where he received in-
formation that the enemy had been seen on the 8th
standing to the northward. Lord Nelson, without the
loss of a moment, continued the pursuit of the enemy
on their return to Europe, where they arrived about the
end of July; and after taking in provisions and water
at Gibraltar, and reconnoitering the harbour of
Cadiz; he returned to England, where he arrived in
the Victory, on the 18th of August, after having been
engaged for nearly four months in one of the most ar-
duous, and, at the same time, one of the most important
and beneficial, although, in its immediate object, unsuc-

cessful enterprises, for which his life was distinguished.
His lordship had now been absent from England more
than two years, on the Mediterranean station.

The concluding scene of this extraordinary man's
naval career, kindles emotions of admiration and re-
gret; and at once excites both transport and extreme
of sorrow. Perhaps no action, in point of splendour
and magnanimity, can equal that which deprived his
country of one of the greatest heroes it ever produced.
Britons appear to be sensible of its vast importance; yet
it is not improbable that perversity will consider it as still
more splendid, their love and admiration not being
damped by the poignant recollection that they person-
ally saw the man by whose loss it was accomplished.
When Lord Nelson perceived that, in consequence of
his manoeuvres, he had reduced the enemy to the abso-
lute necessity of engaging him, he exclaimed in the
presence of Captain Hardy and the other officers who
surrounded him on the quarter deck: 'Now they can-
not escape us; I think we shall at least make sure of
twenty of them.—I shall probably lose a leg, but that
will be purchasing a victory cheaply.' But alas! am-
idsit the inexpressible satisfaction and delight, which
a victory so splendid could not fail to inspire, he has
left us to lament that it was purchased by the loss of a
life so incomparably valuable.

His lordship's flag ship fell on board the Redoubtable,
by which means he was exposed to the fire of the mus-
ketry from the tops; and the insignia of his grandeur and
dignity, it is supposed, singled him out to the aims of the
enemy, which in the issue were too fatally successful.
His secretary was cut in two by his side with a chain
shot, and soon after a ball grazed his lordship's shoul-
der, entered his left breast, and passed through his
lungs. He lived about three hours after this tragical
event, during which he remained perfectly recollected,
and he displayed the same heroic magnanimity in the
arms of death, which had so eminently distinguish-
ed him through the whole of his career. His last
words to Captain Hardy were, 'I know I am dying.
I could have wished to survive to breathe my last upon
British ground, but the will of God be done!' In a
few moments he expired. His last signal ought not,
and will not be forgotten, which was by telegraph,—
'That England expected every man would do his du-
ty.' He spoke in raptures concerning the event of the
day only a short time before his dissolution, and sent
word to Admiral Collingwood, desiring that he would
make his affectionate farewell to all his brother seamen
throughout the fleet. In this manner died, in the 47th
year of his age, the greatest commander that perhaps
ever adorned the British navy, leaving behind him a
name dear to Great Britain, and a people of heroism,
which will inspire his companions in arms to emulate
his virtues, that they too may live in the remembrance
of a grateful posterity.

His singular plan of attack on this memorable occa-
sion was communicated by his lordship to all his cap-
tains, who unanimously gave it as their opinion that it
could not possibly fail of success, being concerted with
such consummate wisdom; and they even pledged their
lives for the favourable result of it. His titles were,
Viscount Nelson, and Duke of Bronté.—The united
parliament voted him a pension of 3000l. a year, to con-
continue during his own life and his two next heirs; the
East
NEMEAUSIS, or NEMAUSUM, in Ancient Geography, the capital of the Arausoni in Gallia Narbonensis; a colony, (Coei), with the surname of Augustae, (Inscription). In it stands a Roman amphitheatre, which is still almost entire. Now Nimes in Languedoc.

NEMEA (Strabo, Livy); a river of Achaia, running between Sicyon and Corinth, the common boundary of both territories, and falling into the Corinthian bay.

NEMEA, in Ancient Geography, situated between Cleone and Philus in Argolis; whether town, district, or other thing, uncertain; there a grove stood in which the Argives celebrated the Nemean games, and there happened all the fabulous circumstances of the Nemean lion. The district Nemea is called Bembonidia, (Plisty); a village, Bembôna, standing near Nemea, (Strabo). Stephanus places Nemea in Elis; though not in Elis, but on its borders; Plisty, erroneously in Arcadia. In the adjoining mountain is still shown the den of the lion, distant 15 stadia from the place Nemea, (Pausanias); in which stands a considerable temple of Jupiter Nemeus and Cleoneus, from the vicinity of these two places. This place gave name to the Nemean games, celebrated every third year.

NEMEAN GAMES, so called from Nemea, a village between the cities of Cleone and Philus, where they were celebrated every third year. The exercises were chariot-races, and all the parts of the pentathlon. These games were instituted in memory of Opheltes or Archermus, the son of Euphetes and Cleone, and who was nursed by Hypsipyle; who leaving him in a meadow while she went to show the beauties of Thebes a fountain, at her return found him dead, and a serpent twined about his neck: whence the fountain, before called Lasegias, was named Archemorus; and the captives, to comfort Hypsipyle, instituted these games.—

Others attribute their institution to Hercules, after his victory over the Nemean lion. Others allow, that they were instituted first in honour of Archemorus; but intermitted, and revived again by Hercules. The victors were crowned with palm, and had a branch from Archemorus's blood.

The Argives prevailed at these games.

NEMERIANUS, AURELIUS OLYMPIUS, a Latin poet who was born at Carthage, and flourished about 
the year 281, under the emperors Carus, and his son Carinus and Numerian; the last of which emperors was so fond of poetry, that he contested the glory with Nemesianus, who had written a poem upon fishing and maritime affairs. We have still remaining a poem of our author called Cynegeticus, and four elegies: they were published by Paulus Manutius in 1538; by Barthelet in 1613; at Leyden in 1653; with the notes of Janus Vitalis. Giraldi hath preserved a fragment of Nemesianus, which was communicated to him by Sansazarus, to whom we are obliged for our poet's works; for having found them written in Gothic characters, he procured them to be put into the Roman, and then sent them to Paulus Manutius. Although this poet has acquired some reputation, it is greatly inferior to those of Oppian and Gratian upon the same subject; yet Nemesianus's style is natural enough, and has some degree of elegance. The world was so much possessed with an opinion of his poem in the eighth century, that it was read among the classics in the public schools, particularly in the time of Charlemagne, as appears from a letter of the celebrated Hincmar bishop of Rheims, to his nephew Hincmar of Leon.

NEMESIS, in Pagan worship, the daughter of Jupiter and Necessity, or, according to others, of Oceanus and Nax, had the care of revenging the crimes which human justice left unpunished. She was also called Adivatera, because Adivaterus, king of Argos first raised an altar to her; and Rhumenus, from her having a magnificent temple at Rhenus in Attica. She had likewise a temple at Rome in the Campus. She is represented with a stern countenance, holding a whip in one hand and a pair of scales in the other.

NEMEUSIUS, a Greek philosopher who embraced Christianity, and was made bishop of Emea in Phrygia, where he had his birth; he flourished in the beginning of the fifth century. There is a work of his extant, entitled De Naturae Homines, in which he refutes the falsity of the Stoics and the errors of the Manichees, the Apollinarists, and the Eunomians; but he exposes the opinion of Origen concerning the pre-existence of souls. (A). This treatise was translated by Vitalis, and printed in 1535. Another version was afterwards made of it by Eliebodie, and printed in 1565; it is also inserted in the Bibliotheca Patrum, in Greek and Latin. Lastly, Another edition was published at Oxford in 1671, folio, with a learned preface, wherein the author endeavours to prove, from a passage in this book, that

(A) It is much more probable that he and Origen both brought their opinion with them from the schools of philosophy, than that either of them borrowed it from the other. See Metaphysics, Part III, Chap. IV.
NEOGENE, the circulation of the blood was known to Nemesis; but which, however, was since shown to be a mistake by Dr. Frind, in his History of Physics.

NEMINE CONTRADICENTE, "none contradicting it;" a term chiefly used in parliament when anything is carried without opposition.

NEMOURS, a town in France, in the department of Seine and Marne, containing 3,569 inhabitants in 1801. It is seated on the river Loing, in E. Long 24. 45; N. Lat. 48. 15.

NEAGH, a post and fair town of Ireland, in the county of Tipperary and province of Munster, 75 miles from Dublin. It is situated on a branch of the river Shannon which runs into Lough-Derg. Here stand the ruins of an old castle called Neagh-round. Also those of an hospital founded in the year 1200, for canons following the rule of St. Augustin. It was dedicated to St. John the Baptist, and was usually called Teachon, or St. John's house. In the reign of Henry III. a friary for conventual Franciscans was also founded here, and esteemed the richest foundation of that order in the kingdom. Here is a barrack for two troops of horse. This town was burnt on St. Stephen's day, 1348, by the Irish. The fairs held here are four.

NENIA, or Nenia, in the ancient poetry, a kind of funeral song sung to the music of flutes at the obsequies of the dead. Authors represent them as sorry compositions, sung by hired women mourners called Praefices. The first rise of these Nenia is ascribed to the physicians. In the heathen antiquity, the goddess of tears and funerals was called Nenia; whom some suppose to have given that name to the funeral song, and others to have taken her name from it.

NECESARIA, (Pliny), a town of Pontus on the south or the left side of the Lyceus. About the year 342, when Leontius and Sallustius were consuls, it was entirely ruined by a dreadful earthquake, no edifice having withstood the violence of the shock, except the church and the bishop's habitation, who was saved, with the clergy and some other pious persons, while the rest of the inhabitants were buried in its ruins.

NEOMAGUS, (Ptolem); NOVIOMAGUS, (Antonine); a town of the Regni in Britain: now thought to be Guildford in Surrey, (Lurid); or Croydon, (Talbot). But Camden takes it to be Woodcote, two miles to the south of Croydon, where traces of an ancient town are still to be seen.

NEOMAGUS, (Ptolem); NOVIOMAGUS (Antonine); a town of the Treveri on the Moselle. Now Numagen 14 miles east, below Trier.

NEOMAGUS, (Ptolem); NOVIOMAGUS Lexoviorum, (Antonine); a town of Gallia Celta. Now Lisieux, in Normandy.

NEOMAGUS, (Ptolem); NOVIOMAGUS Nemetum, (Antonine). Now Spire, a city of the Palatinate, on the left or west side of the Rhine.

NEOMAGUS, (Ptolem); a town of Gallia Narbonensis, on the confines of the Tricastini. Now Nyons in Dauphine.

NEOMENIA, or NOUMENIA, a festival of the ancient Greeks, at the beginning of every lunar month, which, as the name imports, was observed upon the day of the new moon, in honour of all the gods, but especially Apollo, who was called Neomenios, because the sun is the fountain of light; and whatever distinction of times and seasons may be taken from other planets, yet they are all owing to him as the original of those borrowed rays by which they shine. The games and public entertainments at these festivals were made by the rich, to whose tables the poor flocked in great numbers. The Athenians at these times offered solemn prayers and sacrifices for the prosperity of their country during the ensuing month. See Games.

The Jews had also their neomenia, or feast of the new moon, on which peculiar sacrifices were appointed: and on this day they had a sort of family entertainment and rejoicing. The most celebrated neomenia of all others was that at the beginning of the civil year, or first day of the month Tisri, on which no sacrifices were performed: they then offered particular burnt sacrifices, and sounded the trumpets of the temple. The modern Jews keep the neomenia only as a feast of devotion, which any one may observe or not as he pleases.

NEOPHYTEES, "new plants," a name given by the ancient Christians to those heathens who had newly embraced the faith; such persons being considered as regenerated, or born anew by baptism. The term neophytes has been also used for new priests, or those just admitted into orders, and sometimes for the novices in monasteries. It is still applied to the converts made by the missionaries among the infidels.

NEPA, a genus of insects belonging to the order of hemiptera. See Entomology Index.

NEPAL, a kingdom of India, to the north-east of the city of Patna, inclosed among the secondary branches of the Himmaleh mountains, of great extent from east to west, but scarcely exceeding a degree of latitude; the height of the country above the sea, as indicated by the barometer, is not less than 4000 feet; yet Colonel Kirkpatrick found the thermometer on one occasion at 87°. But the neighbouring mountains afford the inhabitants every variety of climate, from the heat of Bengal to the cold of Russia. The high grounds are very healthy; in the valleys fever prevails; gout or gouters are found in both. Iron and copper abound in this country. Though stones are found, the houses are built of brick, cemented with mud. The cattle are similar to those of Bengal, and the honey is excellent. The soil is fertile, and besides wheat, rice, and sugar, yields the Zoora a species of yam, and the Kuraila a kind of wild asparagus, which form a considerable part of the subsistence of the poorer inhabitants. The inhabitants consist principally of the two superior classes of Hindoos, and a race called Newars, who are probably of Chinese or Tartar origin. The former, who compose the army, engross all situations of trust, and are found dispersed all over the country. The Newars are confined almost entirely to the valley of Nepal Proper. The latter are divided into several castes or orders. The total population is estimated at about half a million. The Newars are a peaceable and industrious people, of a middle size, with broad shoulders and chests, very stout limbs, round and flat faces, but open and cheerful. The Newar women change their husbands as often as they please on the slightest pretences. The religion of the country is the same as the Hinduism of Bengal. The government is despotic. The trade is inconsiderable, being crushed by monopolies.

Khatmandu, the capital, is supposed to contain about 50,000
NEPETA, CATMINT, or *Nep*, a genus of plants belonging to the

gynandria class; and in the natural method ranking

among those of which the order is doubtful. See BOTANY INDEX.

NEPHELIDEM, a genus of plants belonging to the
didynamia class; and in the natural method ranking

under the 42d order, *Verticillate*. See BOTANY INDEX.

NEPHRITIC, something that relates to the

kidneys. See KIDNEY.

*Nephritic Wood*, (*Lignum nephriticum*), a wood of

a very dense and compact texture, and of a fine grain,
brought to us from New Spain in small blocks, in its

natural state, and covered with its bark. This wood

is said to be a good diuretic; and we are told it is used

among the Indians in all diseases of the kidneys and

bladder, and in suppression of urine, from whatever

cause. It is also recommended in fevers, and in ob-

structions of the viscera. The way of taking it among

the Indians is only an infusion in cold water. These

uses are not however properly ascertained. See GIU-

LANDINA, BOTANY INDEX.

*Nephritic Stone*. See Nephrite or Jade, MINERALOGY INDEX.

Nephritis, in *Pharmacy*, medicines proper for
diseases of the kidneys. See MATERIA MEDICA INDEX.

Nephritis, or inflammation of the kidneys. See MEDICINE INDEX.

NEPOS, CORNELIUS, a celebrated Latin biog-

ographer, who flourished in the time of Julius Caesar, and

lived, according to St Jerome, to the sixth year of

Augustus. He was an Italian, if we may credit Cat-

ullus, and born at Hostilia, a small town in the terri-

tory of Verona, in Cisalpine Gaul. Anxiousness, however,

will have it that he was born in the Gaul. Leander

Alberi thinks Nepos's country was Verona. Cicero

and Atticus were friends of our author; who wrote the

lives of the Greek historians, as he himself attests in

that of Dion, speaking of Philistus. What he says, also,

in the lives of Cato and Hannibal, proves that he had

also written the lives of the Latin captains and historians.

He wrote some other excellent works which are lost.

All that we have left of his at present is, "The Lives

of the illustrious Greek and Roman Captains;" which were a long time ascribed to *Emilius Probus*,

who published them, as it is said, under his own name,

to insinuate himself thereby into the favour of the

emperor Theodosius; but, in the course of time, the fraud

has been discovered, although several learned persons

have confounded the two authors. This piece has been

translated into French by the Sieur de Claverton, with

a dedication to the duke of Longueville, in 1663; and

again by M. le Gras, then of the congregation of the

Oratory at Paris, 1739, 12mo. We have an excel-

lent translation of it into English, by several hands at

Oxford, which has gone through several editions.

NEPTUNE, in Pagan worship, the god of the

sea, was the son of Saturn and Venus, or sea, and the

brother of Jupiter and Pluto. He assisted Jupiter in

his expeditions; on which that god, when he arrived

at the supreme power, assigned him the sea and the

islands for his empire. He was, however, expelled

from heaven with Apollo for conspiring against Ju-

piter, when they were both employed by the king of
Phrygia in building the walls of Troy; but

that prince dismissing Neptune without a reward, he

sent a sea monster to lay waste the country, on which

he was obliged to expose his daughter Hesione. He

is said to have been the first inventor of horsemen-

ship and chariot racing; on which account in honor

of Pontus threw chariots drawn by four horses

into the sea in honour of this god; and the Romans

instituted horse races in the circus at his festival,
during which all other horses left working, and the

mules were adorned with wreaths of flowers.

In a contest with Minerva he produced a horse by

striking the earth with his trident; and on another

occasion, in a trial of skill with Minerva and Venus,

produced a bull, whence that animal was sacrificed

by him. His favourite wife was Amphitrite, whom he

long courted in vain, till sending a dolphin inter-

cede for him, he met with success; on which he re-

warded the dolphin by placing him among the stars.

He had also two other wives, one of whom was called

Sccolius from the salt water; the other *Perseus*

from the ebbing and flowing of the tides. He had li-

kewise many concubines, by whom he had a great number

of children. He is represented with black hair, with a

garment of an azure or sea green: holding his trident

in his hand, and seated in a large shell drawn by sea

horses: attended by the sea gods *Poseidon*, *Ceres*,

and *Phorcys*, and the sea goddesses *Thetis*, *Minet*,

and *Panopha*, and a long train of tritons and sea

 nymphs.

This deity was known in Egypt by the name of *Os-

nos*, or *Canopus*, and was worshipped as the same

*aquarius* or spirit of the Nile. His emblem was the

figure of certain vases or pitchers, with which the Egyp-

tians filtered the water of the sacred river, in order

to purify and render it fit for use. From the mouth

deach of these vessels, which were charged with hi-
oglyphics, arose the head and sometimes the head and

hands of a man or woman. Such are the emblems

which still remain of the Egyptian Neptune or Can-

opus; and it was by this emblem that the tutelar god

of Egypt vanquished the god of Chaldea in the mili-

tious manner mentioned by Rufinus in his Ecclesiastical

History. 12

1 2

"The Chaldeans (says he) who adored the god of

Carried their god into various countries that he might

try his strength in contests with other gods. He

vanquished, as we may easily conceive, the images

made of gold, silver, brass, and wood, &c. by reducing

them to ashes; and thus the worship of fire was every-

where established. The priest of Canopus, when he

became god, to admit the superiorities of other gods,

contrived to make his god vanquish the god of

Chaldea in a pitched battle. The vessels which were

worshipped as the emblems of Canopus, being used for

filtering the waters of the Nile, were of course per-

forated on all sides with very small holes. The

faithful priest having stopped all the holes in one

of
NERI, in the Pagan theology, sea nymphs, daughters of Nereus and Doris.—The Nereids were esteemed very handsome; insomuch that Cassiope, the wife of Cepheus, king of Ethiopia, having triumphed over all the beauties of the age, and daring to vie with the Nereids, they were so enraged that they sent a prodigious sea monster into the country, and, to appease them, she was commanded by the oracle to expose her daughter Andromeda, bound to a rock, to be devoured by the monster. In ancient monuments, the Nereids are represented riding upon sea horses; sometimes with an entire human form, and at other times with the tail of a fish.

NEREIS, a genus of animals belonging to the order of Vermes mollusca. See Helmintology Index.

NEREUS, in fabulous history, a marine deity, was son of Oceanus and Theitis. He settled in the Ægean sea, was considered as a prophet, and had the power of assuming what form he pleased. He married his sister Doris, by whom he had 50 daughters called the Nereids, who constantly attended on Neptune, and when he went abroad surrounded his chariot.

NERI, Anthony, a learned writer who published a curious book printed at Florence 1612, in 4to, with this title, Dell' Arte Verraria Libri VII; or the Art of Glassmaking.

NERIUM, a genus of plants belonging to the pentandria class; and in the natural method ranging under the 30th order, Contortes. See Botany and Dyeing Index.

NERO, Claudius Domitius Caesar, a celebrated Roman emperor, son of Caius Domitius Ahenobarbus and Agrippina the daughter of Germanicus. He was adopted by the emperor Claudius, A. D. 50, and four years after he succeeded him on the throne. In the beginning of his reign he showed several marks of the greatest kindness and condescension, affability, complaisance, and popularity. The object of his administration seemed to be the good of his people; and when he was desired to sign his name to a list of malefactors that were to be executed, he exclaimed, "Would to Heaven I could not err!" He hated flattery; and when the senate had publicly commended the wisdom of his government, he desired them to keep their praises till he deserved them. These promising virtues soon, however, proved to be artificial: Nero soon displayed the real propensities of his nature. He delivered himself from the sway of his mother, and at last ordered her to be murdered. This unnatural act of barbarity might astonish some, but Nero had his devoted adherents; and when he declared that he had taken away his mother's life to save himself from ruin, the senate applauded his measures, and the people signified their approbation. Many of his courtiers shared her unhappy fate; and Nero sacrificed to his fury or caprice all such as obstructed his pleasure or diverted his inclination. In the night he generally went from his palace to visit the nearest taverns, and all the scenes of debauchery which Rome contained. In this nocturnal riot he was fond of insulting the people in the streets; and his attempts to offer violence to the wife of a Roman senator nearly cost him his life. He also turned actor, and openly appeared on the Roman stage in the meanest characters. In his attempts to excel in music, and to conquer the disadvantages of a hoarse disagreeable voice, he moderated his meals, and often passed the day without eating. The Olympic games attracted his notice: he went into Greece, and presented himself a candidate for the public honour. He was defeated in wrestling; but the flattery of the spectators adjudged him the victory, and he returned to Rome with all the splendour and pomp of an eastern conqueror, drawn in the chariot of Augustus, and attended by a band of musicians, actors, and stage dancers from every part of the empire. These private and public amusements of the emperor were indeed innocent; his character only was injured, and not the lives of the people. His conduct, however, soon became more abominable: he disguised himself in the habit of a woman, and was publicly married to one of his senecuchs. This violence to nature and decency was soon exchanged for another: Nero resumed his sex, and celebrated his nuptials with one of his meanest catamites; and it was on this occasion that one of the Romans observed that the world would have been happy if Nero's father had had such a wife. But his cruelty was now displayed in a still higher degree, for he sacrificed to his wantonness his wife Octavia Poppaea, and the celebrated writers Seneca, Lucan, Petronius, &c. Nor did the Christians escape his barbarity. He had heard of the burning of Troy, and as he wished to renew that dismal scene, he caused Rome to be set on fire in different places. The conflagration became soon universal, and during nine successive days the fire continued. All was desolation: nothing was heard but the lamentations of mothers whose children had perished in the flames, the groans of the dying, and the continual fall of palaces and buildings. Nero was the only one who enjoyed the general consternation. He placed himself on the top of a high tower, and he sung on his lyre the destruction of Troy, a dreadful scene which his barbarity had realized before his eyes. He attempted to avert the public odium from his head by a pretended commiseration of the miseries of his subjects. He began to repair the streets and public buildings at his own expense. He built himself a celebrated palace, which he called his golden house. It was liberally adorned with gold, with precious stones, and with every thing rare and exquisite. It contained spacious fields, artificial lakes, woods, gardens, orchards, and whatever exhibited a beautiful scene. The entrance of this edifice could admit a large colossal of the emperor 120 feet high; the galleries were each a mile long, and the whole was covered with gold.
gold. The roofs of the dining halls represented the
firmament, in motion as well as in figure; and contin-
nuously turned round night and day, showering down
all sorts of perfumes and sweet waters. When this
grand edifice, which, according to Pliny, extended
tall round the city, was finished, Nero said, that now
he could lodge like a man. His profusion was not less
remarkable in all his other actions. When he went
fishing his nets were of gold and silk. He never ap-
ppeared twice in the same garment, and when he took
a voyage, there were thousands of servants to take care
of his wardrobe. This continuation of debauchery and
extravagance at last roused the people. Many
conspiracies were formed against him; but they were
generally discovered, and such as were accessory suf-
fered the severest punishments. The most dangerous
conspiracy against Nero’s life was that of Piso, from
which he was saved by the confession of a slave.
The conspiracy of Galba proved more successful, who, when
he was informed that his plot was known to Nero, de-
clared himself emperor. The unpopularity of Nero fa-
voured his cause; he was acknowledged by all the
Roman empire, and the senate condemned the tyrant
to be dragged naked through the streets of Rome, and
whipped to death, and afterwards to be thrown down
from the Tarpeian rock like the meanest malefactor.
This, however, was not executed; for Nero pre-
vented it by a voluntary death. He killed himself,
A. D. 68, in the 32d year of his age, after a reign of
of 13 years and eight months. Rome was filled with
acclamations on the occasion; and the citizens, more
strongly to indicate their joy, wore caps, such as
were generally used by slaves who had received their
freedom. Their vengeance was not only exercised
against the statues of the deceased monster, but many
of his friends were the object of the public resentment;
and many were crushed to pieces in such a violent
manner, that one of the senators, amid the universal
joy, said that he was afraid they should soon have
cause to wish for Nero. The tyrant, as he expired,
requested that his body might be cut up, and exposed
himself, and exposed to the insolence of the popu-
lace, but that the whole might be burned on the
funeral pile. His request was granted by one of Galba’s
freedmen, and his obsequies were performed with the
usual ceremonies. Though his death seemed to be the
source of general gladness, yet many of his favourites
lamented his fall, and were grievous to see that their
pleasures and amusements were stopped by the death
of this patron of debauchery and extravagance. Even
the king of Parthia sent ambassadors to Rome, to con-
dole with the Romans, and to beg that they would
honour and revere the memory of Nero. His statues
were also crowned with garlands of flowers; and
many imagined that he was not dead, but that he
would soon make his appearance and take vengeance
on his enemies. It will be sufficient to observe, in
finishing the character of this tyrannical monster, that
the name of Nero is even now used emphatically to ex-
press a barbarous and unfeeling oppressor. Pliny calls
him the common enemy and fury of mankind; and so
indeed he has been called by all writers, who exhibit
Nero as a pattern of the most execrable barbarity and
unpardonable wantonness. The same Pliny furnishes us
with this singular anecdote of him: “Nero had or-
dered himself to be painted under the figure of a co-
lossus, upon cloth or canvas, 120 feet in height.” He
adds, “that this preposterous picture, when it was fin-
nished, met with its fate from lightning, which con-
sumed it, and involved likewise the most beautiful part
of the gardens where it was placed in the confuga-
tion.”

NERVA, Cocceius, a Roman emperor after Do-
mitian, who was the last of the 12 Caesars. He was a
native of Narnia in Umbria; his family, however, was
originally of Crete. Dion Cassius says he was born on
the 17th of March, in the 18th year of Trajan’s reign,
and of the Christian era the 332d. Nerva in the 12th
year of his reign made him proconsul, and erected a state
for him in the palace on account of his poems (for he was
one of the best poets of his age), some of which were
inscribed to him. He was consul in 71 with Vespasian,
and in 95 with Domitian.

Ancient authors uniformly celebrate him as a prince
of the most mild and humane temper, of great moderation
and generosity, who looked on his office as emperor,
not as if it was for his own advantage, but for that of
his people; and whilst he reigned, which was however
but for a short time, he made the happiness of his sub-
jects his only end and pursuit. He narrowly escaped
death under Domitian; was naturally of a weak and
timorous disposition; and, as some say, addicted to ex-
cessive drinking. The Romans unanimously chose him
emperor; and they had no cause to repent of their
choice, for he was constantly attentive to what could
make them happy; he was generous, merciful, and dis-
interested. An instance of his great lenity appears in
his pardoning Calpurnius Crassus who conspired against
him. In short, he omitted nothing that might con-
tribute to the restoring of the empire to its former state:
recalling those who had been banished for religion, and
repressing all grievances that came to his knowledge.
He however found his strength failing, and that it
would be impossible for him to finish his designs, in
consequence of which he adopted Trajan. After his
death, which happened in the year 98, he was held
among the gods. He was the first Roman emperor of
foreign extraction.

NERVES, in Anatomy, certain white glistening
cords, proceeding from the brain and spinal marrow,
and dividing into very small branches, which are sent
off throughout all parts of the body; and which are
found to be the organs of sensation and motion. See
Anatomy Index.

NERVOUS FLUID. See Anatomy Index.

NESSUS, in fabulous history, a celebrated Centaur,
son of Ixion and a Cloud. He offered violence to De-
janira, whom Hercules had intrusted to his care, with
orders to carry her across the river Euenus. Hercules
saw the distress of his wife from the opposite shore of
the river, and immediately he let fly one of his poison-
ed arrows, which struck the Centaur to the heart. Ne-
sus, as he expired, gave the tunic he then wore to De-
janira, assuring her that from the poisoned blood which
had flowed from his wounds, it had received the power
of calling a husband away from unlawful loves. De-
janira received it with pleasure, and this mournful pre-
cept caused the death of Hercules. — A river which se-
parates Thrace from Macedonia. It is also called Ne-
nestos, and Nestus.
NESS. See NIDUS.

ESTOR. See Birds Nests.

NESTOR, in fabulous history, a son of Neleus and Chloris, nephew to Pelias and grandson to Neptune. He had eleven brothers, who were all killed with his father by Hercules. His tender age detained him at home, and was the cause of his preservation. The conqueror spared his life and placed him upon the throne of Pylos. He married Eurydice the daughter of Clymenus; or, according to others, Anaxibia, the daughter of Ateus. He soon distinguished himself in the field of battle; and was present at the murtials of Perithous, when a bloody engagement took place between the Lapithae and Centaurs. As king of Pylos and Messenia he led his subjects to the Trojan war, where he distinguished himself among the rest of the Grecian chiefs, by eloquence, address, wisdom, justice, and uncommon prudence. Homer displays his character as the most perfect of all his heroes; and Agamemnon explains, that if he had 20 generals like Nestor, he should soon see the walls of Troy reduced to ashes. After the Trojan war Nestor retired to Greece, where he enjoyed in the bosom of his family the peace and tranquillity which were due to his wisdom and to his age. The manner and the time of his death are unknown: the ancients are all agreed that he lived three generations of men; which length of time is supposed to be 300 years, though more probably only 90 years, allowing 30 years for each generation. From that circumstance, therefore, it was usual among the Greeks and the Latins, when they wished a long and happy life to their friends, to wish them to see the year of Nestor. He had many children; two daughters, Pisdice, and Polyxena; and seven sons, Perseus, Stratides, Areus, Echethon, Panistratus, Antiochus, and Thrasymedes. Nestor was one of the Argonauts, according to Valerius Flaccus, v. 380, &c.—A poet of Lycaonia in the age of the emperor Severus. He was father to Pison, who under the emperor Alexander wrote some fabulous stories. One of the body guards of Alexander.

Nestor, whose secular name is not known, was a native of Russia, and the earliest historian of the north. He was born in 1056 at Bielozero; and in the 19th year of his age he assumed the monastic habit in the convent of Pecherski at Kiev, and took the name of Nestor. He there made a considerable proficiency in the Greek language: but seems to have formed his style and manner rather from the Byzantine historians, Cedrenus, Zonaras, and Syncellus, than from the ancient classics. The time of Nestor's death is not ascertained; but he is supposed to have lived to an advanced age, and to have died about the year 1115.

His great work is his Chronicle, to which he has prefixed an introduction, which after a short sketch of the early state of the world, taken from the Byzantine writers, contains a geographical description of Russia and the adjacent regions; an account of the Slavonian nations, their manners, their emigrations from the banks of the Danube, their dispersion, and settlement in the several countries wherein their descendants are now established. He then enters upon a chronological series of the Russian annals, from the year 858 to about 1133. His style is simple and unadorned, such as suits mere recorder of facts; but his chronological exactness, though it renders his narrative dry and tedious, contributes to ascertain the era and authenticity of the Nestorians, events which he relates.

It is remarkable (says Mr. Coxe, from whom we have taken this narrative), that an author of such importance, whose name frequently occurs in the early Russian books, should have remained in obscurity above 650 years; and been scarcely known to his modern countrymen, the origin and actions of whose ancestors he records with such circumstantial exactness. A copy of his Chronicle was given in 1668 by Prince Radzivil to the library of Konigshuerg, where it lay unnoticed till Peter the Great, in his passage through that town, ordered a transcript of it to be sent to Petersburg. But it still was not known as the performance of Nestor: for when Muller in 1732 published the first part of a German translation, he mentioned it as the work of the abbot Theodosius of Kiev; an error which arose from the following circumstance: The ingenious editor not being at that time sufficiently acquainted with the Slavonian tongue, employed an interpreter, who, by mistaking a letter in the title, supposed it to have been written by a person whose name was Theodosius. This ridiculous blunder was soon circulated and copied by many foreign writers, even long after it had been candidly acknowledged and corrected by Muller.

NESTORIANS, a sect of ancient Christians, still said to be subsisting in some parts of the Levant; whose distinguishing tenet is, that Mary is not the mother of God. They take their name from Nestorius bishop of Constantinople, whose doctrines were spread with much zeal through Syria, Egypt, and Persia.

One of the chief promoters of the Nestorian cause was Barsumas, created bishop of Niissibis, A.D. 435. Such was his zeal and success, that the Nestorians, who still remain in Chaldea, Persia, Assyria, and the adjacent countries, consider him alone as their parent and founder. By him Phroszes the Persian monarch was persuaded to expel those Christians who adopted the opinions of the Greeks, and to admit the Nestorians in their place, putting them in possession of the principal seat of ecclesiastical authority in Persia, the see of Seleucia, which the patriarch of the Nestorians has always filled even down to our time.—Barsumas also erected a school at Niissibis, from which proceeded those Nestorian doctors who in the fifth and sixth centuries spread abroad their tenets through Egypt, Syria, Arabia, India, Tartary, and China.

He differed considerably from Nestorius, holding that there are two persons in Jesus Christ, as well as that the Virgin was not his mother, as God, but only as man.

The advocates of this doctrine refuse the title Nestorians; alleging that it had been handed down from the earliest times of the Christian church.

In the tenth century, the Nestorians in Chaldea, whence they are sometimes called Chaldeans, extended their spiritual conquests beyond Mount Imaus, and introduced the Christian religion into Tartary properly so called, and especially into that country called Karif, bordering on the northern part of China. The prince of that country, whom the Nestorians converted to the Christian faith, assumed, according to the vulgar tradition, the name of John after his baptism, in which he added
To this spiritual motive he added one, that, though carnal, he possibly judged of equal force:—"Join with me (said he) in war against them, and I will assist you against the Persians." Although the wiser and better part of his audience were amazed to see a man, before he had tasted (as the historian expresses him) of the water of his city, declare that he would persecute all who were not of his opinion; yet the majority of the people approved of this discourse, and encouraged him to execute his purpose. Accordingly, five days after his consecration, he attempted to demolish the church in which the Arians secretly held their assemblies; and he succeeded so far in his design, that these people, growing desperate, set it on fire themselves, and consumed with it some of the neighbouring houses. This fire excited great commotions in the city, and Nestorius was afterwards called an ascetic.

From the Arians he turned his persecution against the Novatians, but was stopped in his career by the interposition of the emperor. He then let loose his fury upon those Christians of Asia, Lydia, and Caria, who celebrated the feast of Easter upon the 14th day of the moon; and for this unimportant deviation from the Catholic practice, many of those people were murdered by his agents both at Miletum and Sardis. One cannot be sorry that such a relentless persecutor should himself be afterwards condemned as a heretic, for holding an opinion which no man who speaks or thinks with philosophic accuracy will now venture to controvert. This obnoxious tenet, which produced a schism in the church, and was condemned by a general council, was nothing more than that the Virgin Mary cannot with propriety be called the mother of God. The people being accustomed to hear this expression, were much inflamed against their bishop, imagining that he had revived the error of Paschasimon and Photinus, who taught that Jesus Christ was a mere man. The monks declared openly against him, and, with some of the most considerable men of Constantinople, separated themselves from his communion. Several bishops wrote to him earnestly to acknowledge that Mary was the mother of God; and when he would not comply, they procured his condemnation in the council of Ephesus, which deprived him of his see. He then retired to his ancient monastery at Antioch, whence he was taken four years afterwards by the emperor's order, and banished in 433 to Tarsus. That city being taken and destroyed by the Barbarians, he was removed to Panopolis, a city of the Thebais; where he was not suffered to remain long, but was compelled to go from place to place, till, being in one of his journeys mortally bruised by a fall, death relieved him from the fury of his persecutors.

If we examine such of his writings as remain, we shall find that he was very unjustly condemned. It appears that he rejected the errors of Eutocius, Paschasimon, and Photinus; that he maintained in express terms, that the divine Word was united to the human nature in Jesus Christ in the same degree and to the same extent as possible; that these two natures, in this state of union, make but one Christ and one person; that the properties of the Divine and human natures may both be attributed to this person; and that Jesus Christ may be said to have been born of a virgin, to have suffered and
NET

WIN and died; but he never would admit that God could be said to have been born, to have suffered, or to have died.—When we consider that every person partakes of the substance of his mother, and that it is this which constitutes the parental and filial relation between them, it is indeed surprising that the expression "Mother of God" should ever have been admitted into the Christian church, or that any man who understands the meaning of the words should condemn Nestorius for not having used them.

NESTUS, or Nessus, a river which separates Thrace from Macedonia. It falls into the Aegean sea near the island Thassos. It is sometimes called Nessus and Nessus.

NET, a device for catching fish and fowl. See the article Fishery.

The taking fowls by nets is the readiest and most advantageous of all others, where numbers are to be taken. The making the nets is very easy, and what every true sportsman ought to be able to do for himself. All the necessary tools are wooden needles, of which there should be several of different sizes, some round and others flat; a pair of round pointed and flat scissors; and a wheel to wind off the thread. The packthread is to be of different strength and thickness, according to the sort of birds to be taken; and the general size of the meshes, if not for very small birds, is two inches from point to point. The nets should either be made too deep nor too long, for they are then difficult to manage; and they must be verged on each side with twisted thread. The natural colour of the thread is too bright and pale, and is therefore in many cases to be altered. The most usual colour is the russet; which is to be obtained by plunging the net, after it is made, into a tanners pit, and letting it lie there till it be sufficiently tinged: this is of a double service to the net, since it preserves the thread as well as alters the colour. The green colour is given by chopping some green weeds and boiling it in water, and then soaking the net in this green tincture. The yellow colour is given in the same manner with the decoction of celandine; which gives a pale straw-colour, which is the colour of stubble in the harvest-time. The brown nets are to be used on ploughed lands, the green on grass grounds, and the yellow on stubble lands.

Day-Net, among fowlers, a net generally used for taking such small birds as play in the air, and will stoop either to prey, gig, or the like; as larks, linnets, buntings, &c. The time of the year for using this net is from August to November; and the best time is very early in the morning: and it is to be observed, that the milder the air, and the brighter the sun is, the better will be the sport, and of longer continuance. The place where this net should be laid, ought to be plain champain, either on short stubbles, green, or flat meadows, near corn fields, and somewhat remote from towns and villages: you must be sure to let your net lie close to the ground, so that the birds creep not out and make their escape.—The net is made of a fine packthread with a small mesh, not exceeding half an inch square; it must be three fathoms long, and but one broad: it must be verged about with a small but strong cord; and the two ends extended upon two small long poles, suitable to the breadth of the net, with four stakes, tail-strings, and drawing-lines.—This net is composed of two, which must be exactly alike; and are to be laid opposite to one another, so even and close, that when they are drawn and pulled over, the sides must meet and touch each other. You must stake this net down with strong stakes, very stiff on their lines, so that you may have a nimble touch cast them to and fro at pleasure; then fasten your drawing-cord or hand-lines (of which there must be a dozen at least, and each two yards long) to the upper end of the foremost staves: and so extend them of such a strangeness, that with a little strength they may rise up in the nets and cast them over.

Your nets being thus laid, place your gigs, or playing-wantons, about 20 or 30 paces beyond, and as much on this side your nets: the gigs must be fastened to the tops of long poles, and turned into the wind, so as they may play to make a noise therein. These gigs are a sort of toys made of long goose-feathers, like shuttle-cocks, and with little small tunnels of wood running in broad and flat swan-quills, made round like a small hoop; and so, with longer strings fastened to a pole, will, with any small wind or air, move after such a manner, that birds will come in great flocks to play about them.

When you have placed your gigs, then place your stake; which is a small stake of wood, to prick down into the earth, having in it a mortice-hole, in which a small and slender piece of wood, about two feet long, is fastened, so as it may move up and down at pleasure: and fasten to this longer stick a small line, which, running through a hole in the stick above-mentioned, and so coming up to the place where you are to sit, you may, by drawing the line up and down with your right hand, raise up the longer stick as you see occasion.

Fasten a live lark, or such like bird, to this longer stick, which, with the line making it to stir up and down by your pulling, will entice the birds to come to your net.

There is another stake, or enticement, to draw on these birds, called a looking-glass; which is a round stake of wood, as big as a man's arm, made very sharp at the end, to thrust it into the ground: they make it very hollow in the upper part, above five fingers deep; into which hollow they place a three-square piece of wood about a foot long, and each two inches broad, lying upon the top of the stake, and going with a foot into the hollowness: which foot must have a great knob at the top, and another at the bottom, with a deep skenderness between; to which slenderness you are to fasten a small packthread, which, running through a hole in the side of the stake, must come up to the place where you sit. The three square pieces of wood which lies on the top of the stake, must be of such a poise and evenness, and the foot of the socket so smooth and round, that it may whir and turn round upon the least touch; winding the packthread so many times about it, which being suddenly drawn, and as suddenly let go, will keep the engine in a constant rotary motion: then fasten with glue on the upper part flat squares of the three-square piece, about 20 small pieces of looking-glass, and paint all the square wood between them of a light and lively red; which, in

by the Romans; and that part which lies towards the
Gaul continued in their subjection till the decline of
that empire; after which the Franks became masters
of it; and under the French monarchy, it was part of
the kingdom of Metz or Austrasia.

Towards the end of the 16th century Maximilian of
Austria, son of the emperor Ferdinand III. acquired,
by marrying the only daughter of the duke of Burg-
dy, the duchies of Brabant, Limburg, and Luxemburg;
the counties of Flanders, Burgundy, Hainaut, Hol-
lund, Zeeland, and Namur; and the lordship of Fries-
land. Philip of Austria, son to Maximilian and Mary,
marrried Jane the daughter of Ferdinand king of Ara-
gon and of Isabella queen of Castile; by which means
their son Charles inherited not only almost all Spain
and the great countries then lately discovered in Am-
rica, but also those noble provinces of the Netherlands,
and was chosen emperor under the name of Charles V.
Towards the latter end of the 1539, he added to his
domains the temporalities of the bishoprick of Utrecht
on both sides of the Yssel; and Henry of Bavaria,
being distressed through war with the duke of Gelder-
land, and tired with the continued rebellion of his own
subjects, surrendered to the emperor the temporalities
of his diocese, which was confirmed by the pope, and
the states of the country. In 1536, Charles V. bought
of Charles of Egmond the reversion of the duchy of
Gelderland and of the county of Zutphen, in case that
prince should die without issue. The same year the
city of Groningen took the oath of allegiance, and
submitted to Charles V. and in 1543 he put a garrison
in to the city of Cambrai, and built a citadel there. Hav-
ing thus united the 17 provinces, as it were in one
body, he ordered that they should continue for ever under
the same prince, without being ever separated or de-
membered; for which purpose he published in Novem-
ber 1549, with the consent and at the request of
the states of all the provinces, a perpetual and irrevoca-
ble edict or law, by which it was enjoined, that in order
to keep all those provinces together under one and the
same prince, the right of representation, with regard to
the succession of a prince or princess, should take place
for ever both in a direct and collateral line, notwithstanding
the common laws of some provinces to the
contrary. Charles had even a mind to incorporate
these provinces with the Germanick body, and to make
of them a circle of the empire, under the title of the cir-
cle of Burgundy, in order thereby to engage the princes
of the empire to concern themselves for the preserva-
tion of those provinces. But the Netherlands, always
jealous of their liberty, did not seem to like that incor-
poration; and when they were demanded to pay their
share towards the expences of the empire, they refused
it: whereupon the princes of Germany refused, in their
turn, to take any part in the wars in Flanders, and
looked upon those provinces as by no means belonging
to the Germanick body.

Philip of Austria and his son Charles, who were born
in the Netherlands, had for these provinces that natural
affection which men use to have for their native coun-
try; and, knowing how jealous the inhabitants were of
their liberty, and of the privileges granted to them by
their former princes, they took great care to preserve
them and suffered willingly that the states, who were
the guardians of the people’s liberty and privilages,
should
NET

NET

should in a manner share the supreme authority with them. Philip II. son to the emperor Charles V. had not the same affection for the Netherlands, nor those generous sentiments which his father had endeavoured to inspire him with. Being born in Spain of a Portuguese woman, he had no regard but for his native country; and, when he removed out of the Netherlands, he left them to the weak government of a woman, to the proud and haughty spirit of Cardinal de Grenville, and to the wild ambition of some lords of these provinces, who availing themselves of the imprudent conduct and continual blunders of the council of Spain, found their private interest in the disturbances they could not fail to produce. Philip II. also, instead of the mild and moderate measures which his predecessors had successfully employed on many occasions, as best suiting the genius and temper of the people, had recourse to the most violent and cruel proceedings; which, far from curing the evil, served only to exasperate it more and render it incurable. The Spaniards, whom he sent thither, being born and educated in an absolute monarchy, jealous of the liberties and envious of the riches of the people, broke through all their privileges, and used them almost after the same manner as they had done the inhabitants of their new and ill-gotten dominions in America. This treatment occasioned a general insurrection. The counts Hoorn, Egmont, and the prince of Orange, appeared at the head of it, and Luther's reformation gaining ground about the same time in the Netherlands, his disciples joined the malecontents: whereupon King Philip introduced a kind of inquisition in order to suppress them, and many thousands were put to death by that court, besides those that perished by the sword; for these persecutions and encroachments had occasioned a civil war, in which several battles were fought. The counts Hoorn and Egmont were taken and beheaded: but the prince of Orange, retiring into Holland, with the assistance of England and France, preserved Holland and some of the adjacent provinces, which entered into a treaty for their mutual defence at Utrecht in 1579, and they have ever since been styled the United Provinces; but the other provinces were reduced to the obedience of Spain by the duke of Alva and other Spanish generals. However, their ancient privileges were in a great measure restored; every province was allowed its great council or parliament, whose concurrence was required to the making of laws, and raising money for the government, though these assemblies were too often obliged to follow the dictates of the court.

The emperor Joseph II. endeavoured to deprive them even of the form of their free constitution; and he might very probably have succeeded, had he not attempted at the same time a reformation of the church. The Austrian Netherlands are wholly Catholic, and so bigotted to the Romish superstition, that though they had tamely submitted to many encroachments of the archducal house on their civil rights, no sooner did the monarch encroach upon the property of the holy mother church, than they resisted his authority, and claimed all their ancient privileges political and religious.

The Spaniards continued possessed of almost eight of these provinces, until the duke of Marlborough, general of the allies, gained the memorable victory of Ramilies. After which Brussels the capital, and great part of these provinces, acknowledged Charles VI. (afterwards emperor) their sovereign; and his daughter, the late empress queen, remained possessed of them till the war that followed the death of her father, when the French made an entire conquest of them, except part of the province of Luxemburg; but they were restored by the peace of Aix-la-Chapelle in 1748, and the French retained only Artois, the Cambrésis, part of Flanders, part of Hainault, and part of Luxemburg. These provinces were overrun by the French in 1790, and formally ceded to them by the treaty of Campo Formio in 1797. They kept possession of them till 1814, when they were separated from France, and along with the seven Dutch provinces, formed into a kingdom under the prince of Orange, who assumed the title of king of the Netherlands. By the new constitution promulgated in 1815, the people of the two countries were to be represented in an assembly called the States-General, whose sittings were to be held alternately in a town in Holland and a town in Belgium. The States consist of two chambers; the deliberations of the lower are public, those of the upper private. The constitution guarantees the liberty of the press, the right of petitioning, and the independence of the judges.

The soil is generally fruitful, but differs in the several parts. The climate also differs in the several provinces; in those towards the south it does not differ much from that of England, though the seasons are more regular. In the northern provinces the winter is generally very sharp, and the summer sultry hot; but the extreme cold and excessive heat seldom continue above five or six weeks. The air is reckoned very wholesome, but is subject to thick fogs in winter, through the moistness of the country, which would be very noxious, were it not for the dry easterly winds, which, blowing off a long continent for two or three months in the year, clear the air, and occasion very sharp frosts in January and February; during which, the ports, rivers, and canals are commonly shut up. The face of the country is low and flat; for, except some small hills and a few rising grounds in Utrecht and Gelderland, and in the parts lying towards Germany, there is no hill to be seen in the whole 17 provinces. This is the reason why they have been called the Low Countries. French Flanders abounds in grain, vegetables, flax and cattle, but is in want of wood.

For the Dutch Netherlands, see United Provinces.

NEITHINIMS, among the Jews, the posterity of the Gibeonites, who were condemned by Joshua to be hewers of wood and drawers of water for the house of God.

NETOPION, a name given by the ancients to a very fragrant and costly ointment, consisting of a great number of the finest spicy ingredients. Hippocrates, in his Treatise on the Diseases of Women, frequently prescribes the netopion in diseases of the uterus; and in other places he speaks of its being poured into the ear as a remedy for deafness; these compositions, by their attenuating qualities, dividing the viscous and thick humour. The word netopion is also sometimes used to express the unguentum Egyptianum, and sometimes simply for oil of almonds.

NETTINGS, in a ship, a sort of grates made of small ropes seized together with rope yarn or twine, and
Length of the abutment on the north end, 63 feet 6\(\frac{1}{2}\) in. 
Length of the abutment on the south end, 65\(\frac{1}{2}\) in. 
Length of the whole structure, including the abutments, 220\(\frac{1}{2}\) ft.

The plane of the road upon its first ascent makes an angle of five degrees with the ordinary surface of the river.

Mean level of the river to the top of the bridge in the centre, 16\(\frac{1}{2}\) ft.
Ditto to the bottom of the bridge in the centre, 12\(\frac{1}{2}\) ft.
Height of the bridge from the bottom to the top in the centre, 42\(\frac{1}{2}\) ft.
Height from the bottom of the bridge in the centre to the road, 7\(\frac{1}{2}\) ft.
Height from the bottom of ditto to the water, 8\(\frac{1}{2}\) ft.

So that there is a difference of 35 feet between the road at the spring of the arch and the road at the centre; in other words, an ascent of 3\(\frac{1}{2}\) feet in half a mile, or in the space of 400 feet, which is little more than eight-tenths of an inch to a foot. The bridge is broadest towards the sides, and diminishes towards the centre.

In the broadest part it is 16\(\frac{1}{2}\) ft.
In the centre or narrowest, 42\(\frac{1}{2}\) ft.
The breadth of the road is 28\(\frac{1}{2}\) ft.

The artist informed me, that to complete the bridge would require 49,630 iron nails, 12,008 large trees, 5,500 beams to strengthen them: and that it would cost 300,000 rubles or 60,000 dollars. He spoke of this bold project with the usual warmth of genius; and is perfectly convinced that it would be practicable. I must own that I am of the same opinion, though I hazard it with great diffidence. What a noble elect would be produced by a bridge striking across the Neva, with an arch 980 feet wide, and towering 16\(\frac{1}{2}\) feet from the surface of the water! The description of such a bridge seems almost chimerical; and yet upon inspection of the model we become reconciled to the idea. But whether the execution of this stupendous work may be deemed possible or not, the model itself is worthy of attention, and reflects the highest honors on the inventive faculties of that unimproved genius. It is so compactly constructed, and of such uniform solidity, that it has supported 3,540 pond, or 227,440 pounds, without having in the least swerved from its direction, which I am told is far more, in proportion to its size, than the bridge if completed would have occasion to sustain from the pressure of the carriages added to its own weight.

The person who projected this plan is a common Russian peasant. This extraordinary genius was an apprentice to a shoemaker at Nisheve, Neugerd; opposite to his dwelling was a wooden clock, which excited his curiosity. By repeated examination he comprehended the internal structure, and without any assistance formed one exactly similar in its proportion and materials. His success in this first essay urged him to undertake the construction of metal clocks and watches.
watches. The empress, hearing of these wonderful ex-
tractions of his native genius, took him under her pro-
tection, and sent him to England; from whence, on
account of the difficulties attending his ignorance of
the language, he soon returned to Russia. I saw a
repeating watch of his workmanship at the Academy
of Sciences: it is about the bigness of an egg; in the
inside is represented the tomb of our Saviour, with
the stone at the entrance, and the centelles upon duty:
suddenly the stone is removed, the centelles fall down,
the angels appear, the women enter the sepulchre, and
the same chant is heard which is performed on Easter-
eve. These are trifling, although curious performances;
but the very planning of the bridge was a sublime
conception. This person, whose name is Kudin,
bears the appearance of a Russian peasant; he has a
long beard, and wears the common dress of the coun-
try. He receives a pension from the empress, and is
encouraged to follow the best of his mechanical gen-
ius (A).

NEVEL, or NEVEL, in the Jewish antiquities, a
kind of musical instrument. See NAUM.

NEVEWS, a town of France, in the department of
Nievre, and situated in E. Long. 3° 14'. N. Lat. 46° 59'.
on the river Loire, which here receives the rivulet
Nievre. It contained 10,310 inhabitants in 1800. It

is a place of great antiquity, supposed to be Cesar's No-
viocodunum in Zebedo, where he erected a magazine for
his arms. Francis I. made it a duchy and peerage in
1521, in favour of Francis of Cleves, to whom it came
by marriage. It devolved afterwards to the house of
Mantua, and then to the Palatine family, who in 1651
gave it to Cardinal Mazarin. The cardinal obtained
a title of duke and peer for his nephew Philip Mancini,
in whose family it continued till the late revolution.
The town is fortified with walls, defended with many
high towers and deep ditches, and is the seat of a bi-
ishopric, suffragan of Sens, as likewise of a bailiwic and
chamber of accounts. There was a stone bridge on the
Loire, which was carried away by the ice, and has been
replaced by a wooden one. This town is famous for
its manufacture of glass, earthen ware, cloth, and
cutlery. In the centre of Nevers, on the summit of a
hill, is built the palace of the ancient dukes. It ap-
ppears to have been constructed in the sixteenth centu-
ry, and exhibits a model of the beauty and delicacy of
Gothic architecture. The apartments are hung with
tapestry of 200 years old, which have an air of gro-
tesque and rude magnificence.

NEUCHATEL, a town of Switzerland, capital of
a county of the same name. There are several an-
cient ruins near it, which show its former extent; and
there are two large churches, besides a castle where the
governor resides. The town contains about 3000 in-
habitants. It is situated partly on a small plain, be-
tween Mount Jura and the lake of Neuchatel, which
is 17 miles long and five broad; the side of the har-
bour is the usual walk of the inhabitants. Part of it
too is built upon the side of the mountain; whence
some of its streets are very steep. In this small place
several public works have lately been executed, which
Mr. Cox thinks are far beyond the revenues, or even the
wants, of such a little state. Amongst those he in-
stances a superb causeway and a town-house "built
(says he) of such solid materials, as if it was intended to
survive to the most distant posterity, and to rival the
duration of the much-famed Roman capital." At the
beginning of the 18th century, commerce was very
little followed in this town, owing to an absurd op-
inion which prevailed among the inhabitants, of its be-
ing disgraceful; but this prejudice is now extinguis-
ed, and the town in a much more flourishing situation
than before. The chief article of exportation is wine,
which is much esteemed; and manufactures of printed
linens and cottons have been established with consid-
erable success. The flourishing state of Neuchatel is
principally owing to the benefactions of Mr. David
Pury, late banker of the court at Lisbon. He was
born at Neuchatel in 1709; but having received his
education there, he quitted it in great poverty, and re-
paired to Geneva, where he served his apprenticeship,
but in what line is not mentioned. From Geneva he
went to London, where he acted as clerk to a dealer
in precious stones, and acquired great reputation by
estimating the value of diamonds at sight. After a
long residence in England he went to Lisbon, where
he carried on a very extensive commerce; and having
been appointed court-banker, his fortune rapidly in-
creased. His generosity, however, kept pace with his
wealth; and he not only remitted large sums to Ne-
uchatel while living, but left his country his heir when
he died. His contributions in all are estimated by Mr.
Coxe at 200,000l.; a considerable part of which has
been employed in constructing the public works already
mentioned. Neuchatel has a grand and little council:
the first is composed of 40 persons, with two masters of
the keys; the little council consists of 24 members,
comprehending the mayor, who is president. These two
councils assemble regularly every month. The ecle-
cniastics likewise assemble every month, to consult on
affairs belonging to the church, and to fill up the places
of ministers that die. They choose a dean every year,
who is president of the general assembly, which are
called classes; and sometimes he is confirmed in this
dignity. E. Long. 7° 10'. N. Lat. 47° 5'.

NEUCHATEL, a sovereign county of Switzerland,
bounded on the west by the French Compte, on the
north by the bishopric of Basle, and on the east and

(A) We have given the detail in Mr. Cox's own words, as it appears to us to deserve attention on ac-
count of the greatness of the project, which would have excited admiration had it been attempted by one en-
lighted by science and liberal arts, much more when it comes through the humble medium of a Russian peasant.
It was never executed, as we are just informed by a gentleman who left St. Petersburg about the beginning
of June 1795; but the model remains, and is still shown. The same gentleman (we quote his own words)
adds, "that every mechanic thinks it practicable; and that the general belief is, that the empress would have
built it, had she not found use for all her money in carrying on her warlike and diplomatic transactions with
other courts."
Neuchâtel south by the cantons of Berne and Fribourg. This
principality of Neuchâtel and Vallegin extend from
the lake of Neuchâtel to the borders of Franche
Comté, being in length about 12 leagues, and six in
breadth. The plain with the lower part of the moun-
tains is occupied by the district of Neuchâtel, but
Vallegin is totally enclosed by Jura. Parallel chains
of these mountains run from east to west, forming se-
veral valleys in the most elevated parts. The lower
grounds of this chain consist of arable lands and vine-
yards; the higher of large tracts of forest, which in
many parts have been cleared and converted into pas-
ture grounds, intermixed with fields of barley and oats.
The inhabitants are numerous, and remarkable for
their genius, politeness, and active industry. It con-
tains three cities, one town, 95 villages, and about 300 houses
dispersed in the mountains. The inhabitants are all
Protestants, except two Roman Catholic villages: and
in 1529 they entered into a strict alliance with the can-
tons of Berne, Friburg, Soleure, and Lucern. The air
is healthy and temperate, but the soil not everywhere
equally fertile: however, there are large vineyards,
which produce white and red wine, which last is ex-
cellent. The pastures on the mountains feed a great num-
er of cattle; there are plenty of deer in the forests;
the lakes and rivers abound with fish. The mildness
of the government, and agreeable situation of the in-
habitants in general in these districts is evident from
the great increase of population in the space of 32 years.
In 1752 they contained only 28,017 subjects and 4318
aliens: but in 1784 the number was augmented to
31,576 subjects and 9704 aliens; being an increase of
near a fourth part in that time. The facility with
which the burghership of Neuchâtel is acquired, may
also be accounted one of the means of augmenting its
population; for between the years 1762 and 1770,
the magistrates admitted 41 persons to this privilege;
from 1770 to 1785, 46; from 1780 to 1785, 57; in
all 138; many of whom had children before they pur-
chased their burghership, and 38 of them were foreigners,
either German, French, or Dutch. This country has
experienced similar changes with the rest of Switzer-
land during the usurpation of the French.

NEUCHATTEAU, a commercial town of France,
in the department of the Vosges, containing 2700 in-
habitants. It formerly had an abbey of the monks of St
Clair, a commandery of Malta, and several convents
of monks and nuns. It is seated in a fertile soil, which
produces corn, wine, and all the necessaries of life, on
the river Mouzon. E. Long. 45. N. Lat. 48. 20.

NEVIS, one of the Caribbee islands, lying about
seven leagues north of Montserrat, and separated from
St Christopher's by a narrow channel. It makes a
beautiful appearance from the sea, being a large coni-
cal mountain covered with fine trees, of an easy ascent
on every side, and entirely cultivated. The circums-
ference is about 21 miles, with a considerable tract of
level ground all around. The climate in the lower
part is reckoned to be warmer than Barbadoes, but it
is more temperate towards the summit. The soil is
very fine in the lower part, but grows coarser as we ascend.
The productions are nearly the same with those of St Christopher's. There are three pretty good
roads or bays, with small towns in their vicinity;
Charles Town, Moreton bay, and Newcastle. This
pleasant island was settled under the auspices of Sir
Thomas Warner from St Christopher's. His succes-
sor, Governor Lake, was considered as the Solomon
of this little country, in which he disposed of every thing
with such prudence, wisdom, and justice, as procured
him a high reputation with the French as well as
English. In the Dutch war they met with some dis-
turbance from the French; but by being covered by
an English squadron, the enemy were obliged to desist
from their intended invasion, after a smart engage-
ment in sight of the island. Sir William Stapelton
sometimes resided here, and Sir Nathaniel Johnson con-
stantly, at which time the inhabitants of Nevis were
computed at 30,000. In the war immediately after
the Revolution, they exerted themselves gallantly, and
had two regiments of 300 men each. In that of
Queen Anne they behaved equally well, though they
were less fortunate; for the French landing with a
superior force, and having inveigled most of their
slaves, they were forced to capitulate. About 4000
of these slaves the French carried away and sold to
the Spaniards, to work in their mines. The parlia-
ment, after making a full inquiry into the losses
they had sustained, voted them about a third part of
the sum in which they had suffered. These losses by war,
an epidemical disease, and repeated hurricanes, cer-
tingly diminished the number of the people. They are
now thought not to exceed 2000 or 3000 whites, and
6000 blacks. There is here a lieutenant govern-
ment, with a council, and an assembly, which is com-
posed of three members from each of the five parishes
in which the island is divided. The commodities are
cotton and sugar; and about 20 sail of ships are an-
ually employed in this trade.

NEURADA, in Botany, a genus of plants be-
ing to the decandria class, and in the natural
system ranking under the 13th order, Succulenta. See Bo-
tany Index.

NEUROGRAPHY, signifies a description of the
nerves. See Anatomy.

NEUROPTERA, the name of one of the orders into
which the class of insects is divided according to the
Linnean classification. See Entomology Index.

NEUTER, a person indifferent, who has espoused
neither party, and is neither friend nor foe.

A judge ought to be neuter in the causes he judges:
in questions, where reason appears neuter, a man
should ever incline to the side of the unhappy.

Neuter, in Grammar, denotes a sort of gender
of nouns, which are neither masculine nor feminine. See
Gender.

The Latins have three kinds of genders, masculine,
feminine, and neuter. In English, and other modern
tongues, there is no such thing as neuter nouns. See Noun.

Verbs Neuter, by some grammarians called
intransitive verbs, are those which govern nothing, and
are neither active nor passive. See Verb.

When the action expressed by the verb has no object
to fall upon, but the verb alone supplies the whole idea
of the action; the verb is said to be neuter: as, I step,
you yawnst, he sneezes, we walk, ye run, they walk
still.

Some divide verbs neuter into, t. Such as do or
signify any action, but a quality; as albeit, "it is when".
or a situation, as sedet, "he sits," or have some relation to place; e.g., adect, "he is present;" or to some other state or attribute, as regnat, "he rules," &c. And,

2. Those that signify actions, though those such as do not pass into any subject different from the actor; as to dine, to sup, to play, &c.

But this latter kind sometimes cease to be neuter, and commence active; especially in Greek and Latin, when a subject is given them; as, vivere vitam, ambulare viam, pugnare pugnem. Thus the old French poets say, Soupirer son tourment; the English, to sigh his breast, &c.

But this is observed only to obtain where something particular is to be expressed, not contained in the verb; as, vivere vitam beatam, to live a happy life; pugnare bonam pugnam, to fight a good fight, &c.

According to the abbot de Dangeau, verbs neuter may be divided into active and passive; the first, those that form their tenses in English, by the auxiliary verb to have; in French, by avoir. The second, those that form them in English with the verb to be; in French être.—Thus, to sleep, to yawn, dormir and éternuer, are neuters active.—To come, and to arrive, are neuters passive.

Neutral Salts, in Chemistry, composed of an acid with any other substance capable of uniting with it and destroying its acidity, as sulphuric acid and soda, or Glauber’s salt, mariaric acid and soda, or common salt.

Neutrality, the state of a person or thing that is neuter, or that takes part with neither side.

New-Abbey, situated near Kilcullen bridge in the county of Kildare, and province of Leinster in Ireland. It was founded by Rowland Eustace, of a great and ancient family in this county; the tower is still standing, and some part of the abbey; the ruins of the rest have contributed to build several dwellings near it. In the inside Rowland Eustace and his lady lie buried; their figures, clothed in armour, are to be seen there. Near this is a handsome seat of the Carter family, on the opposite side of the river Liffey.

Newark upon Trent, in the county of Nottingham, is a great thoroughfare in the York road, 124 miles from London. It has bridges over the Trent, which forms an island here, by dividing itself into two streams two miles above the town, which meet again two miles below it. A magnificent castle was built here in the reign of King Stephen, which held out stoutly in the barons wars for King John, who died here, October 19. 1216; and it also stood out for King Charles I. to the last; but after he had put himself into the hands of the Scots army, then before him, the governor by his order surrendered it, after which it was demolished.—It was situated near the river; the walls of the towers are very thick, and of a very great height; and there were no historical testimony, these remains are sufficient evidence that it was formerly of great importance. In the court before these ruins is a very fine bowling green. The town being subject to inundations from the river Trent, and often from that circumstance made impassable, a turnpike road, at the instigation of a publican, was made about twenty years ago, so high as to be passed with safety in the greatest floods, by arches of brick being made in several places to carry off the water, constructed by Mr Smeaton, at the expense of 12,000l. Near the town there is a bridge constructed for the same purpose, made mostly upon dry land, consisting of nine arches. Its church, which is reckoned one of the finest in the kingdom, was built by Henry VI. and has a lofty spire. The population in 1811 was 7236.

Newborough, or Newburgh, in the isle of Anglesey, North Wales, distant from London 254 miles, though but a small town, situated over against Caernarvon in North Wales, about 17 miles southwest from Beaumaris, is governed by a mayor, two bailiffs and a recorder. Its Welsh name is Rhos dai, or Rhos dair.

Newburg, the name of several towns of Germany, two of which are the chief towns of duchies of the same name; one in Bavaria, and the other in the Palatinate.

Newbury, a town in the county of Berks in England, 16 miles from Reading, and 86 from London, arose on the decay of Spinham-Land. Notwithstanding its name signifies New-Borough, it is as old almost as the Conquest. It made so much broad cloth formerly, that in the reign of Henry VIII. here flourished John Wincob, commonly called Jack of Newbury, one of the greatest clothiers that ever was in England, who kept 100 looms in his house; and in the expedition to Flowden Field against the Scots, marched with 100 of his own men, all armed and clothed at his own expense; and he built all the west part of the church. Also Mr Kenric, the son of a clothier here, though afterwards a merchant in London, left 4000l. to the town, as well as 7500l. to Reading, to encourage the woollen manufactory. It makes a great quantity of shalloons and druggets, but not near so much broad cloth now as formerly; yet it is a flourishing town, with spacious streets, and a large market place, in which is the guild-ball. In the neighbourhood, on the banks of the Kennet, there is a stratum of petrified wood dug out for firing, where they frequently find trunks of large oaks yet undecayed, with petrified hazel nuts, fir cones, &c. with the boxes and horns of stags, antelopes, &c. tusks of boars, and heads of beavers. The river Kennet, which abounds with excellent trout, eels, and cray-fish, runs through the town. It was made a corporation by Queen Elizabeth, and is governed by a mayor, high steward, aldermen, &c. The population in 1811 was 4908.

Newcastle-under-Lyme, a town in England, in the county of Stafford, on a branch of the Trent, is 14 miles north of Stafford, 33 south south-east of Warrington, and 149 from London: had a castle, now in ruins; and is so called from an older castle, which formerly stood two miles off, at Chesterton-under-Lyme. It was incorporated by King Henry I. and again by Queen Elizabeth and King Charles II. and is governed by a mayor, two justices, two bailiffs, and 24 common council. The population in 1811 was 6175. The clothing trade flourishes here; but its chief manufactory is hats, here being an incorporated company of felt-makers. A great quantity of stone ware is made near this place.

Newcastle on Tyne, the capital of the county of Northumberland in England, 15 miles north of Durham, 94 north of York, 63 south by east of Berwick, 60 east of Carlisle, and 271 from London, stands at the end of the Picts wall, on the north side of the Tyne, over
NEW [ 774 ] NEW

Newcastle over which it has a stately bridge into the bishopric
of Durham, in which its suburb called Gateside is situ-
ated; for the liberties of Newcastle extend no farther
than the great iron gate upon the bridge, which has the
arms of the bishop of Durham carved on the east side
and those of Newcastle on the west side. W. Long.
1. 27. N. Lat. 55. 5. It is admitted to have been a
Roman station, though no evidence at present appears,
except at Pandon-gate, whose superstructure is of dif-
f erent workmanship and model from any others of the
town, the arches being circular. The Carpenter’s
tower is also of Roman original. In the Saxo-nian
time it was called Moncaster, from the monks here, who all
fled when it was depopulated by the Danes; and after-
wards Newcastle, from a castle built here by William
the Conqueror’s son, Robert, in 1080, to defend the
country against the Scots, whose kings had this town be-
fore the Norman conquest, and sometimes resided here.
—Several monasteries and houses were built here soon
after the castle; and it was greatly enlarged and en-
riched by a good trade to the coasts of Germany, and
by the sale of its coal to other parts of England; for
which, and for other merchandise, it is become the
great emporium of the north of England, it being the
nearest and largest town in those parts, next to York.
In the reign of Edward I. it was burnt by the Scots;
but a very rich burgage, who was taken prisoner, soon
ransomed himself for a good sum of money, and be-
gan the first fortifications of the place, which he ex-
tended from Sandgate to Pampedon, and thence to
the Austin friars gate; which the townsmen finished,
and encompassed with stout walls, which extended two
miles, wherein are seven gates and many turrets, with
several casemates bomb-proof. To which two other
gates were added in more modern times, viz. Bridg-
gate and Sand-gate; the wall between them was after-
wards removed to open the quay. Edward III.
granted the corporation the duties and customs of the
town for seven years, to enable them to complete its
fortification. It is a borough at least as ancient as
King Richard II. who granted that a sword should be
carried before the mayor; and King Henry VI. made
it a town and county incorporate of itself, indepen-
dent of Northumberland. Henry VII. built a monas-
tery here for the Franciscans. Besides which, it had
several religious foundations, several of which structures
have been converted to companies halls and private
residences. In the reign of Henry VIII. this place is
said to have exceeded in the strength and magnifi-
cence of its works all the cities of England, and most
places in Europe. The town is governed by a mayor,
12 aldermen, a recorder, sheriff, town clerk, a clerk of
the chambers, two coroners, eight chamberlains, a
ward-bearer, a water bailiff, and seven sergeants at
mace. Its situation, especially the most busy part of
it towards the river, is very uneven, being built on
the declivity of a steep hill, and the houses very close.
The castle overlooks the whole town. That part built
by Robert was of great strength, and square, and sur-
rounded by two walls; the square was 53 feet by 54,
and the walls 13 feet thick, within which was a cal-
pel. The outward fortifications are now defaced, and
their site crowded with buildings. The tower remains
circular, and is situated on a lofty eminence, and its prin-
cipal entrance is to the south. This castle belongs to
the county, and makes no part of the liberties.—It is New-
now the county prison, and in the great hall the judges
hold the assizes. Here Baliol king of Scotland did ho-
mage to King Edward I. in 1292; as did Edward Baliol
in 1334 to King Edward III. Here is a magnificent
exchange and a custom-house; and a very fine quay.
There is a handsome mansion house for the mayor, who is
allowed 1000l. a-year, for his table, besides a coach
and barge. The old bridge was carried away in a
flood, and the present was erected about 1775, of nine
nicely elliptic arches. With the old bridge 22 houses
were thrown down, and six lives lost. It was originally
built of wood; but having been destroyed by fire in
1248, was rebuilt of stone, and consisted of 12 arches,
three of which on the north side were closed up, and
served for cellars; this was again rebuilt about 1450,
and was crowded with wooden buildings; but near the
middle was a tower with an iron gate, used as a town
prison. A strong building crossed the bridge, which
was used as a magazine. On the south front was a
status of King Charles II. The water which destroy-
ed this bridge, on November 11. 1771, was upwards
of 12 feet above high water mark in spring tides.—On
removing the foundations of the piers of the old bridge
to erect the present, by observations made, and medals
found, part of it is supposed to have existed from the
time of the Romans. It is computed that above 6000
keelmen are employed here, who have formed them-
technicians into a friendly society; and by their own con-
tributions, built a noble hospital containing 50 cham-
bers, for each of their fraternity as are poor, disabled,
or past their labour; and it is supported by the con-
tribution of those that are in health. The town is
extremely populous; and, notwithstanding the multi-
tude of those employed in and about the coal pits,
with which the town is in a manner surrounded, has
abundance of poor; but it has also many wealthy in-
habitants, and it is said they pay above 4000l. a-year
to their relief. It is observed, that this town has the
greatest public revenue in its own right as a corpora-
tion, of any town in England, it being computed at no
less than 8000l. a-year. In 1774, the receipts of the
corporation were 20,350l. 9s. 6d.; and their disburse-
ments about 19,445l. The number of inhabitants in
1811 was 27,587, exclusive of a number of seamen who
cannot be accurately estimated. Here are four churches
or chapels. That of St Nicholas is the mother church:
a curious fabric, built cathedral-wise by David king
of Scots, 240 feet long, 75 broad, and proportionally
high, with a tower steeple 194 feet in height, of Ge-
colic architecture; also St Andrew’s, St John’s, and
All Saints, lately rebuilt on the site of the old struc-
ture, of a circular form. Here are also several meet-
ing houses, and four charity schools for 300 children;
a fine hall for the surgeons, and a large prison called
Newgates; also an hospital for lunatics, another for the
lying-in of married women, as well as a fund raised
for the relief of those who are delivered at their own
houses. Here is a well endowed and large benefic-
ary, and an assembly room that attracts attendance, con-
taining every useful apartment, and a ball room 93 feet
g.: The front is ornamented with six Ionic pillars,
&c. In another part of the town is a new theatre.
Here is a very neat set of baths. A free grammar
school was granted by James I. from an old foun-
castle of St Mary's hospital, in the vestry room of whose
chapel is the election of the officers of the corporation.
There were formerly several palaces in this city, viz. Pam-
perton hall, Lumley place, Earl's Place, Northumber-
land house, Westmoreland place, &c. The free mas-
sions have lately erected an elegant hall, richly orna-
mented, to hold their lodge in, near High friar chair,
capable of holding above 4000 of that ancient frater-
nity. Here is an hospital for 39 decayed freemen and
their widows; and another for three clergyman's
widows and three merchants widows. The Maidens
hospital, built in 1753, is endowed with 2400l. for six
maiden women and six poor men. Dr Thomlin, a pre-
byondry of St Paul's, and rector of Whicham in the
Bishopric of Durham, gave a library of above 6000
valuable books to the corporation, and settled a rent
charge of 4l. a-year for ever for buying new ones;
and Sir Walter Blacket, formerly one of its representa-
tives in parliament, built a neat repository for them,
and settled 25l. a-year for ever on a librarian. The
upper or north part of the town, inhabited by the polier
sort of people, is much pleasanter than that part next
the river, and has three level, well built, and spacious
streets. The road from Shields to Newcastle is broad, the channel safe, and the tide flows with a strong current to the town, and far be-
beyond it. In the beginning of the civil wars, this town
was taken and plundered by the Scotch fanatics, who
were sold their king, Charles I., for 200,000l. in hand,
and security for as much more. The glass works are
very curious, and have more business of the fine sort
than most other places: the duty on this article drawn
by government is said to amount to 200,000l. annually.
Besides, it has a considerable manufacture of broad and
narrow cloths, and several soap boileries; and this
place is famous for grindstones, for which there is such
a demand, that scarce a ship's stores without them; from
whence came the proverb, "That a Scotsman and a
Newcastle grindstone travel all the world over." Ships
fit for the coal trade are built here up to perfections,
with great strength. Here is a considerable manufactory of
hardware and wrought iron, after the manner of that at
Sheffield.—Its markets are on Tuesdays and Saturdays.
Its fairs in August, which last nine days, and October
29th, which last nine days. By an act of Queen Mary,
the price of the carriage of goods hither from London
by waggons was settled at 24. per lib. London alone
is said to consume at least 766,887 chaldrons of its
coal every year; but as for the fish vended in that
city by the name of Newcastle salmon, it is more pro-
perly called Berwick salmon, the fresh salmon being
taken near 50 miles farther, as far as the Tweed, and
brought on the backs of horses to Shields, where it is
cured, pickled, and sent on board for London. It is
worth remembering, that at the assizes here in 1743,
two old men were suppressed as witnesses from a
neighbouring village, viz. one 135 years of age, and
his son 95, both hearty, and having their sight and
hearing; and that in 1744, one Adam Turnbull died in
this town aged 112, who had had four wives, the
last of whom he had married when he was near 100
years old.

The annual amount of the revenue of customs at
this port, which Mr Brand in his History of New-
castle states at 41,000l. is now very considerably up
wards of 70,000l.
The coal carried out of it annually (on an average
from 1785 to 1791) were nearly 448,000 Newcastle
chaldrons; the weight of which is 1,187,200 tons.
The following are the exports of coal from the Tyne
for the years annexed.

The number of persons employed in the coal trade of
the rivers Tyne and Wear in 1792 exceeded 64,000.
The manufacture of earthen ware is greatly in-
creased, and carried on to great perfection in its neighbour-
hood, in seven potteries; and their produce exported
to foreign parts, as well as to the different ports
of this kingdom; some of which potteries constantly
employ upwards of 100 persons, men, women, and
children.

New works of considerable extent for the manufac-
ture of iron have been established, as also a very capita-
lar manufactory for white lead, milled lead, &c. In-
dependent of red and white lead, the quantity of lead
exported from the river Tyne during four years was as
follows:

The trade with the West India islands is increasing,
and may in time become very considerable; as the
port has great advantages, in being able to supply
on the cheapest terms many articles wanted in those
islands; such as coal, grindstones, lime, bricks, tiles,
iron wares, &c.; and is most advantageously situat-
ed for the re-exportation of the West India produce to
the ports on the Baltic, to Germany, the United Pro-
vinces, Flanders, and part of France; and moreover,
the risk of navigation, and the rate of insurance, not
being greater than between those islands and Liver-
pool, and some other ports on the western coast of
this kingdom.
The population of Newcastle in 1811 was 27,587,
and it is daily increasing in inhabitants and opulence.
It has long been noted for hospitality and good living.
Great improvements have been made in the town, by
opening new streets, and paving the principal ones, in
the same manner as in London. To the list of public
edifices of modern erection, and mentioned above, viz.
the grand assembly rooms, and the elegant theatre,
which were built by subscription, and the superb parish
church of All Saints, built at a very great expense by
the parishioners, may be added a commodious riding
house, built also by subscription.

NEWCASTLE, a borough town of Ireland, in the
county of Dublin, and province of Leinster, which for-
merly returned two members to parliament, and holds
two fairs, 3rd of May and 8th of October.

NEWCASTLE is also the name of a handsome town, in,
NEW [ 776 ]

NEwcastle, a town in America, 35 miles below Philadelphia, on the west bank of Delaware river. It was first settled by the Swedes about the year 1627, and called Stockholme. It was afterwards taken by the Dutch, and called New Amsterdam. When it fell into the hands of the English, it was called by its present name. It contained 2438 inhabitants in 1800, including 235 slaves, and was formerly the seat of government. This is the first town that was settled on Delaware river.

NEWCASTLE, Duke of. See CAVENDISH.

NEW ENGLAND. See ENGLAND, New.

NEW Forest of Hampshire in England, is a tract of at least 40 miles in compass, which had many populous towns and villages, and 36 mother churches, till it was destroyed and turned into a forest by William the Conqueror. There are nine walks in it; and to every one a keeper, under a lord warden, besides two rangers, and a bow-bearer. As this large tract lay many ages open and exposed to invasions from foreigners, King Henry VIII built some castles in it; and it has now several pretty towns and villages. It is situated in that part of Hampshire which is bounded on the east by Southampton river, and on the south by the British channel. It possesses advantages of situation, with respect to the convenience of water carriage and nearness to the dock yards, superior to every other forest, having in its neighbourhood several ports and places of shelter for shipping timber, among which Lymington is at the distance of only two miles, Bemley about half a mile, and Redbridge three or four miles from the forest; and the navigation to Portsmouth, the most considerable dock yard in this kingdom, is only about 30 miles from the nearest of those places. This is the only forest belonging to the crown of which the origin is known. Doomsday-book contains the most distinct account of its afforestation by William the Conqueror: the contents of every field, farm, or estate afforested, in hides, carucates, or virgates, by which the extent of land was then computed, together with the names of the hundreds and villages, and of the former proprietors (which are for the most part Saxons), the rent or yearly value of each possession, and the tax which had been paid for it to the crown during the reign of Edward the Confessor, before the inhabitants were expelled, and that part of the country laid waste, are all to be found in that most curious and venerable record. Wishing to discover the original extent of the forest, we extracted, for our own information, all that relates to it in that ancient survey. The extract is far too voluminous for insertion. The names of many of the places having been changed since that time, it is difficult to ascertain with precision what were then the limits of the forest. The oldest perambulation we have met with is among the Pleas of the Forest, in the eighth year of King Edward I. preserved in the Chapter-house at Westminster. The boundaries there described include all the country from Southampton river on the east to the Avon on the west, following the sea coast as far as the southern boundary between those rivers, and extending northwards as far as North Chafeord, or North Charford, on the west, and to Wade and Orbridge, or Overbridge, on the east; and the greatest part, if not the whole, of that extensive district, is mentioned in Doomsday book to be the forest belonging to the crown. Another perambulation was however made in the 30th of the same king, which leaves out a great part of the country contained within the former. This perambulation, which is preserved in the Tower of London, confines the forest to limits which, as far as we can trace them, appear to have been followed in the 22d year of Charles II. when the forest was again perambulated. By the Charta de Foresta, all lands not belonging to the crown which had been afforested by Henry II. Richard I. or King John, were to be disafforested; but as no provision was made for the reduction of the more ancient afforestations, it is easy to account for the great diminution of this forest in the reign of Edward I. who was not a prince likely to submit to any encroachment on his rights. The perambulation of the 22d of Charles II. is the last which we find on record: it contains the present legal extent of the forest, and was given to the surveyors as their guide, in taking the plan which they have made lately by direction. From that plan, with the approbation of the lords commissioners of his majesty's treasury, an engraving was made. According to the last-mentioned perambulation and the plan, the forest extends from Godshill on the north-west to the sea on the south-east, about 20 miles; and from Hardley on the east to Ringwood on the west, about 15 miles; and contains within those limits about 92,365 acres statute measure. The whole of that quantity, however, is not forest land, or now the property of the crown: there are several mansions and other considerable freehold estates within the perambulation, belonging to individuals, to the amount of about 24,797 acres; about 625 acres are copyhold or customary lands belonging to his majesty's manor of Lyndhurst; about 1004 acres are lease-hold under the crown, granted for certain terms of years, and forming part of the demised land revenue, under the management of the surveyor-general of crown lands; about 901 acres are purveyures or encroachments on the forest; about 1193 acres more are enclosed lands held by the master-keepers and groom-keepers, with their respective lodges; and the remainder, being about 63,845 acres, are woods and waste lands of the forest. To perpetuate the spot where William Rufus was killed by the glance of an arrow shot at a stag, a triangular stone was erected in 1745. George III visited
winter hath been computed at 4000. The French, by Newland, the treaty of Utrecht, were permitted to fish from Cape Bonavista on the east side round the north of the island to Point Rich on the west; and by the treaty of Paris, they are allowed the isles of St Pierre and Miquelon, upon which they are to dry their fish, but not to erect fortifications of any kind.

The great importance of this place ariseth from its fishery, which is in part carried on by the inhabitants at the several harbours, which are about 20 in number, who take vast quantities of cod near the coast, which they bring in and cure at their leisure, in order to have it ready for the ships when they arrive. But the great and extensive fishery is on the banks at some distance from the island. The great bank lies 20 leagues from the nearest point of land, from the latitude 41° to 45°, stretching 300 miles in length and 75 in breadth.—To the east of this lies the False Bank; the next is styled Vert, or the Green Bank, about 240 miles long, and 120 over; then Banquero, about the same size; the shoals of Sand Island, Whale Bank, and the Bank of St Peter’s, with several others of less note, all abounding with fish.

The cod are caught only by a hook; an expert fisher will take from 150 to 300 and upwards in a day; for the fish never bite in the night: the labour is very great. The season is from May to October, in the height of which there are from 500 to 700 sail upon the banks at a time. The fish caught in the spring months are best; they are cured in very different ways. Some are styled white fish, others mud fish, which are stewed and salted in the bold, and will not keep long; but the best and most valuable are the dried cod. The quantity taken is prodigious: yet in some seasons and in different places varies considerably, as the fish frequently change their stations. The fishing ships, as they are called, lie upon the banks, with the help of their boats take and cure their own fish, and as soon as they are full sail for a market. The smack ships proceed directly to the island, where they purchase fish from the inhabitants either by barter or bills of exchange. The principal markets for cod are Spain, Portugal, Italy, and the West Indies. The value of this fishery is computed at some hundred thousand pounds annually; employing, besides several hundred ships, some thousands of seamen, and affording a maintenance to a number of tradesmen of different occupations, by which many large towns on the west side of England accumulate much wealth, and at the same time contribute in many respects to the benefit of the public.

The great utility of this fishery was very early seen, and very vigorously pursued; for in the beginning of the reign of King James I. we had two hundred and fifty sail employed therein. It is computed, that three quintals of wet fish make one quintal of dried cod. Besides, the livers of every hundred quintals make a hoghead of oil; and exclusive of these there are many lesser advantages that go in diminution of the expense. The fishery, as we have said above, produces differently in different seasons; but it is judged to be a very good one when it produces 300,000 quintals of fish and 3500 barrels of oil, both equally valuable and valuable commodities. As every ship carries twenty, and each of their boats eight men, and as these return home in six months, there cannot be a more noble nursery for seamen.
The artificers and traders employed in building, victualling, and repairing these vessels, are very numerous in the respective ports from which they sail. These circumstances justify the particular attention paid by government to this branch of the public service; in respect to which they may be well informed, an annual and very distinct account, by which the whole is seen at one view, is delivered by the proper officer to the governor of Newfoundland, that is to the commodore of his majesty’s squadron. Mr Pennant, in the appendix to his Arctic Zoology, gives us, from what appears to be very good authority, the following account of this island.

"Within the circuit of 60 miles of the southern part, the country is hilly, but not mountainous. The hills increase in height as they recede from the sea; their course is irregular, not forming a chain of hills, but rising and falling abruptly. The coasts are high, and the shores most remarkably bold. The same may be said of almost every part of this vast island. The country is much wooded, and the hills (such as have not flat tops to admit the rain to stagnate on them) are clothed with birch, with hazel, spruce, fir, and pine, all small; which is chiefly owing to the inhabitants taking off the bark to cover the fish stages. This peninsula is so indented by the fine and deep bays of Placentia, St Mary, Conception, and Trinity, that it may be penetrated in all parts, which is done for the sake of fouling, or the procuring of spars for masts, cars, &c. The island is on all sides pierced with deep bays, which penetrate it in many places by isthmuses most remarkably narrow.—The mountains on the south-west side, near the sea, are very high, and terminate in lofty headlands; such are Cape Rouge, a most remarkably high promontory, Cape St Mary’s, and Cape le Hone. Such in general is the formation of the island; on the north-east, most of the hills in the interior part of the country terminate pyramidal, but form no chain. The interior parts of the country consist chiefly of morasses, or dry barren hummocks, or level land, with frequent lakes or ponds, and in some places covered with stunted black spruce. The rivers of Newfoundland are unfit for navigation, but they are of use in floating down the wood with the summer floods. Still the rivers and the brooks are excellent guides for the hunters of beavers and other animals, to penetrate up the country, which as yet has never been done deeper than 30 miles. Near the brooks it is that timber is commonly met with, but seldom above three or four miles inland, and in valleys; the hills in the northern district being naked and barren.

"In some parts of Newfoundland there is timber sufficiently large for the building of merchant ships; the hulk is made of juniper, and the pine furnishes masts and yards; but as yet none has been found large enough for a mast for a large cutter. The fishery is divided into two seasons; that on the shore, or the shore season, commences about the 20th of April, and ends about the 10th of October; the boats fish in from four to 20 fathoms of water. The most important, the bank fishing season, begins the 10th of May, and continues till the last of September, and is carried on in 30 to 45 fathoms deep of water. Banking vessels have sailed from St John’s to the bank as early as the 12th of April. At first they use perch or birds for a bait; but as they catch fish, they supply themselves with a shell fish called clams, which is found in the belly of the cod. The next bait is the lobt, after that the herring and the launce, which last till June, when the capelin comes on the coast, and is another bait. In August the squid comes into use, and finally the herring again. The greatest number of cod fish taken by a single fisherman in the season has been 12,000, but the average is 7000. The largest fish which has been taken was four feet three inches long, and weighed 46 pounds. A banking vessel of 10,000 fish ought to be filled in three weeks, and so in proportion; and 80 quintals (112 lb. each) for a boat in the same time.

"In 1785, 541 English vessels fished on the bank, a number exceeding that of the French. A heap of dried fish, 20 feet long and ten wide, and four deep, contains 300 quintals. Such a heap settles, in the course of 48 hours after it is made, about 2½. As extraordinary splitter will split five quintals of fish in an hour. The average in that time is two. There is no fishing during winter, on account of the inclemency of the season. It is supposed that the fish in a great measure quit the banks before that time, as in general they are very scarce when the fishing vessels go upon the banks early in the spring.

"There are a few small towns on the coasts, which have gardens sown with English pulse; but many of the inhabitants quit the country in winter.

"An admiral or some sea officer is generally governor of Newfoundland."

NEWMARKET, in Cambridgeshire, 13 miles from Cambridge, 13 from St Edmundsbury, and 60 from London, is a town with one long street, the north side in Suffolk, the south side in Cambridgeshire. It is a healthy place, and a great thoroughfare in the road from London to Norfolk; but stands mostly by the horse races every year in April and October, here being the finest course in England; on which there is a house for the king when he comes to the races, which was built by Charles II. The king gives a plate or two every year, besides those given by the nobility; and wagers are laid upon the horses, which are seldom under 500l. and often above 1000l. Here are two coffeehouses, at which, every night and morning during the races, there is gaming, as there is also at the houses of the nobility and gentry. Here are also cock matches. Here is a little chapel, which is a chapel of ease to the mother church at Ditton; and another in the Suffolk side, which is parochial. The town was burnt in 1685, but soon rebuilt; and in 1811 contained 1917 inhabitants.

NEWROSS, a borough town in the county of Wexford, and province of Leinster in Ireland, 67 miles from Dublin. This town was formerly walled, and some of the gates still remain. It lies on the river Barrow, which is here very deep, and ships of burthen can come up to the quay even when the tide is out. The church is large, but the customhouse and quay are both small, and sometimes overflooded many feet. It is one of the staple ports for exporting wool, yet its trade is but inconsiderable; beef and butter are the principal articles exported. Here is a barracks for a troop of horse, and a good ferry into the county of Kilkenny. Near this town is a charter school. It is also a post town, and gives title of earl to the family of Gore. It was formerly fortified, and adapted
NEW [ 779 ]

with many religious houses, among which was a Crouched friary, built on the summit of a hill in the town; but one of the friars having killed a principal inhabitant, the whole body of the people arose, put the friars to death, and totally destroying the friary; on the site of which the monastery of St. Saviour, for conventual Franciscans, was afterwards erected by Sir John Devereux; and the east end of this last building is now the parish church. A friary for Eremites, following the rule of St. Augustine, was also founded here in the reign of Edward III.

NEWSPAPERS, periodical publications, daily, weekly, &c. for the purpose of communicating to the world every thing of importance, whether political or literary, &c. which is going on. They have tended much to the dissemination of learning, and have served many other valuable purposes; and while they are carried on with candour, impartiality, and ability, they are unquestionably a great national benefit. When this, however, is not the case, and it often happens, they disgrace their authors, and are highly injurious to the public. They were first published in England, August 22, 1642. Journal de Scavans, a French paper, was first published in 1665, though one was printed in England, under the title of the Public Intelligencer, by Sir Roger L'Estrange, 1663, which dropped, on the publication of the first London Gazette. Newspapers and pamphlets were prohibited by royal proclamation 1680. Though at the Revolution prohibitions of this kind were done away, and the press set at liberty, yet newspapers were afterwards made objects of taxation, and for this purpose were first stamped in 1713. The number of them, however, gradually increased; and there were printed in the whole kingdom during the years 1775, 12,680,000; 1776, 12,830,000; 1777, 13,150,642; 1778, 13,240,599; 1779, 14,166,642; 1780, 14,217,371; 1781, 14,397,630; 1782, 15,272,519. They are now still more numerous. The average number of newspapers printed in England at the close of the reign of George II. was 564,679. The number in 1790 was 14,031,639; in 1810, 15,000,576.

Chalmers' Life of Ruddiman, p. 432.

NEW STYLE, first used in England in 1753, was introduced into the western world by Pope Gregory XIII. See CHRONOLOGY, No. 24.

NEWT, or EFT, the common lizard. See LACERTA ERFETTIO INDEX.

NEWTON, Sir Isaac, one of the greatest philosophers and mathematicians the world has ever produced, was the only child of Mr. John Newton of Cestersworth, not far from Grantham in Lincolnshire, who had an estate of about £200 per annum, which he kept in his own hands. He was born at that place on Christmas day 1642. His father dying when he was young, his mother's brother, a clergyman of the name of Agacough, or Askew, who lived near her, and directed all her affairs after the death of Mr. Newton, put her son to school at Grantham. When he had finished his school learning, his mother took him home, intending, as she had no other child, to have the pleasure of his company; and that he, as his father had done, should occupy his own estate. But his uncle happening to find him in a hay loft at Grantham working a mathematical problem, and having otherwise observed the boy's mind to be uncommonly bent upon learning, prevailed upon her to part with him; and she sent him to Trinity College in Cambridge, where her brother, having himself been a member of it, had still many friends. Isaac was soon taken notice of by Dr. Isaac Barrow; who, observing his bright genius, contracted a great friendship for him. M. de Fontenelle tells us, "That in learning mathematics he did not study Euclid, who seemed to him too plain and simple, and unworthy of taking up his time. He understood him almost before he read him; and a cast of his eye upon the contents of his theorems was sufficient to make him master of them. He advanced at once to the geometry of Des Cartes, Kepler's Optics, &c. It is certain that he had made his great discoveries in geometry, and laid the foundation of his two famous works, the Principia and Optics, by the time he was 24 years of age." In 1664, he took the degree of bachelor of arts; and in 1668 that of master, being elected the year before, fellow of his college. He had before this time discovered the method of fluxions; and in 1669 he was chosen professor of mathematics in the university of Cambridge, upon the resignation of Mr. Barrow. The same year, and the two following, he read a course of optical lectures in Latin, in the public schools of the university; an English translation of which was printed at London in 1728, in 8vo, as was the Latin original the next year in 4to. From the year 1671 to 1679, he held a correspondence by letters with Mr. Henry Oldenburg secretary of the Royal Society, and Mr. John Collins fellow of that society; which letters contain a variety of curious observations.

Concerning the origin of his discoveries, we are told that as he sat alone in a garden, the falling of some apples from a tree led him into a speculation on the power of gravity; that as this power is not diminished at the remotest distance from the centre of the earth to which we can rise, it appeared to him reasonable to conclude, that it must extend much farther than was usually thought; and pursuing this speculation, by comparing the periods of the several planets with their distances from the sun, he found, that if air or any other like gravity held them in their courses, its strength must decrease in the duplicate proportion of the increase of distance. This inquiry was dropped; but resumed again, and gave rise to his writing the tractise which he published in 1687, under the name of Mathematical Principles of Natural Philosophy; a work looked upon as the production of a celestial intelligence rather than of a man. The very same year in which this great work was published, the university of Cambridge was attacked by King James II. When Mr. Newton was one of its most zealous defenders, and was accordingly nominated one of the delegates of that university to the high-commission court; and the next year he was chosen one of their members for the convention parliament, in which he sat till it was dissolved. In 1696, Mr. Montague, then chancellor of the exchequer, and afterwards earl of Halifax, obtained for him of the king the office of warden of the mint; in which employment he was of signal service, when the money was called in to be reckoned. Three years after, he was appointed master of the mint, a place of vast considerable profit, which he held till his death. In 1699, he was elected one of the members of the Royal Academy of Sciences at Paris. In 1701, he was a second
time chosen member of parliament for the university of Cambridge. In 1704, he published his Optics; which is a piece of philosophy so new, that the science may be considered as entirely indebted to our author. In 1705, he was knighted by Queen Anne. In 1707, he published his Arithmetica Universalis. In 1711, his Analysis per Quantitatum Series, Fluxiones et Differentias, &c. was published by William Jones, Esq. In 1712, several letters of his were published in the Commercium Epistolicum. In the reign of George I, he was better known at court than before. The princess of Wales, afterwards queen consort of England, used frequently to propose questions to him, and to declare that she thought herself happy to live at the same time with him, and have the pleasures and advantages of his conversation. He had written a treatise of ancient chronology, which he did not think of publishing; but the princess desired an abstract, which she would never part with. However, a copy of it stole abroad, and was carried into France, where it was translated and printed, with some observations, which were afterwards answered by Sir Isaac. But, in 1728, the Chronicle itself was published at London in quarto; and was attacked by several persons, and as zealously defended by Sir Isaac’s friends. The main design of it was to find out, from some tracts of the most ancient Greek astronomy, what was the position of the colures with respect to the fixed stars, in the time of Chiron the centaur. As it is now known that these stars have a motion in longitude of one degree in 72 years, if it be once known through what fixed stars the colure passed in Chiron’s time, by taking the distance of these stars from those through which it now passes, we might determine what number of years has elapsed since Chiron’s time. As Chiron was one of the Argonauts, this would fix the time of that famous expedition, and consequently that of the Trojan war; the two great events upon which all ancient chronology depends. Sir Isaac places them 500 years nearer the birth of Christ than other chronologers have done.

This great man had all along enjoyed a settled and equal state of health to the age of 80, when he began to be afflicted with an incontinence of urine. However, for the five following years, he had great intervals of ease, which he procured by the observance of a strict regimen. It was then believed that he certainly had the stone; and when the paroxysms were so violent, that large drops of sweat ran down his face, he never uttered the least complaint, or expressed the smallest degree of impatience; but, as soon as he had a moment’s ease, would smile and talk with his usual cheerfulness. Till then he always read and wrote several hours in a day. He had the perfect use of all his senses and understanding till the day before he died, which was on the 20th of March 1726-7, in the 87th year of his age. He lay in state in the Jerusalem chamber at Westminster, and on the 28th of March his body was conveyed into Westminster abbey; the pall being supported by the lord chancellor, the dukes of Montrose and Roxburgh, and the earls of Pembroke, Gower, and Macclesfield. The bishop of Rochester read the funeral service, being attended by all the clergy of the church. The corpse was interred just at the entrance into the choir, where a noble monument is erected to his memory.

Sir Isaac was of a middling stature, and in the latter part of his life somewhat inclined to be fat. His conversation was pleasing, and at the same time venerable. He never made use of spectacles, and lost but one tooth during his whole life.

His temper is said to have been so equal and mild, that no accident could disturb it. Of this the following remarkable instance is related. Sir Isaac had a favourite little dog, which he called Diamond; and being one day called out of his study into the next room, Diamond was left behind. When Sir Isaac returned, having been absent but a few minutes, he had the mortification to find, that Diamond having drawn down a lighted candle among some papers, the nearly finished labour of many years was in flames, and almost consumed to ashes. This loss, as Sir Isaac was then very far advanced in years, was irretrievable; yet without once striking the dog, he only rebuked him with this exclamation, “Oh! Diamond! Diamond! thou little knowest the mischief thou hast done!”

He was a great lover of peace, and would rather have chosen to remain in obscurity than to have the calm of life rifled by those storms and disputes which genius and learning always draw upon those that are peculiarly eminent for them. In contemplating his genius it presently becomes a doubt, which of these dowards had the greatest share, sagacity, penetration, strength or diligence; and after all, the most that seems most to distinguish it is, that he himself made the justest estimation of it, declaring, that if he had done the world any service, it was due to nothing but industry and patient thought; that he kept the subject under consideration constantly before him, and waited till the first dawning opened gradually, by little and little, into a full and clear light. It is said, that when he had any mathematical problems or solutions in his mind, he would never quit the subject on any account. Dinner has been often three hours ready for him before he could be brought to table; and his man often said, when he has been getting up in a morning, he has sometimes begun to dress, and with one leg in his breeches sat down again on the bed, where he has remained for hours before he got his clothes on. From his love of peace, no doubt, arose that unusual kind of horror which he had for all disputes; a steady unbroken attention, free from those frequent recollements inseparably incident to others, was his peculiar felicity; he knew it, and he knew the value of it. No wonder then that controversy was looked on as his bane. When some objections, hastily made to his discoveries concerning light and colours, induced him to lay aside the design he had of publishing his optic lectures, we find him reflecting on that dispute, into which he was unavoidably drawn thereby, in these terms: “I blamed my own imprudence for putting with so real a blessing as my quest, to run after a shadow.” It is true this shadow (as Mr. Fantazzini observes) did not escape him afterwards, nor did it cast him that quiet which he was so much valued, but proved as much a real happiness to him as his quiet itself; yet this was a happiness of his own making: he took a resolution, from these disputes, not to publish any more about that theory till he had put it above the reach of controversy, by the most exact experiments and the strictest demonstrations; and accordingly it has never been called in question since. In the same temper, af
master of so fruitful and general a theory was a mine of
gold to a geometer; but it was a greater glory to
have been the discoverer of so surprising and ingenious
a system. So that Mr Newton finding, by Merca-
tor's book, that he was in the way to it, and that
others might follow in his track, should naturally have
been forward to open his treasures, and secure the pro-
erty, which consisted in making the discovery; but
he entertained himself with his treasure which he had
found, without regarding the glory. What an idea
does it give us of his unparalleled modesty, when we
see him declaring, that he thought Mercator had en-
tirely discovered his secret, or that others would, be-
fore he was of a proper age for writing? His MS. up-
on infinite series was communicated to none but Mr.
John Collins and the lord Brounker; and even that
had not been complied with, but for Dr Barrow, who
would not suffer him to indulge his modesty so much
as he desired.

It is further observed, concerning this part of his
character, that he never talked either of himself or
others, nor ever behaved in such a manner as to give
the most malicious censurers the least occasion even
to suspect him of vanity. He was candid and affable,
and always put himself upon a level with his company.
He never thought either his merit or his reputation suffi-
cient to excuse him from any of the common offices of
social life; no singularities, either natural or affected,
distinguished him from other men. Though he was
firmly attached to the church of England, he was
averse to the persecution of the non-conformists. He
judged of men by their manners; and the true schis-
matics, in his opinion, were the vicious and the wicked.
Not that he confined his principles to natural religion,
for he was thoroughly persuaded of the truth of reve-
lation; and amidst the great variety of books which he
had constantly before him, that which he studied with
the greatest application was the Bible: and he under-
stood the nature and force of moral certainty as well
as he did that of a strict demonstration.

Sir Isaac did not neglect the opportunities of doing
good, when the revenues of his patrimony, and a pro-
table employment, improved by prudent economy,
paid, it in his power. We have two remarkable instan-
ces of his bounty and generosity; one to Mr McLaun,
professor of mathematics at Edinburgh, to whom he
offered 20l. per annum, and the other to his niece Bar-
ton, on whom he settled an annuity of 100l. When
decency upon any occasion required expense and show,
he was magnificent without grudging it, and with a
very good grace; at all other times, that pious which
seems great to low minds only, was utterly restrained,
and the expense reserved for better uses. He never
married, and perhaps he never had leisure to think of
it. Being immersed in profound studies during the
prime of his age, and afterwards engaged in an employ-
ment of great importance, and even quite taken up with
the company which his merit drew to him, he was not
sensible of any vacancy in life, or of the want of a com-
promise at home. He left 30,000l. at his death; but
made no will, which Mr Fontanella tells us was because
he thought a legacy was no gift. As to his works,
besides what were published in his lifetime, there were
found after his death, among his papers, several discus-
ses upon subjects of antiquity, history, divinity, chemi-
Newtonian Philosophy, the doctrine of the universe, and particularly of the heavenly bodies, their laws, affections, &c. as delivered by Sir Isaac Newton.

The term Newtonian Philosophy is applied very differently; whence divers confused notions relating thereto. Some authors under this philosophy include all the corporeal philosophy, considered as it now stands corrected and reformed by the discoveries and improvements made in several parts thereof by Sir Isaac Newton. In which sense it is that Gravescande calls his elements of physics, "Introductio ad Philosophiam Newtonianam." And in this sense the Newtonian is the same with the new philosophy; and stands contradistinguished from the Cartesian, the Peripatetic, and the ancient Corporeal.

Others, by Newtonian philosophy, mean the method or order which Sir Isaac Newton observes in philosophizing; viz. the reasoning and drawing of conclusions directly from phenomena, exclusive of all previous hypotheses; the beginning from simple principles; deducing the first powers and laws of nature from a few select phenomena, and then applying those laws, &c. to account for other things. And in this sense the Newtonian philosophy is the same with the experimental philosophy, and stands opposed to the ancient corporeal.

Others, by Newtonian philosophy, mean that wherein physical bodies are considered mathematically, and where geometry and mechanics are applied to the solution of the appearances of nature. In which sense the Newtonian is the same with the mechanical and mathematical philosophy.

Others again, by Newtonian philosophy, understand that part of the physical knowledge which Sir Isaac Newton has handled, improved, and demonstrated, in his Principia.

Others, lastly, by Newtonian philosophy, mean the new principles which Sir Isaac Newton has brought into philosophy; the new system founded thereon; and the new solutions of phenomena hence deduced; or that which characterizes and distinguishes his philosophy from all others. — Which is the sense wherein we shall chiefly consider it.

As to the history of this philosophy, we have nothing to add to what has been given in the preceding article. It was first made public in the year 1687, by the author, then a fellow of Trinity College, Cambridge, and in the year 1713, republished with considerable improvements. Several authors have since attempted to make it plainer; by setting aside many of the more sublime mathematical researches, and substituting either more obvious reasonings or experiments in lieu thereof; particularly Whiston in his Prelect. Phys. Mathematic. Gravescande in Element. et Inst. and Dr Pemberton in his View.

The whole of the Newtonian philosophy, as delivered by the author, is contained in his Principia or Mathematical Principles of Natural Philosophy. He founds his system on the following definitions:

1. The quantity of matter is the measure of the same, arising from its density and bulk conjunctly. Thus aird of a double density, in a double space, is quadruple in quantity; in a triple space, sextuple in quantity, &c.

2. The quantity of motion is the measure of the same, arising from the velocity and quantity of matter conjunctly. This is evident, because the motion of the whole is the motion of all its parts; and therefore in a body double in quantity, with equal velocity, the motion is double, &c.

3. The vis inertia, or innate force of matter, is a power of resisting, by which every body, as much as it is in it, endeavours to persevere in its present state, whether it be of rest, or moving uniformly forward in a right line. — This definition is proved to be just, only by the difficulty we find in moving any thing out of its place; and this difficulty is by some reckoned to proceed only from gravity. They contend, that in those cases where we can prevent the force of gravity from acting upon bodies, this power of resistance becomes sensible, and the greatest quantities of matter may be put in motion by the very least force. Thus there have been balances formed so exact, that when loaded with 200 weight in each scale, they would turn by the addition of a single drachm. In this case 400 lb. of matter was put in motion by a single drachm, i.e. by a part of its own quantity; and even this small weight, they say, is only necessary on account of the inaccuracy of the machine: so that we have no reason to suppose, that, if the friction could be entirely removed, it would take more force to move a ton weight than a grain of sand. This object, however, is not taken notice of by Sir Isaac, since he bestows on the resisting power above mentioned the name of vis inertiæ; a phrase which is perhaps not well chosen, and with which inferior writers have endeavoured to make their readers merry at the expense of Newton. A force of inactivity, it has been said, is a forceless force; and analogous to a blank sheet, a cold seat, and a tempestuous calm.

But objections of more importance have been made to the whole of this doctrine than those which merely respect the term vis inertiæ. "An endeavour to retain at rest (we are told) is unnecessary, whilst a something attempts to disturb the rest; it is likewise impossible to be conceived, as it implies a contradiction."

A man, by opposing force to force, may endeavour to move not to be moved; but this opposition is an endeavour to move, not with a design to move, but by counter-force; for acting another force to prevent being moved. An endeavour not to move therefore cannot exist in bodies, because it is absurd; and if we appeal to fact, we shall find every body in an actual and constant endeavour to move." It has been likewise observed, and we think justly, that "if bodies could continue to move by any innate force, they might also begin to move by that force. For the same cause which can move a body with a given velocity at one time, could do it, if present, at any other time; and therefore if the force by which bodies continue in motion were innate and essential to them, they would begin to move of themselves, which is not true." Newton indeed says that this innate force is the cause of motion under certain circumstances only, or when the body is acted upon by a force impressed ad extra. But if this impressed force do not continue as well
as begin the motion, if it cease the instant that
the impression is over, and the body continue to
move by its *vis inertiae,* why is the body ever stopped?
If in the beginning of the motion the body, by
its innate force, overcomes a certain resistance of fric-
tion and air, in any following times, the force being
undiminished, it will overcome the same resistance for
ever. These resistances, therefore, could never change
the state of a moving body, because they cannot
change the quantity of its motive force. But this is
counter to universal experience." For these reasons
we are inclined to think that bodies are wholly pas-
sive; that they endeavour nothing; and that they con-
tinue in motion not by any innate force or *vis in-
stantia,* but by that force, whatever it be, which begins
the motion, and which, whilst it remains with the moving
body, is gradually diminished, and at last overcome by
opposite forces, when the body of course ceases to
move.

An impressed force is an action exerted upon a
body, in order to change its state, either of rest or of
moving uniformly forward in a right line.—This force
consists in the action only; and remains no longer in
the body when the action is over. For a body main-
tains every new state it acquires by its *vis inertiae*
only.

It is here implied, and indeed fully expressed, that
motion is not continued by the same power that pro-
duced it. Now there are two grounds on which the
truth of this doctrine may be supposed to rest.

"First, On a direct proof that the impressed force
does not remain in the body, either by showing the
nature of the force to be transitory and incapable of
more than its first action; or that it acts only on the
surface, and that the body escapes from it; or that the
force is somewhere else, and not remaining in the body.
But none of these direct proofs are offered.

"Secondly, It may rest on an indirect proof, that
there is in the nature of body a sufficient cause for
the continuance of every new state acquired; and
that therefore any adventitious force to continue mo-
tion, though necessary for its production, is super-
fluous and inadmissible. As this is the very ground
on which the supposition stands, it ought to have been
jubilantly certain, that the innate force of the body
is sufficient to perpetuate the motion it has once ac-
cquired, before the other agent, by which the motion
was communicated, had been dismissed from the office.
But the innate force of body has been shown not to
be that which continues its motion; and there-
fore the proof, that the impressed force does not re-
main in the body, fails. Nor indeed is it in this case
desirable to support the proof, because we should then
be left without any reason for the continuance of mo-
tion." When we mention an impressed force, we
mean such a force as is communicated either at the
surface of the body or by being diffused through the
mass.

A centripetal force is that by which bodies are
rained, impelled, or any way tend towards a point, as
a centre.—The quantity of any centripetal force may
be considered as of three kinds, absolute, accelerative,
and motive.

The absolute quantity of a centrifugal force is the
course of the same, proportional to the efficacy of the
cause that propagates it from the centre, through the Newtonian
spaces round it.

7. The accelerative quantity of a centripetal force is
the measure of the same, proportional to the velocity
which it generates in a given time.

8. The motive quantity of a centripetal force is a
measure of the same, proportional to the motion
which it generates in a given time. This is always
known by the quantity of a force equal and contrary
to it, that is just sufficient to hinder the descent of
the body.

**Scholia.**

I. Absolute, true, and mathematical time, of itself, of time,
and from its own nature, flows equably, without re-
gard to any thing external, and by another name, is
called *duration.* Relative, apparent, and common time,
is some sensible and external measure of duration,
whether accurate or not, which is commonly used in-
stead of true time; such as an hour, a day, a month, a
year, &c.

II. Absolute space, in its own nature, without re-
Space.

II. Absolute space, in its own nature, without re-
Space.

III. Place is a part of space which a body takes up;

IV. Absolute motion is the translation of a body
from one absolute place into another, and relative
motion the translation from one relative place into an-
other. Thus, in a ship under sail, the relative place of
a body is that part of the ship which the body pos-
sesses, or that part of its cavity which the body fills,
and which therefore moves together with the ship;
and relative rest is the continuance of the body in the
same part of the ship, or of its cavity. But real

Newtonian absolute rest is the continuance of the body in the same part of that immoveable space in which the ship itself, its cavity, and all that it contains, is moved. Wherefore, if the earth is really at rest, the body which relatively rests in the ship will really and absolutely move with the same velocity which the ship has on the earth. But if the earth also moves, the true and absolute motion of the body will arise, partly from the true motion of the earth in immoveable space; partly from the relative motion of the ship on the earth: and if the body moves also relatively in the ship, its true motion will arise partly from the true motion of the earth in immoveable space, and partly from the relative motions as well of the ship on the earth as of the body in the ship; and from these relative motions will arise the relative motion of the body on the earth. As if that part of the earth where the ship is, was truly moved towards the east, with a velocity of 10010 parts; while the ship itself with a fresh gale is carried towards the west, with a velocity expressed by 10 of these parts; but a sailor walks in the ship towards the east with one part of the said velocity: then the sailor will be moved truly and absolutely in immoveable space towards the east with a velocity of 1001 parts; and relatively on the earth, towards the west, with a velocity of 9 of those parts.

Absolute time, in astronomy, is distinguished from relative, by the equation or correction of the vulgar time. For the natural days are truly unequal, though they are commonly considered as equal, and used for a measure of time: astronomers correct this inequality for their more accurate deducing of the celestial motions. It may be that there is no such thing as an equable motion whereby time may be accurately measured. All motions may be accelerated or retarded; but the true or equable progress of absolute time is liable to no change. The duration or perseverance of the existence of things remains the same, whether the motions be swift or slow, or none at all; and therefore ought to be distinguished from what are only sensible measures thereof, and out of which we collect it by means of the astronomical equation. The necessity of which equation for determining the times of a phenomenon is evinced, as well from the experiments of the pendulum clock as by eclipses of the satellites of Jupiter.

Immutability of time and space. As the order of the parts of time is immutable, so also is the order of the parts of space. Suppose those parts to be moved out of their places, and they will be moved (if we may be allowed the expression) out of themselves. For times and spaces are, as it were, the places of themselves as of all other things. All things are placed in time as to order of succession; and in space as to order of situation. It is from their essence or nature that they are places; and that the primary places of things should be moveable is absurd. These are therefore the absolute places; and translations out of those places are the only absolute motions.

But because the parts of space cannot be seen, or distinguished from one another by the senses, therefore in their stead we use sensible measures of them. For, from the positions and distances of things from any body, considered as immoveable, we define all place; and then with respect to such places, we estimate all motion, considering bodies as transferred from one set of those places into others. And so, instead of absolute places and motions, we use relative ones; and that without any inconvenience in common affairs: but in philosophical disquisitions we ought to abstract from our senses, and consider things themselves distinct from what are only sensible measures of them.

But we may distinguish rest and motion, absolute and relative, one from the other, by their properties, causes, and effects. It is a property of rest, that bodies really at rest do rest in respect of each other. And therefore, as it is possible, that in the remote regions of the fixed stars, or perhaps far beyond them, there may be some body absolutely at rest, though it be impossible to know from the position of bodies to one another in our regions, whether any of these do keep the same position to that remote body; it follows, that absolute rest cannot be determined from the position of bodies in our regions.

It is a property of motion, that the parts which in a given time are relative in respect of each other do partake of the true motion of their wholes. For all parts of revolving bodies endeavour to recede from the axis of motion; and the impetus of bodies moving forwards arises from the joint impetus of all the parts. Therefore if we take their surrounding bodies are moved, those that are relatively at rest within them will partake of their motion. Upon which account the true and absolute motion of a body cannot be determined by the translation of it from those only which seem to rest; for the external bodies ought not only to appear at rest, but to be really at rest. For otherwise all included bodies, beside their translation from near the surrounding ones, partake likewise of their true motions; and though that translation was not made, they would not really be at rest, but only seem to be so. For the surrounding bodies stand in the like relation to the surrounded, as the exterior part of a whole does to the interior, or as the shell does to the kernel; but if the shell moves, the kernel will also move, as being part of the whole, without any removal from near the shell.

A property near akin to the preceding is, that if a place is moved, whatever is placed therein moves along with it; and therefore a body which is moved from a place in motion, partakes also of the motion of its place. Upon which account all motions from places in motion, are no other than parts of entire and absolute motions; and every entire motion is composed of the motion of the body out of its first place, and the motion of this place out of its place; and so on, until we come to some immoveable place, as in the above-mentioned case of the sailor. Wherefore entire and absolute motions can be no otherwise determined than by immoveable places. Now, no other places are immoveable but those that from infinity to infinity do all retain the same given positions one to another; and upon this account must ever remain unmoved, and do thereby constitute what we call immoveable space.

The causes by which true and relative motions are distinguished one from the other, are the forces impressed
pressed upon bodies to generate motion. True motion is neither generated nor altered, but by some force impressed upon the body moved: but relative motion may be generated or altered without any force impressed upon the body. For it is sufficient only to impress some force on other bodies with which the former is compared, that by their giving way, that relation may be changed, in which the relative rest or motion of the other body did consist. Again, True motion suffers always some change from any force impressed upon the moving body; but relative motion does not necessarily undergo any changes by such force. For if the same forces are likewise impressed on those other bodies with which the comparison is made, that the relative position may be preserved; then that condition will be preserved, in which the relative motion consists. And therefore any relative motion may be changed when the true motion remains unsalted, and the relative may be preserved when the true motion suffers some change. Upon which account true motion does by no means consist in such relations.

The effects which distinguish absolute from relative motion are, the forces of receding from the axis of an circular motion. For there are no such forces in a circular motion purely relative; but in a true and absolute circular motion, they are greater or less according to the quantity of the motion. If a vessel hung by a long cord, is often turned about that the cord is strongly twisted, then filled with water, and let go, it will be whirled about the contrary way; and while the cord is untwisting itself, the surface of the water will at first be plain, as before the vessel began to move; but the vessel, by gradually communicating its motion to the water, will make it begin sensibly to revolve, and recede by little and little from the middle, and ascend to the sides of the vessel, forming itself into a concave figure; and the swifter the motion becomes, the higher will the water rise, till at last, performing its revolutions in the same times with the vessel, it becomes relatively at rest in it. This ascent of the water shows its endeavour to recede from the axis of its motion; and the true and absolute circular motion of the water, which is here directly contrary to the relative, discovers itself, and may be measured by this endeavour. At first, when the relative motion in the water was greatest, it produced no endeavour to recede from the axis; the water showed no tendency to the circumference, nor any ascent towards the sides of the vessel, but remained of a plane surface; and therefore its true circular motion had not yet begun. But afterwards, when the relative motion of the water had decreased, the ascent thereof towards the sides of the vessel proved its endeavour to recede from the axis; and this endeavour showed the real circular motion of the water perpetually increasing, till it had acquired its greatest quantity, when the water rested relatively in the vessel. And therefore this endeavour does not depend upon any translation of the water in respect of the ambient bodies; nor can true circular motion be defined by such translations. There is only one real circular motion of any one revolving body, corresponding to only one power of endeavouring to recede from its axis of motion, as its proper and adequate effect; but relative motions in one and the same body are innumerable, according to the various relations it bears to external bodies; and, like other relations, are altogether Newtonian. Wherefore relative quantities are not the quantities themselves whose names they bear, but those sensible measures of them, either accurate or inaccurate, which are commonly used instead of the measured quantities themselves. And then, if the meaning of words be determined by their use, by the names time, spaces, place, and motion, their measures are properly to be understood; and the expression will be unusual and purely mathematical, if the measured quantities themselves are meant.

It is indeed a matter of great difficulty to discover, and effectually to distinguish, the true motions of particular bodies from those that are only apparent: because the parts of that immovable mass in which those motions are performed, do by no means come under the observation of our senses. Yet we have some things to direct us in this intricate affair; and these arise partly from the apparent motions which are the difference of the true motions, partly from the forces which are the causes and effects of the true motions. For instance, if two globes kept at a given distance one from the other by means of a cord that connects them, were revolved about their common centre of gravity: we might, from the tension of the cord, discover the endeavor of the globes to recede from the axis of motion, and from thence we might compute the quantity of their circular motions. And then, if any equal forces should be impressed at once on the alternate faces of the globes to augment or diminish their circular motions, from the increase or decrease of the tension of the cord: we might infer the increment or decrement of their motions; and thence would be found on what faces those forces ought to be impressed, that the motions of the globes might be most augmented; that is, we might discover their hindermost faces, or those which follow in the circular motion. But the faces which follow being known, and consequently the opposite ones that precede, we should likewise know the determination of their motions. And thus we might find both the quantity and determination of this circular motion, even in an immense vacuum, where there was nothing external or sensible with which the globes might be compared. But now, if in that space some remote bodies were placed that kept always a given position one to another, as the fixed stars do in our regions; we could not indeed determine from the relative translation of the globes among those bodies, whether the motion did belong to the globes or to the bodies. But if we observed the cord, and found that its tension was that very tension which the motions of the globes required, we might conclude the motion to be in the globes, and the bodies to be

VOL. XIV. Part II.
Newtonian be at rest; and then, lastly, from the translation of the philosophers, among the bodies, we should find the determination of their motions.

Having thus explained himself, Sir Isaac proposes to show how we are to collect the true motions from their causes, effects, and apparent differences; and vice versa, how from the motion, either true or apparent, we may come to the knowledge of their causes and effects. In order to this, he lays down the following axioms or laws of motion.

1. Every body perseveres in its state of rest, or of uniform motion in a right line, unless it is compelled to change that state by forces impressed upon it.—Sir Isaac's proof of this axiom is as follows: "Projectiles persevere in their motions, so far as they are not retarded by the resistance of the air, or impelled downwards by the force of gravity. A top, whose parts, by their cohesion, are perpetually drawn aside from rectilinear motion, does not cease its rotation otherwise than as it is retarded by the air. The greater bodies of the planets and comets, meeting with less resistance in more free spaces, preserve their motions, both progressive and circular, for a much longer time."—Notwithstanding this demonstration, however, the axiom has been violently disputed. It hath been argued, that bodies continue in their state of motion because they are subjected to the continual impulse of an invisible and subtle fluid, which always pours in from behind, and of which all places are full. It hath been affirmed, that motion is as natural to this fluid as rest is to all other matter. It is said, moreover, that it is impossible we can know in what manner a body would be influenced by moving forces if it was entirely destitute of gravity. According to what we can observe, the momentum of a body, or its tendency to move, depends very much on its gravity. A heavy cannonball will fly to a much greater distance than a light one, though both are actuated by an equal force. It is by no means clear, therefore, that a body totally destitute of gravity would have any proper momentum of its own; and if it had no momentum, it could not continue its motion for the smallest space of time after the moving power was withdrawn. Some have imagined that matter was capable of beginning motion of itself, and consequently that the axiom was false; because we see plainly that matter in some cases hath a tendency to change from a state of motion to a state of rest, and from a state of rest to a state of motion. A paper appeared on this subject in the first volume of the Edinburgh Physical and Literary Essays; but the hypothesis never gained any ground.

2. The alteration of motion is ever proportional to the motive force impressed, and is made in the direction of the right line in which that force is impressed.—Thus, if any force generates a certain quantity of motion, double force will generate a double quantity, whether that force be impressed all at once, or in successive moments. To this law no objection of consequence has ever been made. It is founded on this self-evident truth, that every effect must be proportional to its cause. Mr Young, who seems to be very ambitious of detecting the errors of Newton, finds fault indeed with the expressions in which the law is stated; but he owns, that if thus expressed, The alteration of motion is proportional to the actions or resistances which produce it, and is in the direction in which the actions or resistances are made, it would be unexceptionable.

3. To every action there always is opposed an equal reaction: or, the mutual action of two bodies upon each other is always equal, and directed to contrary parts.—This axiom is Obset also disputed by many. In the above-mentioned paper to the first section in the Physical Essays, the author endeavours to make a distinction between action and resistance; and the same attempt has been made by Mr Young. "When an action generates no motion (says he) it is certain that its effects have been destroyed by a contrary and equal action. When an action generates a contrary motion, it is also evident that mutual actions were exerted, equal and contrary to each other. All cases where one of these conditions is not found, are exceptions to the truth of the law. If a larger presses against a stone, the stone, if it does not yield to the pressure, presses as much upon the finger; but if the stone yields, it re-acts less than the finger acts; and if it should yield with all the momentum that the force of the pressure ought to generate, which it would do if it were not impeded by friction, or a medium, it would not re-act at all. So if the stone drawn by a horse, follows after the horse, it does not re-act so much as the horse acts; but only so much as the velocity of the stone is diminished by friction, and it is the re-action of friction only, not of the stone. The stone does not re-act, because it does not act; it resists, but resistance is not action.

4. In the loss of motion from a striking body, equal to the gain in the body struck, there is a plain solution without requiring any re-action. The motion lost is identically that which is found in the other body; this supposition accounts for the whole phenomenon in the most simple manner. If it be not admitted, but the solution by re-action is insisted upon, it will be incumbent on the party to account for the whole effect of communication of motion: otherwise he will lie under the imputation of rejecting a solution which is simple, obvious, and perfect; for one complex, unnatural, and incomplete. However this may be determined, it will be allowed, that the circumstances mentioned, afford no ground for the inference, that action and re-action are equal, since appearances may be explained in another way." (A.)
an Others grant that Sir Isaac's axiom is very true in the respect to terrestrial substances; but they affirm, that, in these, both action and re-action are the effects of gravity. Substances void of gravity would have no momentum; and without this they could not act; they should be moved by the least force, and therefore could not resist or re-act. If therefore there is any fluid which is the cause of gravity, though such fluid could act upon terrestrial substances, yet these could not re-act upon it; because they have no force of their own, but depend entirely upon it for their momentum. In this manner, say they, we may conceive that the planets circulate, and all the operations of nature are carried on by means of a subtle fluid; which being perfectly active, and the rest of matter altogether passive, there is neither resistance nor loss of motion. See Motion.

From the preceding axiom Sir Isaac draws the following corollaries.

1. A body by two forces conjoined will describe the diagonal of a parallelogram in the same time that it would describe the sides by those forces apart.

2. Hence we may explain the composition of any one direct force out of any two oblique ones, viz. by making the two oblique forces the sides of a parallelogram, and the direct one the diagonal.

3. The quantity of motion, which is collected by the sum of the motions directed towards the same parts, and the difference of those that are directed to contrary parts, suffers no change from the action of bodies among themselves; because the motion which one body loses is communicated to another; and if we suppose friction and the resistance of the air to be absent, the motion of a number of bodies which mutually impelled one another would be perpetual, and its quantity always equal.

4. The common centre of gravity of two or more Newtonian bodies do not alter its state of motion or rest by the actions of the bodies among themselves; and therefore the common centre of gravity of all bodies acting upon each other (excluding outward actions and impediments) is either at rest, or moves uniformly in a right line.

5. The motions of bodies included in a given space are the same among themselves, whether that space is at rest, or moves uniformly forward in a right line without any circular motion. The truth of this is evidently shown by the experiment of a ship; where all motions happen after the same manner, whether the ship is at rest, or proceeds uniformly forward in a straight line.

6. If bodies, anyhow moved among themselves, are urged in the direction of parallel lines by equal accelerative forces, they will all continue to move among themselves, after the same manner as if they had been urged by no such forces.

The whole of the mathematical part of the Newtonian philosophy depends on the following lemmas; of which the first is the principal.

LEM. I. Quantities, and the ratios of quantities, which in any finite time converge continually to equality, and before that time approach nearer the one to the other than by any given difference, become ultimately equal. If you deny it; suppose them to be ultimately unequal, and let $D$ be their ultimate difference. Therefore they cannot approach nearer to equality than by that given difference $D$; which is against the supposition.

Concerning the meaning of this lemma philosophers Objections are not agreed; and unhappily it is the very fundamenta of the first position on which the whole of the system rests.

Many objections have been raised to it by people who supposed

equal and contrary loss and gain, remain in equilibrio. Let the original motion of $A$ have been twelve, then $A$ having received a contrary action equal to six, six degrees of its motion will be destroyed or in equilibrio; consequently, a motive force as six will remain to $A$ towards the south, and $B$ will be in equilibrio, or at rest. $A$ will then endeavour to move with six degrees, or half its original motion, and $B$ will remain at rest as before. $A$ and $B$ being equal masses, by the laws of communication three degrees of motion will be communicated to $B$, or $A$ with its six degrees will act with three, and $B$ will re-act also with three. $B$ then will act on $A$ from south to north equal to three, while it is acted upon or resisted by $A$ from north to south, equal also to three, and $B$ will remain at rest as before; $A$ will also have its six degrees of motion reduced to one half by the contrary action of $B$, and only three degrees of motion will remain to $A$, with which it will yet endeavour to move; and finding $B$ still at rest, the same process will be repeated till the whole motion of $A$ is reduced to an infinitely small quantity, $B$ all the while remaining at rest, and there will be no communication of motion from $A$ to $B$, which is contrary to experience.

Let a body, $A$, whose mass is twelve, at rest, be impinged upon first by $B$, having a mass as twelve, and a velocity as four, making a momentum of 48; and secondly by $C$, whose mass is six, and velocity eight, making a momentum of 48 equal to $B$, the three bodies being inelastic. In the first case, $A$ will become possessed of a momentum of 24, and 24 will remain to $B$; and, in the second case, $A$ will become possessed of a momentum of 32, and 16 will remain to $C$, both bodies moving with equal velocities after the shock, in both cases, by the laws of percussion. It is required to know, if in both cases $A$ resists equally, and if $B$ and $C$ act equally? if the actions and resistances are equal, how does $A$ in one case destroy 24 parts of $B$'s motion, and in the other case 32 parts of $C$'s motion, by an equal resistance? And how does $B$ communicate in one case 24 degrees of motion, and $C$ 32, by equal actions? If the actions and resistances are unequal, it is asked how the same mass can resist differently to bodies impinging upon it with equal moments, and how bodies possessed of equal moments can exert different actions, it being admitted that bodies resist proportional to their masses, and that their power of overcoming resistance is proportional to their moments?

It is incumbent on those who maintain the doctrine of universal re-action, to free it from these difficulties and apparent contradictions.
NEW

supposed themselves capable of understanding it. They say, that it is impossible we can come to an end of any infinite series, and therefore that the word ultimate can in this case have no meaning. In some cases the lemma is evidently false. Thus, suppose there are two quantities of matter A and B, the one containing half a pound, and the other a third part of one. Let both be continually divided by 2; and though their ratio, or the proportion of the one to the other, does not vary, yet the difference between them perpetually becomes less, as well as the quantities themselves, until both the difference and quantities themselves become less than any assignable quantity; yet the difference will never totally vanish, nor the quantities become equal, as is evident from the two following series:

\[
\begin{align*}
7 & \quad 7 & \quad 7 & \quad 7 & \quad 7 & \quad 7 \\
6 & \quad 6 & \quad 6 & \quad 6 & \quad 6 & \quad 6 \\
5 & \quad 5 & \quad 5 & \quad 5 & \quad 5 & \quad 5 \\
4 & \quad 4 & \quad 4 & \quad 4 & \quad 4 & \quad 4 \\
3 & \quad 3 & \quad 3 & \quad 3 & \quad 3 & \quad 3 \\
2 & \quad 2 & \quad 2 & \quad 2 & \quad 2 & \quad 2 \\
1 & \quad 1 & \quad 1 & \quad 1 & \quad 1 & \quad 1
\end{align*}
\]

Diff. \[
\begin{align*}
7 & \quad 7 & \quad 7 & \quad 7 & \quad 7 & \quad 7 \\
6 & \quad 6 & \quad 6 & \quad 6 & \quad 6 & \quad 6 \\
5 & \quad 5 & \quad 5 & \quad 5 & \quad 5 & \quad 5 \\
4 & \quad 4 & \quad 4 & \quad 4 & \quad 4 & \quad 4 \\
3 & \quad 3 & \quad 3 & \quad 3 & \quad 3 & \quad 3 \\
2 & \quad 2 & \quad 2 & \quad 2 & \quad 2 & \quad 2 \\
1 & \quad 1 & \quad 1 & \quad 1 & \quad 1 & \quad 1
\end{align*}
\]

Thus we see, that though the difference is continually diminishing, and that in a very large proportion, there is no hope of its vanishing, or the quantities becoming equal. In like manner, let us take the proportions or ratios of quantities, and we shall be equally unsuccessful. Suppose two quantities of matter, one containing 8 and the other 10 pounds; these quantities already have to each other the ratio of 8 to 10, or of 4 to 5; but let us add 2 continually to each of them, and though the ratios continually come nearer to that of equality, it is in vain to hope for a perfect coincidence. Thus,

\[
\begin{align*}
8 & \quad 10 & \quad 12 & \quad 14 & \quad 16 & \quad 18 & \quad 20 & \quad 22 & \quad 24 & \quad \text{&c.} \\
10 & \quad 12 & \quad 14 & \quad 16 & \quad 18 & \quad 20 & \quad 22 & \quad 24 & \quad 26 & \quad \text{&c.}
\end{align*}
\]

Ratio \[
\begin{align*}
\frac{8}{10} & \quad \frac{9}{11} & \quad \frac{10}{12} & \quad \frac{11}{13} & \quad \frac{12}{14} & \quad \frac{13}{15} & \quad \frac{14}{16} & \quad \frac{15}{17} & \quad \frac{16}{18} & \quad \text{&c.}
\end{align*}
\]

For this and his other lemmas Sir Isaac makes the following apology: "These lemmas are presumed, to avoid the tediousness of deducing perplexed demonstrations ad absurdum, according to the method of ancient geometers. For demonstrations are more contracted by the method of indivisibles: but because the hypothesis of indivisibles seems somewhat harsh, and therefore that method is reckoned less geometrical, I chose rather to reduce the demonstrations of the following propositions to the first and last sums and ratios of nascent and evanescent quantities, that is, to the limits of those sums and ratios; and so to premise, as short as I could, the demonstrations of those limits. For hereby the same thing is performed as by the method of indivisibles; and now those principles being demonstrated, we may use them with more safety. Therefore, if hereafter I should happen to consider quantities as made of particles, or should use little curve lines for right ones; I would not be understood to mean indivisibles, but evanescent divisible quantities; not the sums and ratios of determinate parts, but always the limits of sums and ratios; and that the force of such demonstrations always depends on the method laid down in the foregoing lemmas."

Perhaps it may be objected, that there is no ultimate proportion of evanescent quantities, because the proportion, before the quantities have vanished, is not the ultimate, and, when they are vanished, is none. But by the same argument it may be alleged, that a body arriving at a certain place, and there stopping, has no ultimate velocity; because the velocity before the body comes to the place is not its ultimate velocity; when it is arrived, it has none. But the answer is easy: for by the ultimate velocity is meant that with which the body is moved, neither before it arrives at its place and the motion ceases, nor after; but at the very instant it arrives, that is, that velocity with which the body arrives at its last place, and with which the motion ceases. And in like manner, by the ultimate ratio of evanescent quantities is to be understood the ratio of the quantities, not before they vanish, nor afterwards, but with which they vanish. In like manner, the first ratio of nascent quantities is that with which they begin to be. And the first or last sum is that with which they begin and cease to be (or to be augmented and diminished). There is a limit which the velocity at the end of the motion may attain, but not exceed; and this is the ultimate velocity. And there is the like limit in all quantities and proportions that begin and cease to be. And, since such limits are certain and definite, to determine the same is a problem strictly geometrical. But whatever is geometrical may be allowed to make use of in determining and demonstrating any other thing that is likewise geometrical.

"It may also be objected, that if the ultimate ratio of evanescent quantities are given, their ultimate magnitudes will be also given; and so all quantities will consist of indivisibles, which is contrary to what Euclid has demonstrated concerning incommensurables, in the 10th book of his Elements. But this objection is founded on a false supposition. For those ultimate ratios with which quantities vanish are not truly the ratios of ultimate quantities, but limits towards which the ratios of quantities decreasing continually approach."

LEM. II. If in any figure A a c E terminated by the right line A a, A E, and the curve a c E, there be inscribed any number of parallelograms A b, B c, C d, &c. comprehended under equal bases AB, BC, CD, &c. and the sides B b, C c, D d, &c. parallel to one side A a of the figure; and the parallelograms A k b, b L c, m c, M d, &c. are completed. Then if the breadth of those parallelograms be supposed to be diminished, and their number augmented in infinitum; the ultimate ratios which the inscribed figure A K b L c M d D, the circumscribed figure A a b m c E, and curvilineal figure A a b c d E, will have to one another, are ratios of equality. For the difference of the inscribed and circumscribed is the sum of the parallelograms K k, L l, M m, D d; that is (from the equality of all their bases), the rectangle under one of their bases K k, and the sum of their altitudes A a, that is, the rectangle A A k k. But this rectangle, because its breadth AB is supposed diminished in infinitum, becomes less than any given space. And therefore by Lem. I. the figures inscribed and circumscribed become ultimately equal the one to the other; and much more will the intermediate curvilineal figure be ultimately equal to either.

LEM. III. The same ultimate ratios are also ratios of equality, when the breadths AB, BC, CD, &c. of the parallelograms are unequal, and are all diminished in infinitum. The demonstration of this differs but little from that of the former.
NEW [ 789 ] NEW

In his succeeding lemmas, Sir Isaac goes on to prove, in a manner similar to the above, that the ultimate ratios of the sine, chord, and tangent of arcs infinitely diminished, are ratios of equality, and therefore that in all our reasonings about these we may safely use the one for the other:—that the ultimate form of evanescent triangles made by the arc, chord, and tangent, is that of similitude, and their ultimate ratio is that of equality; and hence, in reasonings about ultimate ratios, we may safely use these triangles for each other, whether made with the sine, the arc, or the tangent. He then shows some properties of the ordinates of curvilinear figures; and proves that the spaces which a body describes by any finite force urging it, whether that force be determinate and immutable, or is continually augmented or continually diminished, are, in the very beginning of the motion, one to the other in the duplicate ratio of the powers. And, lastly, Having added some demonstrations concerning the evanescence of angles of contact, he proceeds to lay down the mathematical part of his system, and which depends on the following theorems:

Theor. 1. The areas which revolving bodies describe by radii drawn to an immovable centre of force, lie in the same immovable planes, and are proportional to the times in which they are described.—For, suppose the time to be divided into equal parts, and in the first part of that time, let the body by its innate force describe the right line AB (fig. 2); in the second part of that time, the same would, by Law 1. if not hindered, proceed directly to C along the line BC = AB; so that by the radii AS, BS, CS, drawn to the centre, the equal areas ASB, BSC, would be described. But, when the body is arrived at B, suppose the centripetal force acts at once with a great impulse, and turning aside the body from the right line BC, compels it afterwards to continue its motion along the right line BC. Draw EC parallel to BS, meeting BC in C; and at the end of the second part of the time, the body, by Cor. 1. of the Laws, will be found in C, in the same plane with the triangle ASB. Join SC; and because SB and SC are parallel, the triangle SBC will be equal to the triangle SBC, and therefore also to the triangle SAB. By the like argument, if the centripetal force acts successively in C, D, E, &c. and makes the body in each single particle of time to describe the right lines CD, DE, EF, &c. they will all lie in the same plane; and the triangle SCD will be equal to the triangle SBC, and SDE to SCD, and SED to SDE. And therefore, in equal times, equal areas are described in one immovable plane; and, by composition, any sum of SADS, SABS, of those areas are, one to the other, as the times in which they are described. Now, let the number of those triangles be augmented, and their size diminished in infinitum; and then, by the preceding lemmas, their ultimate perimeter ADF will be a curve line, and therefore the centripetal force by which the body is perpetually drawn back from the tangent of this curve will act continually; and any described areas SADS, SABS, which are always proportional to the times of description, will, in this case also, be proportional to those times. Q. E. D.

Cor. 1. The velocity of a body attracted towards an immovable centre, in spaces void of resistance, is reciprocally as the perpendicular let fall from that centre on the right line which touches the orbit. For the velocities in these places, A, B, C, D, E, are as the bases AB, BC, DE, EF, of equal triangles; and these bases are reciprocally as the perpendiculars let fall upon them.

Cor. 2. If the chords AB, BC, of two arcs, successively described in equal times by the same body, in spaces void of resistance, are completed into a parallelogram ABCV, and the diagonal BV of this parallelogram, in the position in which it ultimately acquires when those arcs are diminished in infinitum, is produced both ways, it will pass through the centre of force.

Cor. 3. If the chords AB, BC, and DE, EF, of arcs described in equal times, in spaces void of resistance, are completed into the parallelograms ABCV, DEFZ, the forces in B and E are one to the other in the ultimate ratio of the diagonals BV, EZ, when those arcs are diminished in infinitum. For the motions BC and EF of the body (by Cor. 1. of the Laws), are compounded of the motions BE, BV, and EF, EZ; but BV and EZ, which are equal to BC and EF, in the demonstration of this proposition, were generated by the impulses of the centripetal force in B and E, and are therefore proportional to those impulses.

Cor. 4. The forces by which bodies, in spaces void of resistance, are drawn back from rectilinear motions, and turned into curvilinear orbits, are one to another as the versed sines of arcs described in equal times; which versed sines tend to the centre of force, and bisect the chords when these arcs are diminished to infinity. For such versed sines are the halves of the diagonals mentioned in Cor. 3.

Cor. 5. And therefore those forces are to the force of gravity, as the said versed sines to the versed sines perpendicular to the horizon of those parabolic arcs which projectiles describe in the same time.

Cor. 6. And the same things do all hold good (by Cor. 5. of the laws) when the planes in which the bodies are moved, together with the centres of force, which are placed in those planes, are not at rest, but move uniformly forward in right lines.

Theor. II. Every body that moves in any curve line described in a plane, and, by a radius drawn to a point either immovable and moving forward with an uniform rectilinear motion, describes about that point areas proportional to the times, is urged by a centripetal force directed to that point.

Case I. For every body that moves in a curve line is (by Law 1.) turned aside from its rectilinear course by the action of some force that impels it; and that force by which the body is turned off from its rectilinear course, and made to describe in equal times the least equal triangles SAB, SBC, SCD, &c. about the immovable point S, (by Prop. 40. E. 1. and Law 2.) acts in the place B according to the direction of a line parallel to C; that is, in the direction of the line BS; and in the place C according to the direction of a line parallel to dD, that is, in the direction of the line CS, &c.; and therefore acts always in the direction of lines tending to the immovable point S. Q. E. D.

Case II. And (by Cor. 5. of the laws) it is indifferent whether the superficies in which a body describes a curvilinear figure be quiescent, or moves together with the body, the figure described, and its point S, uniformly forward in right lines.

Cor.
Cor. 1. In non-resisting spaces or mediums, if the areas are not proportional to the times, the forces are not directed to the point in which the radii meet; but deviate therefrom in consequentia, or towards the parts to which the motion is directed, if the description of the areas is accelerated; but in antecedentia if retarded.

Cor. 2. And even in resisting mediums, if the description of the areas is accelerated, the directions of the forces deviate from the point in which the radii meet, towards the parts to which the motion tends.

Scholium.

A body may be urged by a centripetal force compounded of several forces. In which case the meaning of the proposition is, that the force which results out of all tends to the point S. But if any force acts perpetually in the direction of lines perpendicular to the described surface, this force will make the body to deviate from the plane of its motion, but will neither augment nor diminish the quantity of the described surface; and is therefore not to be neglected in the composition of forces.

Theor. III. Every body that, by a radius drawn to the centre of another body, howsoever moved, describes areas about that centre proportional to the times, is urged by a force compounded of the centripetal forces tending to that other body, and of all the accelerative force by which that other body is impelled.—The demonstration of this is a natural consequence of the theorem immediately preceding.

Hence, if the one body L, by a radius drawn to the other body T, describes areas proportional to the times, and from the whole force by which the first body L is urged, (whether that force is simple, or, according to Cor. 2 of the laws, compounded of several forces), we subduct that whole accelerative force by which the other body is urged; the whole remaining force by which the first body is urged will tend to the other body T, as its centre.

And vice versa, if the remaining force tends nearly to the other body T, those areas will be nearly proportional to the times.

If the body L, by a radius drawn to the other body T, describes areas, which, compared with the times, are very unequal, and that other body T is either at rest, or moves uniformly forward in a right line, the action of the centripetal force tending to that other body T is either none at all, or it is mixed and combined with very powerful actions of other forces; and the whole force compounded of them all, if they are many, is directed to another (inmoveable or moveable) centre. The same thing obtains when the other body is acted upon by any other motion whatever; provided that centripetal force is taken which remains after subtracting that whole force acting upon that other body T.

Scholium.

Because the equable description of areas indicates that a centre is respected by that force with which the body is most affected, and by which it is drawn back from its rectilinear motion, and retained in its orbit, we may always be allowed to use the equable description of areas as an indication of a centre about which all circular motion is performed in free spaces.

Theor. IV. The centripetal forces of bodies which by equable motions describe different circles, tend to the centres of the same circles; and are one to the other as the squares of the areas described in equal times applied to the radii of circles.—For these forces tend to the centres of the circles, (by Theor. 2, and Cor. 2 Theor. 1.) and are to one another as the versed sines of the least area described in equal times (by Cor. 4, Theor. 1.), that is, as the squares of the same areas applied to the diameters of the circles, by one of the lemmas; and therefore, since those areas are as areas described in any equal times, and the diameters are as the radii, the forces will be as the squares of any area described in the same time, applied to the radii of the circles.

Q. E. D.

Cor. 1. Therefore, since these areas are as the velocities of the bodies, the centripetal forces are as a ratio compounded of the duplicate ratio of the velocities directly, and of the simple ratio of the radii inversely.

Cor. 2. And since the periodic times are in a ratio compounded of the ratio of the radii directly, and the ratio of the velocities inversely; the centripetal forces are in a ratio compounded of the ratio of the radii directly, and the duplicate ratio of the periodic times inversely.

Cor. 3. Whence, if the periodic times are equal, and the velocities therefore as the radii, the centripetal forces will be equal among themselves; and the contrary.

Cor. 4. If the periodic times and the velocities are both in the subduplicate ratio of the radii, the centripetal forces will be equal among themselves; and the contrary.

Cor. 5. If the periodic times are as the radii, and therefore the velocities equal, the centripetal forces will be reciprocally as the radii; and the contrary.

Cor. 6. If the periodic times are in the subduplicate ratio of the radii, and therefore the velocities reciprocally in the subduplicate ratio of the radii, the centripetal forces will be in the duplicate ratio of the radii inversely; and the contrary.

Cor. 7. And universally, if the periodic time is as any power $R^0$ of the radius $R$, and therefore the velocity reciprocally as the power $R^{-1}$ of the radius, the centripetal force will be reciprocally as the power $R^{-3}$ of the radius; and the contrary.

Cor. 8. The same things all hold concerning the times, the velocities, and forces, by which bodies describe the similar parts of any similar figures, that have their centres in a similar position within those figures, as appears by applying the demonstrations of the preceding cases to those. And the application is easy, by only substituting the equable description of areas in the place of equable motion, and using the distances of the bodies from the centres instead of the radii.

Cor. 9. From the same demonstration it likewise follows, that the arc which a body uniformly revolving in a circle by means of a given centripetal force describes in any time, is a mean proportional between the diameter of the circle, and the space which the same body, falling by the same given force, would descend through in the same given time.
NEW

By means of the preceding proposition and its corollaries (says Sir Isaac), we may discover the proportion of a centripetal force to any other known force, such as that of gravity. For if a body by means of its gravity revolves in a circle concentric to the earth, this gravity is the centripetal force of that body. But from the descent of heavy bodies, the time of one entire revolution, as well as the arc described in any given time, is given (by Cor. 9. of this theorem). And by such propositions Mr. Huygens, in his excellent book De Horologio Oscillatorio, has compared the force of gravity with the centrifugal forces of revolving bodies.

The preceding proposition may also be demonstrated in the following manner. In any circle suppose a polygon to be inscribed of any number of sides. And if a body, moved with a given velocity along the sides of the polygon, is reflected from the circle at the several angular points; the force with which, at every reflection it strikes the circle, will be as its velocity: and therefore the sum of the forces, in a given time, will be as that velocity and the number of reflections conjunctly; that is (if the species of the polygon be given), as the length described in that given time, and increased or diminished in the ratio of the same length to the radius of the circle; that is, as the square of that length applied to the radius; and therefore, if the polygon, by having its sides diminished to infinitum, coincides with the circle, as the square of the arc described in a given time applied to the radius. This is the centrifugal force, with which the body impels the circle; and to which the contrary force, wherewith the circle continually repels the body towards the centre, is equal.

On these principles hangs the whole of Sir Isaac Newton’s mathematical philosophy. He now shows how to find the centre to which the forces impelling any body are directed, having the velocity of the body given; and finds the centrifugal force to be always as the versed sine of the nascent arc directly, and as the square of the time inversely; or directly as the square of the velocity, and inversely as the chord of the nascent arc. From these premises he deduces the method of finding the centripetal force directed to any given point when the body revolves in a circle; and this whether the central point is near or at an immense distance; so that all the lines drawn from it may be taken for parallels. The same thing he shows with regard to bodies revolving in spirals, ellipses, hyperbolæ, or parabolæ. Having the figures of the orbits given, he shows also how to find the velocities and moving powers; and, in short, solves all the most difficult problems relating to the celestial bodies with an astonishing degree of mathematical skill. These problems and demonstrations are all contained in the first book of the Principia; but to give an account of them here would far exceed our limits; neither would many of them be intelligible, excepting to first-rate mathematicians.

In the second book, Sir Isaac treats of the properties of fluids, and their powers of resistance; and here he lays down such principles as entirely overthrow the doctrine of Descartes’s vortices, which was the fashionable system in his time. In the third book, he begins particularly to treat of the natural phenomena, and apply them to the mathematical principles formerly demonstrated; and, as a necessary preliminary to this part,
Newtonian in its orbit, tends towards the earth; and is reciprocally as the square of the distance of its place from the centre of the earth. The former part of this proposition is evident from Phenom. 5, and Theor. 2; the latter from Phenom. 6, and Theor. 2 or 3. It is also evident from the very slow motion of the moon's apogee; which, in every single revolution, amounting but to 30' 3' in consequentia, may be neglected: and this more fully appears from the next proposition.

Prop. IV. The moon gravitates towards the earth, and by the force of gravity is continually drawn off from a rectilinear motion, and retained in its orbit. —
The mean distance from the moon to the earth in the syzygies, in semidiameters of the latter, is about 604.
Let us assume the mean distance of 60 semidiameters in the syzygies; and suppose one revolution of the moon in respect of the fixed stars to be completed in 27° 7' 43', as astronomers have determined; and the circumference of the earth to amount to 123,249,600 Paris feet.
Now, if we imagine the moon, deprived of all motion, to be let go, so as to descend towards the earth with the impulse of all that force by which it is retained in its orbit, it will, in the space of one minute of time, describe in its fall 154 Paris feet. For the versed sine of that arc which the moon, in the space of one minute of time, describes by its mean motion at the distance of 60 semidiameters of the earth, is nearly 154 Paris feet; or more accurately, 15 feet one inch and one line 3. Wherefore since that force, in approaching to the earth, increases in the reciprocal duplicate proportion of the distance; and, upon that account, at the surface of the earth, is 60 X 60 times greater than that at the moon; a body in our regions, falling with that force, ought, in the space of one minute of time, to describe 60 X 60 X 154 Paris feet; and in the space of one second of time to describe 154 of those feet; or, more accurately, 15 feet one inch and one line 3. And with this very force we actually find that bodies here on earth do really descend.
— For a pendulum oscillating seconds in the latitude of Paris, will be three Paris feet and 8½ lines in length, as Mr. Huygens has observed. And the space which a heavy body describes by falling one second of time, is half the length of the pendulum in the duplicate ratio of the circumference of the circle to its diameter; and is therefore 15 Paris feet 1 inch 1 line 3. And therefore the force by which the moon is retained in its orbit, becomes at the very surface of the earth, equal to the force of gravity which we observe in heavy bodies there. And therefore (by Rule 1. and 2.) the force by which the moon is retained in its orbit is that very same force which we commonly call gravity. For were gravity another force different from that, then bodies descending to the earth with the joint impulsion of both forces would fall with a double velocity, and, in the space of one second of time, would describe 304 Paris feet; altogether against experience.

The demonstration of this proposition may be more diffusely explained after the following manner: Suppose several moons to revolve about the earth, as in the system of Jupiter or Saturn, the periodic times of those moons would (by the argument of induction) observe the same law which Kepler found to obtain among the planets; and therefore their centripetal forces would be reciprocally as the squares of the distances from the centre of the earth, by Prop. I. Now, if the lowest of these were very small, and were near the earth as almost to touch the tops of the highest mountains, the centripetal force thereof, retaining it in its orbit, would be very nearly equal to the weights of any terrestrial bodies that should be found upon the tops of these mountains; as may be known from the foregoing calculation. Therefore, if the same little moon should be detached by its centrifugal force that carries it through its orbit, it would descend to the earth; and that with the same velocity as heavy bodies do actually descend with upon the tops of those very mountains, because of the equality of forces that oblige them both to descend. And if the force by which that lowest moon would descend were different from that of gravity, and if that moon were to gravitate towards the earth, as we find terrestrial bodies do on the tops of mountains, it would then descend with twice the velocity, as being impelled by both these forces conspiring together. Therefore, since both these forces, that is, the gravity of heavy bodies, and the centripetal forces of the moons, respect the centres of the earth, and are similar and equal between themselves, they will (by Rule 1. and 2.) have the same case. And therefore the force which retains the moon in its orbit, is that very force which we commonly call gravity; because otherwise, this little moon at the top of a mountain must either be without gravity, or fall twice as swiftly as heavy bodies use to do.

Having thus demonstrated that the moon is retained in its orbit by its gravitation towards the earth, it is easy to apply the same demonstration to the motions of the other secondary planets, and of the primary planets round the sun, and thus to show that gravitation prevails throughout the whole creation; after which, Sir Isaac proceeds to show from the same principles that the heavenly bodies gravitate towards each other, and contain different quantities of matter, or have different densities in proportion to their bulks.

Prob. V. All bodies gravitate towards every planet; and the weights of bodies towards the same planet, at equal distances from its centre, are proportional to the quantities of matter they contain.

It has been confirmed by many experiments, that all sorts of heavy bodies (allowance being made for the inequality of retardation by some small resistance of the air), descend to the earth from equal heights in equal times; and that equality of times we may distinguish to a great accuracy by the help of pendulums. Sir Isaac Newton tried the thing in gold, silver, lead, glass, sand, common salt, wood, water, and wheat. He provided two wooden boxes, round and equal, filled the one with wood, and suspended an equal weight of gold in the centre of oscillation of the other. The boxes hanging by equal threads of 11 feet, made a couple of pendulums, perfectly equal in weight and figure, and equally receiving the resistance of the air. And placing the one by the other, he observed them to play together forwards and backwards, for a long time, with equal vibrations. And therefore the quantity of matter in the gold was to the quantity of matter in the wood, as the action of the motive force (or vis motrix) upon all the gold, to the action of the same upon all the wood; that is, as the weight...
weight of the one to the weight of the other. And
oply, the like happened in the other bodies. By these expe-
riments, in bodies of the same weight, he could manifestly have discovered a difference of matter less than
the thousandth part of the whole, had any such been.
But without all doubt, the nature of gravity towards
the planets, is the same as towards the earth. For
should we imagine our terrestrial bodies removed to the
orb of the moon, and there, together with the moon,
deprived of all motion, to be let go, so as to fall toget-
ther towards the earth; it is certain from what we have
demonstrated before, that in equal times, they
would describe equal spaces with the moon, and of
consequence are to the moon in quantity of matter,
as their weights to its weight. Moreover, since the
satellites of Jupiter perform their revolutions in times
which observe the sesquiplicate proportion of their
distances from Jupiter’s centre, their accelerative gravi-
tities towards Jupiter will be reciprocally as the squares
of their distances from Jupiter’s centre; that is, equal
at equal distances. And therefore, these satellites, if
supposed to fall towards Jupiter from equal heights,
would describe equal spaces in equal times, in like man-
er as heavy bodies do on our earth. And by the same
argument if the circumsoar planets were supposed to
be let fall at equal distances from the sun, they would,
in their descent towards the sun, describe equal spaces
in equal times. But forces, which equally accelerate
unequal bodies, must be as those bodies: that is to say,
the weights of the planets towards the sun must be as
their quantities of matter. Further, That the weights
of Jupiter and his satellites towards the sun are pro-
portional to the several quantities of their matter, ap-
ppears from the exceeding regular motions of the satel-
lites. For if some of the bodies were more strongly
attracted to the sun in proportion to their quantity of
matter than others, the motions of the satellites would
be disturbed by that inequality of attraction. If, at
equal distances from the sun, any satellite, in propor-
tion to the quantity of its matter, did gravitate to-
wards the sun, with a force greater than Jupiter in propor-
tion to his, according to any given proportion, sup-
pose d to e; then the distance between the centres of
the sun and of the satellite’s orbit would be always
greater than the distance between the centres of the sun
and of Jupiter nearly in the subduplicate of that pro-
portion. And if the satellite gravitated towards the
sun with a force less in the proportion of e to d, the
distance of the centre of the satellite’s orb from the sun
would be less than the distance of the centre of Jupiter’s
from the sun in the subduplicate of the same proportion.
Therefore, if, at equal distances from the sun, the acce-
lerative gravity of any satellite towards the sun were
greater or less than the accelerating gravity of Jupiter
towards the sun but by the part of the whole gravity;
the distance of the centre of the satellite’s orbit from
the sun would be greater or less than the distance of Ju-
piter from the sun by the part of the whole distance;
that is, by a fifth part of the distance of the utmost sat-
ellite from the centre of Jupiter; an eccentricity of
the orbit which would be very sensible. But the orbits
of the satellites are concentric to Jupiter; therefore the
accelerative gravities of Jupiter, and of all its satellites,
towards the sun, are equal among themselves. And by
the same argument, the weight of Saturn and of his sa-

COR. 1. Hence the weights of bodies do not de-
pend upon their forms and textures. For if the weights
could be altered with the forms, they would be
greater or less, according to the variety of forms in equal
matter; altogether against experience.

COR. 2. Universally, all bodies about the earth gra-
vitate towards the earth; and the weights of all, at
equal distances from the earth’s centre, are as the quan-
tities of matter which they severally contain. This
is the quality of all bodies within the reach of our ex-
periments; and therefore (by Rule 3.) to be affirmed
of all bodies whatsoever. If either or any other body,
were either altogether void of gravity, or were to gra-
ivate less in proportion to its quantity of matter; then,
because (according to Aristotle, Des Cartes, and
others) there is no difference betwixt that and other
bodies, but in mere form of matter, by a successive
change from form to form, it might be changed at last
into a body of the same condition with those which
gravitate most in proportion to their quantity of mat-
ter; and, on the other hand, the heaviest bodies, ac-
quiring the first form of that body, might by degrees
quite lose their gravity. And therefore the weights
would depend upon the forms of bodies, and with those
forms might be changed, contrary to what was proved
in the preceding corollary.

COR. 3. All spaces are not equally full. For if all
spaces were equally full, then the specific gravity of the
fluid which fills the region of the air, on account of the
extrm of density of the matter, would fall nothing
short of the specific gravity of quicksilver or gold,
or any other the most dense body, and therefore, neith-
er gold, nor any other body, could ascend in air.
For bodies do not descend in fluids, unless they are
specifically heavier than the fluids. And if the quan-
tity of matter in a given space can by any rarefaction
be diminished, what should hinder a diminution to in-
finity?

COR. 4. If all the solid particles of all bodies are of
the same density, nor can be rarified without pores,
a void space or vacuum must be granted. [By bodies

of
NEW [ 794 ]

Newtonian of the same density, our author means those whose virex Philosophy, inertiæ are in the proportion of their bulks.

PROB. VI. That there is a power of gravity tending to all bodies, proportional to the several quantities of matter which they contain.

That all the planets mutually gravitate one towards another, as we have proved before: as well as that the force of gravity towards every one of them, considered apart, is reciprocally as the square of the distance of places from the centre of the planet. And hence it follows that the gravity tending towards all the planets is proportional to the matter which they contain.

Moreover, since all the parts of any planet A gravitate towards any other planet B, and the gravity of every part is to the gravity of the whole as the matter of the part to the matter of the whole; and (by Law 3.) to every action corresponds an equal re-action: therefore the planet B will, on the other hand, gravitate towards all the parts of the planet A; and its gravity towards any one part will be to the gravity towards the whole, as the matter of the part to the matter of the whole. Q. E. D.

COR. 1. Therefore the force of gravity towards any whole planet, arises from, and is compounded of, the forces of gravity towards all its parts. Magnetic and electric attractions afford us examples of this. For all attraction towards the whole arises from the attractions towards the several parts. The thing may be easily understood in gravity, if we consider a greater planet as formed of a number of lesser planets, meeting together in one globe. For hence it would appear that the force of the whole must arise from the forces of the component parts. If it be objected, that, according to this law, all bodies with us must mutually gravitate one towards another, whereas no such gravitation anywhere appears; it is answered, that, since the gravitation towards these bodies is to the gravitation towards the whole earth, as these bodies are to the whole earth, the gravitation towards them must be far less than to fall under the observation of our senses. [The experiments with regard to the attraction of mountains, however, have now further elucidated this point.]

COR. 2. The force of gravity towards the several equal particles of any body, is reciprocally as the square of the distance of places from the particles.

PROB. VII. In two spheres mutually gravitating each towards the other, if the matter, in places on all sides round about and equidistant from the centres, is similar; the weight of either sphere towards the other will be reciprocally as the square of the distance between their centres.

For the demonstration of this, see the Principia, Book I. Prop. lxxv. and lxxvi.

COR. 1. Hence we may find and compare together the weights of bodies towards different planets. For the weights of bodies revolving in circles about planets are as the diameters of the circles directly, and the squares of their periodic times reciprocally; and their weights at the surfaces of the planets, or at any other distances from their centres, are (by this prop.) greater or less, in the reciprocal duplicate proportion of the distances. Thus from the periodic times of Venus, revolving about the sun, in 224d. 16h.; of the outward circumjovial satellite revolving about Jupiter, in 16d. 16h.; of the Huygenian satellite about Saturn, Nova, in 23d. 22h.; and of the moon about the earth in Phemon 27d. 7h. 43'; compared with the mean distance of Venus from the sun, and with the greatest heliocentric elongations of the outermost circumjovial satellite from Jupiter's centre, 9° 16' of the Huygenian satellite from the centre of Saturn, 3° 44'; and of the moon from the earth, 10° 33'; by computation our author found, that the weight of equal bodies, at equal distances from the centres of the sun, of Jupiter, of Saturn, and of the earth, towards the sun, Jupiter, Saturn, and the earth, were one to another as 1.570, 1.155, and 1.000 respectively. Then, because as the distances are increased or diminished, the weights are diminished or increased in a duplicate ratio; the weights of equal bodies towards the sun, Jupiter, Saturn, and the earth, at the distances 10000, 997, 791, and 109, from their centres, that is, at their very superficies, will be as 10000, 943, 529, and 435 respectively.

COR. 2. Hence likewise we discover the quantity of matter in the several planets. For their quantities of matter are as the forces of gravity at equal distances from their centres, that is, in the sun, Jupiter, Saturn, and the earth, as 1, 1.000, 1.000, and 1.000 respectively. If the parallax of the sun be taken greater or less than 10° 30', the quantity of matter in the earth must be augmented or diminished in the triplets of that proportion.

COR. 3. Hence also we find the densities of the planets. For (by Prop. lxxvi. Book I.) the weights of equal and similar bodies towards similar spheres, are, at the surfaces of those spheres, as the diameters of the spheres. And therefore the densities of dissimilar spheres are as those weights applied to the diameters of the spheres. But the true diameters of the sun, Jupiter, Saturn, and the earth, were one to another as 10000, 997, 791, and 109; and the weights towards the same, as 10000, 943, 529, and 435 respectively; and therefore their densities are as 120, 941, 67, and 400. The density of the earth, which comes out by this computation, does not depend upon the parallax of the sun, but it is determined by the parallax of the moon, and therefore is here truly defined. The sun therefore is a little denser than Jupiter, and Jupiter than Saturn, and the earth four times denser than the sun; for the sun, by its great heat, is kept in a sort of a rarified state. The moon also is denser than the earth.

COR. 4. The smaller the planets are, they are cæteris paribus, of so much the greater density. For as the powers of gravity on their several surfaces come nearer to equality. They are likewise, cæteris paribus, of the greater density as they are nearer to the sun. So Jupiter is more dense than Saturn, and the earth than Jupiter. For the planets were placed at different distances from the sun, that, according to their degrees of density, they might enjoy a greater or less proportion of the sun's heat. Our water, if it were removed as far as the orb of Saturn, would be converted into ice, and in the orb of Mercury would quickly fly away in vapour. For the light of the sun, to which its heat is proportional, is seven times denser in the orb of Mercury than with us; and by the thermometer Sir Isaac found, that a suffused heat of our summer sun will make water boil. Nor are we to doubt, that
and that the matter of Mercury is adapted to its heat, and
therefore more dense than the matter of our earth; since, in a denser matter, the operations of nature re-
quire a stronger heat.

It is shown in the scholium of Prop. xxii. Book II. of the
Principia, that, at the height of 200 miles above the
earth, the air is more rare than it is at the supercicies
of the earth, in the ratio of 30 to 0,0000000000003998,
or as 75,000000000 to 1 nearly. And hence the
planet Jupiter, revolving in a medium of the same density
with that superior air, would not lose by the re-
sistance of the medium the 100000th part of its motion
in 100000 years. In the spaces near the earth, the
resistance is produced only by the air, exhalations,
and vapours. When these are carefully exhausted by
the air pump from under the receiver, heavy bodies fall
within the receiver with perfect freedom, and with-
out the least sensible resistance; gold itself, and the
lightest down, let fall together, will descend with equal
velocity; and though they fall through a space of four,
six, and eight feet, they will come to the bottom at
the same time; as appears from experiments that have
often been made. And therefore the celestial regions
being perfectly void of air and exhalations, the planets
and comets meeting no sensible resistance in those
spaces, will continue their motions through them for
an immense space of time.

Newton, Thomas, lord bishop of Bristol and
dean of St Paul's London, was born on the first of
January 1704. His father, John Newton, was a
considerable brandy and cyder merchant, who, by his
industry and integrity, having acquired what he thought
a competent fortune, left off trade several years before
he died.

He received the first part of his education in the free
school of Litchfield; a school which, the bishop ob-
serves with some kind of exultation, had at all times
sent forth several persons of note and eminence; from
Bishop Smalridge and Mr Wollaston, to Dr Johnson
and Mr Garrick.

From Litchfield he was removed to Westminster
school, in 1717, under the care of Dr Freind and Dr
Nicolll.

During the time he was at Westminster, there were,
he observes, more young men who made a distinguish-
ed figure afterwards in the world, than perhaps at any
other period, either before or since. He particularly
mentions William Murray, the late earl of Mansfield,
with whom he lived on terms of the highest friendship
to the last.

He continued six years at Westminster school, five
of which he passed in the college. He afterwards went
to Cambridge, and entered at Trinity college. Here he
constantly resided eight months at least in every year,
till he had taken his Bachelor of Arts degree. Being
chosen fellow of his college, he came afterwards to
settle in London. As it had been his inclination from
a child, and as he was also designed for holy orders,
he had sufficient time to prepare himself, and composed
some sermons, that he might have a stock in hand
when he entered on the ministry. His title for orders
was his fellowship; and he was ordained deacon in
December 1729, and priest in February following,
by Bishop Gibson.

At his first setting out in his office, he was curate at
St George's Hanover-square; and continued for sev-
eral years assistant preacher to Dr Trebeck. His first
preference was that of reader and afternoon preacher
at Grovvenor Chapel, in South Audley street.

This introduced him to the family of Lord Tyrconnel,
to whose son he became tutor. He continued in
this situation for many years, very much at his ease,
and on terms of great intimacy and friendship with Lord
and Lady Tyrconnel, "without so much (says he) as
an unkind word or a cool look intervening."

In the spring of 1744, he was, through the interest
of the earl of Bath (who was his great friend and pa-
tron, and whose friendship and patronage were return-
ed by grateful acknowledgments and the warmest en-
comiums), presented to the rectory of St Mary Le Bow;
so that he was 40 years old before he obtained any
living.

At the commencement of 1745, he took his doctor's
degree. In the spring of 1747 he was chosen lecturer of
St George's, Hanover-square, by a must respectable
vestry of noblemen and gentlemen of high distinction.
In August following he married his first wife, the el-
est daughter of Dr Trebeck; an unaffected, modest,
decent young woman, with whom he lived very happy
in mutual love and harmony for near seven years.

In 1749 he published his edition of Milton's Para-
dise Lost, which, (says he, very modestly) it is hoped
had not been ill received by the public, having, in
1775, gone through eight editions. After the Para-
dise Lost, it was judged (says he) proper that Dr
Newton should also publish the Paradise Regained,
and other poems of Milton; but these things he thought
detained him from other more material studies, though
he had the good fortune to gain by them more than
Milton did by all his works put together. But his
greatest gain (he says) was their first introducing him
to the friendship and intimacy of two such men as Bi-
s bishop Warburton and Dr Jortin, whose works will speak
for them better than any private commendation.

In 1754 he lost his father at the age of 83; and
within a few days his wife, at the age of 38. This
was the severest trial he ever underwent, and almost
overwhelmed him. At that time he was engaged in
writing his Dissertations on the Prophecies; and hap-
py it was for him: for in any affliction he never found
a better or more effectual remedy than plunging deep
into study, and fixing his thoughts as intensely as he
possibly could upon other subjects. The first volume
was published the following winter; but the other did
not appear till three years afterwards; and as a reward
for his past and an incitement to future labours, he
was appointed, in the mean time, to preach Boyle's
lecture. The bishop informs us, that 1250 copies of
the Dissertations were taken at the first impression, and
1200 at every other edition; and "though (says he)
some things have been since published upon the same
subjects, yet, they still hold up their head above water,
and having gone through five editions, are again pre-
pared for another. Abroad, too, their reception hath
not been unfavourable, if accounts from thence may be
depended upon." They were translated into the Ger-
man and Danish languages; and received the warmest
encomiums from persons of learning and rank.

In the spring of 1757, he was made prebendary of
Westminster, in the room of Dr Green, and promoted
5 H 2 to
to the deanship of Salisbury. In October following, he
was made sub-almoner to his majesty. This he owed
to Bishop Gilbert. He married a second wife in Sep-
tember 1761. She was the widow of the Rev. Mr
Hand, and daughter of John Lord Viscount Lisburn.
In the same month he kissed his majesty's hand for his
bishopsric.

In the winter of 1764, Dr Stone, the primate of
Ireland, died. Mr Grenville sent for Bishop Newton,
and in the most obliging manner desired his acceptan-
cesity of the primacy. Having maturely weighed the matter
in his mind, he declined the offer.

In 1768 he was made dean of St Paul's. His ambition
was now fully satisfied; and he firmly resolved ne-
ever to ask for anything more.

From this time to his death, ill health was almost
his constant companion. It was wonderful that such a
poor, weak, and slender thread as the bishop's life,
should be spun out to such an amazing length as it really
was. In the autumn of 1781 (usually the most fa-
vourable part of the year to him) he laboured under re-
peated illnesses: and on Saturday the 9th of February
1782, he began to find his breath more affected by
the frost. His complaints grew worse and worse till
the Thursday following. He got up five o'clock,
and was placed in a chair by the fire; complained to
his wife how much he had suffered in bed, and repe-
ted to himself that portion of the Psalms, "O my God,
I cry unto thee in the day time," &c. &c. About six
o'clock he was left by his apothecary in a quiet sleep.
Between seven and eight he awoke, and appeared ra-
ther more easy, and took a little refreshment. He con-
tinued dozing till near nine, when he ordered his ser-
vant to come and dress him, and help him down stairs.

As soon as he was dressed, he inquired the hour,
and bid his servant come and look at the dial of
St Paul's. The servant answered, it was upon the
stroke of nine. The bishop made an effort to take out
his watch; with an intent to set it; but sunk down in
his chair, and expired without a sigh or the least visi-
ble emotion, his countenance still retaining the same
placid appearance which was so peculiar to him when
alive. Of his numerous works, his Dissertations on
the Prophecies are by much the most valuable.
His learning was undoubtedly very considerable; but he
seldom exhibits evidence of a very vigorous mind.
On one occasion, indeed, he appears to have thought with
freedom; for we believe he was the first dignitary of
the church of England who avowed his belief of the
final restitution of all things to harmony and hapi-
ness.

NEWTYA, a port little known, on the coast be-
tween Goa the capital of the Portuguese settlements
in India, and the English settlement of Bombay. Mr
Rennel conjectures it to be the Natiras of Pliny; near
which the pirates cruised for the Roman ship. The
same writer places it near to 15° 52' 30'' north lati-
tude, and 73° 16' 30'' east longitude.

NEXI, among the Romans, persons free born, who
for debt were reduced to a state of slavery. By the
laws of the twelve tables it was ordained, that insolvent
debtors should be given up to their creditors to be
bound in fettors and cordis, whence they were called
Nexi; and though they did not entirely lose the rights
of freemen, yet they were often treated more hastily
than the slaves themselves. If any one was indebted
to several persons, and could not within 60 days find
a cautioner, his body according to some, but accord-
ing to others his effects, might be cut in pieces, and
divided among his creditors. The latter opinion seems
by much the most probable, as Livy mentions a law by
which creditors had a right to attach the goods but not
the persons of their debtors.

NEYTREICH, a town of Upper Hungary, capi-
tal of a county of the same name, with a bishop's see;
seated on the river Neutr, 40 miles north-east of Pres-
bury. E. Long. 17° 40', N. Lat. 48° 38'.

NGAN-KING-FOU, a city of China, and capi-
tal of the western part of the province of Kiang-nan.
It is governed by a particular viceroy, who keeps a
large garrison in a fort built on the banks of the river
Yang-tse-kiang. Its situation is delightful; its com-
merce and riches render it very considerable; and every
thing that goes from the southern part of China to
Nan-king must pass through it. All the country be-
longing to it is level, pleasant, and fertile. It has un-
der its jurisdiction only six cities of the third class.

NGO-KIA, a Chinese drug, of which the com-
position will no doubt appear as singular as the numer-
ous properties ascribed to it. In the province Chang-tao,
near Ngo-hien, a city of the third class, is a well
formed by nature, which is reckoned to be seventy
feet in depth, and which has a communication, as the
Chinese say, with some subterranean lake, or other
large reservoir. The water drawn from it is excur-
dingly clear, and much heavier than common; and if it
be mixed with muddy water, it purifies it and ren-
ers it limpid, by precipitating all its impurities to the
bottom of the vessel. This water is employed in mak-
ing the ngo-kia, which is nothing else but a kind of
glue procured from the skin of a black ass.

The animal is killed and flayed, and the skin is steep-
ed for five days in water drawn from this well. At
the end of that time, it is taken out to be scraped and
cleaned; it is afterwards cut into small pieces, which
are boiled over a slow fire, in the same kind of water,
until it is reduced to a jelly, which is strained, while
warm, through a cloth, to free it from all the gross
matter which could not be melted. When this glue is
cool, and has acquired a consistence, it is formed
into square cakes, upon which the Chinese imprint char-
acters and coats of arms, or the signs of their shops.
This well is the only one of the kind in China; it
is always shut, and sealed by the governor of the place
with his own seal, until the customary day of seek-
ing the emperor's glue. This operation generally lasts
from the autumnal harvest till the month of March.
During that time, the neighbouring people and mer-
chants treat for the purchase of the glue with those
who guard the well, and with the people who make it.
The latter manufacture as much of it as they can,
on their own account, with this difference, that it is not so pure, and that they are less scrupu-
los in examining whether the ass be fat, or of a very
black colour; however, all the glue made here is as
much esteemed at Peking as that which the mandarins
who are on the spot transmit to court and to their
friends.

As this drug is in the greatest request, and as the
quantity of it made at Ngo-hien is not sufficient to
supply
The whole empire, there are not wanting people who counterfeit it elsewhere, and who manufacture a spurious kind from the skins of mules, horses, and camels, and sometimes even from old boots; it is, however, very easy to distinguish that which is genuine; it has neither a bad smell nor a disagreeable taste when applied to the mouth; it is brittle and friable, and always of a deep black colour, sometimes inclining to red. The qualities of the counterfeit kind are entirely different; both its taste and smell are disagreeable, and it is viscous and flabby even when made of the skin of a hog, which is that which imitates the true kind the best.

The Chinese attribute a great number of virtues to this drug. They assure us that it dissolves phlegm, facilitates the play and elasticity of the lungs, gives a free respiration to those who breathe with difficulty; that it comforts the breast, increases the blood, stops dysenteries, provokes urine, and strengthens children in the womb. Without warranting the truth of all these properties, it appears, at least, certain, by the testimony of the missionaries, that this drug is serviceable in all diseases of the lungs. It is taken with a decoction of simples, and sometimes in powder, but very seldom.

Niagara, a fort of North America, which was taken from the French in 1759. According to the treaty of 1794, it was delivered up by Britain to the United States in 1796. It is situated on a small peninsula formed by the river Niagara as it flows into the lake Ontario. About six leagues from the fort is the greatest cataract in the world, known by the name of the Waterfall of Niagara. The river at this fall runs from SSE to NNW; and the rock of the fall crosses it not in a right line, but forms a kind of figure like a hollow semicircle or horse shoe. Above the fall, in the middle of the river, is an island about 800 or 1000 feet long; the lower end of which is just at the perpendicular edge of the fall. On both sides of this island runs all the water that comes from the lakes of Cana

Lake Superior, Lake Michigan, Lake Huron, and Lake Erie, which have some large rivers that open themselves into them. Before the water comes to this island, it runs but slowly compared with its motion afterwards, when it grows the most rapid in the world, running with a surprising swiftness before it comes to the fall. It is perfectly white, and in many places is thrown high up into the air. The water that runs down on the west side is more rapid, in greater abundance, and whiter, than that on the east side; and seems almost to outfly an arrow in swiftness. When you are at the fall, and look up the river, you may see that the water is everywhere exceedingly steep, almost like the side of a hill; but when you come to look at the fall itself, it is impossible to express the amazement it occasions. The height of it, as measured by mathematical instruments, is found to be exactly 137 feet; and when the water is come to the bottom, it jumps back to a very great height in the air. The noise may be heard at the distance of 45 miles, but seldom further; nor can it be heard even at Fort Niagara, which is only six leagues distant, unless Lake Ontario is calm. At that fort it is observed, that when they hear the noise of the fall more loud than ordinary, they are sure that a north-east wind will follow; which is the more surpr

pris, as the fort lies south-west from the fall. At some times the fall makes a much greater noise than at others; and this is held for an infallible sign of approaching rain or other bad weather.

From the place where the water falls there arises abundance of vapour like very thick smoke, insomuch that when viewed at a distance you would think that the Indians had set the forests on fire. These vapours rise high in the air when it is calm, but are dispersed by the wind when it blows hard. If you go into this vapour or fog, or if the wind blows it on you, it is so penetrating, that in a few moments you will be as wet as if you had been under water. Some are of opinion that when birds come flying into this fog or smoke of the fall, they drop down and perish in the water; either because their wings are become wet, or that the noise of the fall, astonishes them, and they know not where to go in the darkness: but others think that seldom or never any bird perishes in that manner; because among the abundance of birds found dead below the fall, there are no other sorts than such as live and swim frequently in the water; as swans, geese, ducks, water hens, teal, and the like. And very often great flocks of them are seen going to destruction in this manner: they swim in the river above the fall, and so are carried down lower and lower by the water; and as water fowl commonly take great delight in being carried with the stream, they indulge themselves in enjoying this pleasure so long, till the swiftness of the water becomes so great, that it is no longer possible for them to rise, but they are driven down the precipice and perish. They are observed, when they draw nigh the fall, to endeavour with all their might to take wing and leave the water; but they cannot. In the months of September and October such abundant quantities of dead water fowl are found every morning below the fall, on the shore, that the garrison of the fort for a long time live chiefly upon them. Besides the fowl, they find also several sorts of dead fish, also deer, bears and other animals which have tried to cross the water above the fall; the larger animals are generally found broken to pieces. Just below, a little way from the fall, the water is not rapid, but goes all in circles, and whirls like a boiling pot; which however does not hinder the Indians going upon it in small canoes a-fishing; but a little further, and lower, the other smaller falls begin. When you are above the fall, and look down, your head begins to turn; even such as have been here numberless times, will seldom venture to look down, without at the same time keeping fast hold of some tree with one hand.

It was formerly thought impossible for anybody living to come at the island that is in the middle of the fall; but an accident that happened about 50 years ago made it appear otherwise. The history is this: Two Indians of the Six Nations went out from Niagara fort to hunt upon an island that is in the middle of the river, or strait, above the great fall, on which there used to be abundance of deer. They took some French brandy with them from the fort, which they tasted several times as they were going over the carrying place; and when they were in their canoe, they took now and then a dram, and so went along up the strait towards the island where they proposed
The water runs on the east side of this island is shallow, especially a little above the island towards the eastern shore. The commandant caused poles to be made and painted with iron; two Indians took upon them to walk to this island by the help of these poles, to save the other poor creatures, or perish themselves. They took leave of all their friends, as if they were going to death. Each had two such poles in his hands, to set to the bottom of the stream, to keep them steady; and in this manner reached the island: and having given poles to the two poor Indians there, they all returned safely to the main land. These two Indians (who in the above-mentioned manner were first brought to this island) were nine days on the island, and almost ready to starve to death. Now since the road to this island has been found, the Indians go there often to kill deer, which have tried to cross the river above the fall, and are driven upon it by the stream. On
Each of these posts of sachem has a name which is peculiar to it, and which never changes, as it is always adopted by the successor: nor does the order of precedence of each of these names or titles ever vary. Nevertheless, any sachem, by abilities and activity, may acquire greater power and influence in the nation than those who rank before him in point of precedence; but this is merely temporary, and dies with him.

Each tribe has one or two chief warriors; which dignity is also hereditary, and has a peculiar name attached to it.

These are the only titles of distinction which are fixed and permanent in the nation; for although any Indian may by superior talents, either as a counsellor or as a warrior, acquire influence in the nation, yet it is not in his power to transmit this to his family.

The Indians have also their great women as well as their great men, to whose opinions they pay great deference; and this distinction is also hereditary in families. They do not sit in council with the sachems, but have separate ones of their own. When war is declared, the sachems and great women generally give up the management of public affairs into the hands of the warriors. It may however so happen, that a sachem may at the same time be a chief warrior.

Friendship seems to have been instituted with a view towards strengthening the union between the several nations of the confederacy; and hence friends are called the sinuæ of the Six Nations. An Indian has therefore generally one or more friends in each nation. Besides the attachment which subsists during the lifetime of the two friends, whenever one of them happens to be killed, it is incumbent on the survivor to replace him, by presenting to his family either a scalp, a prisoner, or a belt consisting of some thousands of wampum; and this ceremony is performed by every friend of the deceased.

The purpose and foundation of war parties, therefore, is in general to procure a prisoner or scalp to replace the friend or relation of the Indian who is the head of the party. An Indian who wishes to replace a friend or relation presents a belt to his acquaintance; and as many as choose to follow him accept this belt, and become his party. After this, it is of no consequence whether he goes on the expedition or remains at home (as it often happens that he is a child;) he is still considered as the head of the party. The belt he presented to his party is returned fixed to the scalp or prisoner, and passes along with them to the friends of the person he replaces. Hence it happens, that a war party, returning with more scalps or prisoners than the original intention of the party required, will often give one of these supernumerary scalps or prisoners to another war party whom they meet going out, upon which this party, having fulfilled the purpose of their expedition, will sometimes return without going to war.

Niagara, in Ancient Geography, the metropolis of Bithynia; situated on the lake Ascanius, in a large and fertile plain; in compass 16 stadia: first built by Antigonus, the son of Philip, and thence called Antigonea; afterwards completed by Lysimachus, who called it Nicæa, after his consort the daughter of Antipater. According to Stephanus, it was originally a colony of the Bottiscì, a people of Thrace, and called Ancore; and afterwards called Nicæa. Now Nice in Asia the Lesser. Famous for the first general council.—A second Nicæa, (Diodorus Siculus), of Corsica.—A third, of the Hither India, (Arrian); situated on the west side of the Hydaspes, opposite to Bucephale, on the east side.—A fourth Nicæa, a town of Liguria, at the Maritime Alps, on the east side of the river Paulus, near its mouth, which runs between the Varus and Nicæa, (Mela). A colony of the Massilians, (Stephanus); the last town of Italy to the west. Now Nissa or Niee, capital of the county of that name, on the Mediterranean.—A fifth, of Locris, (Strabo); a town near Thermopylae; one of the keys of that pass. It stood on the Sinus Malaccus.
