In the Philosophical Transactions, N° 114. there is a very remarkable account of a tree standing in a grove near Florence, having an *orange* stock, which had been so grafted upon, that it became in its branches, leaves, flowers and fruit, three-formed: some emulating the orange, some the lemon or citron, and some partaking of both forms in one; and what was very remarkable was, that these mixed fruits never produced any perfect seeds: sometimes there were no seeds at all in them, and sometimes only a few empty ones.

Orange-Dew, a kind of dew which falls in the spring time from the leaves of orange and lemon trees, which is extremely fine and subtile. M. de la Hire observing this, placed some flat pieces of glass under the leaves to receive it: and having procured some large drops of it, was desirous of discovering what it was. He soon found that it was not merely an aqueous fluid, because it did not evaporate in the air; and that it was not a resin, because it readily and perfectly mixed with water: it was natural then to suppose it a liquid gum; but neither did this, on examination, prove to be the case; for being laid on paper, it did not dry as the other liquid gums do. Its answering to none of these characters, and its being of the consistence of honey, and of a sweet sugar-like taste, gave a suspicion of its being a kind of manna; and whatever in the other trials had proved it not a resin, a gum, &c. all equally tends to prove that it is this substance.

Orange, Sea, in *Natural History*, a name given by Count Marsigli to a very remarkable species of marine substance, which he denominates a *plant*. It is tough and firm in its structure, and in many things resembles the common fucus; but instead of growing in the branched form which the generality of those substances have, it is round and hollow, and in every respect resembles the shape of an orange. It has, by way of root, some exceeding fine filaments, which fasten themselves to the rocks, or to shells, stones, or any thing else that comes in the way. From these there grows no pedicle; but the body of the orange, as it is called, is fastened by them to the rock, or other solid substance. The orange itself is usually of about three or four inches in diameter; and while in the sea, is full of water, and even retains it when taken up. In this state it frequently weighs a pound and a half; but when the water is let out, and it is dried, it becomes a mere membrane, weighing scarce any thing. It is best preserved, by stuffing it with cotton as soon as the water is let out of it, and then hanging it up to dry. Its surface is irregular and rough, and its colour a dusky green on the outside, and a clearer but somewhat bluish green within; and its thickness is about an eighth part of an inch. When viewed by the microscope, it is seen to be all over covered with small glandules, or rather composed of them; for they stand so thick one by another as to leave no space between, and seem to make up the whole substance; so that it appears very like the rough shagreen skin used to cover toys. These are indeed so many hollow ducts, through which the sea-water finds a passage into the globe formed by this skin, and by this means it is kept always full and distended; on cutting it with a pair of scissars, the water immediately runs out, and the skins collapse; but there is something extremely remarkable in this, for the whole substance, near the wounded place, is in motion, and seems as if alive, and sensible of the wound. The glandules are found full of water, and resembling small transparent bottles; and what goes to the structure of the plant beside these, is an assemblage of a vast number of filaments, all which are likewise hollow, and filled with a clear and transparent fluid.

There is another substance of this kind, mentioned and described by Count Marsigli, Triumfetti, and others, and called the *ramose* or branched orange. This is very much of the nature of the former; but instead of consisting of one round globule, it is formed of several oblong ones all joined together, and representing the branches of some of the fucuses, only they are shorter; and these are all hollow and full of water, in the same manner as the single globes of the common kind. This has, by way of root, certain fine and slender filaments, which fasten it to the stones or shells near which it is produced; and it is of a dusky greenish colour on the surface, and of a fine bluish green within. The surface view'd by the microscope, appears rough, as in the other, and the glandules are of the same kind, and are always found full of clear water.

ORATION, in *Rhetoric*, a speech or harangue, composed according to the rules of oratory, but spoken in public. Orations may be reduced to three kinds, viz. the demonstrative, deliberative, and judicial. To the demonstrative kind belong panegyrics, genethliaca, epithalamia, congratulations, &c. To the deliberative kind belong persuasion, exhortation, &c. And to the judicial kind belong accusation, confutation, &c.

Funeral

Oration, Orator.

Funeral Oration. See *Funeral Oration*.

ORATOR, among the Romans, differed from a *patronus*: The latter was allowed only to plead causes on behalf of his clients; whereas the former might quit the forum and ascend the rostra or tribunal, to harangue the senate or the people. The orators had rarely a profound knowledge of the law, but they were eloquent, and their style was generally correct and concise. They were employed in causes of importance, instead of the common patrons. Orators in the violence of elocution used all the warmth of gesture, and even walked backwards and forwards with great heat and emotion. This it was which occasioned a witticism of Flavius Virginius, who asked one of those walking orators, *Quot millia passuum declamâsset?* "How many MILES he had declaimed?" Similar to the Roman orators were the Grecian *Rhetores*. See RHETORES.

Public Orator, an office of very considerable dignity, and of some emolument, in the English universities.

The public orator is the principal, and in many cases the only ostensible, agent for the university, in all those matters or forms which are merely external. He carries on or superintends all correspondences which are calculated to promote the dignity, or raise the utility, of the seminary which constitutes him. He has little to do, indeed, with the internal government of the body, for which a variety of officers in different departments are appointed; but in all public affairs he is, as it were, the mouth of the whole; putting their deliberations into proper form, and communicating or publishing them, according to the intention of the university. Thus, if the whole university, or a committee appointed by them, or by statute, or by the will of any particular benefactor, have, after a comparative trial, adjudged a prize to any person or persons, it is the business of the public orator to inform the successful parties of the issue of the trial. Again, If for singular learning, or for any remarkable *good will* shown to the university by any person or persons, the *senate* or *convocation* are pleased to declare their grateful sense of it either by conferring degrees, or otherwise, as they think fit, the public orator is to notify this intention to the person or persons concerned; and so in other cases.

Another part of the public orator's business is to present young noblemen, or those who take *honorary* degrees, *tanquam nobiles*, to the vice-chancellor; this he does in a Latin speech, which, according to circumstances, is either short or long; and of which the subject is generally a defence of that particular statute which allows the sons of noblemen, and some few others, to proceed to degrees before what is called the *statutable time*. In doing this, encomiums, often stronger than just, are made upon the learning and virtue of the noble candidate; a view is taken of the dignity of his ancient house; the honour is mentioned which has accrued to the university from the accession of such a member; and the oration concludes with promising great credit from his future conduct, as well as benefit from the influence of his rank in the state. These circumstances are deemed sufficient grounds for exempting the sons of noblemen from that tedious course of study, through which the duller sons of commoners must all pass before they be thought worthy of academical honours.

Orator, Oratorio.

ORATORIO, in the Italian music, a sort of sacred drama of dialogues; containing recitativos, duettos, trios, ritornellos, choruses, &c. The subjects of those pieces are usually taken from Scripture, or the life of some saint, &c. The music for the oratorios should be in the finest taste and best chosen strains. These oratorios are greatly used at Rome in the time of Lent, and of late in England.

Menestrier attributes the origin of oratorios to the crusades, and says that the pilgrims returning from Jerusalem and the Holy Land, &c. composed songs reciting the life and death of the Son of God, and the mysteries of the Christian faith, and celebrating the achievements and constancy of saints and martyrs. Others, with more probability, observe, that the oratorio was an avowed imitation of the opera, with only this difference, that the foundation of it was always some religious or at least some moral subject. Crescimbeni ascribes its origin to San Filippo Neri, who was born at Florence in 1515, and who, in his chapel after sermons, and other devotions, in order to allure young people to pious offices, had hymns, psalms, and such like prayers, sung by one or more voices. Among the spiritual songs were dialogues; and these entertainments becoming more frequent, and improving every year, were the occasion that in the seventeenth century oratorios were first invented, so called from the place of their origin. See *Hawkins's History of Music*.

ORATORY;

THE ART OF SPEAKING WELL UPON ANY SUBJECT, IN ORDER TO PERSUADE.

INTRODUCTION.

§ 1. *Of the Rise and Progress of Oratory.*

1 The origin of the art of oratory.

THE invention of oratory is, by the Egyptians, and the fables of the poets, ascribed to Mercury. And it is well known, that the Greeks made their deities the authors likewise of other arts, and supposed that they presided over them. Hence they gave Mercury the titles of Λογιος and Ερμης, both which names come from words that signify "to speak." And Aristides calls eloquence *the gift of Mercury*; and for the same reason anciently the tongue who consecrated to him. He was likewise said to be the interpreter or messenger of the gods; which office very well suited him, as he excelled in eloquence. Hence we read in the Sacred Writings, that when the people of Lystra took Barnabas and Paul for gods in human shape, because of that sudden and surprising cure which was wrought upon the lame man, they called Barnabas *Jupiter*, and Paul *Mercury*; for this reason, as the inspired writer tells us, 'because he was the chief speaker,' that is (as the spectators then thought), the interpreter or spokesman of Barnabas.

But to pass over these fictions of the heathen deities, let us hear what Quintilian says of the *origin* of this art; who seems to give a very probable account of it in the following passage. "The faculty of speech (says he) we derive from nature (A); but the art from observation. For as in physic, men, by seeing that some things promote health, and others destroy it, formed the art upon those observations; in like manner, by perceiving that some things in discourse are said to advantage, and others not, they accordingly marked those things, in order to imitate the one and avoid the other. They also added some things from their own reason and judgement, which, being confirmed by use, they began to teach others what they knew themselves." But no certain account can be given when, or by whom, this method of observation first began to take place. And Aristotle supposes, not without reason, that the first lineaments of the art were very rude and imperfect. Pausanias, indeed, in his *Description of Greece*, tells us, that Pittheus, the uncle of Theseus, taught it at Trœzene, a city of Peloponnesus, and wrote a book concerning it, which he read himself, as it was published by one of Epidaurus. But as Pittheus lived above 1000 years before Pausanias, who flourished in the time of the emperor Hadrian, some are of opinion he might be imposed upon by the Epidaurian, who published this book under the name of *Pittheus*. But be that as it will, it is very reasonable to believe, that the Greeks had the principles of this art so early as the time of Pittheus. For Theseus his nephew lived not long before the taking of Troy, which, according to Sir Isaac Newton, happened 904 years before the birth of Chirst; at which time Cicero thought it was in much esteem among them. "Homer (says he) would never have given Ulysses and Nestor in the Trojan war so great commendations on account of their speeches (to one of whom he attributes force, and to the other sweetness of expression), if eloquence had not in those times been in great repute." And lest any one should imagine, that in those days they made use only of such helps as nature and practice could afford them, the same poet informs us, that Peleus sent Phœnix with his son Achilles to the Trojan war, to instruct him not only in the art of war, but likewise of eloquence. But who were the professors of this art for some ages following is not known. For Quintilian says, that afterwards Empedocles is the first upon record who attempted any thing concerning it. And he, by Sir Isaac Newton's account, flourished about 500 years after Troy was taken. At which time, as Cicero observes, men being now sensible of the powerful charms of oratory, and the influence it had upon the mind, there immediately arose several masters of it; the chief of whom are mentioned by Quintilian, who tells us, that 'the oldest writers upon this art are Corax and Tisias, both of Sicily. After them came Gorgias of Leontium in the same island, who is said to have been the scholar of Empedocles, and by reason of his great age (for he lived to be 109 years old) had many cotemporaries. Thrasymachus of Chalcedon, Prodicus of Cea, Protagoras of Abdera, Hippias of Elis, and Alcidamus of Elea, lived in his time; as likewise Antiphon, who first wrote orations, and also upon the art, and is said to have spoken admirably well in his own defence; and besides these, Polycrates, and Theodore of Byzantium.' These persons contributed different ways towards the improvement of the art. Corax and Tisias gave rules for methodizing a discourse, and adjusting its particular parts; as may be conjectured from Cicero's account of them, who says, "Though some had spoke well before their time, yet none with order and method." But Gorgias seems to have excelled all the rest in fame and reputation: for he was so highly applauded by all Greece, that a golden statue was erected to him at Delphos, which was a distinguishing honour conferred upon him only. And he is said to have been so great a master of oratory, that in a public assembly he could undertake to declaim immediately upon any subject proposed to him. He wrote, as Cicero informs us, in the demonstrative or laudatory way; which requires most of the sublime, and makes what Diodorus Siculus says of him the more probable, that "he first introduced the strongest figures, members of periods opposite in sense, of an equal length, or ending with a like sound, and other ornaments of that nature." And hence those figures, which give the greatest force and lustre to a discourse, were anciently called by his name. Cicero tells us further, that Thrasymachus and Gorgias were the first who introduced numbers into prose, which Isocrates afterwards brought to perfection. Quintilian likewise mentions Protagoras, Gorgias, Prodicus, and Thrasymachus, as the first who treated of common places, and showed the use of them for the invention of arguments. Nor must we omit Plato, whose elegant dialogue upon this subject is still extant, which he entitles *Gorgias*. For though he does not lay down the common rules of the art; yet he very well explains the nature of it, and maintains its true end and use against the generality of its professors, who had greatly perverted the original design of it. Thus by the study and industry of so many ingenious and great men, the art of oratory was then carried to a considerable height among the Grecians: though many of those who professed it in those times employed their skill rather to promote their own reputation and applause, than to serve the real interests of truth and virtue. "For they proposed in an arrogant manner (as Cicero says) to teach how a bad cause might be so managed, as to get the better of a good one." That is, they would undertake to charm the ears and strike the passions of their hearers in so powerful a manner, by sophistical reasonings, turns of wit, and fine language, as to impose falsehood upon them for truth: than which nothing could be either more disingenuous in itself, or prejudicial to society.

2 Orators of Greece.

But those who succeeded them seem to have consulted

(A) If Quintilian meant that the human race speak an articulate language by nature or instinct, he certainly deceived himself (see LANGUAGE); but if his meaning was only that men have from nature a capability of speech, the observation is true, but not of much value. Parrots and other birds have a capability of uttering articulate sounds.

ed better, both for their own honour and that of their profession. Isocrates was the most renowned of all Gorgias's scholars, whom Cicero frequently extols with the highest commendations, as the greatest master and teacher of oratory; "whose school (as he says) like the Trojan horse, sent forth abundance of great men." Aristotle was chiefly induced to engage in this province from an emulation of his glory; and would often say in a verse of Sophocles, somewhat varied to his purpose,

> To be silent it is a shame;
> While Isocrates gets such fame.

Quintilian says they both wrote upon the art, though there is no system of the former now extant. But that of Aristotle is esteemed the best and most complete of any in the Greek language. In this age the Grecian eloquence appeared in its highest perfection. Demosthenes was a hearer both of Isocrates and Plato, as also of Isæus (ten of whose orations are yet extant); and by the assistance of a surprising genius, joined with indefatigable industry, made that advantage of their precepts, that he has been always esteemed by the best judges the prince of Grecian orators. His great adversary and rival Æschines, after his banishment, is said to have gone to Rhodes, and employed his time there in teaching of rhetoric. Theodectes and Theophrastus, both of them scholars of Aristotle, imitated their master in writing upon the art. And from that time the philosophers, especially the Stoics and Peripatetics, applied themselves to lay down the rules of oratory; which Socrates had before separated from the province of a philosopher. And there is yet preserved a treatise upon this subject, which some have ascribed to Demetrius Phalereus the Peripatetic, and scholar of Theophrastus, though others more probably to Dionysius of Halicarnassus. Quintilian mentions several other famous rhetoricians in the following ages, who were likewise writers: As Hermagoras, Athenæus, Apollonius Molon, Areus Cæcilius, Dionysius of Halicarnassus, Apollonius of Pergamus, and Theodore of Gadara. But of these nothing now remains upon the subject of oratory, except some tracts of Dionysius, who flourished in the reign of Augustus Cæsar. Nor have there been wanting some eminent writers of this kind among the Greeks since the time of Quintilian: two of whom we cannot omit to mention, Hermogenes, and Longinus the author of the incomparable treatise Of the Sublime, a book which can scarcely be too much commended or too often read.

3 Rise and progress of oratory in Rome.

It was long before Rome received this art, and not without difficulty at first. The reason was, because the Romans were for several ages wholly addicted to military affairs, and to enlarge their territories; so that they not only neglected to cultivate learning, but thought the pursuit of it a thing of ill tendency, by diverting the minds of their youth from the cares and toils of war, to a more soft and indolent kind of life. Therefore so late as the year of their city 592, when by the industry of some Grecians the liberal arts began to flourish in Italy, a decree passed the senate, by which all philosophers and rhetoricians were ordered to depart out of Rome. But in a few years after, when Carneades, Critolaus, and Diogenes, who were not only philosophers but orators, came ambassadors from Athens to Rome, the Roman youth were so charmed with the eloquence of their harangues, that they could no longer be stopt from pursuing the study of oratory. And by a further acquaintance with the Greeks, it soon gained such esteem, that persons of the first quality employed their time and pains to acquire it. And a young gentleman, who was ambitious to advance himself in the service of his country, could have little hopes of success, unless he had laid the foundation of his future prospects in that study.

Seneca tells us, that Lucius Plotius, a Gaul, was the first who taught the art of oratory at Rome in Latin; which, Cicero says, was while he was a boy; and when the most studious persons went to hear him, he lamented that he could not go with them; being prevented by the regard he paid to the opinion of some of his friends, who thought that greater improvements were made by exercises in the Greek language under Grecian masters. Seneca adds, that this profession continued for some time in the hands of freedmen; and that the first Roman who engaged in it was Blandus of the equestrian order, who was succeeded by others; some of whose lives are yet extant, written by Suetonius, as many of the Grecians are by Philostratus and Eunapius. Quintilian likewise gives us the names of those among the Romans, who wrote upon the art. "The first (he says) as far as I can learn, who composed any thing upon this argument, was M. Cato the censor. After him Antony the orator began upon the subject, which is the only work he has left, and that imperfect. Then followed some of less note. But he who carried eloquence to its highest pitch among us, was Cicero; who has likewise by his rules given the best plan both to practise and teach the art. After whom modesty would require us to mention no more, had he not told us himself that his books of rhetoric slipt out of his hands, while he was but a youth. And those lesser things, which many persons want, he has purposely omitted in his discourses of oratory. Cornificius wrote largely upon the same subject; Stertinius and Gallio the father, each of them something. But Celsus and Lenas were more accurate than Gallio; and in our times Virginius, Pliny, and Rutilius. And there are at this day some celebrated authors of the same kind, who, if they had taken in every thing, might have saved my pains." Time has since deprived us of most of the writers mentioned here by Quintilian. But we have the less reason to regret this loss, since it has preserved to us Cicero's treatises upon this subject; which we may well suppose to have been chiefly owing to their own excellency, and the great esteem they have always had in the world. Besides his Two books of Invention, which Quintilian here calls his Books of Rhetoric, there are extant of his, Three books of an Orator; one Of famous Orators; and another, which is called The Orator; as also his Topics, a preface Concerning the best sort of Orators, and a treatise Of the parts of Oratory. Each of which treatises, whether we regard the justness and delicacy of the thoughts, the usefulness of the rules, or the elegance and beauty of the style, deserves to be frequently perused by all who are lovers of eloquence. For who can be thought so well qualified to give the rules of any art, as he who excelled all mankind in the practice of them? But those Four Books to Herennius, which are published among Cicero's works, seem with good reason to be attributed to Cornificius, whom Quintilian here mentions. And Celsus is by some affirmed to to have taught oratory, whom he also places among the rhetoricians, and whose Eight Books of Medicine are yet extant, written in so beautiful a stile as plainly shows him to be a master of eloquence. But Quintilian himself outdid all who went before him in diligence and accuracy as a writer. His Institutions are so comprehensive, and written with such great exactness and judgment, that they are generally allowed to be the most perfect work of the kind. With this excellent author we shall finish the account of the Latin rhetoricians.

There were indeed some others in the following ages, whose works are yet extant; but as they contain nothing of moment which is not to be found in those already mentioned, we shall forbear to name them. Much less shall we descend to that numerous body of writers, who since the revival of learning have treated upon this subject, for the same reason. And a very good judge* has not long since given it as his opinion, that the method of forming the best system of oratory, is to collect it from the finest precepts of Aristotle, Cicero, Quintilian, Longinus, and other celebrated authors; with proper examples taken from the choicest parts of the purest antiquity. And this is the method attempted to be pursued in the following treatise.

* Archbp. Cambray, *Lett.* p. 213.

§ 2. *Of the Nature of Oratory.*

The terms *rhetoric* and *oratory*, having no other difference but that one is taken from the Greek language and the other from the Latin, may be used promiscuously, but the case is not the same with respect to the words *rhetorician* and *orator*. For although the Grecians used the former, both to express those who taught the art, and those who practised it; yet the Romans afterward, when they took that word into their language, confined it to the teachers of the art, and called the rest *orators*. And there seems to have been a sufficient reason for this distinction, since the art was the same in both, and might therefore go by either name: but the different province of rhetoricians and orators made it not improper that they should be called by different names. Besides, anciently, before rhetoric was made a separate and distinct art from philosophy, the same persons taught both. And then they were called not only *rhetoricians* but *sophists*. But because they often employed their art rather to vindicate what was false and unjust, than to support truth and virtue; this disingenuous conduct, by which they frequently imposed upon weak minds, brought a discredit both upon themselves and their profession. And therefore the name *sophist* or *sophister*, has been more generally used in an ill sense, to signify one skilled rather in the arts of cavilling, than qualified to speak well and accurately upon any subject.

4 Oratory an art.

It is not necessary to use many words, to prove that oratory is an art. For it is comprised under certain rules, agreeable to reason, delivered in a regular method, and suited to attain the end it proposes; which are characters sufficient to denominate it an art. Indeed the case is the same here as in most other things, that a good genius is of itself more serviceable than the most exact acquaintance with all the rules of art, where that is wanting. But it is sufficient that art help nature, and carry it farther than it can otherwise advance without it. And he who is desirous to gain the reputation of a good orator, will find the assistance of art very necessary. Some persons have thought, that many of the common systems written upon the subject of oratory have been attended with this inconvenience, that, by burdening the mind with too great a number of rules about things of less importance, they have oftentimes rather discouraged than promoted the study of eloquence. This undoubtedly is an extreme which should be always carefully avoided. But, however, an indifferent guide in a strange road is better than none at all. It may be worth while to hear Quintilian's opinion upon this head. "I would not (says he) have young persons think they are sufficiently instructed, if they have learned one of those compends which are commonly handed about, and fancy themselves safe in the decrees, as it were, of these technical writers. The art of speaking requires much labour, constant study, a variety of exercise, many trials, the greatest prudence, and readiness of thought. However, these treatises are useful, when they set you in a plain and open way, and do not confine you to one narrow track, from which he who thinks it a crime to depart must move as slowly as one that walks upon a rope." We see he is not for having us confine ourselves too closely to systems, though he thinks they are of service at first, till use and experience render them less necessary.

5 The object of it.

The business of oratory is to teach us to speak well; which, as Cicero explains it, is to speak *justly*, *methodically*, *floridly*, and *copiously*.

Now, in order to speak *justly*, or pertinently, a person must be master of his subject, that he may be able to say all that is proper, and avoid whatever may appear foreign and trifling. And he must clothe his thoughts with such words and expressions as are most suited to the nature of the argument, and will give it the greatest force and evidence.

And as it teaches to speak justly, so likewise *methodically*. This requires, that all the parts of a discourse be placed in their proper order, and with such just connexion, as to reflect a light upon each other, and thereby to render the whole both clear in itself, and easy to be retained. But the same method is not proper for all discourses. And very frequently a different manner is convenient in handling the same subject. For it is plain, that art, as well as nature, loves variety; and it discovers the speaker's judgment, when the disposition of his discourse is so framed, as to appear easy and natural, rather than the effect of industry and labour.

To speak *floridly*, is so peculiar a property of this art, that some have wholly confined it to the pomp and ornaments of language. But that it extends farther, and respects things as well as words, we shall have occasion to show hereafter. It contains indeed the whole subject of elocution, but does not wholly consist in it. True and solid eloquence requires not only the beauties and flowers of language, but likewise the best sense and clearest reasoning. Besides, rhetoric gives rules for the several sorts of style, and directs the use of them agreeably to the nature of the subject.

But the force of oratory appears in nothing more than a *copiousness* of expression, or a proper manner of enlargement, suited to the nature of the subject; which is of great use in persuasion, and forms the last property, required by Cicero, of speaking well. A short and concise

cise account of things is often attended with obscurity, from an omission of some necessary circumstances relating to them. Or, however, where that is not the case, yet for want of proper embellishments to enliven the discourse, and thereby to excite and fix the hearers attention, it is apt to slip through their minds without leaving any impression. But where the images of things are drawn in their full proportion, painted in their proper colours, set in a clear light, and represented in different views, with all the strength and beauties of eloquence, they captivate the minds of the audience with the highest pleasure, engage their attention, and by an irresistible force move and bend them to the design of the speaker.

The principal end and design of oratory is to persuade: for which reason it is frequently called the *art of persuasion*. Indeed the orator has often other subordinate views; as when he endeavours either to delight his hearers with what is pleasant and agreeable, or to conciliate their good opinion by a smooth and artful address; but still both these are in order to persuade and excite them to action.

An objection may, perhaps, hence be formed against eloquence, as an art which may be employed for persuading to ill as well as to good. There is no doubt that it may; and so reasoning may also be, and too often is, employed for leading men into error. But who would think of forming an argument from this against the cultivation of our reasoning powers? Reason, eloquence, and every art which ever has been studied among mankind, may be abused, and may prove dangerous in the hands of bad men: but it were perfectly childish to contend, that upon this account they ought to be abolished.

While the orator employs his art in pursuing only those ends for which it was at first designed, the persuading men to good and virtuous actions, and dissuading them from every thing that is ill and vicious; nothing can be more commendable in itself, or useful to human societies.

§ 3. *Of the Division of Oratory.*

8 Oratory consists of four parts.

Oratory consists of four parts; *invention, disposition, elocution*, and *pronunciation*. This will appear by considering the nature of each of them, and what it contributes in forming an orator. Every one who aims to speak well and accurately upon any subject, does naturally, in the first place, inquire after and pursue such thoughts as may seem most proper to explain and illustrate the thing upon which he designs to discourse. And if the nature of it requires that he should bring reasons to confirm what he says, he not only seeks the strongest, and such as are like to be best received; but also prepares to answer any thing which may be offered to the contrary. This is *invention*.—After this he deliberates with himself in what method to dispose of those things which have occurred to his mind, that they may appear in the plainest light, and not lose their force by disorder and confusion. This is the business of *disposition*.—His next concern is to give his thoughts an agreeable dress; by making choice of the fittest words, clearest expressions, smooth and harmonious periods, with other ornaments of style, as may best suit the nature of his subject, brighten his discourse, and render it most entertaining to his hearers. And this is called *elocution*.—The last thing he attends to, is to deliver what he has thus composed, with a just and agreeable *pronunciation*. And daily experience convinces us, how much this contributes both to engage the attention and impress what is spoken upon the mind. This then is the method which nature directs, in order to qualify ourselves for discoursing to the best advantage: Though by custom and habit these things become so familiar to us, that we do not always attend to them separately in their natural order. However, it is the business of art to follow nature, and to treat of things in that manner which she dictates.

PART I. OF INVENTION.

Chap. I. *Of Invention in general; and particularly of Common Places, and State of a Cause.*

7 Invention the discovery of such things as are fitted to persuade.

INVENTION, considered in general, is the discovery of such things as are proper to persuade. And in order to attain this end, the orator proposes to himself three things: To prove or illustrate the subject upon which he treats; to conciliate the mind of his hearers; and to engage their passions in his favour. And as these require different kinds of arguments or motives, invention furnishes him with a supply for each of them, as will be shown in their order.

An argument, as defined by Cicero, is a reason which induces us to believe what before we doubted of.

And as different kinds of discourses require different arguments, rhetoricians have considered them two ways; in general, under certain heads, as a common fund for all subjects; and, in a more particular manner, as they are suited to *demonstrative, deliberative*, or *judicial* discourses. At present we shall treat only upon the former of these. And now, that one thing may receive proof and confirmation from another, it is necessary that there be some relation between them; for all things are not equally adapted to prove one another. Thus, in measuring the quantity of two things which we would show to be either equal or unequal, if they are of such a nature that one cannot be applied to the other, then we take a third thing, which may be applied to them both; and that must be equal at least to one of the two, which if applied to the other, and found equal to that also, we presently conclude that these two things are equal; but if it be unequal to the other, we say that these two things are unequal. Because it is the certain and known property of all quantities, that whatsoever two things are equal to a third, are equal to one another; and where one of any two things is equal to a third, and the other unequal, those two things are unequal to one another. What has been said of quantities, will

Invention. will hold true in all other cases, that so far as any two things or ideas agree to a third, so far they agree to one another. So likewise, on the contrary, as far as one of any two things or ideas does agree to a third, and the other does not, so far they disagree with one another; in which respect, one of them cannot be truly affirmed of the other. Since, therefore, in every proposition, one thing is spoken of another, if we would find out whether the two ideas agree to each other or not, where this is not evident of itself, we must find out some third thing, the idea of which agrees to one of them; and then that being applied to the other, as it does agree or disagree with it, so we may conclude, that the two things proposed do agree or disagree with one another. This will be made more clear by an example or two. Should it be inquired, *Whether virtue is to be loved;* the argument between virtue and love might be found by comparing them separately with happiness, as a common measure to both. For since the idea of happiness agrees to that of love, and the idea of virtue to that of happiness; it follows, that the ideas of virtue and love agree to one another: and therefore it may be affirmed, *That virtue is to be loved.* But, on the contrary, because the idea of misery disagrees with that of love, but the idea of vice agrees to that of misery, the two ideas of vice and love must consequently disagree with one another; and therefore it would be false to assert, *That vice is to be loved.*

8 These called arguments.

Now, this third thing logicians call the *medium*, or *middle term*, because it does as it were connect two extremes; that is, both parts of a proposition. But rhetoricians call it an *argument*, because it is so applied to what was before proposed, as to become the instrument of procuring our assent to it. Thus far as to the nature and use of arguments. We shall next explain by what methods they are to be sought.

A lively imagination, and readiness of thought, are undoubtedly a very great help to invention. Some persons are naturally endued with that quickness of fancy, and penetration of mind, that they are seldom at a loss for arguments either to defend their own opinions, or to attack their adversaries. However, these things being the gift of nature, and not to be gained by art, do not properly fall under our present consideration.

9 Learning necessary to an orator.

It will be readily granted, that great learning and extensive knowledge are a noble fund for invention. An orator therefore should be furnished with a stock of important truths, solid maxims of reason, and a variety of knowledge, collected and treasured up both from observation and a large acquaintance with the liberal arts, that he may not only be qualified to express himself in the most agreeable manner, but likewise to support what he says with the strongest and clearest arguments.

But because all are not born with a like happy genius, and had not the same opportunity to cultivate their minds with learning and knowledge; and because nothing is more difficult than to dwell long upon the consideration of one thing, in order to find out the strongest arguments which may be offered for and against it; upon these accounts, art has prescribed a method to lessen, in some measure, these difficulties, and help every one to a supply of arguments upon any subject. And this is done by the contrivance of *common places*, which Cicero calls the *seats* or *heads of arguments*, and by a Greek name *topics*. They are of two sorts, *internal* and *external*. Invention.

10 Rules of art to supply the place of extensive learning or acute genius.

I. *Internal topics.* Though things, with regard to their nature and properties, are exceedingly various, yet they have certain common relations, by means whereof the truth of what is either affirmed or denied concerning them in any respect may be evinced. The ancient Greek rhetoricians therefore reduced these relations to some general heads, which are termed *loci* or *common places;* because the reasons or arguments suited to prove any proposition are reposited in them, as a common fund or receptacle. And they are called *internal heads*, because they arise from the subject upon which the orator treats; and are therefore distinguished from others named *external*, which he fetches from without, and applies to his present purpose, as will be shown hereafter. Cicero and Quintilian make them 16; three of which comprehend the whole thing they are brought to prove, namely, *definition*, *enumeration*, and *notation:* of the remaining 13, some contain a part of it, and the rest its various properties and circumstances, with other considerations relating to it; and these are, *genus*, *species*, *antecedents*, *consequents*, *adjuncts*, *conjugates*, *cause*, *effect*, *contraries*, *opposites*, *similitude*, *dissimilitude*, and *comparison*.

Definition explains the nature of the thing defined, and shows what it is. And to whatsoever the definition agrees, the thing defined does so likewise. If therefore Socrates be a rational creature, he is a man; because it is the definition of a man, that he is a rational creature.

Enumeration takes in all the parts of a thing. And from this we prove, that what agrees to all the parts agrees to the whole; and what does not agree to any one or more parts, does not agree to the whole: As when Cicero proves to Piso that all the Roman state hated him, by enumerating the several ranks and orders of Roman citizens who all did so.

Notation, or etymology, explains the meaning or signification of a word. From which we reason thus: "If he cannot pay his debts, he is insolvent;" for that is the meaning of the word *insolvent*.

Genus is what contains under it two or more sorts of things, differing in nature. From this head logicians reason thus: "Because every animal is mortal, and man is an animal, therefore man is mortal." But orators make a further use of this argument, which they call *ascending from the hypothesis to the thesis;* that is, from a particular to a general: As should a person, when speaking in praise of justice, take occasion from thence to commend and show the excellency of virtue in general, with a view to render that particular virtue more amiable. For since every species contains in it the whole nature of the genus to which it relates, besides what is peculiar to itself, whereby it is distinguished from it; what is affirmed of the genus, must of necessity be applicable to the species.

Species is that which comprehends under it all the individuals of the same nature. From hence we may argue, "He is a man, therefore he has a rational soul." And orators sometimes take occasion from this head to descend from the thesis to the hypothesis; that

Invention.

that is, in treating upon what is more general, to introduce some particular contained under it, for the greater illustration of the general.

Antecedents are such things, as being once allowed, others necessarily, or very probably, follow. From this head an inseparable property is proved from its subject: as, It is material, and therefore corruptible.

Consequents are such things as, being allowed, necessarily or very probably infer their antecedents. Hence the subject is proved from an inseparable property, in this manner: It is corruptible, and therefore material.

Adjuncts are separable properties of things, or circumstances that attend them. These are very numerous, and afford a great variety of arguments, some of which usually occur in every discourse. They do not necessarily infer their subject; but, if fitly chosen, render a thing credible, and are a sufficient ground for assent. The way of reasoning from them we shall show presently.

Conjugates are words deduced from the same origin with that of our subject. By these the habit is proved from its acts: as, He who does justly is just. He does not act wisely, therefore he is not wise. But this inference will not hold, unless the actions appear continued and constant.

A *cause* is that, by the force of which a thing does exist. There are four kinds of causes, matter, form, efficient, and end, which afford a great variety of arguments. The way of reasoning from them is to infer the effect from the cause: as, Man is endued with reason, therefore he is capable of knowledge.

An *effect* is that which arises from a cause, therefore the cause is proved by it: as, He is endued with knowledge, therefore with reason.

Contraries are things, which, under the same genus, are at the utmost distance from each other; so that what we grant to the one, we utterly deny the other; as, Virtue ought to be embraced, therefore vice should be avoided.

Opposites are such things, which, though repugnant, to each other, yet are not directly contradictory; as, To love and to injure, to hate and to commend. They differ from contraries in this, that they do not absolutely exclude one another. An argument is drawn from things repugnant, thus: He will do a man a mischief, therefore he does not love him. He loves a man, therefore he will not reproach him.

Similitude is an agreement of things in quality. Thus Cicero proves, that pernicious citizens ought to be taken out of the state, by the likeness they bear to corrupted members, which are cut off to prevent further damage to the body.

Dissimilitude is a disagreement of things in quality. From this head Cicero shows the preference of his own exile to Piso's government of Macedonia; by the difference between their conduct, and the people's esteem of them.

Comparison is made three ways: for either a thing is compared with a greater, with a less, or with its equal. This place, therefore, differs from that of similitude on this account, that the quality was considered in that, but here the quantity. An argument from the greater is thus drawn: If five legions could not conquer the enemy, much less will two.

11 The manner of reasoning from these heads.

We shall just give one example of the manner of reasoning from these heads, whereby the use of them may farther appear. If any one, therefore, should have endeavoured to persuade Cicero not to accept of his life upon the condition offered him by Antony, That he would burn his Philippic orations which had been spoken against him, he might be supposed to use such arguments as these; partly taken from the adjuncts of Cicero, partly from those of Antony, and partly from the thing itself. And first, with regard to Cicero, it might be said, That so great a man ought not to purchase his life at so dear a price as the loss of that immortal honour which by so great pains and labour he had acquired. And this might be confirmed by another argument, That now he was grown old, and could not expect to live much longer. And from the character of Antony he might argue thus; That he was very crafty and deceitful; and only designed, by giving him hopes of life, to have the Philippics first burnt, which otherwise he knew would transmit to posterity an eternal brand of infamy upon him, and then he would take off the author. And this might be shown by comparison. For since he would not spare others, who had not so highly exasperated him, and from whom he had not so much to fear, certainly he would not forgive Cicero, since he knew well enough, that so long as he lived, he himself could never be in safety. And, lastly, An argument might also be fetched from the nature of the thing itself in the following manner: That Cicero, by this action, would shamefully betray the state, and the cause of liberty, which he had through his whole life most courageously defended, with so great honour to himself, and advantage to the public. Upon such an account, a person might have used these or the like arguments with Cicero, which arise from the fore-mentioned heads.

12 They are of no solid utility unless there is a previous foundation of learning and genius.

From this account of common places, it is easy to conceive what a large field of discourse they open to the mind upon every subject. At the same time, though we have mentioned them from our respect for the orators of Greece and Rome, we heartily subscribe to the opinion of a celebrated modern, who gives of them the following account.

"The Grecian sophists were the first inventors of this artificial system of oratory; and they showed a prodigious subtility and fertility in the contrivance of these loci. Succeeding rhetoricians, dazzled by the plan, wrought them into so regular a system, that one would think they meant to teach how a person might mechanically become an orator, without any genius at all. They gave him receipts for making speeches on all manner of subjects. At the same time, it is evident, that though this study of common places might produce very showy academical declamations, it could never produce useful discourses on real business. The loci indeed supplied a most exuberant fecundity of matter. One who had no other aim, but to talk copiously and plausibly, by consulting them on every subject, and laying hold of all that they suggested, might discourse without end; and that, too, though he had none but the most superficial knowledge of his subject. But such discourse could be no other than trivial. What is truly solid and persuasive, must be drawn *ex visceribus causæ*, from a thorough knowledge of the subject, and profound meditation on it. They who would direct students of oratory

Blair's Lectures.

Invention.

tory to any other sources of argumentation, only delude them; and by attempting to render rhetoric too perfect an art, they render it, in truth, a trifling and childish study."

13 Of external topics, generally called *testimonies*.

II. *Of external topics.* When the orator reasons from such topics as do not arise from his subject, but from things of a different nature, these are called *external*. They are all taken from authorities, and are by one general name called *testimonies*.

Now a testimony may be expressed by writing, speech, or any other sign proper to declare a person's mind. And all testimonies may be distinguished into two sorts, divine and human. A divine testimony, when certainly known to be such, is incontestable, and admits of no debate, but should be acquiesced in without hesitation. Indeed the ancient Greeks and Romans esteemed the pretended oracles of their deities, the answers of their augurs, and the like fallacies, divine testimonies: but with us no one can be ignorant of their true notion, though they do not so directly come under our present consideration. Human testimonies, considered as furnishing the orator with arguments, may be reduced to three heads; *writings*, *witnesses*, and *contracts*.

14 Reduced to three heads, and separately explained.

1. By *Writings*, here, are to be understood written laws, wills, or other legal instruments, expressed and conveyed in that manner. And it is not so much the force and validity of such testimonies considered in themselves, that is here intended, as the occasion of dispute which may at any time arise concerning their true design and import, when produced in proof upon either side of a controversy. And these are five; Ambiguity, Disagreement between the words and intention, Contrariety, Reasoning, and Interpretation.

A writing is then said to be ambiguous, when it is capable of two or more senses, which makes the writer's design uncertain. Now ambiguity may arise either from single words, or the construction of sentences. From single words; as when either the sense of a word, or the application of it, is doubtful. As, should it be questioned, whether ready money ought to be included under the appellation of chattels left by a will; or, if a testator bequeath a certain legacy to his nephew Thomas, and he has two nephews of that name. But ambiguity is also sometimes occasioned from the construction of a sentence; as when several things or persons having been already mentioned, it is doubtful to which of them that which follows ought to be referred. For example, a person writes thus in his will: 'Let my heir give as a legacy to Titius a horse out of my stable, which he pleases.' Here it may be questioned, whether the word *he* refers to the heir or to Titius; and consequently, whether the heir be allowed to give Titius which horse he pleases, or Titius may choose which he likes best. Now as to controversies of this kind, in the first case above mentioned, the party who claims the chattels may plead, that all moveable goods come under that name, and therefore that he has a right to the money. This he will endeavour to prove from some instances where the word has been so used. The business of the opposite party is to refute this, by showing that money is not here included. And if either side produce precedents in his favour, the other may endeavour to show that the cases are not parallel. As to the second case, arising from an ambiguity in the name, if any other words or expressions in the will seem to countenance either of the claimants, he will not fail to interpret them to his advantage. So likewise, if any thing said by the testator, in his lifetime, or any regard shown to either of these nephews more than the other, may help to determine which of them was intended, a proper use may be made of it. And the same may be said with regard to the third case. In which the legatee may reason likewise from the common use of language, and show that in such expressions it is usual to make the reference to the last or next antecedent; and from thence plead, that it was the design of the testator to give him the option. But in answer to this, it may be said, that allowing it to be very often so, yet in this instance it seems more easy and natural to repeat the verb *give* after *pleases*, and so to supply the sentence, which *he pleases to give him*, referring it to the heir, than to bring in the verb *choose*, which was not in the sentence before; and so, by supplying the sense, *which he pleases to choose*, to give the option to Titius. But where controversies of this kind arise from a law, recourse may be had to other laws where the same thing has been expressed with greater clearness; which may help to determine the sense of the passage in dispute.

A second controversy from writings is, when one party adheres to the words, and the other to what he asserts was the writer's intention. Now he who opposes the literal sense either contends, that what he himself offers is the simple and plain meaning of the writing, or that it must be so understood in the particular case in dispute. An instance of the former is this, as we find it in Cicero. A person who died without children, but left a widow, had made this provision in his will: "If I have a son born to me, he shall be my heir." And a little after: "If my son die before he comes of age, let Curius be my heir." There is no son born: Curius therefore sues for the estate, and pleads the intention of the testator, who designed him for his heir, if he should have no son who arrived at age; and says, there can be no reason to suppose he did not intend the same person for his heir if he had no son, as if he should have one who afterwards died in his minority. But the heir at law insists upon the words of the will; which, as he says, require, that first a son should be born, and afterwards die under age, before Curius can succeed to the inheritance; and there being no son, a substituted heir, as Curius was, can have no claim where the first heir does not exist, from whom he derives his pretension, and was to succeed by the appointment of the will.—Of the latter case, rhetoricians give this example: "It was forbidden by a law to open the city gates in the night. A certain person notwithstanding, in time of war, did open them in the night, and let in some auxiliary troops, to prevent their being cut off by the enemy, who was posted near the town." Afterwards, when the war was over, this person is arraigned, and tried for his life, on account of this action. Now, in such a case, the prosecutor founds his charge upon the express words of the law; and pleads, that no sufficient reason can be assigned for going contrary to the letter of it, which would be to make a new law, and not to execute one already made. The defendant, on the other hand, alleges, That the fact he is charged with

Invention.

with cannot, however, come within the intention of the law; since he either could not, or ought not, to have complied with the letter of it in that particular case, which must therefore necessarily be supposed to have been excepted in the design of that law when it was made. But to this the prosecutor may reply, That all such exceptions as are intended by any law, are usually expressed in it: and instances may be brought of particular exceptions expressed in some laws; and if there be any such exception in the law under debate, it should especially be mentioned. He may further add, That to admit of exceptions not expressed in the law itself, is to enervate the force of all laws, by explaining them away, and in effect to render them useless. And this he may further corroborate, by comparing the law under debate with others, and considering its nature and importance, and how far the public interest of the state is concerned in the due and regular execution of it; from whence he may infer, that should exceptions be admitted in other laws of less consequence, yet, however, they ought not in this. Lastly, He may consider the reason alleged by the defendant, on which he founds his plea, and show there was not that necessity of violating the law in the present case, as is pretended. And this is often the more requisite, because the party who disputes against the words of the law, always endeavours to support his allegations from the equity of the case. If, therefore, this plea can be enervated, the main support of the defendant's cause is removed. For as the former arguments are designed to prevail with the judge, to determine the matter on this side the question from the nature of the case; so the intention of this argument is to induce him to it, from the weakness of the defence made by the opposite party. But the defendant will, on the contrary, use such arguments as may best demonstrate the equity of his cause, and endeavour to vindicate the fact from his good design and intention in doing it. He will say, That the laws have allotted punishments for the commission of such facts as are evil in themselves, or prejudicial to others; neither of which can be charged upon the action of which he is accused: That no law can be rightly executed, if more regard be had to the words and syllables of the writing, than to the intention of the legislator. To which purpose he may allege that direction of the law itself, which says, "The law ought not to be too rigorously interpreted, nor the words of it strained; but the true intention and design of each part of it duly considered." As also that saying of Cicero, "What law may not be weakened and destroyed, if we bend the sense to the words, and do not regard the design and view of the legislator?" Hence he may take occasion to complain of the hardship of such a procedure, that no difference should be made between an audacious and wilful crime, and an honest or necessary action, which might happen to disagree with the letter of the law, though not with the intent of it. And as it was observed before to be of considerable service to the accuser, if he could remove the defendant's plea of equity, so it will be of equal advantage to the defendant, if he can fix upon any words in the law, which may in the least seem to countenance his case, since this will take off the main force of the charge.

The third controversy of this kind is, when two writings happen to clash with each other, or at least seem to do so. Of this Hermogenes gives the following instance. One law enjoins: "He who continues alone in a ship during a tempest, shall have the property of the ship." Another law says, "A disinherited son shall enjoy no part of his father's estate." Now a son, who had been disinherited by his father, happens to be in his father's ship in a tempest, and continues there alone, when every one else had deserted it. He claims the ship by the former of these laws, and his brother tries his right with him by the latter. In such cases, therefore, it may first be considered, "Whether the two laws can be reconciled. And if that cannot be done, then, Which of them appears more equitable. Also, Whether one be positive and the other negative: because prohibitions are a sort of exceptions to positive injunctions. Or, If one be a general law, and the other more particular, and come nearer to the matter in question. Likewise, Which was last made: since former laws are often abrogated, either wholly or in part, by subsequent laws, or at least were designed to be so. Lastly, it may be observed, Whether one of the laws be not plain and express; and the other more dubious, or has any ambiguity in it. All, or any of which things, that party will not omit to improve for his advantage whose interest is concerned in it.

The fourth controversy is *reasoning*. As when something, not expressly provided for by a law, is inferred by a similitude, or parity of reason, from what is contained in it. Quintilian mentions this instance of it. "There was a law made at Tarentum, to prohibit the exportation of wool; but a certain person exports sheep." In this case, the prosecutor may first compare the thing which occasions the charge, with the words of the law, and show their agreement, and how unnecessary it was that particular thing should have been expressly mentioned in the law, since it is plainly contained in it, or at least an evident consequence from it. He may then plead, that many things of a like nature are omitted in other laws for the same reason. And, lastly, He may urge the reasonableness and equity of the procedure. The defendant, on the other hand, will endeavour to show the deficiency of the reasoning, and the difference between the two cases. He will insist upon the plain and express words of the law, and set forth the ill tendency of such inferences and conclusions drawn from similitudes and comparisons, since there is scarce any thing but in some respect may bear a resemblance to another.

The last controversy under this head is *interpretation*, in which the dispute turns upon the true meaning and explication of the law in reference to that particular case. We have the following instance of this in the Pandects: "A man who had two sons both under age, substitutes Titius as heir to him who should die last, provided both of them died in their minority. They both perish together at sea before they came to age. Here arises a doubt, whether the substitution can take place, or whether the inheritance devolves to the heir at law." The latter pleads, That as neither of them can be said to have died last, the substitution cannot take place; which was suspended, upon the condition that one died after the other. But

Invention. But to this it may be said, It was the intention of the testator, that if both died in their nonage, Titius should succeed to the inheritance; and therefore it makes no difference whether they died together, or one after the other: and so the law determines it.

2. The *second* head of external arguments are *Witnesses*. These may either give their evidence, when absent, in writing subscribed with their name; or present, by word of mouth. And what both of them testify, may either be from hearsay; or what they saw themselves, and were present at the time it was done. As the weight of the evidence may be thought greater or less on each of these accounts, either party will make such use of it as he finds for his advantage. The characters of the witnesses are also to be considered; and if any thing be found in their lives or behaviour that is justly exceptionable, to invalidate their evidence, it ought not to be omitted. And how they are affected to the contending parties, or either of them, may deserve consideration; for some allowances may be judged reasonable in case of friendship, or enmity, where there is no room for any other exception. But regard should chiefly be had to what they testify, and how far the cause is affected by it. Cicero is very large upon most of these heads in his defence of Marcus Fonteius, with a design to weaken the evidence of the Gauls against him. And where witnesses are produced on one side only, as orators sometimes attempt to lessen the credit of this kind of proof, by pleading that witnesses are liable to be corrupted, or biassed by some prevailing interest or passion, to which arguments taken from the nature and circumstances of things are not subject; it may be answered on the other hand, that sophistical arguments and false colourings are not exposed to infamy or punishment, whereas witnesses are restrained by shame and penalties, nor would the law require them if they were not necessary.

3. The *third* and last head of external arguments are *Contracts;* which may be either public or private. By public are meant the transactions between different states, as leagues, alliances, and the like; which depend on the laws of nations, and come more properly under deliberative discourses, to which we shall refer them. Those are called *private*, which relate to lesser bodies or societies of men, and single persons; and may be either written or verbal. And it is not so much the true meaning and purport of them that is here considered as their force and obligation. And, as the Roman law declares, "Nothing can be more agreeable to human faith, than that persons should stand to their agreements." Therefore in controversies of this kind, the party whose interest it is that the contract should be maintained, will plead, that such covenants have the force of private laws, and ought religiously to be observed, since the common affairs of mankind are transacted in that manner; and therefore to violate them, is to destroy all commerce and society among men. On the other side it may be said, that justice and equity are chiefly to be regarded, which are immutable; and besides, that the public laws are the common rule to determine all differences, which are designed to redress those who are aggrieved. And indeed, where a compact has been obtained by force or fraud, it is in itself void, and has no effect either in law or reason. But on the other hand, the Roman lawyers seem to have very rightly determined, that all such obligations as are founded on natural equity, though not binding by national laws, and are therefore called *nuda pacta*, ought, however, in honour and conscience, to be performed.

15 Of the state of a controversy, or the manner of referring the principal question in dispute to some particular head for greater ease of argument.

III. *Of the State of a Controversy.* The ancients, observing that the principal question or point of dispute in all controversies might be referred to some particular head, reduced these heads to a certain number, that both the nature of the question might by that means be better known, and the arguments suited to it be discovered with greater ease. And these heads they call *states*.

By the state of a controversy, then we are to understand the principal point in dispute between contending parties, upon the proof of which the whole cause or controversy depends. We find it expressed by several other names in ancient writers: as, the *constitution of the cause*, the *general head*, and the *chief question*. And as this is the principal thing to be attended to in every such discourse; so it is what first requires the consideration of the speaker, and should be well fixed and digested in his mind, before he proceeds to look for arguments proper to support it. Thus Antony, the Roman orator, speaking of his own method in his pleading, says: "When I understand the nature of the cause, and begin to consider it, the first thing I endeavour to do is, to settle with myself what that is to which all my discourse relating to the matter in dispute ought to be referred: then I diligently attend to these other two things, How to recommend myself, or those for whom I plead, to the good esteem of my hearers; and how to influence their minds, as may best suit my design." This way of proceeding appears very agreeable to reason and prudence. For what can be more absurd, than for a person to attempt the proof of any thing, before he has well settled in his own mind a clear and distinct notion what the thing is which he would endeavour to prove? Quintilian describes it to be, 'That kind of question which arises from the first conflict of causes.' In judicial cases, it immediately follows upon the charge of the plaintiff, and plea of the defendant. Our common law expresses it by one word, namely the *issue*. Which interpreters explain, by describing it to be, "That point of matter depending in suit, whereupon the parties join, and put their cause to the trial." Examples will further help to illustrate this, and render it more evident. In the cause of Millo, the charge of the Clodian party is, *Milo killed Clodius*. Milo's plea or defence, *I killed him, but justly*. From hence arises this grand question, or state of the cause, *Whether it was lawful for Milo to kill Clodius?* And that Clodius was lawfully killed by Milo, is what Cicero in his defence of Milo principally endeavours to prove. This is the main subject of that fine and beautiful oration. The whole of his discourse is to be considered as centering at last in this one point. Whatever different matters are occasionally mentioned, will, if closely attended to, be found to have been introduced some way or other the better to support and carry on this design. Now in such cases, where the fact is not denied, but something is offered in its defence, the state of the cause is taken from the defendant's plea, who is obliged to make it good: As in the instance here given, the chief point in dispute was the lawfulness of Milo's action, which it was Cicero's business to demonstrate. But when the defendant denies the fact, the state of of the cause arises from the accusation; the proof of which then lies upon the plaintiff, and not, as in the former case, upon the defendant. So in the cause of Roscius, the charge made against him is, *That he killed his father*. But he denies the fact. The grand question therefore to be argued is, *Whether or not he killed his father:* The proof of this lay upon his accusers. And Cicero's design in his defence of him is to show, that they had not made good their charge. But it sometimes happens, that the defendant neither absolutely denies the fact, nor attempts to justify it; but only endeavours to qualify it, by denying that it is a crime of that nature, or deserves that name, by which it is expressed in the charge. We have an example of this proposed by Cicero: "A person is accused of sacrilege, for taking a thing, that was sacred, out of a private house. He owns the fact, but denies it to be sacrilege; since it was committed in a private house, and not in a temple." Hence this question arises, *Whether to take a sacred thing out of a private house, is to be deemed sacrilege, or only simple theft?* It lies upon the accuser to prove what the other denies; and therefore the state of the cause is here also, as well as in the preceding case, taken from the indictment.

But besides the principal question, there are other subordinate questions, which follow upon it in the course of a dispute, and should be carefully distinguished from it. Particularly that which arises from the reason, or argument, which is brought in proof of the principal question. For the principal question itself proves nothing, but is the thing to be proved, and becomes at last the conclusion of the discourse. Thus, in the cause of Milo, his argument is, *I killed Clodius justly, because he assassinated me.* Unless the Clodian party be supposed to deny this, they give up their cause. From hence therefore this subordinate question follows, *Whether Clodius assassinated Milo!* Now Cicero spends much time in the proof of this, as the hinge on which the first question, and consequently the whole cause, depended. For if this was once made to appear, the lawfulness of Milo's killing Clodius, which was the grand question or thing to be proved, might be inferred as an allowed consequence from it. This will be evident, by throwing Milo's argument, as used by Cicero, into the form of a syllogism.

> *An assassin is lawfully killed:*
> *Clodius was an assassin:*
> *Therefore he was lawfully killed by Milo whom he assassinated.*

If the minor proposition of this syllogism was granted, no one would deny the conclusion: for the Romon law allowed of self-defence. But as Cicero was very sensible this would not be admitted, so he takes much pains to bring the court into the belief of it. Now where the argument brought in defence of the second question is contested, or the orator supposes that it may be so, and therefore supports that with another argument, this occasions a third question consequent upon the former; and in like manner he may proceed to a fourth. But be they more or fewer, they are to be considered but as one chain of subordinate questions dependent upon the first. And though each of them has its particular state, yet none of these is what rhetoricians call *The state of the Cause*, which is to be understood only of the principal question. And if, as it frequently happens, the first or principal question is itself directly proved from more than one argument; this makes no other difference, but that each of these arguments, so far as they are followed by others to support them, become a distinct series of subordinate questions, all dependent upon the first. As when Cicero endeavours to prove, that Roscius did not kill his father, from two reasons or arguments: *Because he had neither any cause to move him to such a barbarous action, nor any opportunity for it.*

Moreover, besides these subordinate questions, there are also incidental ones often introduced, which have some reference to the principal question, and contribute towards the proof of it, though they are not necessarily connected with it, or dependent upon it. And each of these also has its state, though different from that of the cause. For every question, or point of controversy, must be stated, before it can be made the subject of disputation. And it is for this reason, that every new argument advanced by an orator is called a *question;* because it is considered as a fresh matter of controversy. In Cicero's defence of Milo, we meet with several of this sort of questions, occasioned by some aspersions which had been thrown out by the Clodian party to the prejudice of Milo. As, "That he was unworthy to see the light, who owned he had killed a man:" For Milo before his trial had openly confessed he killed Clodius. So likewise, "That the senate had declared the killing of Clodius was an illegal action." And further, "That Pompey, by making a new law to settle the manner of Milo's trial, had given his judgment against Milo." Now to each of these Cicero replies, before he proceeds to the principal question. And therefore, though the question, in which the state of a controversy consists, is said by Quintilian to arise from "the first conflict of causes," yet we find by this instance of Cicero, that it is not always the first question in order, upon which the orator treats.

But it sometimes happens, that the same cause or controversy contains in it more than one state. Thus in judicial causes, every distinct charge occasions a new state. All Cicero's orations against Verres relate to one cause, founded upon a law of the Romans against unjust exactions made by their governors of provinces upon the inhabitants; but as that persecution is made up of as many charges as there are orations, every charge, or indictment, has its different state. So likewise his oration in defence of Cœlius has two states, in answer to a double charge made against him by his adversaries: one, "for borrowing money of Clodia, in order to bribe certain slaves to kill a foreign ambassador;" and the other, "for an attempt afterwards to poison Clodia herself." Besides which, there were several other matters of a less heinous nature, which had been thrown upon him by his accusers, with a design, very likely, to render the two principal charges more credible; to which Cicero first replies, in the same manner as in his defence of Milo.

Though all the examples we have hitherto brought to illustrate this subject have been taken from judicial cases, yet not only these, but very frequently discourses of the deliberative kind, and sometimes those of the demonstrative, are managed in a controversial way.

And

Invention.

And all controversies have their state. And therefore Quintilian very justly observes, that "states belong both to general and particular questions; and to all sorts of causes, demonstrative, deliberative, and judicial." In Cicero's oration for the Manilian law, this is the main point in dispute between him and those who opposed that law: "Whether Pompey was the fittest person to be intrusted with the management of the war against Mithridates?" This is a subject of the deliberative kind. And of the same nature was that debate in the senate concerning the demolition of Carthage. For the matter in dispute between Cato, who argued for it, and those who were of the contrary opinion, seems to have been this: "Whether it was for the interest of the Romans to demolish Carthage?" And so likewise in those two fine orations of Cato and Cæsar, given us by Sallust, relating to the conspirators with Catiline, who were then in custody, the controversy turns upon this: "Whether those prisoners should be punished with death, or perpetual imprisonment?" Examples of the demonstrative kind are not so common; but Cicero's oration concerning the 'Answers of the soothsayers,' may afford us an instance of it. Several prodigies had lately happened at Rome; upon which the soothsayers being consulted, assigned this as the reason of them, Because some places consecrated to the gods had been afterwards converted to civil uses. Clodius charged this upon Cicero; whose house was rebuilt at the public expence, after it had been demolished by Clodius, and the ground consecrated to the goddess Liberty. Cicero in this oration retorts the charge; and shows that the prodigies did not respect him, but Clodius. So that the question in dispute was, "To which of the two those prodigies related?" This oration does not appear to have been spoken in a judicial way, and must therefore belong to the demonstrative kind. His invective against Piso is likewise much of the same nature, wherein he compares his own behaviour and conduct with that of Piso.

As to the number of these states, both Cicero and Quintilian reduce them to three. "We must (says Quintilian) agree with those whose authority Cicero follows, who tells us, that three things may be inquired into in all disputes: Whether a thing is; what it is; and how it is. And this is the method which nature prescribes. For, in the first place, it is necessary the thing should exist about which the dispute is: because no judgment can be made either of its nature or quality till its existence be manifest; which is therefore the first question. But though it be manifest that a thing is, it does not presently appear what it is; and when this is known, the quality yet remains: and after these three are settled, no farther inquiry is necessary." Now the first of these three states is called the *conjectural state*; as if it be inquired, "Whether one person killed another?" This always follows upon the denial of a fact by one of the parties; as was the case of Roscius. And it receives its name from hence, that the judge is left, as it were, to conjecture, whether the fact was really committed or not, from the evidence produced on the other side. The second is called the *definitive state*, when the fact is not denied; but the dispute turns upon the nature of it, and what name it is proper to give it: as in that example of Cicero, "Whether to take a sacred thing out of a private house be theft or sacrilege?" For in this case it is necessary to settle the distinct notion of those two crimes, and show their difference. The third is called the *state of quality*; when the contending parties are agreed both as to the fact, and the nature of it; but the dispute is, "Whether it be just or unjust, profitable or unprofitable, and the like;" as in the cause of Milo.

From what has been said upon this subject, the use of it may in a good measure appear. For whoever engages in a controversy, ought in the first place to consider with himself the main question in dispute, to fix it well in his mind, and keep it constantly in his view; without which he will be very liable to ramble from the point, and bewilder both himself and his hearers. And it is no less the business of the hearers principally to attend to this; by which means they will be helped to distinguish and separate from the principal question what is only incidental, and to observe how far the principal question is affected by it; to perceive what is offered in proof, and what is only brought in for illustration; not to be misled by digressions, but to discern when the speaker goes off from his subject, and when he returns to it again; and, in a word, to accompany him through the whole discourse, and carry with them the principal chain of reasoning upon which the cause depends, so as to judge upon the whole, whether he has made out his point, and the conclusion follows from the premises.

Chap. II. *Of Arguments suited to Demonstrative Discourses.*

16 Of arguments suited to demonstrative discourses.

These consist either in praise or dispraise; and, agreeably to the nature of all contraries, one of them will serve to illustrate the other.

Now we either praise *persons* or *things*.

I. In praising or dispraising *persons*, rhetoricians prescribe two methods. One is, to follow the order in which every thing happened that is mentioned in the discourse; the other is, to reduce what is said under certain general heads, without a strict regard to the order of time.

1. In pursuing the former method, the discourse may be very conveniently divided into three periods. The first of which will contain what preceded the person's birth; the second, the whole course of his life; and the third what followed upon his death.

Under the first of these may be comprehended what is proper to be said concerning his country or family. And therefore, if these were honourable, it may be said to his advantage, that he nowise disgraced them, but acted suitably to such a descent. But if they were not so, they may be either wholly omitted; or it may be said, that, instead of deriving thence any advantage to his character, he has conferred a lasting honour upon them; and that is not of so much moment where, or from whom, a person derives his birth, as how he lives.

In the second period, which is that of his life, the qualities both of his mind and body, with his circumstances in the world, may be separately considered. Though, as Quintilian rightly observes, "All external advantages are not praises for themselves, but according to the use that is made of them. For riches, and power, and interest, as they have great influence, and may be applied either to good or bad purposes, are a

Invention. a proof of the temper of our minds; and therefore we are either made better or worse by them." But these things are a just ground for commendation, when they are the reward of virtue or industry. Bodily endowments are health, strength, beauty, activity, and the like; which are more or less commendable, according as they are employed. And where these, or any of them, are wanting, it may be shown, that they are abundantly compensated by the more valuable endowments of the mind. Nay, sometimes a defect in these may give an advantageous turn to a person's character; for any virtue appears greater, in proportion to the disadvantages the person laboured under in exerting it. But the chief topics of praise are taken from the virtues and qualifications of the mind. And here the orator may consider the disposition, education, learning, and several virtues, which shone through the whole course of the person's life. In doing which, the preference should always be given to virtue above knowledge or any other accomplishment. And in actions, those are most considerable, and will be heard with greatest approbation, which a person either did alone, or first, or wherein he had fewest associates; as likewise those which exceeded expectation, or were done for the advantage of others rather than his own. And further, as the last scene of a man's life generally commands the greatest regard, if any thing remarkable at that time was either said or done, it ought particularly to be mentioned. Nor should the manner of his death, or cause of it, if accompanied with any commendable circumstances, be omitted; as if he died in the service of his country, or in the pursuit of any other laudable design.

The third and last period relates to what followed after the death of the person. And here the public loss, and public honours conferred upon the deceased, are proper to be mentioned. Sepulchres, statues, and other monuments to perpetuate the memory of the dead at the expence of the public, were in common use both among the Greeks and Romans. But in the earliest times, as these honours were more rare, so they were less costly. For as in one age it was thought a sufficient reward for him who died in the defence of his country, to have his name cut in a marble inscription, with the cause of his death; so in others it was very common to see the statues of gladiators, and persons of the meanest rank, erected in public places. And therefore a judgment is to be formed of these things from the time, custom, and circumstances, of different nations; since the frequency of them renders them less honourable; and takes off from their evidence as the rewards of virtue. But, as Quintilian says, "Children are an honour to their parents, cities to their founders, laws to those who compiled them, arts to their inventors, and useful customs to the authors of them."

And this may suffice for the method of praising persons when we propose to follow the order of time, as Isocrates has done in his funeral oration upon Evagoras king of Salamis, and Pliny in his panegyric upon the emperor Trajan. But as this method is very plain and obvious, so it requires the more agreeable dress to render it delightful; lest otherwise it seem rather like a history than an oration: For which reason, we find, that epic poets, as Homer, Virgil, and others, begin with the middle of their story, and afterwards take a proper occasion to introduce what preceded, to diversify the subject, and give the greater the pleasure and entertainment to their readers. Invention.

2. The other method above hinted was, to reduce the discourse to certain general heads, without regarding the order of time. As if any one, in praising the elder Cato, should propose to do it, by showing that he was a most prudent senator, an excellent orator, and most valiant general; all which commendations are given him by Pliny. In like manner, the character of a good general may be comprised under four heads; skill in military affairs, courage, authority, and success: from all which Cicero commends Pompey. And agreeably to this method Suetonius has written the lives of the first twelve Cæsars.

But in the praising of persons, care should always be taken to say nothing that may seem fictitious or out of character, which may call the orator's judgment or integrity in question. It was not without cause, therefore, that Lysippus the statuary, as Plutarch tells us, blamed Apelles for painting Alexander the Great with thunder in his hand; which could never suit his character as a man, however he might boast of his divine descent: for which reason Lysippus himself made an image of him holding a spear, as the sign of a warrior. Light and trivial things in commendations are likewise to be avoided, and nothing mentioned but what may carry in it the idea of something truly valuable, and which the hearers may be supposed to wish for, and is proper to excite their emulation. These are the principal heads of praise with relation to men. In dispraise, the heads contrary to these are requisite; which being sufficiently clear from what has been said, need not particularly be insisted on.

II. We proceed therefore to the other part of the division, which respect *things*, as distinguished from persons. By which we are to understand all beings inferior to man, whether animate or inanimate; as likewise the habits and dispositions of men, either good or bad, when considered separately, and apart from their subjects, as arts and sciences, virtues and vices, with whatever else may be a proper subject for praise or dispraise. Some writers, indeed, have, for their own amusement and the diversion of others, displayed their eloquence in a jocose manner upon subjects of this kind. So Lucian has written in praise of a fly, and Synesius an elegant encomium upon baldness. Others, on the contrary, have done the like in a satirical way. Such is Seneca's apotheosis or consecration of the emperor Claudius; and the Mysopogon or beard-hater, written by Julian the emperor. Not to mention several modern authors, who have imitated them in such ludicrous compositions. But as to these things, and all of the like nature, the observation of Antony in Cicero seems very just: "That it is not necessary to reduce every subject we discourse upon to rules of art." For many are so trivial, as not to deserve it; and others so plain and evident of themselves, as not to require it. But since it frequently comes in the way both of orators and historians to describe countries, cities, and facts, we shall briefly mention the principal heads of invention proper to illustrate each of these.

Countries, then, may be celebrated from the pleasantness

Invention.

santness of their situation, the clemency and wholesomeness of the air, and goodness of the soil; to which last may be referred the springs, rivers, woods, plains, mountains, and minerals. And to all these may be added their extent, cities, the number and antiquity of the inhabitants; their policy, laws, customs, wealth, character for cultivating the arts both of peace and war; their princes, and other eminent men they have produced. Thus Pacatus has given us a very elegant description of Spain, in his panegyric upon the emperor Theodosius, who was born there.

Cities are praised from much the same topics as countries. And here, whatever contributes either to their defence or ornament ought particularly to be mentioned; as the strength of the walls and fortifications, the beauty and splendour of the buildings, whether sacred or civil, public or private. We have in Herodotus a very fine description of Babylon, which was once the strongest, largest, and most regular city in the world. And Cicero has accurately described the city of Syracuse, in the island Sicily, in one of his orations against Verres.

But facts come much oftener under the cognizance of an orator. And these receive their commendation from their honour, justice, or advantage. But in describing them, all the circumstances should be related in their proper order; and that in the most lively and affecting manner suited to their different nature. Livy has represented the demolition of Alba by the Roman army, which was sent thither to destroy it, through the whole course of that melancholy scene, in a style so moving and pathetic, that one can hardly forbear condoling with the inhabitants, upon reading his account.

But in discourses of this kind, whether of praise or dispraise, the orator should (as he ought indeed upon all occasions) well consider where, and to whom, he speaks. For wise men often think very differently both of persons and things from the common people. And we find that learned and judicious men are frequently divided in their sentiments, from the several ways of thinking to which they have been accustomed. Besides, different opinions prevail, and gain the ascendant, at different times. While the Romans continued a free nation, love of their country, liberty, and public spirit, were principles in the highest esteem among them. And therefore, when Cato killed himself, that he might not fall into the hands of Cæsar, and survive the liberty of his country, it was thought an instance of the greatest heroic virtue; but afterwards, when they had been accustomed to an arbitrary government, and the spirit of liberty was now lost, the poet Martial could venture to say,

Death to avoid 'tis madness sure to die.

A prudent orator therefore will be cautious of opposing any settled and prevailing notions of those whom he addresses, unless it be necessary; and then he will do it in the softest and most gentle manner.

Chap. III. *Of Arguments suited to Deliberative Discourses.*

This kind of discourses must certainly have been very ancient; since, doubtless, from the first beginning of men's conversing together, they deliberated upon their common interest, and offered their advice to each other. But neither those of the laudatory nor judicial kind could have been introduced, till mankind were settled in communities, and found it necessary to encourage virtue by public rewards, and bring vice under the restraint of laws. The early practice of suasory discourses appears from sacred writ, where we find, that when Moses was ordered upon an embassy into Egypt, he would have excused himself for want of eloquence. And Homer represents the Greeks at the siege of Troy, as flocking like a swarm of bees to hear their generals harangue them. Nor is this part of oratory less conspicuous for its usefulness to mankind, than for its antiquity; being highly beneficial either in councils, camps, or any societies of men. How many instances have we upon record, where the fury of an enraged multitude has been checked and appeased by the prudent and artful persuasion of some particular person? The story of Agrippa Menenius, when the commons of Rome withdrew from the senators, and retired out of the city, is too well known to need reciting. And how often have armies been animated and fired to the most dangerous exploits, or recalled to their duty, when ready to mutiny, by a moving speech of their general? many instances of which we find in history.

Invention.

17
Of deliberative discourses, and the arguments suited to them.

All deliberation respects something future, for it is in vain to consult about what is already past. The subject matter of it is, either things public or private, sacred or civil; indeed all the valuable concerns of mankind, both present and future, come under its regard. And the end proposed by this kind of discourses is chiefly profit or interest. But since nothing is truly profitable but what is in some respect good; and every thing which is good in itself may not in all circumstances be for our advantage; properly speaking, what is both good and profitable, or beneficial good, is the end here designed. And therefore, as it sometimes happens, that what appears profitable may seem to interfere with that which is strictly just and honourable; in such cases it is certainly most adviseable to determine on the safer side of honour and justice, notwithstanding some plausible things may be offered to the contrary. But where the dispute lies apparently between what is truly honest, and some external advantage proposed in opposition to it, all good men cannot but agree in favour of honesty. Such was the case of Regulus, who, being taken prisoner by the Carthaginians, was permitted to go to Rome upon giving his oath, that unless he could persuade the senate to set at liberty some young Carthaginian noblemen, then prisoners at Rome, in exchange for him, he should return again to Carthage. But Regulus, when he came to Rome, was so far from endeavouring to prevail with the senate to comply with the desire of the Carthaginians, that he used all his interest to dissuade them from hearkening to the proposal. Nor could the most earnest entreaties of his nearest relations and friends, nor any arguments they were able to offer, engage him to continue at Rome, and not return again to Carthage. He had then plainly in his view, on the one side, ease, security, affluence, honours, and the enjoyment of his friends; and on the other, certain death, attended with cruel torments. However, thinking the former

former not consistent with truth and justice, he chose the latter. And he certainly acted as became an honest and brave man, in choosing death, rather than to violate his oath. Though whether he did prudently in persuading the senate not to make the exchange, or they in complying with him, we shall leave others to determine. Now, when it proves to be a matter of debate, whether a thing upon the whole be really beneficial or not; as here arise two parts, advice and dissuasion, they will each require proper heads of argument. But as they are contrary to each other, he who is acquainted with one, cannot well be ignorant of the other. We shall therefore chiefly mention those proper for advice, from whence such as are suited to dissuade will easily be perceived. Now the principal heads of this kind are these following, which are taken from the nature and properties of the thing itself under consideration.

1. *Pleasure* often affords a very cogent argument in discourses of this nature. Every one knows what an influence this has upon the generality of mankind. Though, as Quintilian remarks, pleasure ought not of itself to be proposed as a fit motive for action in serious discourses, but when it is designed to recommend something useful, which is the case here. So, would any one advise another to the pursuit of polite literature, Cicero has furnished him with a very strong inducement to it from the pleasure which attends that study, when he says, "If pleasure only was proposed by these studies, you would think them an entertainment becoming a man of sense and a gentleman. For other pursuits neither agree with all times, all ages, nor all places; but these studies improve youth, delight old age, adorn prosperity, afford a refuge and comfort in adversity, divert us at home, are no hinderance abroad, sleep, travel, and retire with us into the country."

2. *Profit*, or advantage. This has no less influence upon many persons than the former; and when it respects things truly valuable, it is a very just and laudable motive. Thus Cicero, when he sends his *Book of Offices* to his son, which he wrote in Latin for his use, advises him to make the best advantage both of his tutor's instructions and the conversation at Athens, where he then was; but withal to peruse his philosophical treatises, which would be doubly useful to him, not only upon account of the subjects, but likewise of the language, as they would enable him to express himself upon those arguments in Latin, which before had only been treated of in Greek.

3. *Honour;* than which no argument will sooner prevail with generous minds, or inspire them with greater ardour. Virgil has very beautifully described Hector's ghost appearing to Æneas the night Troy was taken, and advising him to depart, from this motive of honour:

> O goddess-born, escape by timely flight
> The flames and horrors of this fatal night.
> The foes already have possess'd the wall;
> Troy nods from high, and totters to her fall.
> Enough is paid to Priam's royal name;
> More than enough to duty and to fame.
> If by a mortal hand my father's throne
> Cou'd be defended, 'twas by mine alone.

The argument here made use of to persuade Æneas to leave Troy immediately, is, that he had done all that could be expected from him, either as a good subject or brave soldier, both for his king and country; which were sufficient to secure his honour; and now there was nothing more to be expected from him when the city was falling, and impossible to be saved; which, could it have been preserved by human power, he himself had done it.

But although a thing considered in itself appear beneficial if it could be attained, yet the expediency of undertaking it may still be questionable; in which case the following heads, taken from the circumstances which attend it, will afford proper arguments to engage in it.

(1.) The *possibility* of succeeding may sometimes be argued, as one motive to this end. So Hannibal endeavoured to convince King Antiochus, that it was possible for him to conquer the Romans, if he made Italy the seat of the war; by observing to him, not only that the Gauls had formerly destroyed their city, but that he had himself defeated them in every battle he fought with them in that country.

(2.) But an argument founded upon *probability* will be much more likely to prevail. For in many affairs of human life, men are determined either to prosecute them or not, as the prospect of success appears more or less probable. Hence Cicero, after the fatal battle at Pharsalia, dissuades those of Pompey's party, with whom he was engaged, from continuing the war any longer against Cæsar; because it was highly improbable, after such a defeat, by which their main strength was broken, that they should be able to stand their ground, or meet with better success than they had before.

(3.) But further, since probability is not a motive strong enough with many persons to engage in the prosecution of a thing which is attended with considerable difficulties, it is often necessary to represent the facility of doing it, as a further reason to induce them to it. And therefore Cicero makes use of this argument to encourage the Roman citizens in opposing Mark Antony (who upon the death of Cæsar had assumed an arbitrary power), by representing to them, that his circumstances were then desperate, and that he might easily be vanquished.

(4.) Again, If the thing advised can be shown to be in any respect necessary, this will render the motive still much stronger for undertaking it. And therefore Cicero joins this argument with the former, to prevail with the Roman citizens to oppose Antony, by telling them, that "The consideration before them was, not in what circumstances they should live, but whether they should live at all, or die with ignominy and disgrace." This way of reasoning will sometimes prevail when all others prove ineffectual. For some persons are not to be moved till things are brought to an extremity, and they find themselves reduced to the utmost danger.

(5.) To these heads may be added the consideration of the *event*, which in some cases carries great weight with it. As when we advise to the doing of a thing from this motive, That whether it succeed or not, it will yet be of service to undertake it. So after the great victory gained by Themistocles over the Persian fleet at the

Invention.

the straits of Salamis, Mardonius advised Xerxes to return into Asia himself, lest the report of his defeat should occasion an insurrection in his absence: but to leave behind him an army of 300,000 men under his command; with which, if he should conquer Greece, the chief glory of the conquest would redound to Xerxes; but if the design miscarried, the disgrace would fall upon his generals.

These are the principal heads which furnish the orator with proper arguments in giving advice. Cicero, in his oration for the Manilian law, where he endeavours to persuade the Roman people to choose Pompey for their general in the Mithridatic war, reasons from three of these topics, into which he divides his whole discourse; namely, the necessity of the war, the greatness of it, and choice of a proper general.—Under the first of these he shows, that the war was necessary, from four considerations; the honour of the Roman state, the safety of their allies, their own revenues, and the fortunes of many of their fellow citizens, which were all highly concerned in it, and called upon them to put a stop to the growing power of King Mithridates, by which they were all greatly endangered. So that this argument is taken from the head of *necessity*. The second, in which he treats of the greatness of the war, is founded upon the topic of *possibility*. For though he shows the power of Mithridates to be very great, yet not so formidable, but that he might be subdued; as was evident from the many advantages Lucullus had gained over him and his associates. In the third head, he endeavours to prevail with them to intrust the management of the war in the hands of Pompey, whom he describes as a consummate general, for his skill in military affairs, courage, authority, and success; in all which qualities he represents him as superior to any other of their generals whom they could at that time make choice of. The design of all which was, to persuade them, that they had very good reason to hope for success, and a happy event of the war, under his conduct. So that the whole force of his reasoning under this head is drawn from *probability*. These are the three general topics which make up that fine discourse. Each of which is indeed supported by divers other arguments and considerations, which will be obvious in perusing the oration itself, and therefore need not be here enumerated. On the contrary, in another oration he endeavours to dissuade the senate from consenting to a peace with Mark Antony, because it was base, dangerous, and impracticable.

But no small skill and address are required in giving advice. For since the tempers and sentiments of mankind, as well as their circumstances, are very different and various; it is often necessary to accommodate the discourse to their inclinations and opinions of things. And therefore the weightiest arguments are not always the most proper and fittest to be used on all occasions. Cicero, who was an admirable master of this art, and knew perfectly well how to suit what he said to the taste and relish of his hearers, in treating upon this subject, distinguishes mankind into two sorts; the ignorant and unpolished, who always prefer profit to honour; and such as are more civilized and polite, who prefer honour and reputation to all other things.—Wherefore they are to be moved by these different views: Praise, glory, and virtue, influence the one: while the other is only to be engaged by a prospect of gain and pleasure. Besides, it is plain, that the generality are much more inclined to avoid evils than to pursue what is good: and to keep clear of scandal and disgrace, than to practise what is truly generous and noble. Persons likewise of a different age act from different principles; young men for the most part view things in a different light from those who are older and have had more experience, and consequently are not to be influenced by the same motives.

Chap. IV. *Of Arguments suited to Judicial Discourses.*

18

Of judicial discourses and the arguments suited to them.

In *judicial* controversies there are two parties; the plaintiff or prosecutor, and the defendant or person charged. The subject of them is always something past. And the end proposed by them Cicero calls *equity*, or *right* and *equity*; the former of which arises from the laws of the country, and the latter from reason and the nature of things. For at Rome the prætors had a court of equity, and were empowered, in many cases relating to property, to relax the rigour of the written laws. But as this subject is very copious, and causes may arise from a great variety of things, writers have reduced them to three heads, which they call *states*, to some one of which all judicial proceedings may be referred; namely, *whether a thing is*, *what it is*, or *how it is*. By the *state* of a cause, therefore, is meant the principal question in dispute, upon which the whole affair depends. Which, if it stops in the first inquiry, and the defendant denies the fact, the state is called *conjectural*; but if the fact be acknowledged, and yet denied to be what the adversary calls it, it is termed *definitive*; but if there is no dispute either about the fact or its name, but only the justice of it, it is called the *state of quality*: as was shown more largely before (see N° 15.). But we there considered these states only in a general view, and deferred the particular heads of argument proper for each of them to this *judicial* kind of discourses; where they most frequently occur, and from which examples may easily be accommodated to other subjects.

All judicial causes are either *private* or *public*. Those are called *private*, which relate to the right of particular persons; and they are likewise called *civil* causes, as they are conversant about matters of property.—*Public* causes are those which relate to public justice and the government of the state; which are also called *criminal*, because by them crimes are prosecuted, whether capital, or those of a less heinous nature. We shall take the heads of the arguments only from this latter kind, because they are more copious, and easy to be illustrated by examples; from which such as agree to the former, namely, *civil* causes, will sufficiently appear.

1. The *conjectural* state. When the accused person denies the fact, there are three things which the prosecutor has to consider; whether he *would* have done it, whether he *could*, and whether he *did* it. And hence arise three topics; from the *will*, the *power*, and the *signs* or circumstances which attended the action. The affections of the mind discover the will; as passion, an old grudge, a desire of revenge, a resentment

Invention.

sentiment of an injury, and the like. Therefore Cicero argues from Clodius's hatred of Milo, that he designed his death; and from thence infers, that he was the aggressor in the combat between them, wherein Clodius was killed. This is what he principally endeavours to prove, and comes properly under this state: for Milo owned that he killed him, but alleged that he did it in his own defence. So that in regard to this point, which of them assaulted the other? the charge was mutual. The prospect of advantage may also be alleged to the same purpose. Hence it is said of L. Cassius, that whenever he sat as judge in a case of murder, he used to advise and move the court to examine to whom the advantage arose from the death of the deceased. And Cicero puts this to Antony concerning the death of Cæsar. "If any one (says he) should bring you upon trial, and use that saying of Cassius *Cui bono?* 'Who got by it?' look to it, I beseech you, that you are not confounded. To these arguments may be added, hope of impunity, taken either from the circumstances of the accused person, or of him who suffered the injury. For persons, who have the advantage of interest, friends, power, or money, are apt to think they may easily escape; as likewise such who have formerly committed other crimes with impunity. Thus Cicero represents Clodius as hardened in vice, and above all the restraint of laws, from having so often escaped punishment upon committing the highest crimes. On the contrary, such a confidence is sometimes raised from the condition of the injured party, if he is indigent, obscure, timorous, or destitute of friends; much more if he has an ill reputation, or is loaded with popular hatred and resentment. It was this presumption of the obscurity of Roscius, who lived in the country, and his want of interest at Rome, which encouraged his accusers to charge him with killing his father, as Cicero shows in his defence of him. Lastly, The temper of a person, his views, and manner of life, are considerations of great moment in this matter. For persons of bad morals, and such as are addicted to vice, are easily thought capable of committing any wickedness. Hence Sallust argues from the evil disposition and vicious life of Catiline, that he affected to raise himself upon the ruins of his country.—The second head is the *power* of doing a thing: and there are three things which relate to this, the *place*, the *time*, and *opportunity*. As if a crime is said to have been committed in a private place, where no other person was present; or in the night; or when the injured person was unable to provide for his defence. Under this head may likewise be brought in the circumstances of the persons; as if the accused person was stronger, and so able to overpower the other; or more active, and so could easily make his escape. Cicero makes great use of this topic in the case of Milo, and shows, that Clodius had all the advantages of *place*, *time*, and *opportunity*, to execute his design of killing him. The third head comprehends the *signs* and circumstances which either preceded, accompanied, or followed, the commission of the fact. So threats, or the accused person being seen at or near the place before the fact was committed, are circumstances that may probably precede murder; fighting, crying out, bloodshed, are such as accompany it; paleness, trembling, inconsistent answers, hesitation, or faltering of the speech, something found upon the person accused which belonged to the deceased, are such as follow it. Thus Cicero proves, that Clodius had threatened the death of Milo, and given out that he should not live above three days at the farthest.—These arguments, taken from conjectures, are called *presumptions*, which, though they do not directly prove that the accused person committed the fact with which he is charged; yet when, laid together, they appeared very strong, sentence by the Roman law might sometimes be given upon them, to convict him.

These are the topics from which the prosecutor takes his arguments. Now the business of the defendant is to invalidate these. Therefore such as are brought from the *will*, he either endeavours to show are not true, or so weak as to merit very little regard. And he refutes those taken from the *power*, by proving that he wanted either opportunity or ability: as, if he can show, that neither the place nor time insisted on was at all proper; or that he was then in another place. In like manner he will endeavour to confute the *circumstances*, if they cannot be directly denied, by showing that they are not such as do necessarily accompany the fact, but might have proceeded from other causes, though nothing of what is alleged had been committed; and it will be of great service to assign some other probable cause. But sometimes the defendant does not only deny that he did the fact, but charges it upon another. Thus Cicero, in his oration for Roscius, not only defends him from each of these three heads, but likewise charges the fact upon his accusers.

2. The *definitive* state, which is principally concerned in defining and fixing the name proper to the fact: though orators seldom make use of exact definitions, but commonly choose larger descriptions, taken from various properties of the subject or thing described.

The heads of argument in this state are much the same to both parties. For each of them defines the fact his own way, and endeavours to refute the other's definition. We may illustrate this by an example from Quintilian: "A person is accused of sacrilege, for stealing money out of a temple, which belonged to a private person." The fact is owned; but the question is, *Whether it be properly sacrilege?* The prosecutor calls it so, because it was taken out of a temple. But since the money belonged to a private person, the defendant denies it to be sacrilege, and says it is only simple theft. Now the reason why the defendant uses this plea, and insists upon the distinction, is, because by the Roman law the penalty of theft was only four times the value of what was stolen? whereas sacrilege was punished with death. The prosecutor then forms his definition agreeable to his charge, and says, "To steal any thing out of a sacred place is sacrilege." But the defendant excepts against this definition, as defective; and urges, that it does not amount to sacrilege, unless the thing stolen was likewise sacred. And this case might once, perhaps, have been a matter of controversy, since we find it expressly determined in the Pandects, that "An action of sacrilege should not lie, but only of theft, against any one who should steal the goods of private persons deposited in a temple."

The second thing is the proof brought by each party to support his definition; as in the example given.

Invention.

given us by Cicero, of one "who carried his cause by bribery, and was afterwards prosecuted again upon an action of prevarication." Now, if the defendant was cast upon this action, he was, by the Roman law, subjected to the penalty of the former prosecution. Here the prosecutor defines prevarication to be, *Any bribery or corruption in the defendant, with a design to pervert justice*. The defendant, therefore, on the other hand, restrains it to *bribing only the prosecutor*.

And if this latter sense agrees better with the common acceptation of the word, the prosecutor in the third place pleads the intention of the law, which was to comprehend all bribery in judicial matters under the term of *prevarication*. In answer to which the defendant endeavours to show, either from the head of contraries, that a real prosecutor and a prevaricator are used as opposite terms in the law; or from the etymology of the word, that a prevaricator denotes one who pretends to appear in the prosecution of a cause, while in reality he favours the contrary side; and consequently, that money given for this end only can, in the sense of the law, be called *prevarication*.

Lastly, The prosecutor pleads, that it is unreasonable that he who does not deny the fact should escape by a cavil about a word. But the defendant insists upon his explication as agreeable to the law; and says, the fact is misrepresented and blackened, by affixing to it a wrong name.

3. The third state is that of *quality*, in which the dispute turns upon the justice of an action. And here the defendant does not deny he did the thing he is charged with; but asserts it to be right and equitable, from the circumstances of the case, and the motives which induced him to it.

And, first, He sometimes alleges, the reason of doing it was in order to prevent some other thing of worse consequence, which would otherwise have happened. We have an instance of this in the life of Epaminondas, who, with two other generals joined in the command with him, marched the Theban army into Peloponnesus against the Lacedæmonians; but by the influence of a contrary faction at home, their commissions were superseded, and other generals sent to command the army. But Epaminondas, being sensible that, if he obeyed this order at that time, it would be attended with the loss of the whole army, and consequently the ruin of the state, refused to do it; and having persuaded the other generals to do the like, they happily finished the war in which they were engaged; and upon their return home, Epaminondas taking the whole matter upon himself, on his trial was acquitted. The arguments proper in this case are taken from the justice, usefulness, or necessity, of the action. The accuser therefore will plead, that the fact was not just, profitable, nor necessary, considered either in itself or comparatively with that for the sake of which it is said to have been done: and he will endeavour to show, that what the defendant assigns for the reason of what he did might not have happened as he pretends. Besides, he will represent of what ill consequence it must be, if such crimes go unpunished. The defendant, on the other hand, will argue from the same heads, and endeavour to prove the fact was just, useful, or necessary. And he will further urge, that no just estimate can be made of any action, but from the circumstances which attend it; as the design, occasion, and motives for doing it, which he will represent in the most favourable light to his own cause, and endeavour to set them in such a view, as to induce others to think they could not but have done the same in the like circumstances.

Again, The cause of an action is sometimes charged by the defendant upon the party who received the damage, or some other person, who either made it necessary, or enjoined him to do it. The first of these was Milo's plea for killing Clodius, because he assaulted him with a design to take away his life. Here the fact is not denied, as in the case of Roscius above mentioned, under the *conjectural* state; but justified from the reason of doing it. For that an assassin might be justly killed, Cicero shows both from law and reason. The accuser, therefore, in such a case, will, if there be room for it, deny the truth of this allegation. So the friends of Clodius affirmed that Milo was the aggressor, and not Clodius; which Cicero, in his defence of Milo, principally labours to refute. In the second case, the prosecutor will say, No one ought to offend because another has offended first; which defeats the course of public justice, renders the laws useless, and destroys the authority of the magistrate. The defendant, on the other hand, will endeavour to represent the danger and necessity of the case, which required an immediate remedy, and in that manner; and urges, that it was vain and impracticable to wait for redress in the ordinary way, and therefore no ill consequence can arise to the public. Thus Cicero, in defending Sextius, who was prosecuted for a riot in bringing armed men into the forum, shows that his design was only to repel force with force; which was then necessary, there being no other means left for the people to assemble, who were excluded by a mob of the contrary party. Of the third case we have also an example in Cicero, who tells us, that, "in making a league between the Romans and Samnites, a certain young nobleman was ordered by the Roman general to hold the swine (designed for a sacrifice); but the senate afterwards disapproving the terms, and delivering up their general to the Samnites, it was moved, Whether this young man ought not likewise to be given up." Those who were for it might say, that, to allege the command of another, is not a sufficient plea for doing an ill action; and this is what the Roman law now expressly declares. But in answer to that, it might be replied, that it was his duty to obey the command of his general, who was answerable for his own orders, and not those who were obliged to execute them; and therefore, to give up this young nobleman would be to punish one person for the fault of another.

Lastly, A fact is sometimes rather excused than defended, by pleading that it was not done designedly, or with any ill intent. This is called *concession;* and consists of two parts, *apology* and *entreaty*. The former represents the matter as the effect of inadvertency, chance, or necessity. Aristotle gives us an example of inadvertency or imprudence in a woman at Athens, who gave a young man a love potion, which killed him; for which she was tried, but acquitted: though afterwards this was made criminal by the Roman law. The case of

Invention.

of Adrastus, as related by Herodotus, is an instance of chance; who being intrusted by Crœsus with the care of his son, as they were hunting, killed him accidentally with a javelin which he threw at a boar. It is necessity, when a person excuses his making a default, from stress of weather, sickness, or the like. Thus Cicero pleaded his illness, contracted by the fatigue of a long journey, as an excuse for not appearing in the senate upon the summons of Mark Antony, who threatened to oblige him to it by pulling his house down. But what the defendant here attributes to inadvertency, chance, or necessity, the opposite party will attribute to design, negligence, or some other culpable reason; and represent it as a matter injurious to the public to introduce such precedents; and also produce instances, if that can be done, where the like excuses have not been admitted. On the other hand, the defendant will insist on his innocence, and show the hardship and severity of judging men's actions rather by the event, than from the intention: that such a procedure makes no difference between the innocent and the guilty; but must necessarily involve many honest men in ruin and destruction, discourage all virtuous and generous designs, and turn greatly to the prejudice of human society. He will also consider the instances alleged by the accuser, and show the difference between them and his own case. And, lastly, He will have recourse to entreaty, or a submissive address to the equity and clemency of the court, or party offended, for pardon; as Cicero has done in his oration to Cæsar, in favour of Ligarius.

Chap. V. *Of the Character and Address of an Orator.*

19 Propriety of manners necessary in an orator, both with respect to character and address.

Having considered and explained the first part of Invention, which furnishes the orator with such arguments as are necessary for the proof of his subject, we are next to show what are the proper means to conciliate the minds of his hearers; to gain their affection; and to recommend both himself, and what he says, to their good opinion and esteem. For the parts of invention are commonly thus distinguished; that the first respects the *subject* of the discourse, the second the *speaker*, and the third the *hearers*. Now the second of these, what we have at present to explain, is by Quintilian called a *propriety of manners*. And in order to express this it is necessary, as he tells us, "that every thing apper easy and natural, and the disposition of the speaker be discovered by his words." We may form an easy conception of this from the conduct of such persons as are most nearly concerned in each others welfare. As when relations or friends converse together upon any affairs of importance, the temper and disposition of the speaker plainly shows itself by his words and manner of address. And what nature here directs to without colouring or disguise, the orator is to endeavour to perform by his art. Though indeed, if what a person says be inconsistent with his usual conduct and behaviour at other times, he cannot expect it should gain much credit, or make any deep impression upon his hearers; which may be one reason why the ancient rhetoricians make it so necessary a qualification in an orator, that he be a good man; since he should always be consistent with himself, and as we say, talk in character. And therefore it is highly requisite, that he should not only gain the skill of assuming those qualities which the nature and circumstances of his discourse require him to express; but, likewise, that he should use his utmost endeavours to get the real habits implanted in his mind. For as by this means they will be always expressed with greater ease and facility; so, by appearing constantly in the course of his life, they will have more weight and influence upon particular occasions.

Invention.

Now there are four qualities, more especially suited to the character of an orator, which should always appear in his discourses, in order to render what he says acceptable to his hearers; and these are *wisdom*, *integrity*, *benevolence*, and *modesty*.

1. *Wisdom* is necessary; because we easily give into those whom we esteem wiser and more knowing than ourselves. Knowledge is very agreeable and pleasant to all, but few make very great improvements in it; either by reason they are employed in other necessary affairs, and the mind of man cannot attend to many things at once; or because the way to knowledge at first is hard and difficult, so that persons either do not care to enter upon the pursuit of it, or, if they do, they are many times soon discouraged, and drop it, for want of sufficient resolution to surmount its difficulties. Such, therefore, as either cannot, or do not care to give themselves the trouble of examining into things themselves, must take up with the representation of others: and it is an ease to them to hear the opinion of persons whom they esteem wiser than themselves. No one loves to be deceived; and those who are fearful of being misled, are pleased to meet with a person in whose wisdom, as they think, they can safely trust. The character of wisdom therefore is of great service to an orator, since the greater part of mankind are swayed by authority rather than arguments.

2. But this of itself is not sufficient, unless the opinion of *integrity* be joined with it. Nay so far from it, that the greater knowledge and understanding a man is supposed to have, unless he likewise have the character of an honest man, he is often the more suspected. For knowledge without honesty, is generally thought to dispose a person, as well as qualify him, to deceive.

3. And to both these qualities the appearance of kindness and *benevolence* should likewise be added. For though a person have the reputation of wisdom and honesty, yet if we apprehend he is either not well affected to us, or at least regardless of our interest, we are in many cases apt to be jealous of him. Mankind are naturally swayed by their affections, and much influenced through love or friendship; and therefore nothing has a greater tendency to induce persons to credit what is said, than intimations of affection and kindness. The best orators have been always sensible what great influence the expressions of kindness and benevolence have upon the minds of others, to induce them to believe the truth of what they say; and therefore they frequently endeavour to impress them with the opinion of it. Thus Demosthenes begins his celebrated oration for Ctesiphon. "It is my hearty prayer (says he) to all the deities, that this my defence may be received by you with the same affection which I have always expressed for you and your city." And it is a very fine image of it which we have in Cicero, where,

Invention. where, in order to influence the judges in favour of Milo, he introduces him speaking thus, as became a brave man, and a patriot, even upon the supposition he should be condemned by them: "I bid my fellow citizens adieu: may they continue flourishing and prosperous; may this famous city be preserved, my most dear country, however it has treated me; may my fellow citizens enjoy peace and tranquillity without me, since I am not to enjoy it with them, though I have procured it for them: I will withdraw, I will be gone."

4. *Modesty*. It is certain, that what is modestly spoken is generally better received than what carries in it an air of boldness and confidence. Most persons, though ignorant of a thing, do not care to be thought so; and would have some deference paid to their understanding. But he who delivers himself in an arrogant and assuming way seems to upbraid his hearers with ignorance, while he does not leave them to judge for themselves, but dictates to them, and as it were demand their assent to what he says; which is certainly a very improper method to win upon them. For not a few, when convinced of an error in such a way, will not own it; but will rather adhere to their former opinion, than seem forced to think right, when it gives another the opportunity of a triumph. A prudent orator therefore will behave himself with modesty, that he may not seem to insult his hearers; and will set things before them in such an engaging manner, as may remove all prejudice either from his person or what he asserts. This is particularly necessary in the exordium of a discourse. If the orator set out with an air of arrogance and ostentation, the self-love and pride of the hearers will be presently awakened, and will follow him with a very suspicious eye throughout all his progress. His modesty should discover itself not only in his expressions at the beginning, but in his whole manner; in his looks, in his gestures, in the tone of his voice. Every auditory take in good part those marks of respect and awe, which are paid to them by one who addresses them. Indeed the modesty of an introduction should never betray any thing mean or abject. It is always of great use to an orator, that together with modesty and deference to his hearers, he should show a certain sense of dignity, arising from a persuasion of the justice or importance of the subject of which he is to speak. For to speak timorously, and with hesitation, destroys the credit of what is offered; and so far as the speaker seems to distrust what he says himself, he often induces others to do the like.

But, as has been said already, great care is to be taken that these characters do not appear feigned and counterfeit. For what is fictitious can seldom be long concealed. And if this be once discovered, it makes all that is said suspected, how specious soever it may otherwise appear.

It is further necessary, that the orator should know the world, and be well acquainted with the different tempers and dispositions of mankind. Nor indeed can any one reasonably hope to succeed in this province, without well considering the circumstances of time and place, with the sentiments and dispositions of those to whom he speaks; which, according to Aristotle, may be distinguished four ways, as they discover themselves by the several *affections*, *habits*, *ages*, and *fortunes*, of mankind. And each of these requires a different conduct and manner of address.

The *affections* denote certain emotions of the mind, which, during their continuance, give a great turn to the disposition. For love prompts to one thing, and hatred to another. The like may be said of anger, lenity, and the rest of them.

Persons differ likewise according to the various *habits* of their mind. So a just man is inclined one way, and an unjust man another; a temperate man to this, and an intemperate man to the contrary.

And as to the several *ages* of men, Aristotle has described them very accurately; and how persons are differently affected in each of them. He divides the lives of men, considered as hearers, into three stages; youth, middle age, and old age.—Young men, he says, have generally strong passions, and are very eager to obtain what they desire, but are likewise very mutable, so that the same thing does not please them long. They are ambitious of praise, and quick in their resentments: lavish of their money, as not having experienced the want of it: frank and open, because they have not often been deceived; and credulous for the same reason. They readily hope the best, because they have not suffered much, and are therefore not so sensible of the uncertainty of human affairs; for which reason they are likewise more easily deceived. They are modest, from their little acquaintance with the world. They love company and cheerfulness, from the briskness of their spirits. In a word, they generally exceed in what they do; love violently, hate violently, and act in the same manner through the rest of their conduct.—The disposition of old men is generally contrary to the former. They are cautious, and enter upon nothing hastily; having in the course of many years been often imposed upon; having often erred, and experienced the prevailing corruption of human affairs; for which reason they are likewise suspicious, and moderate in their affections either of love or hatred. They pursue nothing great and noble, and regard only the necessaries of life. They love money; having learned by experience the difficulty of getting it, and how easily it is lost. They are fearful, which makes them provident. Commonly full of complaints, from bodily infirmities, and a deficiency of spirits. They please themselves rather with the memory of what is past, than with any future prospect; having so short a view of life before them, in comparison of what is already gone: for which reason also, they love to talk of things past; and prefer them to what is present, of which they have but little relish, and know they must shortly leave them. They are soon angry, but not to excess. Lastly, They are compassionate, from a sense of their own infirmities, which makes them think themselves of all persons most exposed.—Persons of a middle age, betwixt these two extremes, as they are freed from the rashness and temerity of youth, so they have not yet suffered the decays of old age. Hence in every thing they generally observe a better conduct. They are neither so hasty in their assent as the one, nor so minutely scrupulous as the other, but weigh the reasons of things. They regard a decency in their actions; are careful and industrious; and as they undertake what appears just and laudable upon better and more deliberate consideration than young persons, so they pursue them

Invention.

them with more vigour and resolution than those who are older.

As to the different *fortunes* of mankind, they may be considered as noble, rich, or powerful; and the contrary to these. Those of high birth, and noble extraction, are generally very tender of their honour, and ambitious to increase it; it being natural for all persons to desire an addition to those advantages of which they find themselves already possessed. And they are apt to consider all others as much their inferiors, and therefore expect great regard and deference should be shown them.—Riches, when accompanied with a generous temper, command respect, from the opportunities they give of being useful to others; but they usually elate the mind, and occasion pride. For as money is commonly said to command all things, those who are possessed of a large share of it, expect others should be at their beck: since they enjoy that which all desire, and which most persons make the main pursuit of their lives to obtain.—But nothing is more apt to swell the mind than power. This is what all men naturally covet, even when perhaps they would not use it. But the views of such persons are generally more noble and generous than of those who only pursue riches and the heaping up of money. A state contrary to these gives a contrary turn of mind; and in lower life, persons dispositions usually differ according to their station and circumstances. A citizen and a courtier, a merchant and a soldier, a scholar and a peasant, as their pursuits are different, so is generally their turn and disposition of mind.

It is the orator's business, therefore, to consider these several characters and circumstances of life, with the different bias and way of thinking they give to the mind; that he may so conduct himself in his behaviour and manner of speaking, as will render him most acceptable, and gain him the good esteem of those whom he addresses.

Chap. VI. *Of the Passions.*

20

It is necessary, though difficult, to engage the interest of the passions.

As it is often highly necessary for the orator, so it requires his greatest skill, to engage the passions in his interest. Quintilian calls this *the soul and spirit of his art.* And, doubtless, nothing more discovers its empire over the minds of men, than this power to excite, appease, and sway their passions, agreeably to the design of the speaker. Hence we meet with the characters of *admirable*, *divine*, and other splendid titles, ascribed to eloquence by ancient writers. It has indeed been objected by some, that whatever high encomiums may be given of this art by the admirers of it, it is however disingenuous to deceive and impose upon mankind, as those seem to do, who, by engaging their passions, give a bias to their minds, and take them off from the consideration of the truth; whereas every thing should be judged of from the reasons brought to support it, by the evidence of which it ought to stand or fall. But in answer to this, it may be considered that all fallacy is not culpable. We often deceive children for their good; and physicians sometimes impose on their patients to come at a cure. And why, therefore, when persons will not be prevailed with by reason and argument, may not an orator endeavour, by engaging their passions, to persuade them to that which is for their advantage? Besides, Quintilian makes it a necessary qualification of an orator, that he be an honest man, and one who will not abuse his art. But since those of a contrary character will leave no methods untried in order to carry their point, it is requisite for those who design well to be acquainted with all their arts, without which they will not be a match for them; as in military affairs it is highly advantageous for the general of an army to get himself informed of all the designs and stratagems of the enemy, in order to counteract them. Indeed this part of oratory is not necessary at all times, nor in all places. The better prepared persons are to consider truth, and act upon the evidence of it, the less occasion there appears for it. But the greater part of mankind either do not duly weigh the force of arguments, or refuse to act agreeably to their evidence. And where this is the case, that persons will neither be convinced by reason, nor moved by the authority of the speaker, the only way left to put them upon action, is to engage their passions. For the passions are to the mind, what the wind is to a ship: they move, and carry it forward; and he who is without them, is in a manner without action, dull and lifeless. There is nothing great or noble to be performed in life wherein the passions are not concerned. The Stoics, therefore, who were for eradicating the passions, both maintained a thing in itself impossible, and which, if it was possible, would be of the greatest prejudice to mankind. For while they appeared such zealous assertors of the government of reason, they scarce left it any thing to govern; for the authority of reason is principally exercised in ruling and moderating the passions, which, when kept in a due regulation, are the springs and motives to virtue. Thus hope produces patience, and fear industry; and the like might be shown of the rest. The passions therefore are not to be extirpated, as the Stoics asserted, but put under the direction and conduct of reason. Indeed where they are ungovernable, and resist the controul of reason, they are, as some have fitly called them, *diseases of the mind;* and frequently hurry men to vice, and the greatest misfortunes of life: just as the wind, when it blows moderately, carries on the ship; but if it be too boisterous and violent, may overset her. The charge therefore brought against this art, for giving rules to influence the passions, appears groundless and unjust; since the proper use of the passions is, not to hinder the exercise of reason, but engage men to act agreeably to reason. And if an ill use be sometimes made of this, it is not the fault of the art but of the artist.

We shall here consider the passions, as they may be separately referred, either to *demonstrative*, *deliberative*, or *judicial* discourses; though they are not wholly confined to any of them.

21

Of the passions which may be referred to demonstrative discourses.

1. To the *demonstrative* kind, we may refer *joy* and *sorrow*, *love* and *hatred*, *emulation* and *contempt*.

Joy is an elation of the mind, arising from a sense of some present good. Such a reflection naturally creates a pleasant and agreeable sensation, which ends in a delightful calm and serenity. This is heightened by a description of former evils, and a comparison between them and the present felicity. Thus Cicero endeavours to excite in the minds of his fellow citizens the highest sense of joy and delight at Catiline's departure from Rome, by representing to them the imminent danger which threatened

Invention.

threatened both them and the city while he continued among them.

Sorrow, on the contrary, is an uneasiness of mind arising from a sense of some present evil. This passion has generally a place in funeral discourses. And it may be heightened, like the former, by comparison, when any past happiness is set in opposition to a present calamity. Hence Cicero aggravates the sorrow at Rome occasioned by the death of Metellus, from his character, and great services to the public, while living.

Love excites us to esteem any person for some excellency, and to do him all the good in our power. It is distinguished from *friendship*, which is mutual; and therefore love may continue where friendship is lost; that is, the affection may remain on one side. And when we assist a person from no other motive but to do him a kindness, Aristotle calls this *good-will*. Love takes its rise from a variety of causes. Generosity, benevolence, integrity, gratitude, courtesy, and other social virtues, are great incitements to love any one endued with such qualities. And persons generally love those who are of a like disposition with themselves, and pursue the same views. It is therefore the chief art of a flatterer to suit himself in every thing to the inclination of the person whose good graces he courts. When the orator would excite this affection towards any person, it is proper to show, that he is possessed of at least some, if not all, of these agreeable qualities. When the conspirators with Catiline were to be brought to justice, Cicero was very sensible of the envy he should contract on that account, and how necessary it was for him to secure the love of the Roman senate for his support and protection in that critical juncture. And this he endeavours to do in his fourth oration against Catiline, by representing to them in the most pathetic manner, that all the labours he underwent, the difficulties he conflicted with, and the dangers to which he was exposed on that account, were not for his own sake, but for their safety, quiet, and happiness.

Hatred is opposed to love, and produced by the contrary dispositions. And, therefore, persons hate those who never did them any injury, from the ill opinion they have of their base and vicious inclinations. So that the way to excite this passion is by showing that any one has committed some heinous fact with an ill intent. And the more nearly affected persons are by such actions, in what they account of the greatest concern, the higher in proportion their hatred rises. Since life, therefore, is esteemed the most valuable good, Cicero endeavours to render Mark Antony odious to the citizens of Rome, by describing his cruelty.

Emulation is a disquiet, occasioned by the felicity of another, not because he enjoys it, but because we desire the like for ourselves. So that this passion is in itself good and laudable, as it engages men to pursue those things which are so. For the proper objects of emulation are any advantages of mind, body, or fortune, acquired by study or labour.

Emulation therefore is excited by a lively representation of any desirable advantages which appear to be attainable, from the example of others who are or have been possessed of them. But where the felicity of another occasions an uneasiness, not from the want of it, but, because he enjoys it, this passion is called *envy*, which the ancients describe as a hideous monster, feeding upon itself, and being its own tormentor. Aristotle justly observes, that it most usually affects such persons as were once upon a level with those they envy. For most men naturally think so well of themselves, that they are uneasy to see those who were formerly their equals advanced above them. But as this is a base and vicious passion, the orator is not to be informed how to excite it, but how to lessen or remove it. And the method prescribed by Cicero for this purpose is, to show that the things which occasioned it have not happened to the envied person undeservedly, but are the just reward of his industry or virtue; that he does not so much convert them to his own profit or pleasure, as to the benefit of others; and that the same pains and difficulties are necessary to preserve them with which they were at first acquired.

Contempt is opposed to *emulation*, and arises from misconduct in things not of themselves vicious: As where a person either acts below his station and character, or affects to do that for which he is not qualified. Thus Cicero endeavours to expose Cæcilius, and bring him into contempt of the court, for pretending to rival him in the accusation of Verres, for which he was altogether unfit.

22
Of the passions which may be referred to deliberative discourses.

2. To *deliberative* discourses may be referred *fear*, *hope*, and *shame*.

Fear arises from the apprehension of some great and impending evil. For the greatest evils, while they appear at a distance, do not much affect us. Such persons occasion fear, who are possessed of power, especially if they have been injured, or apprehend so: likewise those who are addicted to do injuries, or who bear us an ill will. And the examples of others, who have suffered in a like case, or from the same persons, help to excite fear. From the circumstances therefore either of the thing or person, it will not be difficult for the orator to offer such arguments as may be proper to awaken this passion. So Demosthenes, when he would persuade the Athenians to put themselves in a condition of defence against King Philip, enumerates the several acts of hostility already committed by him against the neighbouring states. And because men's private concerns generally more affect them than what relates to the public, it is proper sometimes to show the necessary connexion these have with each other, and how the ruin of one draws the other after it.

The contrary passion to *fear* is *hope*; which arises either from a prospect of some future good, or the apprehension of safety from those things which occasion our fear. Young persons are easily induced to hope the best, from the vigour of their spirits. And those who have escaped former dangers are encouraged to hope for the like success for the future. The examples of others also, especially of wise and considerate men, have often the same good effect. To find them calm and sedate when exposed to the like dangers, naturally creates confidence and the hopes of safety. But nothing gives persons such firmness and steadiness of mind under the apprehension of any difficulties, as a consciousness of their own integrity and innocence. Let dangers come from what quarter they will, they are best prepared

Invention. prepared to receive them. They can calmly view an impending tempest, observe the way of its approach, and prepare themselves in the best manner to avoid it. In Cicero's oration for the Manilian law, he encourages the Roman citizens to hope for success against Mithridates, if they chose Pompey for their general, from the many instances of his former successes which he there enumerates.

Shame arises from the apprehension of those things that hurt a person's character. *Modesty* has been wisely implanted in mankind by the great Author of nature, as a guardian of virtue, which ought for this reason to be cherished with the greatest care; because, as Seneca has well observed, "if it be once lost, it is scarce ever to be recovered." Therefore the true cause or foundation of shame is any thing base or vicious; for this wounds the character, and will not bear reflection. And he must arrive at no small degree of insensibility, who can stand against such a charge, if he be conscious to himself that it is just. Therefore, to deter persons from vicious actions, or to expose them for the commission of them, the orator endeavours to set them in such a light as may most awaken this passion, and give them the greatest uneasiness by the reflection. And because the bare representation of the thing itself is not always sufficient for this purpose, he sometimes enforces it by enlarging the view, and introducing those persons as witnesses of the fact for whom they are supposed to have the greatest regard. Thus, when some of the Athenians, in an arbitration about certain lands which had been referred to them by the contending parties, proposed it as the shortest way of deciding the controversy, to take the possession of them in their own hands; Cydias, a member of the assembly, to dissuade them from such an unjust action, desired them to imagine themselves at that time in the general assembly of the states of Greece (who would all hear of it shortly), and then consider how it was proper to act. But where persons labour under an excess of modesty which prevents them from exerting themselves in things fit and laudable, it may sometimes be necessary to shew that it is faulty and ill grounded. On the other hand, *immodesty*, or impudence, which consists in a contempt of such things as affect the reputation, can never be too much discouraged and exposed. And the way of doing this is to make use of such arguments as are most proper to excite shame. We have a very remarkable instance of it in Cicero's second Philippic, wherein he affixes this character upon Mark Antony through every scene of his life.

23
Of the passions which may be referred to *judicial* discourses.

3. To *judicial* discourses, may be referred *anger* and *lenity*, *pity* and *indignation*.

Anger is a resentment, occasioned by some affront or injury, done without any just reason. Now men are more inclined to resent such a conduct, as they think they less deserve it. Therefore persons of distinction and figure, who expect a regard should be paid to their character, can the less bear any indications of contempt. And those who are eminent in any profession or faculty, are apt to be offended if reflections are cast either upon their reputation or art. Magistrates also, and persons in public stations, sometimes think it incumbent on them to resent indignities for the support of their office. But nothing sooner inflames this passion, than if good services are rewarded with slights and neglect. The instance of Narses, the Roman general, is remarkable in this kind; who, after he had been successful in his wars with the Goths, falling under the displeasure of the emperor Justin, was removed from the government of Italy, and received by the empress with this taunt, *That he must be sent to weave among the girls;* which so provoked him, that he said he would weave such a web as they would never be able to unravel. And accordingly, he soon after brought down the Longobards, a people of Germany into Italy; where they settled themselves in that part of the country, which from them is now called *Lombardy*. (See NARSES). The time and place in which an injury was done, and other circumstances that attended it, may likewise contribute very much to heighten the fact. Hence Demosthenes, in his oration against Midias, endeavours to aggravate the injury of being struck by him, both as he was then a magistrate, and because it was done at a public festival. From hence it appears, that the persons who most usually occasion this passion are such as neglect the rules of decency, contemn and insult others, or oppose their inclinations; as likewise the ungrateful, and those who violate the ties of friendship, or requite favours with injuries. But when the orator endeavours to excite anger, he should be careful not to exceed due bounds in aggravating the charge, lest what he says appear rather to proceed from prejudice, than a strict regard to the demerit of the action.

Lenity is the remission of anger. The designs of men's actions are principally to be regarded; and therefore what is done ignorantly, or through inadvertency, is sooner forgiven. Also to acknowledge a fault, submit, and ask pardon, are the ready means to take off resentment. For a generous mind is soon cooled by submission. Besides, he who repents of his fault, does really give the injured party some satisfaction, by punishing himself; as all repentance is attended with grief and uneasiness of mind, and this is apt very much to abate the desire of revenge. As, on the contrary, nothing is more provoking, that when the offender either audaciously justifies the fact, or confidently denies it. Men are likewise wont to lay aside their resentment, when their adversaries happen by some other means to suffer what they think a sufficient satisfaction. Lastly, Easy circumstances, a lucky incident, or any thing which gives the mind a turn to mirth and pleasure, has a natural tendency to remove anger. For anger is accompanied with pain and uneasiness, which very ill suit joy and cheerfulness. The orator therefore, in order to assuage and pacify the minds of his auditors, will endeavour to lessen their opinion of the fault, and by that means to take off the edge of their resentment. And to this purpose, it will be proper either to represent that the thing was not designed, or that the party is sorry for it; or to mention his former services; as also to show the credit and reputation which will be gained by a generous forgiveness. And this last topic is very artfully wrought up by Cicero, in his address to Cæsar in favour of Ligarius.

Pity arises from the calamities of others, by reflecting, that we ourselves are liable to the like misfortunes. So that evils, considered as the common lot of human nature, are principally the cause of pity. And this makes the difference between *pity* and *good will*, which arises merely from a regard to the circumstances of those who want

Invention. want our assistance. But considering the uncertainty of every thing about us, he must seem in a manner divested of humanity, who has no compassion for the calamities of others; since there is no affliction which happens to any man, but either that, or some other as great, may fall upon himself. But those persons are generally soonest touched with this passion, who have met with misfortunes themselves. And by how much greater the distress is, or by how much the person appears less deserving it, the higher pity does it excite; for which reason, persons are generally most moved at the misfortunes of their relations and friends, or those of the best figure and character. The orator, therefore, in order to excite the greater pity, will endeavour to heighten the idea of the calamity, from the several circumstances both of the thing itself and the person who labours under it. A fine example of this may be seen in Cicero's defence of Muræna, *Cap.* 40, &c.

Indignation, as opposed to *pity*, is an uneasiness at the felicity of another who does not seem to deserve it. But this respects only external advantages, such as riches, honours, and the like; for virtues cannot be the object of this passion. Aristotle therefore says, "that pity and indignation are generally to be found in the same persons, and are both evidences of a good disposition." Now the orator excites this passion, by showing the person to be unworthy of that felicity which he enjoys. And as, in order to move compassion, it is sometimes of use to compare the former happy state of the person with his present calamity; so here, the greater indignation is raised, by comparing his former mean circumstances with his present advancement: as Cicero does in the case of Vatinius.

These are the passions with which an orator is principally concerned. In addressing to which, not only the greatest warmth and force of expression is often necessary; but he must likewise first endeavour to impress his own mind with the same passion he would excite in others.

A man may convince, and even persuade others to act, by mere reason and argument. But that degree of eloquence which gains the admiration of mankind, and properly denominates one an orator, is never found without warmth or passion. Passion, when in such a degree as to rouse and kindle the mind, without throwing it out of the possession of itself, is universally found to exalt all the human powers. It renders the mind infinitely more enlightened, more penetrating, more vigorous and masterly, than it is in its calm moments. A man, actuated by a strong passion, becomes much greater than he is at other times. He is conscious of more strength and force; he utters greater sentiments, conceives higher designs, and executes them with a boldness and a felicity of which on other occasions he could not think himself capable. But chiefly, with respect to persuasion, is the power of passion felt. Almost every man in passion is eloquent. Then he is at no loss for words and arguments. He transmits to others, by a sort of contagious sympathy, the warm sentiments which he feels; his looks and gestures are all persuasive; and nature here shows herself infinitely more powerful than art. This is the foundation of that just and noted rule, *Si vis me flere, dolendum est primum ipsi tibi.*

The warmth, however, which we express, must be suited to the occasion and the subject; for nothing can be more preposterous than an attempt to introduce great vehemence into a subject, which is either of slight importance, or which, by its nature, requires to be treated of calmly. A temperate tone of speech is that for which there is most frequent occasion; and he who is on every subject passionate and vehement, will be considered as a blusterer, and meet with little regard.

PART II. OF DISPOSITION.

AS *Invention* supplies the orator with necessary materials, so *Disposition* directs him how to place them in the most proper and suitable order. Disposition, therefore, considered as a part of oratory, naturally follows invention. And what is here chiefly intended by it is, the placing the several parts of a discourse in a just method and dependence upon one another.

Writers are not all agreed in determining the parts of an oration; though the difference is rather in the manner of considering them, than in the things themselves. But Cicero, whom we shall here follow, mentions six, namely, *Introduction*, *Narration*, *Proposition*, *Confirmation*, *Confutation*, and *Conclusion*.

Chap. I. *Of the Introduction.*

14 Introduction gains the hearts and attention of the audience, and gives a general notion of the subject.

The design of this is to prepare the minds of the hearers for a suitable reception of the remaining parts that are to follow. And for this end, three things are requisite; that the orator gain the *good opinion* of his hearers, that he secure their *attention*, and give them some *general notion* of his subject.

1. *Good opinion.* When the orator introduces his discourse with his own person, he will be careful to do it with modesty, and seem rather to extenuate his virtues and abilities, than to magnify them. And where the nature of the subject may seem to require it, he will endeavour to show, that some just and good reason induced him to engage in it. We have a very fine example of this in Cicero's oration for the poet Aulus Licinius Archias, which begins thus: "If I have any natural genius, which I am sensible is very small, or any ability in speaking, wherein I own I have been very conversant; or any skill acquired from the study and precepts of the best arts, to which my whole life has been devoted; this Aulus Licinius has in a particular manner, a right to demand of me the fruit of all these things. For as far back as I can remember, and call to mind what passed in my youth to the present time, he has been my chief adviser and encourager both to undertake and pursue this course of studies." When the orator sets out with the persons of those to whom the discourse is made, it is not unusual to commend them for their virtues, and those especially which have a more immediate relation to the present subject. Thus Cicero begins his oration of thanks for the pardon of Marcellus, with an encomium upon the mildness, clemency, and wisdom of Cæsar, to whom it was addressed.

But

Disposition.

But sometimes the orator expresses his gratitude for past favours; as Cicero has done in his orations, both to the people and senate of Rome, after his return from banishment.—And at other times he declares his concern for them and their interest; in which manner Cicero begins his fourth oration against Catiline, which was made in the senate." "I perceive (says he) that all your countenances and eyes are turned on me; I perceive that you are solicitous, not only for your own danger, and that of the state, but for mine likewise, if that should be removed. Your affection for me is pleasant in misfortunes, and grateful in sorrow; but I adjure you to lay it aside, and, forgetting my safety, consider yourselves and your children." But in judicial cases, both the character of the person whose cause he espouses, and that of the adverse party likewise, furnish the orator with arguments for exciting the good will of his hearers: The former, by commemorating his virtues, dignity, or merits, and sometimes his misfortunes and calamities. So Cicero, in his defence of Flaccus, begins his oration in commending him on the account of his services done to the public, the dignity of his family, and his love to his country. And Demosthenes, in his oration against Midias, sets out with a recital of his vices, in order to recommend his own cause to the favourable opinion of the court.

2. *Attention.* On this head, Cicero says, "We shall be heard attentively on one of these three things; if we propose what is great, necessary, or for the interest of those to whom the discourse is addressed." So that, according to him, the topics of attention are much the same with those of good opinion, when taken from the subject. And indeed, people are naturally led to attend either to those things or persons of which they have entertained a favourable opinion. But in order to gain this point, the orator sometimes thinks it proper to request the attention of his audience. Thus Cicero, in his defence of Cluentius, after having shown the heinousness of the charge against him, concludes his introduction in the following manner, speaking to the judges; "Wherefore I entreat, that while I briefly and clearly reply to a charge of many years standing, you will, according to your usual custom, give me a kind and attentive hearing." And again, in his second Philippic, addressing himself to the senate: "But as I must say something for myself, and many things against Mark Antony; one of these I beg of you, that you will hear me kindly, while I speak for myself; and the other I will undertake for, that when I speak against him, you shall hear me with attention." But though the introduction be the most usual and proper place for gaining attention, yet the orator finds it convenient sometimes to quicken and excite his hearers in other parts of his discourse, when he observes they flag, or has something of moment to offer.

3. Some *general account* of the subject of the discourse. This is always necessary; which the two others are not. And therefore it must be left to the prudence of the orator when to use or omit them as he shall judge proper, from the nature of his discourse, the circumstance of his hearers, and how he stands with them. But some account of the subject is what cannot be neglected. For every one expects to be soon informed of the design of the speaker, and what he proposes to treat of. Nor when they are all made use of, is it necessary they should always stand in the order we have here placed them. Cicero sometimes enters immediately upon his subject, and introduces the other heads afterwards. As in his third oration against Catiline, made to the body of the Roman people, which begins thus: "You see that the state, all your lives, estates, fortunes, wives, and children, and this seat of the greatest empire, the most flourishing and beautiful city, having by the favour of heaven towards you, and my labours, counsels, and dangers, been this day rescued from fire and sword and the very jaws of destruction, are preserved and restored to you." And then he proceeds to recommend himself to their esteem and benevolence, from the consideration of these benefits.

25
Introduction is not confined to these heads, but can admit of other matter, if furnished by the circumstances of the case.

These are the heads which commonly furnish matter for this part of a discourse. But orators often take occasion from the time, place, largeness of the assembly, or some other proper circumstance, to compliment their hearers, recommend themselves, or introduce the subject upon which they are about to treat. Instances of each of these may be met with in several of Cicero's orations. And sometimes they set out with some comparison, similitude, or other ornament, which they accommodate to the occasion of their discourse. Thus Isocrates enters upon his celebrated panegyric in praise of his countrymen the Athenians with the following comparison: "I have often wondered what could be their design who brought together these assemblies, and instituted the gymnastic sports, to propose so great rewards for bodily strength; and to vouchsafe no honour to those who applied their private labours to serve the public, and so cultivated their minds as to be serviceable to others, to whom they ought to have shown greater regard. For although the strength of a champion was doubled, no benefit would from thence accrue to others; but all enjoy the prudence of one man, who will hearken to his advice." In some cases, orators have recourse to a more covert and artful way of opening their subject, endeavour to remove jealousies, apologize for what they are about to say, and seem to refer it to the candour of the hearers to judge of it as they please. Cicero appears to have been a perfect master of this art, and used it with great success. Thus in his seventh Philippic, where he seems to express the greatest concern, lest what he was about to say should give any offence to the senate to whom he was speaking: "I (says he) who always declared for peace, and to whom peace among ourselves, as it is wished for by all good men, was in a particular manner desirable; who have employed all my industry in the forum, in the senate, and in the defence of my friends, whence I have arrived to the highest honours, a moderate fortune, and what reputation I enjoy; I therefore, who owe what I am to peace, and without it could not have been the person I am, be that what it will, for I would arrogate nothing to myself; I speak with concern and fear, how you will receive what I am going to say; but I beg and entreat you, from the great regard I have always expressed for the support and advancement of your honour, that if any thing said by me should at first appear harsh or unfit to be received, you will notwithstanding please to hear it without offence, and not reject it till I have explained myself: I then, for I must repeat it again, who have always approved of peace, and promoted it, am against a peace with Mark Antony."

Antony." This is called *insinuation;* and may be necessary, where a cause is in itself doubtful, or may be thought so from the received notions of the hearers, or the impressions already made upon them by the contrary side. An honest man would not knowingly engage in a bad cause; and yet, through prevailing prejudice, that may be so esteemed which is not so in itself. In these cases, therefore, great caution and prudence are necessary to give such a turn to things, and place them in that view as may be least liable to offence. And because it sometimes happens that the hearers are not so much displeased at the object as the person, Quintilian's rule seems very proper, when he says, "If the subject displease, the character of the person should support it; and when the person gives offence, he should be helped by the cause."

Chap. II. *Of Narration.*

26 Narration brings forward all those circumstances of a case, &c. in their proper and natural order, which are calculated to set it in a just or a strong light.

The orator having prepared his hearers to receive his discourses with candour and attention, and acquainted them with his general design in the introduction, before he proceeds directly to his subject, often finds it necessary to give some account of what preceded, accompanied, or followed upon it. And this he does in order to enlarge the view of the particular point in dispute, and place it in a clearer light. This is called *narration;* which is a recital of something done, in the order and manner in which it was done. Hence it is easy to perceive what those things are which properly enter into a narration. And such are the cause, manner, time, place, and consequences of an action; with the temper, fortune, views, ability, associates, and other circumstances of those concerned in it. Not that each of these particulars is necessary in every narration: but so many of them at least as are requisite to set the matter in a just light, and make it appear credible. Besides, in relating a fact, the orator does not content himself with such an account of it as is barely sufficient to render what he says intelligible to his hearers; but describes it in so strong and lively a manner, as may give the greatest evidence to his relation, and make the deepest impression upon their minds. And if any part of it appear at present less probable, he promises to clear up and remove any remaining doubts in the progress of his discourse. For the foundation of his reasoning afterwards is laid in the narration, from whence he takes his arguments for the confirmation. And therefore it is a matter of no small importance that this part be well managed, since the success of the whole discourse so much depends upon it. See Narration.

There are four properties required in a good narration; that it be short, clear, probable, and pleasant.

1. The *brevity* of a narration is not to be judged of barely from its length: for that may be too long, which contains but a little; and that too short, which comprehends a great deal. Wherefore this depends upon the nature of the subject, since some things require more words to give a just representation of them, and others fewer. That may properly, therefore, be called a *short narration*, which contains nothing that could well have been omitted, nor omits any thing which was necessary to be said. Now, in order to avoid both these extremes, care should be taken not to go farther back in the account of things, nor to trace them down lower, than the subject requires; to say that only in the general, which does not need a more particular explication; not to assign the causes of things, when it is enough to show they were done; and to omit such things as are sufficiently understood, from what either proceeded, or was consequent upon them. But the orator should be careful, lest, while he endeavours to avoid prolixity, he run into obscurity. Horace was very sensible of this danger, when he said,

By striving to be short, I grow obscure.

2. *Perspicuity.* This may justly be esteemed the chief excellency of language. For as the design of speech is to communicate our thoughts to others, that must be its greatest excellence which contributes most to this end; and that, doubtless, is perspicuity. As perspicuity therefore is requisite in all discourse, so it is particularly serviceable in a narration, which contains the substance of all that is to be said afterwards. Wherefore, if this be not sufficiently understood, much less can those things which receive their light from it. Now the following things render a narration clear and plain: Proper and significant words, whose meaning is well known and determined; short sentences, though full and explicit, whose parts are not perplexed, but placed in their just order; proper particles to join the sentences, and show their connexion and dependence on each other; a due regard to the order of time, and other circumstances necessary to be expressed; and, lastly, suitable transitions.

3. *Probability.* Things appear probable when the causes assigned for them appear natural; the manner in which they are described is easy to be conceived; the consequences are such as might be expected; the characters of the persons are justly represented; and the whole account is well attested, consistent with itself, and agreeable to the general opinion. Simplicity likewise in the manner of relating a fact, as well as in the style, without any reserve or appearance of art, contributes very much to its credibility. For truth loves to appear naked and open, stript of all colouring or disguise. The conspiracy of Catiline was so daring and extravagant, that no one but such a desperado could ever have undertaken it with any hopes of success. However, Cicero's account of it to the senate was so full and exact, and so well suited to the character of the person, that it presently gained credit. And therefore, when upon the conclusion of Cicero's speech, Catiline, who was present, immediately stood up, and desired they would not entertain such hard thoughts of him, but consider how much his family had always been attached to the public interest, and the great services they had done the state; their resentment rose so high, that he could not be heard: upon which he immediately left the city, and went to his associates.

4. The last thing required in a narration is, that it be *pleasant* and *entertaining*. And this is more difficult, because it does not admit of that accurate composition and pompous dress which delight the ear, and recommend some other parts of a discourse. For it certainly requires no small skill in the speaker, while he endeavours to express every thing in the most natural, plain, and easy manner, not to grow flat and tiresome.

For

Disposition.

for Quintilian's remark is very just, that "the most experienced orators find nothing in eloquence more difficult, than what all who hear it fancy they could have said themselves." And the reason of this seems very obvious. For as all art is an imitation of nature, the nearer it resembles that, the more perfect it is in its kind. Hence unexperienced persons often imagine that to be easiest which suits best with those natural ideas to which they have been accustomed; till, upon trial, they are convinced of their mistake. Wherefore, to render this part of a discourse pleasant and agreeable, recourse must be had to variety both in the choice of words and turns of the expression. And therefore questions, admirations, interlocutions, imagery, and other familiar figures, help very much to diversify and enliven a narration, and prevent it from becoming dull and tedious, especially when it is carried on to any considerable length.

27
The uses of narration.

Having given a brief account of the nature and properties of a narration, we shall now proceed to consider the uses of it.

Laudatory orations are usually as it were a sort of continued narration, set off and adorned with florid language and fine images proper to grace the subject, which is naturally so well fitted to afford pleasure and entertainment. Wherefore a separate narration is more suited to *deliberative* and *judicial* discourses. In Cicero's oration for the Manilian law (which is of the former kind), the design of the narration is to show the Roman people the necessity of giving Pompey the command of the army against King Mithridates, by representing the nature of that war, which is done in the following manner: "A great and dangerous war (says he) threatens your revenues and allies from two very powerful kings, Mithridates and Tigranes; one of whom not being pursued after his defeat, and the other provoked, they think they have an opportunity to seize Asia. Letters are daily brought from those parts to worthy gentlemen of the equestrian order, who have large concerns there in farming your revenues: they acquaint me, as friends, with the state of the public affairs, and danger of their own; that many villages in Bithynia, which is now your province, are burnt down; that the kingdom of Ariobarzanes, which borders upon your revenues, is entirely in the enemy's power; that Lucullus, after several great victories, is withdrawn from the war; that he who succeeds him is not able to manage it; that all the allies and Roman citizens wish and desire the command of that war may be given to one particular person; and that he alone, and no other, is dreaded by the enemies. You see the state of the case; now consider what ought to be done." Here is an unhappy scene of affairs, which seemed to call for immediate redress. The causes and reasons of it are assigned in a very probable manner, and the account well attested by persons of character and figure. And what the consequences would be, if not timely prevented, no one could well be ignorant. The only probable remedy suggested in general is, the committing that affair to one certain person, which he afterwards shows at large could be no other than Pompey. But in Cicero's defence of Milo (which is of the *judicial* kind), the design of the narration, which is greatly commended by Quintilian, is to prove that, in the combat between Clodius and Milo, the former was the aggressor. And in order to make this appear, he gives a summary account of the conduct of Clodius the preceding year; and from the course of his actions and behaviour, shows the inveterate hatred he bore to Milo, who obstructed him in his wicked designs. For which cause he had often threatened to kill him, and given out that he should not live beyond such a time; and accordingly he went from Rome without any other apparent reason, but that he might have an opportunity to attack him in a convenient place near his own house, by which he knew Milo was then obliged to pass. Milo was in the senate that day, where he staid till they broke up, then went home, and afterwards set forward on his journey. When he came to the place in which he was to be assaulted, Clodius appeared every way prepared for such a design, being on horseback, and attended with a company of desperate ruffians ready to execute his commands; whereas Milo was with his wife in a chariot, wrapped up in his cloak, and attended with servants of both sexes. These were all circumstances which preceded the fact. And as to the action itself, with the event of it, the attack, as Cicero says, was begun by the attendants of Clodius from a higher ground, who killed Milo's coachman; upon which Milo, throwing off his cloak, leaped out, and made a brave defence against Clodius's men, who were got about the chariot. But Clodius, in the heat of the skirmish, giving out that Milo was killed, was himself slain by the servants of Milo, to avenge, as they thought, the death of their master. Here seems to be all the requisites proper to make this account credible. Clodius's open and avowed hatred of Milo, which proceeded so far as to threaten his life; the time of his leaving Rome; the convenience of the place; his habit and company so different from those of Milo; joined with his known character of a most profligate and audacious wretch, could not but render it very probable that he had formed that design to kill Milo. And which of them began the attack might very reasonably be credited from the advanced ground on which Clodius and his men were placed; the death of Milo's coachman at the beginning of the combat; the skirmish afterwards at the chariot; and the reason of Clodius's own death at last, which does not appear to have been intended, till he had given out that Milo was killed.

But a distinct and separate narration is not always necessary in any kind of discourse. For if the matter be well known before, a set and formal narrative will be tedious to the hearers. Or if one party has done it already, it is needless for the other to repeat it. But there are three occasions especially, in which it may seem very requisite: when it will bring light to the subject; when different accounts have already been given out concerning it; or when it has been misrepresented by the adverse party. If the point in controversy be of a dubious nature, or not sufficiently known to the hearers, a distinct account of the matter, with the particular circumstances attending it, must be very serviceable, in order to let them into a true state of the case, and enable them to judge of it with greater certainty.

Moreover, where the opposite party has set the matter in a false light by some artful and invidious turn, or loaded it with any odious circumstances, it seems no less necessary that endeavours should be used to remove any ill impressions, which otherwise might remain upon the minds

Disposition.

minds of the hearers, by a different and more favourable representation. And if any thing can be fixed upon to make the contrary account appear absurd or incredible, it ought particularly to be remarked. Thus Cicero, in his defence of Sextus Roscius, shows that he was many miles distant from Rome at the time he was charged with having killed his father there. "Now (says he), while Sextus Roscius, was at Ameria, and this Titus Roscius [*his accuser*] at Rome, Sextus Roscius [*the father*] was killed at the baths on Mount Palatine, returning from supper. From whence I hope there can be no doubt who ought to be suspected of the murder. And, were not the thing plain of itself, there is this farther suspicion to fix it upon the prosecutor; that, after the fact was committed, one Manlius Glaucia, an obscure fellow, the freedman, client, and familiar, of this Titus Roscius, first carried the account of it to Ameria, not to the son of the deceased, but to the house of Titus Capito his enemy;" with more to the same purpose. But what we bring it for is, to show the use which Cicero makes of this narration for retorting the crime upon the prosecutors.

But the orator should be very careful, in conducting this part, to avoid every thing which may prejudice the cause he espouses. Falsehood, and a misrepresentation of facts, are not to be justified; but no one is obliged to say those things which may hurt himself. We shall just mention one instance of this from Cicero, where he has shown great skill in this respect, in pleading before Cæsar for the pardon of Ligarius, who had joined with Pompey in the civil war. For Ligarius, having been represented by the adverse party as an enemy to Cæsar, and so esteemed by Cæsar himself; Cicero very artfully endeavours in his narration to take off the force of this charge, by showing, that, when the war first broke out, he refused to engage in it; which he would not have done, had he borne any personal hatred to Cæsar. "Quintus Ligarius (says he), before there was any suspicion of a war, went into Africa as a legate to the proconsul Caius Confidius; in which he so approved himself, both to the Roman citizens and allies, that, when Confidius left the province, the inhabitants would not be satisfied he should leave the government in the hands of any other person. Therefore Quintus Ligarius having excused himself in vain for some time, accepted of the government against his will; which he so managed during the peace, that both the citizens and allies were greatly pleased with his integrity and justice. The war broke out on a sudden, which those in Africa did not hear of till it was begun: but upon the news of it, partly through inconsiderate haste, and partly from blind fear, they looked out for a leader, first for their own safety, and then as they were affected; when Ligarius, thinking of home, and desirous to return to his friends, would not be prevailed on to engage in any affairs. In the mean time, Publius Accius Varus, the prætor, who was formerly governor of Africa, coming to Utica, recourse was immediately had to him, who very eagerly took upon himself the government; if that can be called a *government*, which was conferred on a private man by the clamour of the ignorant multitude, without any public authority. Ligarius, therefore, who endeavoured to avoid every thing of that kind, ceased to act soon after the arrival of Varus." Here Cicero ends his narrative. For though Ligarius afterwards joined with Pompey's party, yet to have mentioned that, which was nothing more than what many others had done, whom Cæsar had already pardoned, could have served only to increase his displeasure against him. And therefore he doubtless showed great skill in so managing his account, as to take off the main force of the accusation, and by that means make way for his pardon, which he accordingly obtained.

Chap. III. *Of the Proposition.*

28 The proposition is a distinct and express manner of laying down the subject on which an orator means to treat.

In every just and regular discourse, the speaker's intention is to prove or illustrate something. And when he lays down the subject upon which he designs to treat, in a distinct and express manner, this is called the *proposition*.

Orators use several ways in laying down the subject of their discourses. Sometimes they do it in one general proposition. We have an instance of this in Cicero's speech to the senate, the day after Cæsar was killed (as it is given us by Dion Cassius), in which his design was to persuade them to peace and unanimity. "This (says he) being the state of our affairs, I think it necessary that we lay aside all the discord and enmity which have been among us, and return again to our former peace and agreement." And then he proceeds to offer his reasons for this advice.

At other times, to give a clearer and more distinct view of their discourse, they subjoin to the proposition the general heads of argument by which they endeavour to support it. This method Cicero uses in his seventh Philippic, where he says, "I who have always commended and advised to peace, am against a peace with Mark Antony. But why am I averse to peace? Because it is base, because it is dangerous, and because it is impracticable. And I beseech you to hear me with your usual candour, while I make out these three things."

29 When the subject refers to several different things, and requires to be laid down in distinct propositions, it is called a partition.

But when the subject relates to several different things, which require each of them to be separately laid down in distinct propositions, it is called a *partition*; though some have made two kinds of *partition*, one of which they call *separation*, and the other *enumeration*. By the former of these, the orator shows in what he agrees with his adversary, and wherein he differs from him. So, in the case formerly mentioned, of a person accused of sacrilege for stealing private money out of a temple, he who pleads for the defendant says, "He owns the fact; but it being private money, the point in question is, Whether this be sacrilege?" And in the cause of Milo, Cicero, speaking of Clodius, says, "The point which now comes before the court, is not, Whether he was killed or not; that we confess; but, Whether justly or unjustly." Now in reality here is no partition, since the former branch of the proposition is what is agreed upon, and given up; and consequently it is only the latter that remains to be disputed. It is called *enumeration*, when the orator acquaints his hearers with the several parts of his discourse upon which he designs to treat. And this alone, properly speaking, is a *partition*. Thus Cicero states his plea in his defence of Muræna: "I perceive the accusation consists of three parts: the first respects the conduct of his life; the second his dignity; and the third contains a charge of bribery."

There are three things requisite in a good partition;

Disposition.

tion; that it be *short*, *complete*, and consist but of a *few members*

A partition is said to be *short*, when each proposition contains in it nothing more than what is necessary. So that the brevity here required is different from that of a narration; for that consists chiefly in things, this in words. And, as Quintilian justly observes, brevity seems very proper here, where the orator does not show what he is then speaking of, but what he designs to discourse upon.

Again, It ought to be *complete* and perfect. And for this end, care must be taken to omit no necessary part in the enumeration.

But however, there should be as *few heads* as is consistent with the nature of the subject. The ancient rhetoricians prescribe three or four at the most. And we do not remember that Cicero ever exceeds that number. But it is certain, the fewer they are, the better, provided nothing necessary be omitted. For too large a number is both difficult of retention, and apt to introduce that confusion which partition is designed to prevent.

Hitherto we have been speaking only of those heads into which the subject or general argument of the discourse is at first divided. For it is sometimes convenient to divide these again, or at least some of them, into several parts or members. And when this happens, it is best done, as the speaker comes to each of them in the order at first laid down; by which means the memory of the hearers will be less burdened than by a multitude of particulars at one and the same time. Thus Cicero, in his oration for the Manilian law, comprises what he designs to say under three general heads. "First (says he) I shall speak of the nature of the war, then of its greatness, and lastly about the choice of a general." And when he comes to the first of these, he divides it again into four branches; and shows, "how much the glory of the Romans, and safety of their allies, their greatest revenues, and the fortunes of many of their citizens, were all concerned in that war." The second head, in which he considers the greatness of the war, has no division. But when he comes to the third head, concerning the choice of a general, he divides that likewise into four parts; and shows, that so many virtues are necessary in a consummate general, such a one as was proper to have the management of that war, namely, *skill in military affairs*, *courage*, *authority*, and *success*: all which he attributes to Pompey. And this is the scheme of that celebrated oration.

This subdividing, however, should never have place but when it is absolutely necessary. To split a subject into a great many minute parts, by divisions and subdivisions without end, has always a bad effect in speaking. It may be proper in a logical treatise; but it makes an oration appear hard and dry, and unnecessarily fatigues the memory. In a sermon, there may be from three to five or six heads, including subdivisions; seldom should there be more.

30 Negative and positive divisions of a subject.

Further, Some divide their subject into two parts, and propose to treat upon it *negatively* and *positively*; by showing first what it is not, and then what it is. But while they are employed to prove what it is not, they are not properly treating upon that, but something else; which seems as irregular as it is unnecessary. For he who proves what a thing is, does at the same time show what it is not. However, in fact, there is a sort of division by affirmation and negation, which may sometimes be conveniently used. As if a person, charged with killing another, should thus state his defence: *I had done right if I had killed him, but I did not kill him.* Here indeed, if the latter can be plainly made to appear, it may seem needless to insist upon the form. But if that cannot be so fully proved, but there may be room left for suspicion, it may be proper to make use of both: for all persons do not see things in the same light, and he who believes the fact, may likewise think it just; while he who thinks it unjust, may not believe it, but rather suppose, had it really been committed by the party, he would not have denied it, since he looked upon it as defensible. And this method of proceeding, Quintilian compares to a custom often used in traffic, when persons make a large demand at first, in order to gain a reasonable price. Cicero uses this way of reasoning in his defence of Milo; but in the contrary order; that is, he first answers the charge; and then justifies the fact, upon the supposition that the charge was true. For he proves, first, that Clodius was the aggressor; and not Milo, as the contrary party had asserted: and then, to give the greater advantage to his cause, he proceeds to show, that if Milo had been the aggressor, it would however have been a glorious action to take off such an abandoned wretch, who was not only a common enemy to mankind, but had likewise often threatened his life.

A good and just partition is attended with considerable advantages. For it gives both light and ornament to a discourse. And it is also a great relief to the hearers, who, by means of these stops and rests, are much better enabled to keep pace with the speaker without confusion, and by casting their thoughts either way, from what has been said, both know and are prepared for what is to follow. And as persons, in travelling a road with which they are acquainted, go on with greater pleasure and less fatigue, because they know how far it is to their journey's end; so to be apprised of the speaker's design, and the several parts of his discourse which he proposes to treat on, contributes very much to relieve the hearer, and keep up his attention. This must appear very evident to all who consider how difficult it is to attend long and closely to one thing, especially when we do not know how long it may be before we are like to be released. Whereas, when we are beforehand acquainted with the scheme, and the speaker proceeds regularly from one thing to another, opportunity is given to ease the mind, by relaxing the attention, and recalling it again when necessary. In a sermon, or in a pleading at the bar, few things are of greater consequence than a proper or happy division. It should be studied with much accuracy and care; for if one take a wrong method at first setting out, it will lead him astray in all that follows. It will render the whole discourse either perplexed or languid; and though the hearers may not be able to tell where the fault or disorder lies, they will be sensible there is a disorder somewhere, and find themselves little affected by what is spoken. The French writers of sermons study neatness and elegance in the division of their subjects much more than the English do; whose distributions, though sensible and just, yet are often inartificial and verbose.

Disposition.

Chap. IV. *Of Confirmation.*

31 Confirmation is used for the arguments brought in defence of a subject.

The orator having acquainted his hearers, in the proposition, with the subject on which he designs to discourse, usually proceeds either to prove or illustrate what he has there laid down. For some discourses require nothing more than an enlargement or illustration, to set them in a proper light, and recommend them to the hearers; for which reason, likewise, they have often no distinct proposition. But where arguments are brought in defence of the subject, this is properly *confirmation*. For as Cicero defines it, "confirmation is that which gives proof, authority, and support to a cause, by reasoning." And for this end, if any thing in the proposition seems obscure, or liable to be misunderstood, the orator first takes cares to explain it, and then goes on to offer such arguments for the proof of it, and represent them in such a light, as may be most proper to gain the assent of his hearers.

But here it is proper to observe, that there are different ways of reasoning suited to different arts. The mathematician treats his subject after another manner than the logician, and the orator in a method different from them both. Two methods of reasoning are employed by orators, the *synthetic and analytic*.

32 Synthetic reasoning may always be resolved into a syllogism or series of syllogisms.

I. Every piece of synthetic reasoning may be resolved into a syllogism or series of syllogisms, (see Logic). Thus we may reduce Cicero's argument, by which he endeavours to prove that Clodius assaulted Milo, and not Milo Clodius, to a syllogism in this manner:

He was the aggressor, whose advantage it was to kill the other.
But it was the advantage of Clodius to kill Milo, and not Milo to kill him.
Therefore Clodius was the aggressor, or he assaulted Milo.

The thing to be proved was, that Clodius assaulted Milo, which therefore comes in the conclusion: and the argument, by which it is proved, is taken from the head of profit or advantage. Thus the logician would treat this argument; and if either of the premises were questioned, he would support it with another syllogism. But this short and dry way of reasoning does not at all suit the orator: who not only for variety changes the order of the parts, beginning sometimes with the minor, and at other times with the conclusion, and ending with the major; but likewise clothes each part with such ornaments of expression as are proper to enliven the subject, and render it more agreeable and entertaining. And he frequently subjoins either to the major proposition, or minor, and sometimes to both, one or more arguments to support them; and perhaps others to confirm or illustrate them as he thinks it requisite. Therefore, as a logical syllogism consists of three parts or propositions, a rhetorical syllogism frequently contains four, and many times five parts. And Cicero reckons this last the most complete. But all that is said in confirmation of either of the premises is accounted but as one part. This will appear more evident by examples: By a short syllogism Cicero thus proves, that the Carthaginians were not to be trusted: "Those who have often deceived us, by violating their engagements, ought not to be trusted. For if we receive any damage by their treachery, we can blame nobody but ourselves. But the Carthaginians have often so deceived us. Therefore it is madness to trust them." Here the major proposition is supported by a reason. The minor needed none; because the treachery of the Carthaginians was well known. So that the syllogism consists of four parts. But by a syllogism of five parts he proves somewhat more largely and elegantly, that the world is under the direction of a wise governor. The major is this: "Those things are better governed which are under the direction of wisdom, than those which are not." This he proves by several instances: "A house managed with prudence has every thing in better order, and more convenient than that which is under no regulation. An army commanded by a wise and skilful general is in all respects better governed than one which has a fool and a madman at the head of it. And the like is to be said of a ship, which performs her course best under the direction of a skilful pilot." Then he proceeds to the minor thus: "But nothing is better governed than the universe." Which he proves in this manner: "The rising and setting of the heavenly bodies keep a certain determined order; and the several seasons of the year do not only necessarily return in the same manner, but are suited to the advantage of the whole; nor did the vicissitudes of night and day ever yet become prejudicial, by altering their course." From all which he concludes, "that the world must be under the direction of a wise governor." In both these examples, the regular order of the parts is observed. We shall therefore produce another, in which the order is directly contrary; for beginning with the conclusion, he proceeds next to the minor proposition, and so ends with the major. In his defence of Cœlius, his design is to prove that Cœlius had not led a loose and vicious life, with which his enemies had charged him. And this he does, by showing he had closely followed his studies, and was a good orator. This may probably at first sight appear but a weak argument; though to him who considers what Cicero every where declares necessary to gain that character, it may perhaps be thought otherwise. The sense of what he says here may be reduced to this syllogism.

Those who have pursued the study of oratory, so as to excel in it, cannot have led a loose and vicious life.
But Cœlius has done this.
Therefore his enemies charge him wrongfully.

But let us hear Cicero himself. He begins with the conclusion, thus: "Cœlius is not chargeable with profuseness, extravagancy, contracting of debts, or intemperance, a vice which age is so far from abating, that it rather increases it. Nay, he never engaged in amours, and those pleasures of youth, as they are called, which are soon thrown off, as reason prevails." Then he proceeds to the minor, and shows from the effects, that Cœlius had closely applied himself to the best arts, by which he means those necessary for an orator: "You have now heard him make his own defence, and you formerly heard him engaged in a prosecution (I speak this to vindicate, not to applaud him), you could not but perceive his manner of speaking, his ability, his good sense, and command of language. Nor did he only discover a good genius,

Disposition.

genius, which will oftentimes do much of itself when it is not improved by industry; but what he said (if my affection for him did not bias my judgment) appeared to be the effect of learning, application, and study." And then he comes to the major: "But be assured, that those vices charged upon Cœlius, and the studies upon which I am now discoursing, cannot meet in the same person. For it is not possible that a mind, disturbed by such irregular passions, should be able to go through what we orators do, I do not mean only in speaking, but even in thinking." And this he proves by an argument taken from the scarcity of good orators. "Can any other reason be assigned, why so few, both now, and at all times, have engaged in this province, when the rewards of eloquence are so magnificent, and it is attended with so great delight, applause, glory, and honour? All pleasures must be neglected; diversions, recreations, and entertainments omitted; and even the conversation of all our friends must in a manner be laid aside. This it is which deters persons from the labour and study of oratory; not their want of genius or education."

33
Orators do not often use complete syllogisms, but most commonly imperfect ones, called *enthymems*.

2. By *Enthymem*. But orators do not often use complete syllogisms, but most commonly enthymems. An *enthymem*, as is shown elsewhere, is an imperfect syllogism, consisting of two parts; the conclusion, and one of the premises. And in this kind of syllogism, that proposition is omitted, whether it be the major or minor, which is sufficiently manifest of itself, and may easily be supplied by the hearers. But the proposition that is expressed is usually called the *antecedent*, and the conclusion the *consequent*. So if the major of that syllogism be omitted, by which Cicero endeavours to prove that Clodius assaulted Milo, it will make this enthymem:

> *The death of Milo would have been an advantage to Clodius.*
> *Therefore Clodius was the aggressor; or, therefore, he assaulted Milo.*

In like manner, that other syllogism above mentioned, by which he shows that the Carthaginians ought not to be trusted, by omitting the minor, may be reduced to the following enthymem:

> *Those who have often broke their faith ought not to be trusted.*
> *For which reason the Carthaginians ought not to be trusted.*

Every one would readily supply the minor, since the perfidiousness of the Carthaginians was known to a proverb. But it is reckoned a beauty in enthymems, when they consist of contrary parts, because the turn of them is most acute and pungent. Such is that of Micipsa in Sallust: "What stranger will be faithful to you who are an enemy to your friends?" And so likewise that of Cicero for Milo, speaking of Clodius: "You sit as avengers of his death; whose life you would not restore, did you think it in your power." Orators manage enthymems in the same manner they do syllogisms; that is, they invert the order of the parts, and confirm the proposition by one or more reasons; and therefore a rhetorical enthymem frequently consists of three parts, as a syllogism does of five. Though, strictly speaking, a syllogism can consist of no more than three parts, and an enthymem but of two: and the arguments brought to support either of the propositions constitute so many new enthymems, of which the part they are designed to prove is the conclusion. To illustrate this by an example:

> *An honest man thinks himself under the highest obligation to his country.*
> *Therefore he should shun no danger to serve it.*

In this *enthymem* the major is wanting, which would run thus: "He who is under the highest obligations to another, should shun no danger in order to serve him." This last proposition is founded upon the common principle of gratitude; which requires that, to the utmost of our power, a return should be made in proportion to the kindness received. And this being a maxim generally allowed, it is omitted by the orator. But now this enthymem, consisting of the minor and conclusion, might be managed in some such manner as this, beginning with the conclusion: "An honest man ought to shun no danger, but readily expose his life for the safety and preservation of his country." Then the reason of this conduct might be added, which is the antecedent of the enthymem, or minor of the syllogism: "For he is sensible that his obligations to his country are so many, and so great, that he can never fully requite them." And this again might be confirmed by an enumeration of particulars: "He looks upon himself as indebted to his country for every thing he enjoys; for his friends, relations, all the pleasures of life, and even for life itself. Now the orator calls this *one enthymem*, though in reality there are two: For the second reason, or argument, added to the first, becomes the antecedent of a new enthymem, of which the first reason is the consequent. And if these two enthymems were expressed separately in the natural order of the parts, the former would stand thus: "An honest man thinks himself under the highest obligations to his country; therefore he ought to shun no danger for its preservation." The latter thus: "An honest man esteems himself indebted to his country for every thing he enjoys; therefore he thinks he is under the highest obligations to it." The same thing might be proved in the like way of reasoning, by arguments of a different kind. From comparison, thus: "As it would be thought base and ungrateful in a son not to hazard himself for the preservation of his father; an honest man must certainly esteem it so when his country is in danger." Or from an example, in this manner: An honest man in like circumstances would propose to himself the example of Decius, who freely gave up his life for the service of his country. He gave up his life indeed, but did not lose it; for he cannot be said to have lost his life, who lives in immortal honour." Orators frequently intermix such arguments to adorn and illustrate their subject with others taken from the nature and circumstances of things. And now, if we consider a little this method of reasoning, we shall find it the most plain and easy imaginable. For when any proposition is laid down, and one or more reasons subjoined to prove it, each reason joined with the proposition makes a distinct enthymem, of which the proposition is the conclusion. Thus Cicero, in his seventh Philippic, lays down this as the foundation of his discourse, "That he is against a peace with Mark Antony;" for which he gives three reasons: "Because it is base, because it is dangerous, and

Disposition.

and because it is impracticable. These severally joined with the proposition, form three enthymems; and upon each of these he discourses separately, which make up that oration. And this method is what persons for the most part naturally fall into, who know nothing of the terms *syllogism* or *enthymem*. They advance something, and think of a reason to prove it, and another perhaps to support that; and, so far as their invention will assist them, or they are masters of language, they endeavour to set what they say in the plainest light, give it the best dress, embellish it with proper figures and different turns of expression; and, as they think convenient, illustrate it with similitudes, comparisons, and the like ornaments, to render it most agreeable, till they think what they have advanced sufficiently proved. As this method of arguing therefore is the most plain, easy, and natural; so it is what is most commonly used in oratory. Whereas a strict syllogistical way of discoursing is dry and jejune, cramps the mind, and does not admit of those embellishments of language which are a great advantage to the orator; for which reason he seldom uses complete syllogisms; and when he does, it is with great latitude. In every discourse care should be taken not to blend arguments confusedly together that are of a separate nature. "All arguments (says the elegant Dr Blair,) are directed to prove one or other of these three things; that something is true; that it is morally right or fit; or that it is profitable and good. These make the three great subjects of discussion among mankind; truth, duty, and interest. But the arguments directed towards any one of them are generally distinct; and he who blends them all under one topic, which he calls his argument, as, in sermons especially, is too often done, will render his reasoning indistinct and inelegant. Suppose, for instance, that I am recommending to an audience benevolence, or the love of our neighbour; and that I take my first argument from the inward satisfaction which a benevolent temper affords; my second, from the obligation which the example of Christ lays upon us to this duty; and third, from its tendency to procure us the good will of all around us; my arguments are good, but I have arranged them wrong: for my first and third arguments are taken from considerations of interest, internal peace, and external advantages; and between these, I have introduced one, which rests wholly upon duty. I should have kept those classes of arguments, which are addressed to different principles in human nature, separate and distinct."

34
The analytic method of reasoning nearly the same with the Socratic.

II. The other method of reasoning is the analytic, in which the orator conceals his intention concerning the point he is to prove, till he has gradually brought his hearers to the designed conclusion. They are led on, step by step, from one known truth to another, till the conclusion be stolen from them, as the natural consequence of a chain of propositions. As, for instance, when one intending to prove the being of a God, sets out with observing that every thing which we see in the world has had a beginning; that whatever has had a beginning, must have had a prior cause; that in human productions, art shown in the effect, necessarily infers design in the cause; and proceeds leading you on from one cause to another, till you arrive at one supreme first cause, from whom is derived all the order and design visible in his works. This is much the same with the Socratic method, by which that philosopher silenced the sophists of his age.

He proceeded by several questions, which being separately granted, the thing designed to be inferred was afterwards put, which, by reason of its similitude with several cases allowed before, could not be denied. But this is a captious way of reasoning; for while the respondent is not aware of what is designed to be inferred, he is easily induced to make those concessions, which otherwise he would not. Besides, it is not so well suited to continued discourses, as to those which are interlocutory; and therefore we meet with it oftenest in the Socratic dialogues both of Plato and Xenophon. However, it may be made use of in oratory by a figure called *subjection*, when the same person first puts the question, and then makes the answer. So in the famous cause of Epaminondas, general of the Thebans, who was accused for refusing to surrender his command to his successor appointed by the state, till after he had engaged the enemy, and given them a total defeat, Cicero thus represents his accuser pleading for the words of the law against Epaminondas, who alleged the intention of it in his defence: "Should Epaminondas add that exception to the law, which, he says, was the intention of the writer namely, *Except any one refuse to give up his command when it is for the interest of the public he should not;* would you admit of it? I believe not. Should you yourselves, which is a thing most remote from your justice and wisdom, in order to screen him, order this exception to be added to the law, without the command of the people; would the Thebans suffer it to be done? No, certainly. Can it be right then to come into that, as if it was written, which it would be a crime to write? I know it cannot be agreeable to your wisdom to think so."

Under the analytic method may be comprehended reasoning by *example*. Rhetoricians use this word in a different sense from the common acceptation. For that is usually called an *example*, which is brought either to prove or illustrate some general assertion: As if any one should say, that *human bodies may be brought to sustain the greatest labours by use and exercise;* and in order to prove this should relate what is said of Milo of Croton, that "by the constant practice of carrying a calf several furlongs every day, he would carry it as far after it had grown to its full size." But in oratory the word *example* is used for any kind of similitude; or, as Vossius defines it, "When one thing is inferred from another, by reason of the likeness which appears between them." Hence it is called an *imperfect induction*, which infers something from several others of a like nature, and has always the greatest force when the examples are taken from facts. Now facts may be compared with respect to some agreement or similitude between them, which in themselves are either equal or unequal. Of the former kind this is an instance: Cato acted as became a patriot and a lover of his country's liberty, in opposing the arms of Cæsar: and therefore so did Cicero." The reason of the inference is founded in the parity of the case, which equally concerned all good subjects of the Roman government at that time. For all were alike obliged to oppose a common enemy, who endeavoured to subvert the constitution, and subject them to his own arbitrary power. But though an example 35

35
May comprehend reasoning by *example*.

ample consists in the comparison of two single facts, yet several persons may be concerned in each fact. Of this kind is that which follows: "As Pompey, Cæsar, and Crassus, acted illegally in the first triumvirate, by engrossing the sole power into their own hands, and by that means violating the public liberty; so likewise did Augustus, Mark Antony, and Lepidus, in the second triumvirate, by pursuing the same measures." But when Cicero defends Milo for killing Clodius, from the like instances of Ahala Servilius, Scipio Nasica, Lucius Opimius, and others; that is not an example, but an induction: because one thing is there inferred from its similitude to several others. But when a comparison is made between two facts that are unequal, the inference may be either from the greater to the less, or from the less to the greater. From the greater to the less in this manner: "Cæsar had no just pretensions to the Roman government, and therefore much less had Antony." The reason lies in the difference between the two persons. Cæsar had very much enlarged the bounds of the Roman empire by his conquests, and greatly obliged the populace by his generosity; but as he had always acted by an authority from the senate and people of Rome, these things gave him no claim to a power over them. Much less then had Antony any such pretence, who always acted under Cæsar, and had never performed any signal services himself. Cicero has described the difference between them in a very beautiful manner in his second Philippic, thus speaking to Antony: "Are you in any thing to be compared to him? He had a genius, sagacity, memory, learning, care, thought, diligence; he had performed great things in war, though detrimental to the state; he had for many years designed to get the government into his hands, and obtained his end by much labour and many dangers; he gained over the ignorant multitude by public shows, buildings, congiaries, and feasts; obliged his friends by rewards, and his enemies by a show of clemency. In a word, he subjected a free state to slavery, partly through fear, and partly compliance. I can liken you to him for ambition of power; but in other things you are in no respect to be compared with him." By a comparison from the less to the greater. Cicero thus argues against Catiline: "Did the brave Scipio, when a private man, kill Tiberius Gracchus, for attempting to weaken the state; and shall we consuls bear with Catiline endeavouring to destroy the world by fire and sword?" The circumstances of these two cases were very different; and the comparison runs between a private man and a consul instrusted with the highest authority; between a design only to raise a tumult, and a plot to destroy the government: whence the orator justly infers, that what was esteemed lawful in one case, was much more so in the other. The like way of reasoning is sometimes used from other similitudes, which may be taken from things of all kinds, whether animate or inanimate. Of the former sort is that of Cicero speaking of Muræna, when candidate for the consulship, after he had himself gone through that office: "If it is usual (says he) for such persons as are safely arrived in port, to give those who are going out the best account they can with relation to the weather, pirates, and coasts; because thus nature directs us to assist those who are entering upon the same dangers which we ourselves have escaped: how ought I, who now after a great storm am brought within a near prospect of land, to be affected towards him, who, I perceive, must be exposed to the greatest tempests of the state?" He alludes to the late disturbances and tumults occasioned by the conspiracy of Catiline, which had been so happily suppressed by him in the time of his consulate. Of the latter kind is that of Quintilian: "As the ground is made better and more fruitful by culture, so is the mind by instruction." There is both a beauty and justness in this simile.

But comparisons are sometimes made between facts and other things, in order to infer some difference or opposition between them. In comparing two facts, on account of some disagreement and unlikeness, the inference is made from the difference between one and the other in that particular respect only. As thus: "Though it was not esteemed cruelty in Brutus to put his two sons to death for endeavouring to betray their country; it might be so in Manlius who put his son to death, only for engaging the enemy without orders, though he gained the victory." The difference between the two facts lies in the different nature of the crime. The sons of Brutus entered into a conspiracy to betray their country; and though they miscarried in it, yet the intention and endeavours they used to accomplish it were criminal in the highest degree. But young Manlius could only be charged with rashness. His design was honourable, and intended for the interest of his country; only it was irregular, and might have proved of ill consequence to military discipline. Now in all such cases, the force of the argument is the stronger the greater the difference appears. But the same facts which differ in one respect may agree in many others; as in the example here mentioned. Brutus and Manlius were both magistrates as well as fathers; they both killed their sons, and that for a capital crime by the Roman law. In any of which respects they may be compared in a way of similitude: as, "If Brutus might lawfully put his son to death for a capital crime, so might Manlius." But now contrary facts do not only differ in some certain respect, but are wholly opposite to each other; so that what is affirmed of the one must be denied of the other; and if one be a virtue, the other is a vice. Thus Cicero compares the conduct of Marcellus and Verres in a way of opposition. "Marcellus (says he), who had engaged, if he took Syracuse, to erect two temples at Rome, would not beautify them with the spoils he had taken: Verres, who had made no vows to Honour and Virtue, but to Venus and Cupid, endeavoured to plunder the temple of Minerva. The former would not adorn the gods with the spoils of other deities: the latter carried the ornaments of Minerva, a virgin, into the house of a strumpet." If therefore the conduct of Marcellus was laudable and virtuous, that of Verres must bear the contrary character. But this way of reasoning has likewise place in other respects. Thus Cicero, in the quarrel between Cæsar and Pompey, advised to peace from the difference between a foreign and domestic war: "That the former might prove beneficial to the state; but in the latter, whichever side conquered, the public must suffer." And thus the ill effects of intemperance may be shown in a way of opposition: "That as temperance preserves the health of the body, keeps up the vigour of the mind, and prolongs life; so excess must necessarily have the contrary effects.

Thus we have given a brief account of the principal ways

Disposition.

ways of reasoning commonly made use of by orators. As to the disposition of arguments, or the order of placing them, some advise to put the weaker, which cannot wholly be omitted, in the middle: and such as are stronger, partly in the beginning, to gain the esteem of the hearers, and render them more attentive; and partly at the end, because what is last heard is likely to be retained longest: But if there are but two arguments, to place the stronger first, and then the weaker; and after that to return again to the former, and insist principally upon that. But this must be left to the prudence of the speaker, and the nature of the subject. Though to begin with the strongest, and so gradually descend to the weakest, can never be proper, for the reason last mentioned. Nor ought arguments to be crowded too close upon one another; for that takes off from their force, as it breaks in upon the attention of the hearers, and does not leave them sufficient time duly to consider them. Nor indeed should more be used than are necessary; because the fewer they are, the more easily they are remembered. And the observation of a great master of eloquence upon this subject is certainly very just, that *arguments ought rather to be weighed than numbered.*

CHAP. V. *Of Confutation.*

36
Forms of confutation the same with those of confirmation, but more difficult.

THE forms of reasoning here are the same as have been already explained under *confirmation. Confutation* however, is often the more difficult task; because he who is to prove a thing comes usually prepared; but he who is to confute it is frequently left to a sudden answer. For which reason, in *judicial* cases, Quintilian says, "It is as much easier to accuse than defend, as it is to make a wound than to heal it." Therefore, not only a good judgment, but a readiness of thought also, seems necessary for this province. But, in all disputes, it is of the greatest consequence to observe where the stress of the controversy lies. For without attending to this, persons may cavil about different matters, without understanding each other, or deciding any thing. And in confutation, what the adversary has advanced ought carefully to be considered, and in what manner he has expressed himself. As to the things themselves, whether they immediately relate to the matter in dispute, or are foreign to it. Those things that are foreign to the subject may either be past over in silence, or in a very few words shown to be insignificant. And there ought likewise to be a distinction made between such things as relate to the subject, according to their importance. Those that appear to have no great weight should be slightly remarked. For to insist largely upon such matters is both tiresome to the hearers, and apt to bring the judgment of the speaker in question. And therefore things of that nature are generally better turned off with an air of neglect, a pungent question, or an agreeable jest, than confuted by a serious and laboured answer. But those things, which relate to the merits of the cause, may be confuted either by *contradicting* them, or by showing some *mistake* in the reasoning, or their *invalidity* when granted.

Things may be *contradicted* several ways. What is apparently false may be expressly *denied.* Thus Cicero in his defence of Cluentius. "When the accuser had said that the man fell down dead after he had drunk off his cup, denies that he died that day." And things which the adversary cannot prove, may likewise be denied. Of which we have also an instance in Cicero, who first upbraids Mark Antony as guilty of a breach not only of good breeding, but likewise of friendship, for reading publicly a private letter he had sent him. And then adds, "But what will you say now, if I should deny that ever I sent you that letter? How will you prove it? By the hand-writing? In which I confess you have a peculiar skill, and have found the benefit of it. But how can you make it out? For it is in my secretary's hand. I cannot but envy your master who had so great a reward for teaching you to understand just nothing. For what can be more unbecoming not only an orator, but even a man, than for any one to offer such things, which if the adversary denies he has nothing more to say?" It is a handsome way of contradicting a thing, by showing that the adversary himself maintained the contrary. So when Oppius was charged with defrauding the soldiers of their provision, Cicero refutes it, by proving, that the same persons charged Oppius with a design to corrupt the army by his liberality. An adversary is never more effectually silenced than when you can fasten contradictions upon him; for this is stabbing him with his own weapon. Sometimes a thing is not in express terms denied, but represented to be utterly incredible. And this method exposes the adversary more than a bare denial. So when some persons reproached Cicero with cowardice, and a shameful fear of death, he recites their reasons in such a manner, that any one would be inclined to think the charge entirely false. "Was it becoming me (says he) to expect death with that composedness of mind as some have imagined? Well, and did I then avoid it? Nay, was there any thing in the world that I could apprehend more desirable? Or, when I had done the greatest things in such a crowd of ill-minded persons about me, do you think banishment and death were not always in my view, and continually sounding in my ears as my certain fate, while I was so employed? Was life desirable when all my friends were in such sorrow, and myself in so great distress, deprived of all the gifts both of nature and fortune? Was I so unexperienced, so ignorant, so void of reason and prudence? Had I never seen or heard any thing in my whole life? Did all I had read and studied avail nothing? What! did not I know that life is short, but the glory of generous actions permanent? When death is appointed for all, does it not seem eligible, that life, which must be wrested from us, should rather be freely devoted to the service of our country, than reserved to be worn out by the decays of nature? Was not I sensible, there has been this controversy among the wisest men, that some say, the minds of men and their consciences utterly perish at death; and others, that the minds of wise and brave men are then in their greatest strength and vigour, when they are set free from the body? The first state is not greatly to be dreaded, to be void of sense: but the other, of enjoying larger capacities, is greatly to be desired. Therefore, since I always aimed at dignity, and thought nothing was worth living for without it; how should I, who am past the consulship, and did so great things in it, be afraid to die?" Thus far Cicero. There is likewise an an ironical way of contradicting a thing, by retorting that and other things of the like nature upon the

the adverse party: Thus Cicero, in his oration against Vatinius, says: "You have objected to me, that I defended Cornelius, my old friend, and your acquaintance. But pray why should I not have defended him? Has Cornelius carried any law contrary to the omens? Has he violated any law? Has he assaulted the consul? Did he take possession of a temple by force of arms? Did he drive away the tribune, who opposed the passing a law? Has he thrown contempt upon religion? Has he plundered the treasury? Has he pillaged the state? No, these, all these, are your doings." Such an unexpected return is sometimes of great service to abate the confidence of an adversary.

A second way of confutation is, by observing some *flaw* in the reasoning of the adverse party. We shall endeavour to illustrate this from the several kinds of reasoning treated of before under *confirmation*. And first, as to syllogisms; they may be refuted, either by showing some mistake in the premises, or that the conclusion is not justly deduced from them. So when the Clodian party contended, that Milo ought to suffer death for this reason, Because he had confessed that he had killed Clodius; that argument, reduced to a syllogism, would stand thus:

He who confesses he has killed another, ought not to be allowed to see the light.
But Milo confesses this.
Therefore he ought not to live.

Now the force of this argument lies in the major or first proposition; which Cicero refutes, by proving, that the Roman people had already determined contrary to what is there asserted: "In what city (says he) do these men dispute after this weak manner? In that wherein the first capital trial was in the case of the brave Horatius, who, before the city enjoyed perfect freedom, was saved by the suffrages of the Roman people, though he confessed that he killed his sister with his own hand." But when Cicero accused Verres for mal-administration in his government of Sicily, Hortensius, who defended him, being sensible the allegations brought against him could not be denied, had no other way left to bring him off, but by pleading his military virtues in abatement, which at that time were much wanted, and very serviceable to the state. The form of the argument was this:

That the Romans then wanted good generals.
That Verres was such.
And consequently, that it was for the interest of the public that he should not be condemned.

But Cicero, who knew his design, states the argument for him in his charge; and then answers it by denying the consequence, since the crimes of Verres were of so heinous a nature, that he ought by no means to be pardoned on the account of any other qualifications: Though indeed he afterwards refutes the minor or second proposition, and shows that he had not merited the character of a good general. Enthymems may be refuted, either by showing that the antecedent is false, or the consequent not justly inferred from it. As thus, with respect to the former case;

A strict adherence to virtue has often proved detrimental.
Therefore virtue ought not constantly to be embraced.

Here the antecedent may be denied. For virtue is alway beneficial to those who strictly adhere to it, both in the present satisfaction it affords them, and the future rewards they may certainly expect from it. And as to the latter case, in this manner:

She is a mother.
Therefore she loves her children.

Now as the certainty of that inference depends upon this general assertion, That all mothers love their children, which is not true, the mistake of the reasoning may be shown from the instance of Medea and others, who destroyed their own children. As to *induction* and *example*, by which the truth or equity of a thing is proved from its likeness to one or more other things; the reasoning in either is invalid, if the things so compared can be shown not to have that similitude or agreement on which the inference is founded. One instance therefore may serve for both. As when Cicero, after the death of Cæsar, pleaded for the continuance of his laws, but not of those which were made afterwards by Mark Antony: Because, though both were in themselves invalid, and impositions upon the public liberty; yet some of Cæsar's were useful, and others could not be set aside without disturbance to the state, and injuring particular persons; but those of Antony were all detrimental to the public.

The last method of *confutation* before mentioned was, when the orator does in some sense *grant* the adversary his argument, and at the same time shows its *invalidity*. And this is done by a variety of ways, according to the different nature of the subject. Sometimes he allows what was said may be true; but pleads, that what he contends for is necessary. This was the method by which Hortensius proposed to bring off Verres, as we have already shown from Cicero, whose words are these, addressing himself to the judges; "What shall I do? which way shall I bring in my accusation? where shall I turn myself; for the character of a brave general is placed like a wall against all the attacks I can make. I know the place, I perceive where Hortensius intends to display himself. He will recount the hazards of war, the necessities of the state, the scarcity of commanders; and then he will entreat you, and do his utmost to persuade you not to suffer the Roman people to be deprived of such a commander upon the testimony of the Sicilians, nor the glory of his arms to be sullied by a charge of avarice." At other times the orator pleads, that although the contrary opinion may seem to be attended with advantage, yet that his own is more just, or honourable. Such was the case of Regulus, when his friends endeavoured to prevail with him to continue at Rome, and not return to Carthage, where he knew he must undergo a cruel death. But as this could not be done without violating his oath, he refused to hearken to their persuasions. Another way of confutation is, by retorting upon the adversary his own argument. Thus Cicero, in his defence of Ligarius, says: "You have, Tubero, that which is most desirable to an accuser, the confession of the accused party; but yet such a confession,

Disposition.

confession, that he was on the same side that you, Tubero, chose yourself, and your father too, a man worthy of the highest praise. Wherefore, if there was any crime in this, you ought first to confess your own before you attempt to fasten any upon Ligarius." The orator takes this advantage where an argument proves too much, that is, more than the person designed it for, who made use of it. Not much unlike this is what they call *inversion*, by which the orator shows that the reasons offered by the opposite party make for him. So when Cæcilius urged, that the province of accusing Verres ought to be granted to him, and not to Cicero, because he had been his treasurer in Sicily at the time those crimes were committed with which he was charged, and consequently knew most of that affair; Cicero turns the argument upon him, and shows, for that very reason he was the most unfit of any man to be intrusted with his prosecution; since having been concerned with him in his crimes, he would certainly do all in his power to conceal or lessen them. Again, sometimes the charge is acknowledged, but the crime shifted off to another. Thus, when Sextius was accused of sedition, because he had got together a body of gladiators, and brought them into the forum, where a warm engagement happened between them and Clodius's faction; Cicero owns the fact, but charges the crime of sedition upon Clodius's party in being the aggressors. Another method made use of for the same purpose is to alleviate the charge, and take off the force of it, by showing, that the thing was not done with that intention which the adversary insinuates. Thus Cicero, in his defence of King Dejotarus, owns he had raised some forces, though not to invade the Roman territories, as had been alleged, but only to defend his own borders, and send aid to the Roman generals.

We have hitherto been speaking of the methods of confutation used by orators, in answering those arguments which are brought by the contrary party. But sometimes they raise such objections themselves to what they have said, as they imagine may be made by others; which they afterwards answer, the better to induce their hearers to think that nothing considerable can be offered against what they have advanced, but what will admit of an easy reply. Thus, when Cicero, at the request of the Sicilians, had undertaken the accusation of Verres, it came under debate, whether he, or Cæcilius, who had been Verres's quæstor in Sicily, should be admitted to that province. Cicero, therefore, in order to set him aside, among other arguments shows his incapacity for such an undertaking, and for that end recounts at large the qualifications necessary for an orator. Which he represents to be so many and great, that he thought it necessary to start the following objection to what he had himself said upon that subject. "But you will say perhaps, Have you all these qualifications?" To which he thus replies: "I wish I had; but it has been my constant study from my youth to gain them. And if, from their greatness and difficulty, I have not been able to attain them, who have done nothing else through my whole life; how far, do you imagine, you must be from it, who never thought of them before; and even now, when you are entering upon them, have no apprehension what, and how great, they are?" This is an effectual way of defeating an adversary, when the objection is well founded, and clearly answered. But we shall have occasion to consider this matter more largely hereafter, under the figure *prolepsis*, to which it properly relates.

Chap. VI. *Of the Conclusion.*

37

The conclusion is a recapitulation and address to the passions.

Rhetoricians make the *conclusion* of a discourse to consist of two parts: *recapitulation*, and *an address to the passions*.

1. *Recapitulation* is a summary account of what the speaker has before offered in maintenance of his subject, and is designed both to refresh the memory of the hearers, and to bring the principal arguments together into a narrow compass, that they may appear in a stronger light. Now there are several things necessary to a good repetition.

And first, it must be short and concise; since it is designed to refresh the memory, and not to burden it. For this end, therefore, the chief things only are to be touched upon; those on which the cause principally depends, and which the orator is most desirous should be regarded by his hearers. Now these are, The general heads of the discourse, with the main arguments brought to support them. But either to insist particularly upon every minute circumstance, or to enlarge upon those heads which it may be thought proper to mention, carries in it not so much the appearance of a repetition, as of a new discourse.

Again, it is convenient in a repetition to recite things in the same order in which they were at first laid down. By this means the hearers will be enabled much better to keep pace with the speaker as he goes along; and if they happen to have forgot any thing, they will the more readily recal it. And besides, this method appears most simple and open, when the speaker reviews what he has said in the same manner it was before delivered, and sets it in the clearest light for others to judge of it. But though a repetition contains only the same things which had been more largely treated of before; yet it is not necessary they should be expressed in the same words. Nay, this would many times be tiresome and unpleasant to the hearers; whereas a variety of expression is grateful, provided the sense be the same. Besides, every thing ought now to be represented in the strongest terms, and in so lively a manner as may at the same time both entertain the audience, and make the deepest impression upon their minds. We have a very exact and accurate example of repetition in Cicero's oration for Quintius. Cicero was then a young man, and seems to have kept more closely to the rules of art, than afterwards, when, by use and practice, he had gained a greater freedom of speaking. We formerly cited the partition of this speech, upon another occasion, which runs thus: "We deny, Sextus Nevius, that you were put into the possession of the estate of P. Quintius, by the prætor's edict. This is the dispute between us. I will therefore show, first, that you had no just cause to apply to the prætor for the possession of the estate of P. Quintius; then that you could not possess it by the edict; and lastly, that you did not possess it. When I have proved these three things, I will conclude." Now Cicero begins his conclusion with a repetition of those three heads, and a summary account of the several arguments he made use of under each of them. But they are too long to be here exhibited. In his

Disposition.

his oration for the Manilian law, his repetition is very short. He proposed in the partition to speak to three things: The nature of the war against King Mithridates, the greatness of it, and what sort of general was proper to be intrusted with it. And when he has gone through each of these heads, and treated upon them very largely, he reduces the substance of what he has said to this general and short account: "Since therefore the war is so necessary, that it cannot be neglected; and so great, that it requires a very careful management; and you can intrust it with a general of admirable skill in military affairs, of singular courage, the greatest authority, and eminent success: do you doubt to make use of this so great a blessing, conferred and bestowed upon you by heaven, for the preservation and enlargement of the Roman state?" Indeed this repetition is made by Cicero, before he proceeds to the confutation; and not at the end of his discourse, where it is usually longer and more particular: however, this may serve to show the nature of such a recital.

But sometimes a repetition is made, by running a comparison between the speaker's own arguments and those of the adverse party; and placing them in opposition to each other. And this method Cicero takes in the conclusion of his third oration upon the Agrarian law. And here sometimes the orator takes occasion to find fault with his adversary's management, in these and such like expressions: "This part he has entirely dropt. To that he has given an invidious turn, or a false colouring. He leaves arguments, and flies to intreaties; and not without good reason, if we consider the weakness of his cause."

But when the discourse is very long, and the arguments insisted on have been many, to prevent the hearers growing out of patience by a more particular recital, the orator sometimes only just mentions such things, which he thinks of least consequence, by saying, that he omits or passes over them, till he comes to what is of greater moment, which he represents more fully. This method Cicero has taken in his defence of Cluentius; where, having run over several lesser heads in the manner now described, he then alters his expression, and introduces what was of more importance, by saying, "What I first complain of, is that wickedness, which is now discovered." And so he proceeds more particularly to recite those things which immediately related to Cluentius. And this is what the writers upon this art call *preterition*. But this much may serve for repetition or recapitulation.

2. We now proceed to the other part of the conclusion, which consists in an *address to the passions*. Indeed the orator sometimes endeavours occasionally to work upon the passions of his hearers in other parts of his discourse, but more especially in the conclusion, where he is warmest himself, and labours to make them so. For the main design of the introduction is to conciliate the hearers, and gain their attention; of the narration, proposition, and confirmation, to inform them; and of the conclusion, to move them. And therefore, to use Quintilian's words, "Here all the springs of eloquence are to be opened. It is here we secure the minds of the hearers, if what went before was well managed. Now we are past the rocks and shallows, all the sails may be hoisted. And as the greatest part of the conclusion consists in illustration, the most pompous language and strongest figures have place here." Now the passions, to which the orator more particularly addresses, differ according to the nature of the discourse. In demonstrative orations, when laudatory,—love, admiration, and emulation, are usually excited; but in invectives,—hatred, envy, and contempt. In deliberative subjects, either the hope of gratifying some desire is set in view, or the fear of some impending evil. And in judicial discourses, almost all the passions have place, but more especially resentment and pity; insomuch that most of the ancient rhetoricians mention only these two. But having treated upon the nature of the passions, and the methods suited both to excite and allay them, in a former chapter, we shall at present only add a few general observations, which may not be improper in this place, where the skill of the orator in addressing to them is more especially required.

The orator will observe what circumstances either of things, or persons, or both, will furnish him with motives proper to apply to those passions he desires to excite in the minds of his hearers. Thus Cicero, in his orations for Plancus and Sylla, moves his hearers from the circumstances of the men; but in his accusation of Verres, very frequently from the barbarity and horrid nature of his crimes; and from both, in his defence of Quintius.

But the same passion may be excited by very different methods. This is plain from the writings of those Roman satirists which are yet extant; for they have all the same design, and that is to engage men to a love of virtue, and hatred of vice: but their manner is very different, suited to the genius of each writer. Horace endeavours to recommend virtue, by laughing vice out of countenance; Persius moves us to an abhorrence and detestation of vice, with the gravity and severity of a philosopher; and Juvenal, by open and vehement invectives. So orators make use of all these methods in exciting the passions; as may be seen by their discourses, and particularly those of Cicero. But it is not convenient to dwell long upon the same passion. For the image thus wrought up in the minds of the hearers does not last a great while; but they soon return to reflection. When the emotion, therefore, is once carried as high as it well can be, they should be left under its influence, and the speaker proceed to some new matter, before it declines again.

Moreover, orators sometimes endeavour to raise contrary passions to each other, as they are concerned for opposite parties. So the accuser excites anger and resentment, but the defendant pity and compassion. At other times, one thinks it sufficient to allay and take off that passion which the other has raised, and bring the hearers to a calm and sedate consideration of the matter before them.

But this especially is to be regarded, that the orator express the same passion himself with which he endeavours to affect others; and that not only in his action and voice, but likewise in his language: and therefore his words, and manner of expression, should be suited to that perturbation and disorder of mind which he designs to represent. However, a decency and propriety of character is always carefully to be observed; for, as Cicero very well remarks, "A neglect of this is not only very culpable in life, but like-wise

Disposition.

wise in discourse. Nor do the same things equally become every speaker, or every audience; nor every time, and every place." And therefore he greatly commends that painter, who, designing to represent in a picture the sacrifice of Iphigenia, Agamemnon's daughter, drew Calchas the priest with a sad countenance; Ulysses, her father's great friend, more dejected; and her uncle Menelaus, most disconsolate; but threw a veil over the face of Agamemnon himself, as being unable to express that excess of sorrow which he thought was proper to appear in his countenance. And this justness of character is admirably well observed by Cicero himself, in his defence of Milo; for as Milo was always known to be a man of the greatest resolution, and most undaunted courage, it was very improper to introduce him (as the usual method then was in capital cases) moving pity, and begging for mercy. Cicero therefore takes this part upon himself; and what he could not do with any propriety in the person of Milo, he performs in his own, and thus addresses the judges: "What remains, but that I entreat and beseech you, that you would show that compassion to this brave man, for which he himself does not solicit, but I, against his inclination, earnestly implore and request. Do not be less inclined to acquit him, if in this our common sorrow, you see no tear fall from Milo's eyes; but perceive in him the same countenance, voice, and language, as at other times, steady and unmoved. Nay, I know not whether for this reason, you ought not much sooner to favour him: For if, in the contests of gladiators (persons of the lowest condition and fortune in life), we are wont to be displeased with the timorous and suppliant, and those who beg for their life; but interpose in favour of the brave and courageous, and such as expose themselves to death; and we show more compassion to those who do not sue for it, than to those who do: with how much greater reason ought we to act in the same manner towards the bravest of our fellow citizens?" And as these words were agreeable to his own character, while soliciting in behalf of another; so, immediately after, he introduces Milo speaking like himself, with a generous and undaunted air: "These words of Milo (says he) quite sink and dispirit me, which I daily hear from him. Farewell, farewell, my fellow citizens, farewell! may you be happy, flourish, and prosper; may this renowned city be preserved, my most dear country, however it has treated me; may it continue in peace, though I cannot continue in it, to whom it owes its peace. I will retire, I will be gone."

But as persons are commonly more affected with what they see than with what they hear, orators sometimes call in the assistance of that sense in moving the passions. For this reason it was usual among the Romans, in judicial cases, for accused persons to appear with a dejected air and a sordid garb, attended by their parents, children, or other relations and friends, with the like dress and aspect; as likewise to show their scars, wounds, bloody garments, and other things of the like nature, in open court. So when, upon the death of Cæsar, Mark Antony harangued the populace, he at the same time exposed to their view the garment in which he was stabbed, fixed upon a pole; at which sight they were so enraged, that immediately they ran with lighted torches to set fire to the houses of the conspirators. But this custom at last became so common, and was sometimes so ill conducted, that the force of it was greatly abated, as we learn from Quintilian. However, if the Romans proceeded to an excess on the one hand, the strictness of the Areopagites at Athens may perhaps be thought too rigid on the other; for in that court, if the orator began to say any thing which was moving, an officer immediately stood up and bade him be silent. There is certainly a medium between these two extremes, which is sometimes not only useful, but even necessary; for as Quintilian very justly says, "It is necessary to apply to the passions, when those things which are true, just, and of common benefit, cannot be come at any other way."

Chap. VII. *Of Digression, Transition, and Amplification.*

38 Digression, transition, and amplification, defined, and explained.

The number, order, and nature of the parts which constitute a complete and regular oration, we have endeavoured to explain in several preceding chapters. But there are two or three things yet remaining, very necessary to be known by an orator, which seem most properly to come under the second branch of his art. And these are, *Digression*, *Transition*, and *Amplification*.

I. *Digression*, as defined by Quintilian, is, "A going off from the subject we are upon to some different thing, which may however be of service to it." We have a very beautiful instance of this in Cicero's defence of Cœlius, who was accused of having first borrowed money of Clodia, and then engaging her servants to poison her. Now, as the proof of the fact depended upon several circumstances, the orator examines them separately; and shows them to be all highly improbable. "How (says he) was the design of this poison laid? Whence came it? how did they get it? by whose assistance, to whom, or where, was it delivered?" Now to the first of these queries he makes the accuser give this answer: "They say Cœlius had it at home, and tried the force of it upon a slave provided on purpose, whose sudden death proved the strength of the poison." Now as Cicero represents the whole charge against Cœlius as a fiction of Clodia, invented out of revenge for some slights he had put upon her; to make this the more probable, he insinuates that she had poisoned her husband, and takes this opportunity to hint it, that he might show how easy it was for her to charge another with poisoning a servant, who had done the same to her own husband. But not contented with this, he steps out of his way, and introduces some of the last words of her husband Metellus, to render the fact more barbarous and shocking, from the admirable character of the man. "O immortal gods! why do you sometimes wink at the greatest crimes of mankind, or delay the punishment of them to futurity! For I saw, I myself saw (and it was the most doleful scene of my whole life) when Q. Metellus was taken from the bosom of his country; and when he, who thought himself born to be serviceable to this state, within three days after he had appeared with such advantage in the senate, in the forum, and everywhere in public, was snatched from us in the flower of his age, and prime of his strength and vigour. At which time, when

Disposition

when he was about to expire, and his mind had lost the sense of other things, still retaining a concern for the public, he looked upon me, as I was all in tears, and intimated in broken and dying words how great a storm hung over the city and threatened the whole state; often striking the wall which separated his house from that of Quintus Catulus, and frequently calling both upon him and me, and seeming to grieve not so much at the approach of his own death, as that both his country and I should be deprived of his assistance. Had he not been wickedly taken off on a sudden, how would he after his consulship have withstood the fury of his kinsman Publius Clodius, who, while in that office, threatened, in the hearing of the senate, to kill him with his own hand, when he first began to break out? And will this woman dare to come out of those doors, and talk of the force of poison? will not she fear, lest the house itself should speak the villany? will not she dread the conscious walls, nor that sad and mournful night? But I return to the accusation." And then he proceeds to consider and refute the several circumstances of the accusation. All this was no part of his argument; but having mentioned the charge of poison, he immediately takes occasion to introduce it, in order to excite the indignation of the hearers against Clodia, and invalidate the prosecution as coming from a person of her character. Digression cannot properly be said to be a necessary part of a discourse; but it may sometimes be very convenient, and that upon several accounts.

As first, when a subject is of itself flat and dry, or requires close attention, it is of use to relieve and unbend the mind by something agreeable and entertaining. For which reason Quintilian observes, that the orators of his time generally made an excursion in their harangues upon some pleasing topic, between the narration and the proof. But he condemns the practice as too general; for while they seemed to think it necessary, it obliged them sometimes to bring in things trifling and foreign to the purpose. Besides, a digression is confined to no one part of a discourse, but may come in anywhere, as occasion offers; provided it fall in naturally with the subject, and be made some way subservient to it. We never meet with it in Cicero, without some evident and good reason. So in his prosecution of Verres for his barbarous and inhuman outrages against the Sicilians, he takes an occasion to launch out in a beautiful description of the island, and to recount the advantages which accrued from it to the Romans. His subject did not necessarily lead him to this, but his view in it was to heighten and aggravate the charge against Verres.

Again, as a *digression* ought not to be made without sufficient reason, so neither should it be too frequent. And he who never does it but where it is proper and useful, will not often see occasion for it. Frequently to leave the subject, and go off to other things, breaks the thread of the discourse, and is apt to introduce confusion. Indeed some kinds of writing admit of a more frequent use of digressions than others. In history they are often very serviceable. For as that consists of a series of facts, and a long continued narrative without variety is apt to grow dull and tedious; it is necessary at proper distances to throw in something entertaining, in order to enliven it, and keep up the attention. And accordingly we find the best historians often embellish their writings with descriptions of cities, rivers, and countries, as likewise with the speeches of eminent persons upon important occasions, and other ornaments to render them the more pleasing and delightful. Poets take a still greater liberty in this respect; for as their principal view is most commonly to please, they do not attend so closely to connection; but as an image offers itself, which may be agreeably wrought up, they bring it in, and go off more frequently to different things, than other writers.

Another property of a *digression* is, that it ought not to be too long, lest the hearers forget what preceded, before the speaker again returns to his subject.

For a digression being no principal part of a discourse, nor of any further use than as it serves some way or other to enforce or illustrate the main subject; it cannot answer this end, if it be carried to such a length, as to cause that either to be forgotten or neglected. And every one's memory will not serve him to connect together two parts of a discourse, which lie at a wide distance from each other. The better therefore to guard against this, it is not unusual with orators, before they enter upon a digression of any considerable length, to prepare their hearers by giving them notice of it, and sometimes desiring leave to divert a little from the subject. And so likewise at the conclusion they introduce the subject again by a short transition. Thus Cicero in the example cited above, when he has finished his digression concerning the death of Metellus, proceeds to his subject again with these words: "But I return to the accusation."

Indeed we find orators sometimes, when sore pressed, and the cause will not bear a close scrutiny, artfully run into digressions with a design to divert the attention of the hearers from the subject, and turn them to a different view. And in such cases, as they endeavour to be unobserved, so they do it tacitly without any transition or intimation of their design; their business being only to get clear of a difficulty, till they have an opportunity of entering upon some fresh topic.

39 Transitions often used on various occasions.

II. *Transitions* are often used not only after a digression, but likewise upon other occasions. A transition is, "A form of speech, by which the speaker in a few words tells his hearers both what he has said already, and what he next designs to say." Where a discourse consists of several parts, this is often very proper in passing from one to another, especially when the parts are of a considerable length; for it assists the hearers to carry on the series of the discourse in their mind, which is a great advantage to the memory. It is likewise a great relief to the attention, to be told when an argument is finished, and what is to be expected next. And therefore we meet with it very frequently in history. But we consider it at present only as made use of by orators. Cicero, in his second oration against Catiline, who had then left Rome, having at large described his conduct and designs, he adds, "But why do I talk so long concerning one enemy, and such an one; who owns himself an enemy, and whom I do not fear, since, what I always desired, there is now a wall between us; and say nothing

Disposition.

of those, who conceal themselves, who remain at Rome, and among us?" And then he proceeds to give an account of the other conspirators.

But sometimes, in passing from one thing to another, a general hint of it is thought sufficient to prepare the hearers, without particularly specifying what has been said, or is next to follow. Thus Cicero in his second Philippic says, "But those things are old, this is yet fresh." And again: "But I have insisted too long upon trifles; let us come to things of greater moment." And at other times, for greater brevity, the transition is imperfect, and mention made only of the following head, without any intimation of what has been said already. As in Cicero's defence of Muræna, where he says: "I must now proceed to the third part of my oration concerning the charge of bribery." And soon after: "I come now to Cato, who is the support and strength of this charge."

40 Amplification defined and explained.

III. The third and last head is, *Amplification*. Now by amplification is meant, not barely a method of enlarging upon a thing: but so to represent it in the fullest and most comprehensive view, as that it may in the liveliest manner strike the mind and influence the passions. Cicero, speaking of this, calls it *the greatest commendation of eloquence;* and observes, "that it consists not only in magnifying and heightening a thing, but likewise in extenuating and lessening it." But though it consists of these two parts, and may be applied either way; yet to amplify, is not to set things in a false light, but to paint them in their just proportion and proper colours, suitable to their nature and qualities. Rhetoricians have observed several ways of doing this.

One is to ascend from a particular thing to a general. Thus Cicero, in his defence of Archias, having commended him as an excellent poet, and likewise observed, that all the liberal arts have a connection with each other, and a mutual relation between them, in order to raise a just esteem of him in the minds of his hearers, takes occasion to say many things in praise of polite literature in general, and the great advantages that may be received from it. "You will ask me (says he), why we are so delighted with this man? Because he supplies us with those things which both refresh our minds after the noise of the forum, and delight our ears when wearied with contention. Do you think we could either be furnished with matter for such a variety of subjects, if we did not cultivate our minds with learning; or bear such a constant fatigue, without affording them that refreshment? I own I have always pursued these studies; let those be ashamed, who have so given up themselves to learning, as neither to be able to convert it to any common benefit, nor discover it in public. But why should it shame me, who have so lived for many years, that no advantage or ease has ever diverted me, no pleasure allured me, nor sleep retarded me from this pursuit. Who then can blame me, or who can justly be displeased with me, if I have employed that time in reviewing these studies, which has been spent by others in managing their affairs, in the celebration of festivals or other diversions, in refreshments of mind and body, in unseasonable banquets, in dice, or tennis? And this ought the rather to be allowed me, because my ability as an orator has been improved by those pursuits, which, such as it is, was never wanting to assist my friends. And if it be esteemed but small, yet I am sensible from what spring I must draw those things which are of the greatest importance." With more to the same purpose; from which he draws this inference: "Shall I not therefore love this man? shall I not admire him? shall I not by all means defend him?"

A contrary method to the former is, to descend from a general to a particular. As if any one, while speaking in commendation of eloquence, should illustrate what he says from the example of Cicero, and show the great services he did his country, and the honours he gained to himself, by his admirable skill in oratory. Our common way of judging of the nature of things is from what we observe in particular instances, by which we form general notions concerning them. When therefore we consider the character of Cicero, and the figure he made in the world, it leads us to conclude, there must be something very admirable in that art by which he became so celebrated. And this method he has taken himself in his oration for the Manilian law, where having first intimated the scarcity of good generals at that time among the Romans, he then describes the virtues of a complete commander as a proof of it, and shows how many and great qualifications are necessary to form such a character, as courage, prudence, experience, and success: all which he afterwards applies to Pompey.

A third method is by an enumeration of parts. So when Cicero, upon the defeat of Mark Antony before Mutina, proposed that a funeral monument should be erected in honour of the soldiers who were killed in that battle, as a comfort to their surviving relations; he does it in this way, to give it the greater weight: "Since (says he) the tribute of glory is paid to the best and most valiant citizens by the honour of a monument, let us thus comfort their relations, who will receive the greatest consolation in this manner; their parents who produced such brave defenders of the state; their children who will enjoy these domestic examples of fortitude; their wives, for the loss of such husbands, whom it will be more fitting to extol than lament; their brethren, who will hope to resemble them no less in their virtues than their aspect. And I wish we may be able to remove the grief of all these by our resolutions." Such representations greatly enlarge the image of a thing, and afford the mind a much clearer view of it than if it were contracted into one single proposition.

Again, another method not much unlike the former is, when any thing is illustrated from a variety of causes. Thus Cicero justifies his behaviour in retiring, and not opposing his enemies, when they spirited up the mob in order to banish him, from the following reasons, which at that time determined him to such a conduct: "When (says he) unless I was given up, so many armed fleets seemed ready to attack this single ship of the state, tossed with the tempests of seditions and discords, and the senate was now removed from the helm; when banishment, murder, and outrage, were threatened; when some, from an apprehension of their own danger, would not defend me; others were incited by an inveterate hatred to all good men, others thought I stood in the way, others took this opportunity to express their resentment, others envied the peace and tranquillity

Disposition.

tranquillity of the state; and upon all these accounts I was particularly struck at: should I have chosen rather to oppose them (I will not say to my own certain destruction, but to the greatest danger both of you and your children), than alone to submit to and undergo what threatened us all in common?" Such a number of reasons brought together, must set a thing in a very strong and clear light.

The like may be said of a number and variety of effects. Thus Cicero describes the force and excellence of oratory from its great and surprising effects, when he says, "Nothing seems to be more excellent, than by discourse to draw the attention of a whole assembly, delight them, and sway their inclinations different ways at pleasure. This, in every free state, and especially in times of peace and tranquillity, has been always in the highest esteem and reputation. For what is either so admirable, as for one only, or a very few, out of a vast multitude, to be able to do that which all have a natural power of doing? or so delightful to hear, as a judicious and solid discourse in florid and polite language? or so powerful and grand, as to influence the populace, the judges, the senate, by the charms of eloquence? Nay, what is so noble, so generous, so munificent, as to afford aid to supplicants, to support the afflicted, give safety, deliver from dangers, and preserve from exile? Or what is so necessary as to be always furnished with arms to guard yourself, assert your right, or repel injuries? And, not to confine our thoughts wholly to the courts of justice or the senate, what is there in the arts of peace more agreeable and entertaining than good language and a fine way of speaking? For it is in this especially wherein we excel other animals, that we can discourse together, and convey our thoughts to each other by words. Who therefore would not esteem, and in a particular manner endeavour to surpass others in that wherein mankind principally excels brute beasts? But to proceed to its chief advantages: What else would have drawn men into societies, or taken them off from a wild and savage life, and soften them into a polite and civilized behaviour; or, when settled in communities, have restrained them by laws?" Who but, after such a description, must conceive the strongest passion for an art attended with so many great and good effects?

A thing may likewise be illustrated by its opposite. So the blessings and advantages of peace may be recommended from the miseries and calamities of war; and thus Cicero endeavours to throw contempt upon Catiline and his party, by comparing them with the contrary side: "But if, omitting all these things with which we abound, and they want, the senate, the knights, the populace, the city, treasury, revenues, all Italy, the provinces, and foreign nations; if, I say, omitting these things, we compare the causes themselves in which each side is engaged, we may learn from thence how despicable they are.—For on this side modesty is engaged, on that impudence; on this chastity, on that lewdness; on this integrity, on that fraud; on this piety, on that profaneness; on this constancy, on that fury; on this honour, on that baseness; on this moderation, on that unbridled passion. In a word, equity, temperance, fortitude, prudence, and all virtues, contend with injustice, luxury, cowardice, rashness, and all vices; plenty with want; reason with folly; sobriety with madness; and, lastly, good hope with despair. In such a contest, did men desert us, would not heaven ordain that so many and so great vices should be defeated by these most excellent virtues?"

Gradation is another beautiful way of doing this. So when Cicero would aggravate the cruelty and barbarity of Verres for crucifying a Roman citizen, which was a sort of punishment only inflicted upon slaves, he chooses this way of doing it. "It is a crime (says he) to bind a Roman citizen, wickedness to whip him, and a sort of parricide to kill him; what then must I call it to crucify him? No name can sufficiently express such a villany." And the images of things may be thus heightened, either by ascending, as in this instance; or descending, as in that which follows, relating to the same action of Verres: "Was I not to complain of or bewail these things to Roman citizens, nor the friends of our state, nor those who had heard of the Roman name; nay, if not to men, but beasts; or, to go yet further, if in the most desert wilderness, to stones and rocks; even all mute and inanimate creatures would be moved by so great and heinous cruelty."

And, to name no more, facts may be amplified from their circumstances; as time, place, manner, event, and the like. But instances of this would carry us too far; and therefore we shall only add, that as the design of *amplification* is not barely to prove or evince the truth of things, but also to adorn and illustrate them, it requires a florid and beautiful style, consisting of strong and emphatical words, flowing periods, harmonious numbers, lively tropes, and bright figures. But the consideration of these things comes under the Third Part of Oratory, upon which we are now to enter.

PART III. OF ELOCUTION.

ELOCUTION directs us to suit both the words and expressions of a discourse to the nature of the subject, or to speak with propriety and decency. This faculty is in one word called *eloquence;* and those persons who are possessed of it are therefore styled *eloquent.*

Elocution is twofold, general and particular. The former treats of the several properties and ornaments of language in common; the latter considers them as they are made use of to form different sorts of style.

I. GENERAL ELOCUTION.

41 General elocution defined.

THIS, according to rhetoricians, consists of three parts; *Elegance*, *Composition*, and *Dignity*. A discourse which has all these properties suitably adjusted, must, with respect to the language, be perfect in its kind, and delightful to the hearers.

CHAP.

Elocution.

CHAP I. *Of Elegance.*

ELEGANCE consists in two things, *Purity* and *Perspicuity:* And both these, as well with respect to single words, as their construction in sentences. These properties in language give it the name of *elegant*, for a like reason that we call other things so which are clean and neat in their kind. But in the common use of our tongue, we are apt to confound *elegance* with *eloquence;* and say, *a discourse is elegant*, when we mean by the expression, that it has all the properties of fine language.

§ 1. *Purity.*

42 Purity explained and illustrated.

By this we are to understand the choice of such words and phrases as are suited and agreeable to the use of the language in which we speak: And so grammarians reduce the faults they oppose to it to two sorts, which they call *barbarism* and *solecism;* the former of which respects single words, and the latter their construction. But we shall consider them jointly, and in a manner different from grammarians; for with them all words are esteemed pure which are once adopted into a language, and authorised by use. And as to phrases, or forms of expression, they allow them all the same claim, which are agreeable to the analogy of the tongue. But in oratory, neither all words nor all expressions are so called which occur in language; but such only as come recommended by the authority of those who speak or write with accuracy and politeness. Indeed it is a common saying *that we should think with the learned, and speak with the vulgar.* But the meaning of that expression is no more than that we should speak agreeably to the common usage of the tongue, that every one may understand us; and not choose such words or expressions as are either difficult to be understood, or may carry in them an appearance of affectation and singularity. But in order to set this matter in a clearer light, we shall here recount the principal things which vitiate the purity of language.

And first, it often happens, that such words and forms of speaking as were introduced by the learned are afterwards dropped by them as mean and sordid, from a seeming baseness contracted by vulgar use. For polite and elegant speakers distinguish themselves by their discourse, as persons of figure do by their garb; one being the dress of the mind, as the other is of the body. And hence it comes to pass, that both have their different fashions, which are often changed; and as the vulgar affect to imitate those above them in both, this frequently occasions an alteration when either becomes too trite and common. But beside these sordid words and expressions, which are rendered so by the use of the vulgar, there is another sort first introduced by them, which is carefully to be avoided by all those who are desirous to speak well. For the vulgar have their peculiar words and phrases, suited to their circumstances, and taken from such things as usually occur in their way of life. Thus in the old comedians, many things are spoken by servants, agreeable to their character, which would be very unbecoming from the mouth of a gentleman. And we cannot but daily observe the like instances among ourselves.

Again, this is common to language with all other human productions, that it is in its own nature liable to a constant change and alteration. For, as Horace has justly observed,

> All human works shall waste;
> Then how can feeble words pretend to last.

Nothing could ever please all persons, or at least for any length of time. And there is nothing from which this can less be expected than language. For as the thoughts of men are exceedingly various, and words are the signs of their thoughts, they will be constantly inventing new signs to express them by, in order to convey their ideas with more clearness, or greater beauty. If we look into the different ages of the Latin writers, what great alterations and changes do we find in their language? How few now understand the remaining fragments of the *twelve tables?* Nay, how many words do we meet with even in Plautus, the meaning of which has not yet been fixed with certainty by the skill of the best critics? And if we consider our own language, it will appear to have been in a manner entirely changed from what it was a few ages since. To mention no others, our celebrated Chaucer is to most persons now almost unintelligible, and wants an expositor. And even since our own memory, we cannot but have observed, that many words and expressions, which a few years ago were in common use, are now in a manner laid aside and antiquated; and that others have constantly succeeded, and daily do succeed in their room. So true is that observation of the same poet:

> Some words that have or else will feel decay
> Shall be restor'd, and come again in play;
> And words now fam'd shall not be fancied long;
> They shall not please the ear, nor move the tongue;
> As use shall these approve, and those condemn;
> Use, the sole rule of speech, and judge supreme.

We must therefore no less abstain from antiquated or obsolete words and phrases, than from sordid ones. Though all old words are not to be thought antiquated. By the former we mean such as, though of an ancient standing, are not yet entirely disused nor their signification lost. And from the use of these we are not to be wholly debarred, especially when they appear more significant than any others we can fix upon. But as to phrases or expressions, greater caution seems still necessary: and such as are old should doubtless, if at all, be used more sparingly. The Latin tongue was brought to its greatest perfection in the reign of Augustus, or somewhat sooner; and he himself studied it very carefully. For, as Suetonius tells us, "He applied himself to eloquence, and the study of the liberal arts, from his childhood, with great diligence and labour. He chose a manner of speaking which was smooth and elegant; he avoided the ill savour, as he used to call it, of antiquated words; and he was wont to blame Tiberius for his affectation of them." In our own language, such words are to be esteemed antiquated, which the most polite persons have dropped, both in their discourse and writings; whose example we should follow, unless we would be thought to converse rather with the dead than the living.

But further: As on the one hand we must avoid obsolete words and phrases; so, on the other, we should refrain

Elocution. refrain from new ones, or such whose use has not yet been sufficiently established, at least among those of the best taste. Words may be considered as new in two respects; either when they are first brought into a language, or when they are used in a new sense. As the former of these may sometimes leave us in the dark by not being understood, so the latter are most apt to mislead us; for when we hear a word that has been familiar to us, we are presently led to fix that idea to it with which it has usually been attended. And therefore, in both cases, some previous intimation may be necessary. Cicero, who perhaps enlarged the furniture of the Roman tongue more than any one person besides, appears always very cautious how he introduces any thing new, and generally gives notice of it when he attempts it, as appears in many instances scattered through his works. What bounds we are now to fix to the purity of the Latin tongue, in the use of it, the learned are not well agreed. It is certain, our furniture is much less than when it was a living language, and therefore the greater liberty must of necessity be sometimes taken. So that their opinion seems not unadvisable, who direct us to make choice principally of what we are furnished with from the writers of the Augustan age; and where we cannot be supplied from them, to make use of such authors as lived nearest to them, either before or since. And as to our own tongue, it is certainly prudent to be as careful how we admit any thing into it that is uncouth or disagreeable to its genius, as the ancient Romans were into theirs; for the perfection of a language does in a great measure consist in a certain analogy and harmony running through the whole, by which it may be capable of being brought to a standard.

But besides those things already mentioned, any mistake in the sense of words, or their construction, is opposed to purity. For to speak purely, is to speak correctly. And such is the nature of these faults in elocution, that they are often not so easy to be observed by hearing as by reading. Whence it is, that, many persons are thought to speak better than they write; for while they are speaking, many slips and inaccuracies escape disregarded, which in reading would presently appear. And this is more especially the case of persons unacquainted with arts and literature; who, by the assistance of a lively fancy and flow of words, often speak with great ease and freedom, and by that means please the ear; when, at the same time, what they say, would not so well bear reading.

We shall only add, that a distinction ought likewise to be made between a poetic diction and that of prose writers. For poets in all languages have a sort of peculiar dialect, and take greater liberties, not only in their figures, but also in their choice and disposition of words; so that what is a beauty in them would often appear unnatural and affected in prose.

§ 2. *Of Perspicuity.*

43 Perspicuity explained and illustrated.

Perspicuity, as well as *purity*, consists partly in *single words*, and partly in their *construction*.

44 As to single words.

I. As to *single words*, those are generally clearest and best understood which are used in their proper sense. But it requires no small attention and skill to be well acquainted with the force and propriety of words; which ought to be duly regarded, since the perspicuity of a discourse depends so much upon it. Cæsar seems plainly to have been of this mind, when he tells us, "The foundation of eloquence consists in the choice of words." It may not be amiss, therefore, to lay down some few observations, by which the distinct notions of words and their peculiar force may more easily be perceived. All words may be divided into *proper words* and *tropes*. Those are called *proper words*, which are expressed in their proper and usual sense. And *tropes* are such words as are applied to some other thing than what they properly denote, by reason of some similitude, relation, or contrariety between the two things. So, when a subtle artful man is called a *fox*, the reason of the name is founded in a similitude of qualities. If we say, *Cicero will always live*, meaning *his works*, the cause is transferred to the effect. And when we are told, *Cæsar conquered the Gauls*, we understand that he did it with the assistance of his army; where a part is put for the whole, from the relation between them. And when Cicero calls Antony *a fine guardian of the state*, every one perceives he means the contrary. But the nature and use of tropes will be explained more fully hereafter in their proper place. All words must at first have had one original and primary signification, which, strictly speaking, may be called their *proper sense*. But it sometimes happens, through length of time, that words lose their original signification, and assume a new one, which then becomes their proper sense. So *hostis* in the Latin tongue at first signified a *stranger;* but afterwards that sense of the word was entirely laid aside, and it was used to denote a *public enemy*. And in our language, it is well known, that the word *knave* anciently signified a *servant*. The reason of the change seems to be much the same, as in that of the Latin word *latro;* which first signified a *soldier*, but afterwards a *robber*. Besides, in all languages, it has frequently happened, that many words have gradually varied from their first sense to others somewhat different; which may, notwithstanding, all of them, when rightly applied, be looked upon as proper. Nay, in process of time, it is often difficult to say which is the original, or most proper sense. Again, sometimes two or more words may appear to have the same signification with each other, and may therefore be used indifferently; unless the beauty of the period, or some other particular reason, determine to the choice of one rather than another. Of this kind are the words *ensis* and *gladius* in the Latin tongue; and in ours, *pity* and *compassion*. And there are other words of so near an affinity to each other, or at least appear so from vulgar use, that they are commonly thought to be synonymous. Such are the words *mercy* and *pity;* though mercy in its strict sense is exercised towards an offender, and pity respects one in distress. As this peculiar force and distinction of words is carefully to be attended to, so it may be known several ways. Thus the proper signification of substantives may be seen by their application to other substantives. As in the instance just now given, a person is said to show *mercy to a criminal*, and *pity to one in distress*. And in the like manner, verbs are distinguished, by being joined to some certain nouns, and not to others. So a person is said *to command an inferior*, *to intreat a superior*, and *to desire an equal*. Adjectives also, which denote the properties

Elocution.

properties of things, have their signification determined by those subjects to which they most properly relate. Thus we say, *an honest mind*, and *a healthful body; a wise man*, and *a fine house*. Another way of distinguishing the propriety of words, is by their use in gradations. As if one should say, *Hatreds, grudges, quarrels, tumults, seditions, wars, spring from unbridled passions*. The proper sense of words may likewise be known by observing to what other words they are either opposed, or used as equivalent. So in that passage of Cicero, where he says, "I cannot perceive why you should be angry with me: if it be because I defend him whom you accuse, why may not I be displeased with you for accusing him whom I defend? You say, I accuse my enemy; and I say, I defend my friend." Here the words *accuse* and *defend, friend* and *enemy*, are opposed; and *to be angry* and *displeased*, are used as terms equivalent. Lastly, the derivation of words contributes very much to determine their true meaning. Thus because the word *manners* comes from the word *man*, it may properly be applied either to that or any other put for it. And therefore we say, *the manners of men*, and *the manners of the age*, because the word *age* is there used for *the men of the age*. But if we apply the word *manners* to any other animal, it is a trope. By these and such like observations we may perceive the proper sense and peculiar force of words, either by their connection with other words, distinction from them, opposition to them, equivalency with them, or derivation. And by thus fixing their true and genuine signification, we shall easily see when they become tropes. But though words, when taken in their proper signification, generally convey the plainest and clearest sense; yet some are more forcible, sonorous, or beautiful, than others. And by these considerations we must often be determined in our choice of them. So whether we say, *he got*, or *he obtained, the victory*, the sense is the same; but the latter is more full and sonorous. In Latin, *timeo* signifies *I fear; pertimeo* is more full and significant; and *pertimesco* more sonorous than either of the former. The Latin and Greek languages have much the advantage of ours in this respect, by reason of their compositions; by the help of which they can often express that in one word for which we are obliged to put two words, and sometimes more. So *pertimeo* cannot be fully expressed in our language by one word; but we are forced to join one or two particles to the verb, to convey its just idea, and say, *I greatly*, or *very much fear:* and yet even then we scarce seem to reach its full force. As to tropes, though generally speaking they are not to be chosen where plainness and perspicuity of expression is only designed, and proper words may be found; yet through the penury of all languages, the use of them is often made necessary. And some of them, especially metaphors, which are taken from the similitude of things, may, when custom has rendered them familiar, be considered as proper words, and used in their stead. Thus, whether we say *I see your meaning*, or, *I understand your meaning*, the sense is equally clear, though the latter expression is proper, and the former metaphorical, by which the action of seeing is transferred from the eyes to the mind.

45
As to the construction of sentences.

II. But *perspicuity* arises not only from a choice of *single words*, but likewise from the *construction* of them in sentences. For the meaning of all the words in a sentence, considered by themselves, may be very plain and evident; and yet, by reason of a disorderly placing them, or confusion of the parts, the sense of the whole may be very dark and obscure. Now it is certain that the most natural order is the plainest; that is, when both the words and parts of a sentence are so disposed, as best agrees with their mutual relation and dependence upon each other. And where this is changed, as is usually done, especially in the ancient languages, for the greater beauty and harmony of the periods; yet due regard is had by the best writers to the evidence and perspicuity of the expression.

But to set this subject in a clearer light, on which the perfection of language so much depends, we shall mention some few things which chiefly occasion obscurity; and this either with respect to single words, or their construction.

And first, all ambiguity of expression is one cause of obscurity. This sometimes arises from the different senses in which a word is capable of being taken. So we are told, that upon Cicero's addressing himself to Octavius Cæsar, when he thought himself in danger from his resentment, and reminding him of the many services he had done him, Octavius replied, *He came the last of his friends*. But there was a designed ambiguity in the word *last*, as it might either respect the time of his coming, or the opinion he had of his friendship. And this use of ambiguous words we sometimes meet with, not only in poetry, where the turn and wit of an epigram often rest upon it, but likewise in prose, either for pleasantry or ridicule. Thus Cicero calls Sextus Clodius *the light of the senate*, which is a compliment he pays to several great men, who had distinguished themselves by their public services to their country. But Sextus, who had a contrary character, was a relation of P. Clodius, whose dead body, after he had been killed by Milo, he carried in a tumultuous manner into the senate-house, and there burnt it with the senators benches, in order to inflame the populace against Milo. And it is in allusion to that riotous action, that Cicero, using this ambiguous expression, calls him *the light of the senate*. In such instances, therefore, it is a beauty, and not the fault we are cautioning against: as the same thing may be either good or bad, as it is differently applied.—Though even in such designed ambiguities, where one sense is aimed at, it ought to be sufficiently plain, otherwise they lose their intention. And in all serious discourses they ought carefully to be avoided. But obscurity more frequently arises from the ambiguous construction of words, which renders it difficult to determine in what sense they are to be taken. Quintilian gives us this example of it: "A certain man ordered in his will, that his heir should erect for him a statue holding a spear made of gold." A question arises here, of great consequence to the heir from the ambiguity of the expression, whether the words *made of gold* are to be applied to the *statue* or the *spear;* that is, whether it was the design of the testator by this appointment, that the whole statue, or only the spear, should be made of gold. A small note of distinction, differently placed between the parts of this sentence, would clear up the doubt, and determine the sense either way

Elocution. way. For if one comma be put after the word *statue*, and another after *spear*, the words *made of gold* must be referred to the statue, as if it had been said, *a statue, made of gold, holding a spear*. But if there be only the first comma placed after *statue*, it will limit the words *made of gold* to the *spear* only; in the same sense as if it had been said, *A statue holding a golden spear*. And either of these ways of expression would in this case have been preferable, for avoiding the ambiguity, according to the intention of the testator. The ancient heathen oracles were generally delivered in such ambiguous terms. Which, without doubt, were so contrived on purpose, that those who gave out the answers might have room left for an evasion. See ORACLE.

Again, obscurity is occasioned either by too short and concise a manner of speaking, or by sentences too long and prolix; either of these extremes have sometimes this bad consequence. We find an instance of the former in Pliny the Elder, where speaking of hellebore, he says, "They forbid it to be given to aged persons and children, and less to women than men." The verb is wanting in the latter part of the sentence, *and less to women than men:* which in such cases being usually supplied from what went before, would here stand thus; *and they forbid it to be given less to women than men*. But this is directly contrary to the sense of the writer, whose meaning is, either that it is ordered to be given in a less quantity to women than men, or not so frequently to women as men. And therefore the word *order* is here to be supplied, which being of a contrary signification to *forbid*, expressed in the former part of the sentence, occasions the obscurity. That long periods are often attended with the same ill effect, must be so obvious to every one's experience, that it would be entirely needless to produce any examples in order to evince the truth of it. And therefore we shall only observe, that the best way of preventing this seems to be by dividing such sentences as exceed a proper length into two or more; which may generally be done without much trouble.

Another cause of obscurity, not inferior to any yet mentioned, is *parenthesis*, when it is either too long or too frequent. This of Cicero, in his oration for Sylla, is longer than we usually find in him: "O immortal gods! (for I must attribute to you what is your own; nor indeed can I claim so much to my own abilities, as to have been able of myself to go through so many, so great, such different affairs, with that expedition, in that boisterous tempest of the state), you inflamed my mind with a desire to save my country." But where any obscurity arises from such sentences, they may frequently be remedied by much the same means as was just now hinted concerning long and prolix periods; that is, by separating the parenthesis from the rest of the sentence, and placing it either before or after. So in this sentence of Cicero, the parenthesis may stand last, in the following manner:— "O immortal gods! you inflamed my mind with a desire to save my country: for I must attribute to you what is your own; nor indeed can I claim so much to my own abilities, as to have been able of myself to go through so many, so great, such different affairs, with that expedition, in that boisterous tempest of the state." This order of the sentence is very plain, and less involved than the former. Elocution.

CHAP. II. *Of Composition.*

46 Composition defined and divided.

COMPOSITION, in the sense it is here used, gives rules for the structure of sentences, with the several members, words, and syllables, of which they consist, in such a manner as may best contribute to the force, beauty, and evidence of the whole.

Composition consists of four parts, which rhetoricians call *period, order, juncture*, and *number*. The first of these treats of the structure of sentences; the second, of the parts of sentences, which are words and members; and the two last, of the parts of words, which are letters and syllables. For all articulate sounds, and even the most minute parts of language, come under the cognizance of oratory.

§ 1. *Of Period.*

47 Period defined and explained.

In every sentence or proposition, something is said of something. That of which something is said, logicians call the *subject*, and that which is said of it, the *predicate:* but in grammatical terms, the former is *a noun substantive of the nominative case*, and the latter *a finite verb*, denoting affirmation, and some state of being, acting, or suffering. These two parts may of themselves constitute a sentence: As when we say, *The sun shines*, or *the clock strikes*, the words *sun* and *clock* are the subject in these expressions, *shines* and *strikes* imply each the copula and predicate. Most commonly, however, the noun and the verb are accompanied with other words, which in grammatical construction are said either to be connected with or to depend upon them; but in a logical consideration they denote some property or circumstance relating to them. As in the following sentence: *a good man loves virtue for itself*. The subject of this sentence is *a good man:* and the predicate, or thing affirmed of him, that he *loves virtue for itself*. But the two principal or necessary words, on which all the rest depend, are *man* and *loves*. Now, a simple sentence consists of one such noun and verb, with whatever else is joined to either or both of them. And a compound sentence contains two or more of them; and may be divided into so many distinct propositions, as there are such nouns and verbs, either expressed or understood. So in the following sentence, *Compliance gains friends but truth procures hatred*, there are two members, each of which contains in it an entire proposition. For, *Compliance gains friends* is one complete sentence, and *Truth procures hatred* is another; which are connected into one compound sentence by the particle *but*. Moreover, it frequently happens, that compound sentences are made up of such parts or members, some if not all of which are themselves compounded, and contain in them two or more simple members. Such is that of Sallust: "Ambition has betrayed many persons into deceit; to say one thing, and to mean another; to found friendship and enmity, not upon reason, but interest; and to be more careful to appear honest, than really to be so." This sentence consists of four members; the last of which three, consisting of opposite parts, are all compounded, as will

appear

appear by expressing them at length in the following manner; *Ambition has betrayed many persons into deceit;* [that is, ambition] *has betrayed them to say one thing, and to mean another; it has betrayed them to found friendship and enmity, not upon reason, but interest; and it has betrayed them to be more careful to appear honest, than really to be so.* The three last of these members, beginning with the words *it betrays*, are all of them compounded, and consists of two opposite members; which might each of them be expressed at length in the same manner, by supplying the ellipsis. As, *Ambition has betrayed many persons to say one thing, and it has betrayed them to mean another.* And so of the rest. From this instance we see how much is left to be supplied by the mind in all discourse, which if expressed would both destroy its harmony and render it exceedingly tedious. But still regard must be had to that which is omitted, so as to render what is said consistent with it; otherwise there can be no propriety in what is spoken. Nor can the members of a sentence be distinguished and duly arranged in their proper order, without this. But to proceed: Some sentences consist either wholly, or in part, of such members as contain in them two or more compound ones, which may therefore, for distinction's sake, be called *decompound members.*—Of this kind is that of Cicero, in his defence of Milo: "Great is the force of conscience, great either way: that those persons are not afraid who have committed no offence; and those who have offended always think punishment present before their eyes." The latter member of this sentence, which begins with the word *that*, contains in it two compound members, which represent the different state of mind between innocent and guilty persons. And it is in the proper distinction and separation of the members in such complex sentences that the art of pointing chiefly consists. For the principal use of a comma is to divide the simple members, a semicolon the compound ones, a colon such as are decompounded, and a period the whole from the following sentence. We mention this the rather, to show the different acceptation of these terms by grammarians, from that of the ancient writers upon oratory. For these latter apply them to the sense, and not to any points of distinction. A very short member, whether simple or compound, with them is a comma, and a longer a colon; for they have no such term as a semicolon. Besides, they call a very short sentence, whether simple or compound, a *comma*, and one of somewhat a greater length, a *colon*. And therefore if a person expressed himself either of these ways in any considerable number of sentences together, he was said to speak by commas or colons. But a sentence containing more words than will consist with either of these terms, they call a simple period; the least compound period with them requiring the length of two colons. However, this way of denominating sentences, and the parts of them, rather from their length than the nature of them, appearing not so suitable, we have chosen rather to make use of the terms *simple* and *compound members;* and to call all those *compound periods*, which contain two or more members, whether simple or compounded.

But to proceed: Sentences, with respect to their form or composition, are distinguished into two sorts, called by Cicero *tracta*, "straight or direct;" and *contorta*, "bent or winding." By the former are meant those whose members follow each other in a direct order, without any inflection; and by the latter, those which strictly speaking are called *periods.* For περιοδος in Greek signifies a *circuit* or *circle.* And so the Latins call it *circuitus* and *ambitus.* By which both of them mean a sentence consisting of correspondent parts, so framed, that the voice in pronouncing them may have a proper elevation and cadency, and distinguish them by its inflection; and as the latter part returns back, and unites with the former, the period, like a circle, surrounds and incloses the whole sense. This elevation of the voice in the former part of the period, is by the Greeks called προτασις, and by the Latins *propositio;* and the depression of it in the latter part, by the one αποδοσις, and by the other *redditio.*

Now as simple sentences have not these correspondent parts, which require any inflection of the voice; nor a circular form, by reason of their brevity; they are not properly periods, in the strict sense of the word: though, in common speech, the words *sentence* and *period* are often used as equivalent terms. Thus, if we say, *Generous minds are incited to the performance of noble exploits from motives of glory;* here is no distinction of parts, nor inflection of the voice in this sentence. And indeed there is not any thing which relates to the structure of these sentences, but what will more properly be taken notice of in the second part of *composition*, which is *order.*

And as to those compound sentences, whose members follow each other in a direct order, without any inflection, there is little art required in their composition. We shall produce one example of this kind from Cicero: "Natural reason inclines men to mutual converse and society; and implants in them a strong affection for those who spring from them; and excites them to form communities, and join in public assemblies; and, for these ends, to endeavour to procure both the necessaries and conveniences of life: and that not for themselves only, but likewise for their wives, children, and others who are dear to them, and have a right to their assistance." Here are five short members in this sentence, placed in a series, without any inflection of the parts, or orbit of the whole. And as such sentences have no other boundary but the conclusion of the sense, suited to the breath of the speaker, he may either contract or lengthen them at pleasure, without offending the ear. So, should the sentence last mentioned conclude with the first member in this manner, *Natural reason inclines men to mutual converse and society;* the sense would be perfect, and the ear satisfied. The case would be the same at the end of the second member, thus: *Natural reason inclines men to mutual converse and society, and implants in them a strong affection for those who spring from them.* And the like may be said of the rest. Since such sentences therefore may be thus limited at pleasure, it seems more convenient both for the speaker and hearers to confine them to a moderate length.

But because the principal art relating to this part of composition lies in the frame and structure of such compound sentences as are properly called *periods*, we shall treat upon these somewhat more largely. In the formation

Elocution.

tion of these periods, two things are chiefly to be regarded; their *length* and *cadency*. As the length ought to be suited to the breath of the speaker, the ancient rhetoricians scarce admit of more than four colons; by which we may here understand compound members of a moderate size, which will be generally found a suitable and proportionate length. For to extend them farther than the voice can well manage, must be painful to the speaker, and of consequence unpleasant to the hearers. As to the cadency, what Cicero has observed, is found true by experience, that the ears judge what is full and what is deficient; and direct us to fill up our periods, that nothing be wanting of what they expect. When the voice is raised at the beginning of a sentence, they are in suspense till it be finished; and are pleased with a full and just cadency, but are sensible of any defect, and are displeased with redundancy. Therefore care must be taken that periods be neither deficient, and as it were maimed, that is, that they do not drop before their time, and defraud the ears of what seemed to be promised them; nor, on the other hand, offend them by too long and immoderate excursions. This rise and cadency of the voice in pronunciation, depend on the nature and situation of the members, as we shall endeavour to show by particular instances; in the explication of which, by the word *members*, are to be understood such as are uncompounded. In a period of two members, the turn of the voice begins with the latter member. Of this kind is the following sentence of Cicero: "If impudence prevailed as much in the forum and courts of justice, as insolence does in the country and places of less resort; Aulus Cæcina would submit as much to the impudence of Sextus Ebutius in this cause, as he did before to his insolence when assaulted by him." Here the cadency begins at the words *Aulus Cæcina*. If a sentence consists of three members, the inflection is best made at the end of the second member: for if it begin immediately after the first, the voice will be either apt to sink too low, and not be heard, before it reach the end; or else be precipitated, in order to prevent it. Cicero begins his oration for Milo with a sentence of this form: "Although I fear, it may be a shame to be dismayed at the entrance of my discourse in defence of a most valiant man; and that it nowise becomes me, while Milo is more concerned for the safety of the state than for himself, not to show the same greatness of mind in his behalf: *yet* this new form of prosecution terrifies my eyes, which, whatever way they turn, want the ancient custom of the forum, and former manner of trials." Here the cadency, beginning at the third member with the word *yet*, makes a proper division of the sentence, and easy for the speaker. But a period of four members is reckoned the most complete and perfect, where the inflection begins at the middle, that is, with the third member. Nor is it the same case here, as if, in a sentence of three members, the cadency be made at the second. For in proportion to the time of raising the voice may the space be allowed for its sinking. The following sentence of Cicero gives us an instance of this, where he speaks to his son: "Although, son Mark, having now been a hearer of Cratippus for a year, and this at Athens, you ought to abound in the precepts and doctrines of philosophy, by reason of the great character both of your instructor and the city; one of which can furnish you with knowledge, and the other with examples: yet, as I always to my advantage joined the Latin tongue with the Greek, and have done it not only in oratory, but likewise in philosophy; I think you ought to do the same, that you may be equally conversant in both languages." The turn in this period begins at the word *yet*; which standing near the middle, the voice is raised to that pitch in pronouncing the former part, as to admit of a gradual cadency, without being lost before the conclusion of the sentence. But where the sense does not suit with this division at the entrance upon the third member, it is best made at the fourth. Such is the following sentence of Cicero: "If I have any genius, which I am sensible is very small; or any readiness in speaking, wherein I do not deny but I have been much conversant; or any skill in oratory, from an acquaintance with the best arts, to which I confess I have been always inclined; *no one* has a better right to demand of me the fruit of all these things than this Aulus Cæcina." The cadency of this sentence does not begin till the words *no one*; yet it ends handsomely, and without disappointing the ear. Though indeed the three first members having each of them an inflection, check the elevation of the voice, and by that variety in the pronunciation add to the harmony of the sentence. An equality of the members should likewise be attended to in the composition of a period, the better to adjust their rise and cadency. And for this reason, in sentences of three members, where the cadency begins with the third; or in those of four members, where it begins at the fourth; it promotes the harmony to make the last member longest. This is properly the nature of rhetorical periods, which when rightly formed have both an equal beauty and dignity in their composition.

But as all discourse is made up of distinct sentences, and whenever we express our thoughts it is in some of the forms above mentioned; so the use of them is not promiscuous, but suited to answer different designs in speaking. And in this view they are considered and made use of by the orator, as will be shown hereafter.

§ 2. *Of Order.*

48 Order defined and illustrated.

By *order*, rhetoricians mean the placing each word and member of a sentence in such a manner as will most contribute to the force, beauty, or evidence of the whole.

Order is of two kinds, *natural* and *artificial*. And each of these may be considered with respect to the parts either of simple or compound sentences.

As to simple sentences, we may call that order *natural*, when all the words in a sentence are so placed, as they are connected with or follow each other in a grammatical construction. And it may properly enough admit of this name, as it is founded in the nature of a proposition, and the relation of the several words of which it consists to each other. This we explained in the last chapter, and illustrated by proper examples; and shall therefore only give one instance of it here, to introduce the subject we are now upon. And it is this: *The fame of Isocrates excited Aristotle to the profession of oratory.* Here these words, *the fame of Isocrates*, contain the subject of this sentence, with what relates to it; and all those which follow, *excited Aristotle to the profession of oratory*, make up the predicate and its dependents, Elocution. pendents. And in both parts each word grammatically considered stands in its proper order of construction. And this seems agreeable to the natural way of conveying our thoughts, which leads us first to express the subject or thing of which some other thing is said, before the predicate or that which is said concerning it; and with respect to both, as every idea succeeds another in the order of our conceptions, to range it in the same order when we communicate them to others. Our language in the general keeps pretty much to this method. But in one thing particularly it recedes from it; and that is, in placing adjectives, which denote the properties of things, before their substantives or subjects, whose properties they are: As when it is said, *Evil communication corrupts good manners*. And this we always do, except something follows which depends upon the adjective. So we say, *He was a man eminent for his virtue*: not *an eminent man*.

Artificial order, as it respects simple sentences, has little or no regard to the natural construction of words; but disposes them in such a manner as will be most agreeable to the ear, and best answer the design of the speaker. The Latins take a much greater liberty in this respect than we do, or than the nature of our language will permit. Quintilian says, it is best for the verb to stand last, when there is no particular reason to the contrary. And he gives this reason for it, *because the force of the sentence lies in the verb*. So that, according to him, they seem to have had this view in putting the verb at the end; that as the whole sentence is imperfect without the verb, the mind being thus held in suspense might receive the deeper impression from it at last. They likewise separate such words as have an immediate relation between them or dependence one upon another, and place any of them first or last as they please. In short their order seems in a manner arbitrary, if he does not break in upon perspicuity, to which they usually attend. But most of these things are unsuitable to the genius of our language. One might say indeed, *Convince him you cannot*: instead of saying, *You cannot convince him*: Or, *With my own eyes I saw it*; for, *I saw it with my own eyes*. And again: *in proportion to the increase of luxury the Roman state declined*: for, *The Roman state declined in proportion to the increase of luxury*. But this inversion of words is proper in English composition only when it gives force to the expression; as in the higher style it often does. It serves to impress known truths upon the mind, but is unfit for communicating the first principles of knowledge.

As to compound sentences, that is, such as consist of two or more members, either simple or compounded; what relates to the words in each member separately is the same as in simple sentences. But with regard to the disposition of the several members, that may be called the *natural order*, which so places them as they mutually depend on each other. Thus the antecedent member naturally precedes the relative; as in this expression, *Men are apt to forgive themselves what they blame in others*. In hypothetical sentences the conditional member naturally stands first. Thus: *If Socrates be a rational creature, he is a man*. That member which expresses the effect of an action naturally comes last; as, *Though you offer ever so good reasons, you will not prevail with him*. The like may be said of time, with regard to things done in it; as, *The Roman eloquence soon declined when Cicero was dead*. And to name no more, the reason of a thing naturally follows that of which it is the reason; as thus: *All the pleasures of life must be uncertain, since life itself is not secure*.

When this order is inverted, it must be styled *artificial*. So to keep to the instances already given, the two members in the first sentence may be thus inverted: *What they blame in others, men are apt to forgive themselves*. In the second, in this manner: *Socrates is a man, if he be a rational creature*. In the third, thus: *You will not prevail with him, though you offer ever so good reasons*, And so on in the rest: As, *When Cicero was dead, the Roman eloquence soon declined*; and, *Since life itself is not secure, all the pleasures of life must be uncertain*. The variety of inversions in a sentence may generally be greater or less in proportion to the number of its members. In the following sentence of Cicero, the natural order seems to be this: *If that greatness of mind be void of justice, which shows itself in dangers and labours, it is blameable*. Which may be varied by changing the place of the first and third member, in the following manner: *That greatness of mind is blameable which shows itself in dangers and labours, if it want justice*. Or by altering the place of all the three members thus: *That greatness of mind is blameable, if it be void of justice, which shews itself in dangers and labours*. But oftentimes one member may be included in another, as in the instance here given: *If that greatness of mind which shows itself in dangers and labours, be void of justice, it is blameable*. Here the relative member is included in the conditional, which is placed first, and the antecedent member follows both. But in Cicero it stands thus: *That greatness of mind, which shows itself in dangers and labours, if it want justice, is blameable*; where the relative and conditional members are both included in the antecedent member. The Latin tongue commonly admits of a much greater variety in the transposition of members, as well as in that of single words, than suits with our idiom. In the following sentence the natural order is much preferable, as it best suits with the proper elevation and cadency of the voice in its pronunciation: *I am willing to remit all that is past, provided it may be done with safety*. But should we invert the members, and say, *Provided it may be done with safety, I am willing to remit all that is past*; the harmony of the cadency would be lost. And if the latter member be included in the former, the alteration will still be worse; as, *I am willing, provided it may be done with safety, to forgive all that is past*. Here the inflection of the voice falls upon the same member as before, and destroys the beauty of the period by its elevation afterwards. Some sentences admit of no involution of their members. Such are those whose members are connected by conjunctive or disjunctive particles. As, *Virtue furnishes the mind with the truest pleasure in prosperity, and affords it the greatest comfort in adversity*. And, *A wise man is neither elated by prosperity, nor depressed by adversity*. And the like may be said of those where the latter member begins with some illative or redditive particle. As in these instances: *The chief thing to be regarded in life is virtue, for all other things are vain and uncertain*. And, *Though fortune is always inconstant, yet she has many votaries*. Neither of the members in any of these ways of expression, and

Elocution. and some others which might be named, can be included one in the other. In all the examples hitherto given, the sentences consist only of simple members; and indeed compound members are not so often inverted, nor included one in another, by reason of their length. However, we shall here produce one instance of each: *Whoever considers the uncertainty of human affairs, and how frequently the greatest hopes are frustrated; he will see just reason to be always on his guard, and not place too much dependence upon things so precarious.* This sentence consists of two compound members, which here stand in their natural order, but may be thus inverted: *He will see just reason to be always on his guard, and not place too much dependence on things so precarious; whoever considers the uncertainty of human affairs, and how often the greatest hopes are frustrated.* In the following sentence one compound member is included in another: *Let us not conclude while dangers are at a distance, and do not immediately approach us, that we are secure; unless we use all necessary precaution to prevent them.* Here the natural order would be: *While dangers are at a distance, and do not immediately approach us; let us not conclude that we are secure, unless we use all necessary precaution to prevent them.*

But there are some other considerations relating to order, which, being taken from the nature of things, equally suit all languages. So, in amplifying, there should be a constant gradation from a less to a greater; as when Cicero says, *Ambition creates hatred, shyness, discords, seditions, and wars.* On the contrary, in extenuating, we should descend from a greater to a less; as if, speaking of the ancient laws of Rome, one should say, *They were so far from suffering a Roman citizen to be put to death, that they would not allow him to be whipt, or even to be bound.* In constituting any whole, we put the parts first; as, *Invention, disposition, elocution, and pronunciation, make up the art of oratory.* But in separating any whole, the parts follow: as, *The art of oratory may be divided into these four parts; invention, disposition, elocution, and pronunciation.* In every enumeration care must be taken not to mix the whole with the parts; but if it be mentioned at all, it must either be put first or last. So it would be wrong to say, *He was a man of the greatest prudence, virtue, justice, and modesty:* for the word *virtue* here contains in it the other three, and therefore should not be inserted among them. See LANGUAGE, N° 17.

§ 3. *Of Juncture and Number.*

Quintilian, speaking of composition, represents a discourse as very happy in that respect, when the *order*, *juncture*, and *number*, are all just and proper. The first of these, which gives rules for the due placing of the words and members of a sentence, has been already explained. We now proceed to the other two, which relate to letters and syllables; the former treating of their connection, and the latter of their quantity.

49 The nature and use of *juncture* explained and illustrated.

I. As to *juncture*. A due attention is to be paid to the nature of the vowels, consonants, and syllables in the connection of words, with regard to the sound.

As to the *first*, when a word ends with a vowel, and the next begins either with a different vowel, or the same repeated, it usually renders the pronunciation hollow and unpleasant. For, as Quintilian has justly observed, "This makes a chasm in the sentence, and stops the course of it." For there must be some pause, in order to pronounce them both, or otherwise the sound of one will be lost. So, for instance, in pronouncing these words, *the other day*, unless you stop a little after the word *the*, the sound of *e* will not be heard; and if it is dropt, it will occasion a rougher sound, from the aspiration of *th* twice repeated so near together, as *th'other day*. Therefore to prevent both these inconveniences, we usually say, *t'other day*. But the different consonants, which together with the vowels make up those syllables, often cause a considerable difference in the pronunciation, so as to render it more or less agreeable. As, if we say, *he overdid it*, the words *he over* have not so harsh a sound as *the other*; though still they require some pause to keep them distinct. Besides, some vowels meet more amicably, and admit of a softer pronunciation than others. Those which have the weakest and smallest sound, follow best; because they occasion the least alteration of the organ in forming the two sounds. Such are *e* and *i*; and therefore, without any chasm in the sound, or hesitation of the voice, we say *he is*. But where the action of the organs is greater, and the sound stronger, the pronunciation is more difficult: as when we say, *tho' all*. For here is a contrary motion of the lips, which are first put forward in sounding the *o*, and then drawn backward to pronounce the *a*; and therefore the sound is much softer to say, *tho' every*, where their action is less. And the like ill effect commonly happens from the repetition of the same vowel: as if we say, *go on*, or, *usually act thus*. There is a considerable difference between these two expressions, in repeating the sound of the vowel, and where either of them is doubled in a single word. For then the same sound only is protracted by one continued motion of the organ; as in the words *good*, and *deem*. But here the sound is repeated again by a new action of the organ; which, if precipitated, obscures the sound of one of the vowels; and, if too much retarded, makes a chasm in the pronunciation; either of which is unpleasant to the ear.

But as the coalition of two vowels occasions an hollow and obscure sound, so the meeting of some consonants renders it very harsh and rough. Thus the words *king Xerxes*, and *public good*, when so placed have not only a roughness, but likewise a difficulty in their pronunciation, from the contrary action of the lips; which in the former are first drawn back and then forwards, but in the latter the contrary way; and in both of them with some considerable force. But this may very easily be avoided, by saying, with a little alteration in the words, *Xerxes, the king*, and *the good of the public*. So likewise the words *ill company*, have a softer sound than *bad company*, for the same reason. To multiply instances of this kind seems unnecessary, which so frequently occur in all discourses.

The repetition of the same syllable at the end and beginning of words, is the last thing to be considered. And a little observation will convince us, that where this happens, it generally renders the sound either confused or unpleasant. Cicero was often rallied on account of this verse:

O fortunatam natam me consule Romam.

Every one will easily perceive a disagreeable sound in the

Elocution. the following expression: "A man many times does that unadvisedly, of which he afterwards repents." The chime of the words *man many* both seems affected, and displeases the ear. But this will soon be remedied, if we separate these two words, and say, "A man does that many times unadvisedly."

From the short account here given of this part of composition, it is easy to perceive what things are necessary to render it most complete and accurate; which are these following. If a word end with a vowel, the next ought to begin with a consonant, or such a vowel whose sound may agree well with the former. But if a word conclude with a consonant, either a vowel should follow, or such a consonant whose pronunciation will suit with it. And lastly, the same syllable ought not to be repeated at the end of one word, and the beginning of the next. It has been observed by some critics, that the following verse at the beginning of Virgil's Æneid has all these properties:

Arma virumque cano, Trojæ qui primus ab oris.

Where any word in this verse ends with a vowel, the next begins with a consonant; and where any one ends with a consonant, the next begins with a vowel; and there is no repetition of the same sound throughout the whole. But this is what rarely happens, especially in our language, which abounds with consonants. And what Quintilian says of the coalition of vowels, in treating upon this subject, seems applicable to the whole. "This (says he) is a thing not much to be dreaded; and I know not whether the neglect of it, or too great a concern about it, be worse. It necessarily checks the vigour of the mind, and diverts it from matters of greater importance. And therefore as it shows negligence to permit it, so to be in constant fear of it discovers a low genius." This was the opinion of that judicious writer. And as these things cannot always be attended to, it may be sufficient to avoid them, where they prove very offensive to the ear, and it may be done without some greater inconvenience. So in this sentence, *Honesty is the best policy*, the coalition of *t* and *p* in the two last words *best policy* produces a roughness in their pronunciation; but as the expression is strong, and cannot perhaps be well altered for the better, the sound here ought to give way to the sense.

50 The nature and use of *number*.

II. *Number*. This respects the quantity of syllables, as *Juncture* does their quality. In the Greek and Roman languages every syllable has its distinct quantity; and is either long, short, or common: two or more of which joined together in a certain order make a foot, and a determinate number of these in a different order constitute their several sorts of metre. This variety of sounds gives a much greater harmony to their poetry, than what can arise only from the seat of the accent, and the similitude of sound at the end of two verses, which chiefly regulate our metre. And although their prose was not so confined with regard to feet, either as to the kind or place of them, as their metrical compositions; yet it had a sort of measure, more especially in the rise and cadency of their periods. This they call *rhetorical number*. And accordingly the ancient writers upon this art acquaint us what feet are best suited to the beginning, middle, or conclusion of a sentence. Such rules are not applicable to our language, which has not that accurate distinction of quantity in its syllables. For we are apt to confound accent with quantity, and pronounce those syllables longest on which we lay the accent, though in their nature they are not so. As in the word *admirable*, where none but the first syllable *ad* is pronounced long; though that is only rendered so by position, and the two following are so by nature. And again, in the word *avárice*, we sound the first *a* long for the same reason, and the second short; contrary to the nature of both these vowels. However, we shall offer a few things that may be of some use to modulate our periods and adjust their cadency.

A great number of monosyllables do not stand well together. For as there ought to be a greater distance in the pronunciation between one word and another, than between the syllables of the same word; such pauses, though short, yet, when too frequent, make the sound rough and uneven, and by that means spoil its harmony. And this may seem more necessary to be attended to, because the English language abounds so much with monosyllables. On the contrary, a continuation of many long words makes a sentence move too slow and heavily. And therefore such periods generally run best, which have a proper mixture of words of a different length. Besides, as every word has its accent, which with us stands for quantity, a number either of monosyllables, or long words, coming together, so far abates the harmony, as it lessens the variety.

Again, several words of the same ending do not stand well together, especially where the accent falls upon the same syllable in each of them. For this creates too great a jingle by the similitude of sound; and is apt to displease, from an appearance of affectation. Of this kind is the following sentence: *Nothing is more wélcome, delightsome, or whólesome, than rest to a wearied man.* In such expressions, therefore, if the order of the words cannot well be altered, some other word should be substituted in the room of one of them at least, to diversify the sound. So in the example here given, the sound might be varied by saying, *Nothing is more wélcome, pleásant, or whólesome.*

But to add no more, if a sentence end with a monosyllable, it is apt to hurt the cadency, and disappoint the ear: whereas words of a moderate length carry a greater force with them by the fulness of their sound, and afford the ear what it expected. And there is one sort of monosyllables more especially, which never stand well at the conclusion of a period, though we frequently find them there; and these are the signs of cases. Thus we say, *Avarice is a crime, which wise men are too often guilty of.* But the cadency would doubtless be more agreeable if it was altered thus: *Avarice is a crime, of which wise men are too often gúilty.* Every one must perceive, when the accent falls upon the last syllable in the sentence, as it does if it end with *óf*, the sound is not so pleasant as when it rests upon the preceding syllable in the word *gúilty*. Nor are very long words well suited either to the beginning or conclusion of a period; for they retard the pronunciation at first, and fall too heavy at the end.

Chap. III. *Of Dignity*.

51 The necessity of dignity in an oration.

Dignity consists in the right use of tropes and figures. It is not sufficient for an orator to express himself

Elocution. self with propriety and clearness, or in smooth and harmonious periods; but his language must likewise be suited to the nature and importance of the subject. And therefore, as *elegance* gives rules for the first of these, and *composition* for the second; so does *dignity* for the last of them. It is very evident, that different subjects require a different style and manner of expression; since, as Quintilian says, "What is magnificent in one discourse would be turgid in another; and those expressions which appear low upon a sublime subject, would suit lesser matters: and as in a florid harangue a mean word is remarkable, and like a blemish; so any thing lofty and bright upon a trivial argument is disproportionate, and like a tumour upon an even surface." Now this variety in the manner of expression arises in a great measure from *tropes* and *figures*, which not only enliven and beautify a discourse, but give it likewise force and grandeur; for which reason this part of elocution seems to have been called *dignity*.

Tropes and figures are distinguished from each other in several respects. Tropes mostly affect single words, but figures whole sentences. A trope conveys two ideas to the mind by means of one word; but a figure throws the sentence into a different form from the common and usual manner of expression. Besides, tropes are chiefly designed to represent our thoughts, but figures our passions.

§ 1. *Of Tropes.*

52 Tropes, what. A *trope*, which is a figure of words, has been usually defined to be *the change of a word from its proper signification to some other with advantage, either as to beauty or strength.* The words, *with advantage*, are added in the definition, because a trope ought not to be chosen, unless there is some good reason for using it rather than the proper word. But in what manner, or how far, it can be said of all tropes in general, that they change the proper signification of words, will best appear by considering the nature of each kind of them separately. Now in every trope a reference is had to two things, which occasions two ideas; one of the thing expressed, and another of that thing to which it has a respect, and is supplied by the mind. For all tropes are taken either from things internally related as the whole and a part; or externally, as cause and effect, subject and adjunct; or from some similitude that is found between them; or from a contrariety. The first of these is called *synecdoche*, the second *metonymy*, the third *metaphor*, and the last *irony*. We shall endeavour to illustrate this by examples. When we say, *Hannibal beat the Romans;* the meaning is, that Hannibal and his army did this. So that although in some sense a part may here be said to stand for the whole, which makes it a *synecdoche;* yet, strictly speaking, the word *Hannibal* does not alter its sense, but there is an ellipsis in the expression, Hannibal being put for himself and his army. But if we say, *Cicero should be read by all lovers of eloquence;* here indeed the word *Cicero* appears to be changed from its proper sense, and to signify the books of Cicero; which is a *metonymy*, the author being put for his works; and therefore such expressions need not be deemed elliptical. Again, if any one, speaking of a subtle and crafty man, should say *he is a fox;* the meaning is, he is like a fox; which is a *metaphor;* where the word *fox* retains its proper sense, and denotes that animal, to which the man is compared on account of his craft. Lastly, If a person say to another, *Well done;* meaning that the thing was ill done, the word *well* keeps its own sense; but from the manner of its pronunciation, or some other circumstance attending the expression, it will be evident that the contrary is intended; which is called an *irony*. From these instances it may appear in what latitude we must understand the common definition of a trope, which makes it to consist in the change of a word from its proper sense into some other. But though in reality there are but four kinds of tropes, which are distinguished by so many different respects which things bear one to another; yet as these several respects are found in a variety of subjects, and attended with different circumstances, the names of *tropes* have from hence been greatly multiplied: which, however, may all be referred to some or other of those already mentioned, as will be shown when we come to treat of them in their order. And for distinction sake we shall call the former *primary*, and the latter *secondary, tropes*.

We now proceed to consider the reasons which have occasioned the introduction of tropes. And these, as Quintilian observes, are three; *necessity*, *emphasis*, and *beauty*.

53 Why introduced. 1. Tropes were first introduced from *necessity*, deriving their origin unquestionably in a considerable degree from the barrenness of language, because no language which we know contains a sufficient number of proper words to express all the different conceptions of our minds: but the principal cause of their introduction seems to be that extensive influence which imagination possesses over every kind of speech. The mind considers the same thing various ways; views it in different lights; compares it with other things; and observes their several relations and affections; wherein they agree, and in what they differ. From all which reflections it is furnished with almost an infinite number of ideas; which cannot all of them be distinguished and expressed by proper words, since new ones occur daily. And were this possible, yet would it be impracticable, because the multitude of words must be so vastly great, that the memory could not retain them, nor be able to recal them as occasion required. Tropes have in a good measure redressed both these inconveniences; for by means of them the mind is not burdened with a numberless stock of different words, and yet nothing seems to want a name. Thus sometimes where a word is wanting to express any particular thing, it is clearly enough represented by the name of some other thing, by reason of the similitude between them. At other times, the cause is signified by the effect, the subject by the adjunct; or the contrary. And the whole is often understood by a part, or a part by the whole. And thus by the use of tropes the mind is helped to conceive of something not expressed, from that which is expressed. It is much the same case, as when we have occasion to speak of a person, whose name we are either unacquainted with, or have forgot; for by describing his person, abode, or some other circumstances relating to him, those we converse with as well understand whom we mean, as if we mentioned his name. So the shepherd in Virgil, when

Elocution. when he could not think of the name of Archimedes, describes him by his works:

> And what's his name who form'd the sphere,
> And show'd the seasons of the sliding year?

Besides, it sometimes happens in a discourse, that those things are necessary to be said, which, if expressed in their proper terms, would be offensive; but being clothed with metaphors, may be conveyed to the mind with decency. Thus then the imagination never contemplates any one idea single and alone, but always along with other ideas, which may be called its *accessories*, and which often operate more forcibly upon the mind than the principal idea itself does. In their nature they are often more agreeable, and frequently also more familiar, to our conceptions; or perhaps they remind us of a greater variety of important circumstances. Hence the name of the accessory is often preferred, as e. g. when we want to point out the time in which a state enjoyed its chief reputation, &c. the proper words might do, but the imagination suggests the flourishing period of a plant or tree; and we say "the Roman empire flourished most under Augustus:" Catiline, we say, was the *head* instead of the *leader* of his party, because the head is the principal part of the human figure.

2. A second reason above mentioned for the use of tropes was *emphasis*. Tropes do many times express things with greater force and evidence than can be done by proper words. We receive much the greater part of our knowledge by our senses. And similitudes taken from sensible things, as in metaphors, very much assist the mind in its reflections upon those things which do not come under the cognizance of the senses. For it is certain, that we are sooner or more strongly affected with sensible objects, than with things of which we can have no ideas but from the internal operations of our own minds. Nay, sometimes one bright and lively trope shall convey a fuller and more just idea of a thing than a large periphrasis. So when Virgil calls the Scipios *two thunderbolts of war*, he gives a more lively image of the rapid force and speedy success of their arms, than could have been conveyed by a long description in plain words. And in many cases the tropical use of words is so emphatical, and suited to the idea we design to excite, that in this respect it may be justly esteemed the most proper. So *incensed with anger*, *inflamed with desire*, *fallen into an error*, are all metaphorical expressions, used in a way of similitude; and yet perhaps no proper words can be made use of, which will convey a more lively image of the thing we design to represent by them.

But *beauty* and ornament, as was observed before, have been another cause of the use of tropes. Some subjects require a more florid and elegant dress than others. When we describe or applaud, ornaments of speech and a gaiety of expression are requisite. And it is the business of an orator to entertain his hearers at the same time that he instructs them. Now Cicero, who was an admirable judge of the force and power of eloquence; has observed, that tropical expressions give the mind the greatest delight and entertainment. "I have often wondered (says he) why tropes should give greater pleasure than proper words. I imagine the reason must be, either that there is an appearance of wit in neglecting what is at hand, and making choice of something at a distance; or that the hearer is furnished with a different thought, without being led into a mistake, which affords a very agreeable pleasure; or that a whole similitude is conveyed to the mind by a single word; or that, particularly in the best and most lively metaphor, the image is presented to our sight, which is the quickest of our senses." And therefore he supposes, that "as garments were first invented from necessity, to secure us from the injuries of the weather, but improved afterwards for ornament and distinction; so the poverty of language first introduced tropes, which were afterwards increased for delight." Besides, a variety of expression is pleasing in a discourse. It is many times necessary that the same thing should be repeated; and if this be done in the same words, it will grow tiresome to the hearers, and sink their esteem of the speaker's ability. Therefore, to prevent this, it is proper the expression should be varied, that although the sense be the same, it may give the mind a new pleasure by its different dress.

We come now, in the last place, to lay down some directions proper to be observed in the choice of tropes.

And first, as every trope gives us two ideas; one, of the word expressed; and another, which, by means of that, the mind connects with it; it is necessary, that the relation between these two appear very plain and evident. For an obscure trope is always faulty, unless where some particular reason makes it necessary. And therefore tropes ought not to be too far-fetched, lest that should render them dark. For which reason Cicero says, he should not choose to call any thing destructive to a person's fortune, *the Syrtis of his patrimony*, but rather the *rock of it*; nor the *Charybdis of his estate*, but the *gulf of it*. For those who either did not know that the Syrtes were two quicksands upon the coast of Africa, or that Charybdis was a gulf in the strait of Sicily, both of them very destructive to mariners, would be at a loss to understand the meaning of the metaphor. Besides, metaphors taken from things we have seen, affect the mind more forcibly than those which are taken from such things as we have only heard of. Now there is scarcely any one who has not seen a rock or a gulf; but there are very few persons, comparatively, who have been either at Charybdis or the Syrtes. It is necessary therefore in a good trope, not only that there be a near affinity between the two ideas, but likewise that this affinity be very obvious and generally known, so that the word be no sooner pronounced but both images do immediately present themselves to the mind.

Again, as a trope ought to be very plain and evident, so likewise should it bear a due proportion to the thing it is designed to represent, so as neither to heighten nor diminish the just idea of it. Indeed, sometimes when we speak of things indefinitely, we say too much, lest we should seem to say too little. And this manner of speaking is called an *hyperbole;* which is not uncommon in the sacred writings. So, for instance, Saul and Jonathan are said to be *swifter than eagles, and stronger than lions*. But even in this way of expression a proportion is to be observed. For some very considerable and unusual excess of the thing in its kind is at least designed by it; which, perhaps, cannot, or however is not necessary to be defined. And therefore Quintilian blames Cato for calling the top of a hill a *wart;* because

cause the proportion between the two ideas is nowise adequate. And so on the contrary Aristotle censures Euripides for calling rowing *the empire of the oar*. Poets indeed are allowed a greater liberty in this respect; but an orator should be modest in his expressions, and take care that he neither so heighten nor diminish the natural ideas of things by tropes, as to lead his hearers into mistakes.

But further: as a moderate use of tropes, justly applied, beautifies and enlivens a discourse; so an excess of them causes obscurity, by running into an abstruse allegories and riddles. Tropes are not the common and ordinary dress of our thoughts, but a foreign habit: and therefore he who fills his discourse with a continued series of them, seems to act like one who appears in public in a strange dress: which no man of character would choose to do.

Moreover, as one use of tropes is pleasure and entertainment, we should endeavour to make choice of such as are smooth and easy. But if at any time we think it necessary to use a harsh trope, it is proper to soften it by some precaution. For, as Cicero very handsomely says, *a trope should be modest, since it stands in a place which does not belong to it; for which reason it should seem to come thither by permission, and not by force.* And therefore when he thought it harsh to say, *The death of Cato made the senate an orphan;* he guards the expression by saying, *The death of Cato has (if I may be allowed to say so) rendered the senate an orphan.*

And, to add no more, care should be taken how we transfer tropes from one language into another. For as they are frequently taken not only from natural things, or such notions as are common to the generality of mankind, but likewise from the manners, customs, and occurrences of particular nations; so they may be very plain and obvious to those among whom they took their rise, but altogether unintelligible to others who are unacquainted with the reason of them. It was customary for the Roman soldiers to carry their money in their girdles: hence it was the same thing with them to say, *a person had lost his girdle*, as that *he had lost his money*. And because the Romans wore the *toga*, which was a long gown, in time of peace, and a different garb when engaged in war, their writers sometimes use the word *toga* to signify peace. But as neither of these customs is in use among us, so neither would the tropes suit our language, or be generally understood by us. And even in such tropes as are taken from the common nature of things, languages very much differ. There is a very beautiful trope in the account of St Paul's shipwreck, where it is said, *The ship was caught, and could not bear up into the wind.* The original word, that we translate *bear up*, is αντοφθαλμειν; and properly signifies, *to look or keep its eyes against it;* which is a very strong and lively image, taken from animate beings, and when applied to men, often signifies *to withstand* or *resist;* as, αντοφθαλμειν πολεμιω, *to resist an enemy;* and Plutarch says of Demosthenes, that he could not αντοφθαλμειν τω αργυριω, *look against* or *resist the power of money.* Nothing is more common with Latin writers, than to call men of a public spirit and true patriots, *lumina et ornamenta reipublicæ*, that is, *the lights and ornaments of the state* And we have borrowed from them the use of both these metaphors. But because tropes and figures illustrate and heighten the style, they call them also *lumina orationis*, or *the lights of a discourse*. It sometimes happens, that only the tropical sense of a word is taken from one language into another, and not the proper signification of the same word. So *scrupulus* in Latin properly signifies *a little stone, which getting into the shoe hurts a person as he walks;* hence it is applied to the mind, and used to express *a doubt, or uneasy thought that gives it pain.* We have borrowed this latter sense of the word, but not the former.

Art. I. Primary Tropes.

34 Metaphor, what.

I. *Metaphor.* A metaphor, as usually defined, is, *A trope, which changes words from their proper signification to another different from it, by reason of some similitude between them.* But that a word, when used metaphorically, does not alter its signification, but retains its proper sense, was shown above. However, it may not be amiss to explain this matter more fully, and set it in a clearer light. Every *metaphor*, then, is nothing else but a short similitude. Cicero calls it a *similitude reduced to a single word.* And Quintilian to the same purpose says, that "a metaphor is a short similitude, and differs from it only in this, that the former is compared to the thing we design to express, and the latter is put for it. It is a similitude, when I say of a man, he has acted like a lion; and a metaphor, when I say, he is a lion." Thus far Quintilian. Now in every similitude three things are requisite; two things that are compared together, and a third in which the similitude or likeness between them consists. And therefore, to keep to this example, when Horace calls a Roman soldier *a lion*, if the word *lion* did not retain its proper sense, there could be no similitude; because there would not be two things to be compared together with respect to a third, which is necessary in every similitude, and was designed by this expression. The sense of which is plainly this: *That as a lion seizes his prey with the greatest fierceness, so a Roman soldier with like rage and fury attacked his enemies.* In the same manner, when Cicero calls Piso *the vulture of the province*, his meaning is, that he was like a vulture, or acted in such a manner as a vulture acts, that is, rapaciously. So that the real difference between a metaphor and a similitude consists in this; that a metaphor has not those signs of comparison which are expressed in a similitude. But some persons have run into mistakes in reasoning from tropes of this kind. For they have so argued from metaphorical words, as if all the affections and properties of the things expressed by them might be attributed to those other things to which they are applied, and by that means have strained the comparison (which has usually but one particular view), in order to make it tally in other respects, where there is not that similitude of ideas. We will endeavour to make this evident by another example from Cicero, where he calls Mark Antony *the torch of the state*. The similitude between Antony and a torch lay in this: *That as a torch burns and destroys every thing within its reach, so Antony brought devastation and ruin wherever he came.* Now a torch has not only a property to burn, but also to give light; but the similitude would not hold in this respect, nor was it at all designed. For Cicero never calls a wicked profligate man, as Antony was, *the light of the state;* though he often gives that character to good and virtuous

tuous men, who by their examples do as it were enlighten others, and show them the way to be happy themselves and useful to others. But though metaphors are usually taken from a similitude between two things, as in the instances here mentioned; yet sometimes they are founded in the similitude which two things bear to two others in some particular respect, by means whereof what properly belongs to one of them is transferred to the other: the former of which are called *simple metaphors*, and the latter *analogous*. Hence the rudder of a ship may be called its *reins;* for what the reins are to a horse, that the rudder is to a ship in guiding and directing it. So that here is a double similitude, one between a ship and a horse, and another between the rudder of the former and the reins of the latter; and from the analogy between the use of the rudder to the one and reins to the other, the reins, which belong properly to the horse, are applied to the ship. Again, some metaphors are reciprocal, in which the similitude holds either way. Thus to steer and to govern are used reciprocally both of a ship and a state: the proper expressions being, *to steer a ship, and govern a state;* and the contrary metaphorical. But though we say, *the foot of a mountain*, borrowing the similitude from animals; yet we do not say, on the contrary, *the bottom of an animal*, meaning his feet; and therefore that metaphor is not reciprocal. From this account therefore of the nature of a metaphor, it may be said to be, *The application of a word by way of similitude to some other thing than what it properly signifies.* And the plainer this similitude appears, the greater beauty there is in the trope.

The use of metaphors is very extensive, as large as universal nature. For there are scarce any two things which have not some similitude between them However, they may all be reduced to four kinds; which was the second thing proposed to be considered.

The first kind of metaphors therefore may be taken from similitudes between animate beings. As where those things, which properly relate to brutes, are accommodated to men; or those which belong to men are applied to brutes. Of the former sort is that joke of Cicero: *My brother being asked by Philip, why he barked so?* answered, *Because he saw a thief.* Here *barking*, the property of a dog, is applied to a man: And the reply does not seem to carry more severity or harshness with it than the question. By the latter sort we say, *a crafty fox*, and *a generous horse;* which are affections that properly relate to men. And to this kind of metaphors may those likewise be referred, when that which properly belongs to the senses is applied to the mind. Thus we often say, *that we see a thing*, when we mean *that we understand* or *apprehend it.* And in the same sense we say, *that we hear such a thing*, or *person.* And by the like manner of expression, a person is said *to smell out a thing.* And those who have a genius or disposition for any art or science, are said *to have a taste for it;* and such as have entered upon the study of it, are said *to have a touch of it.* These are common ways of speaking in most languages, and very expressive of what is intended by them. And we may also bring those metaphors under this head, by which the properties and affections of men are attributed to the Deity: as, when God is said *to hear*, *see*, *be angry*, *repent*, and the like; which are forms of expression very frequent in the sacred writings.

A second kind of metaphors lies between inanimate things, whether natural or artificial, which bear some similitude to each other. And this head is very extensive. Thus we say, *floods of fire, and clouds of smoke*, for large quantities. And so likewise, *to inflame an account*, that is, to heighten or increase it; with innumerable others of the like sort. In the two first of these instances, the terms proper to one element are applied to another; and as those elements of fire and water are opposite to each other, they show the extensiveness of this trope, that there are no things in nature so contrary, but may come within the limits of it, and be accommodated to each other in a way of similitude. In the last example, a natural action is applied to what is artificial.

A third sort of metaphors is, when inanimate things are applied to animals, on account of some like properties between them. Thus Homer calls Ajax, *the bulwark of the Greeks*, on account of his valour, which like a wall defended them from the Trojans. And nothing is more common with Cicero, than to brand ill men with the character of being *the pest of the state*, by reason of the mischief which they bring to the public. So likewise he calls Zeno the philosopher *an acute man*, for his great discernment and quick perception of things; fetching the allusion from metals when brought to an edge or a point. As, on the contrary, old Chremes in Terence calls himself a *stone*, for want of apprehension. And we say, *a gay person*, and *a bright genius*, by this kind of metaphor.

The fourth and last kind of metaphors is that by which the actions and other attributes of animals are accommodated to inanimate things. Thus Cicero, speaking of Clodius, says: "The very altars, when they saw that monster fall, seemed to move themselves and assert their right against him." Here the words *saw*, *move*, and *assert*, are all metaphors taken from the properties of animals. And Virgil, when he would represent the impetuous force and rapidity of the river Araxes, says, *it disdained a bridge.* And it is a very usual epithet, which Homer gives to words, to call them πτερόεντα, or *winged*, to intimate the swiftness of speech.

Lastly, as to the choice of metaphors, those are esteemed the finest and strongest, which *give life and action to inanimate things.* The reason of which is, because they do as it were invigorate all nature, introduce new forms of beings, and represent their images to the sight, which of all the senses is the quickest, most active, and yet most unwearied. What can be more moving, or in stronger terms express the villany of Clodius, than when Cicero says, "The very altars of the gods seemed to exult at his death." And the same great orator particularly commends those metaphors, for their sprightliness and vivacity, which are taken from the sense of seeing; as when we say *a bright thought*, or *a gay expression.*

However, care must be taken not to venture upon too bold and daring metaphors. Poets indeed claim greater liberty in this respect, whose view is often to amuse, terrify, or delight, by heightening the just and natural images of things. But it is expected the orator should reason coolly, though strongly and forcibly; and not by theatrical representations so transport the mind, as to take it off from reflection, unless perhaps on some particular

cular occasion. And yet, on the other hand, metaphors ought not to sink below the dignity of what they are designed to express; but the idea they convey should at least be equal to the proper word in the place of which they are substituted.

But there is a very great difference in the choice of metaphors, as they are designed either to praise or dispraise. One thing may be compared to another in a great variety of respects. And the same thing may be made to appear either noble or base, virtuous or vicious, by considering it in a different light. Such metaphors, therefore, as are chosen to commend, must be taken from great and laudable things; and on the contrary, those which are designed to discommend, from things vile and contemptible. Aristotle gives us a very pleasant example of this in the poet Simonides. A certain person, who had carried the prize at a race of mules, offered him a reward to write a poem in honour of that action. Simonides thought he did not bid high enough; and therefore put him off with saying, the subject was too mean to write in praise of mules, which were the offspring of asses. But upon his being offered a larger sum, he undertook the task; and, as Aristotle observes, when he has occasion to speak of the mules in that poem, he does not mention them by that name, but calls them *the daughters of fleet and generous horses*, though he might with as much propriety have called them *the daughters of dull asses*. But it was the poet's business, in praising, to take the most advantageous part of the character. Where things are capable of such different turns, metaphorical expressions are generally most beautiful. And sometimes the same metaphor may be applied contrary ways, both in praise and dispraise, as it will suit different properties of the thing to which it refers. So a *dove*, in a metaphorical sense, may represent either *innocence* or *fear;* and an *iron heart*, may denote either *courage* or *cruelty;* as a *hard head, strength* or *weakness of thought*. And this ambiguity in the application of metaphorical words often affords occasion for jests and concise wit. We observed before, that Cicero never calls ill men *lights of the state*. But he once in this manner calls Sextius Clodius *the light of the senate*. For when his kinsman Publius Clodius had been killed by Milo, and his corpse was brought to Rome, Sextius raised the mob, and in a tumultuous manner carried it into the senate house, where they burnt it, and by that means set the building on fire: For which seditious act Cicero passes that joke upon him, under the metaphor of light, which elsewhere he always uses in a good sense.

But to proceed: All forced and harsh metaphors should be avoided; the one being no less disagreeable to the mind than the other to the ear. Nor should they come too thick in a discourse. In a word, they ought not to be used, but either where a proper word is wanting, or they are more significant or beautiful than the proper word.

55 Metonymy defined and explained.

II. *Metonymy*. This, as defined by Quintilian, is, *the putting one word for another*. But Vossius describes it more fully, when he calls it, "A trope, which changes the name of things that are naturally united, but in such a manner as that the one is not of the essence of the other." That a metonymy is thus distinguished from the other tropes, has been sufficiently shown already in the two last chapters. When it is said, *to put one word for another*, or, *to change the names of things*, the meaning is, that the word so used changes its sense, and denotes something different from its proper signification. Thus, when *Mars* is put for *war*, and *Ceres* for *corn*, they lose their personal sense, and stand for the effects of which those deities were said to be the cause. So likewise, when Virgil says,

He drank the frothing bowl,

the word *bowl* must necessarily signify the liquor in the bowl. And when in another place, describing the temple of Juno at Carthage, in which the actions of the Trojan war were represented, and the images of the heroes, he makes Æneas, upon discovering that of Priam among the rest, cry out,

Lo here is Priam;

it is plain the word *Priam* there must stand not for his person, but his *image* or *figure*. And this property of changing the sense of the word appears peculiar to metonymy. In treating upon a metaphor, we observed the mistake of those who teach, that a word used metaphorically loses its proper signification; whereas it only changes its place, but not its sense; being applied to a thing to which it does naturally belong, by way of similitude. And as the not attending to this has run some persons into very great absurdities, in treating upon metaphorical expressions, and reasoning from them in the tropical sense; so the like has happened to others in some instances of a metonymy, where, by misapprehending their true nature, they have reasoned from them in the literal sense, as we shall show presently. A metonymy is not so extensive as a metaphor, nor altogether so necessary; because nothing is said by a metonymy, which cannot be expressed in proper words; whereas metaphors are often used for want of proper words to express some ideas. However, metonymies are very useful in language; for they enrich a discourse with an agreeable variety, and give both force and beauty to an expression. And what we observed with relation to a metaphor, is true also of this trope: that some metonymies, even in common discourse, are more frequently made use of than the proper words in whose room they are put. So, *pale death*, *a blind way*, and *a happy state*, are very common expressions with us. And it is more usual to say, *This is such a person's hand*, or *I know his hand*, than his writing, when we intend this latter sense of the word.

We now proceed to the division of metonymies; which are commonly distinguished into four kinds, from the different manner in which things are naturally, but externally, united to one another. Now things are thus united, or one thing depends upon another, either with respect to its production, or in the manner of its existence when produced. In the former way the effect depends upon its cause, and in the latter the adjunct upon its subjects. And hence arise four sorts of metonymies, which receive their names from the *cause* and *effect*, the *subject* and the *adjunct*.

It is called a *metonymy* of the *cause*, when the external cause is put for the effect. The external cause is twofold, the agent and end, which are usually called the *efficient* and *final cause*. Of the former kind are such metonymies, where the inventor or author is put for what was invented or effected by him. Thus, as we we said before, *Ceres* is sometimes put for *corn*, the use of which she was said first to have introduced; and *Mars* for *war*, over which he was thought to preside. And by this way of speaking, any artist or writer is put for his work. So Juvenal, blaming the luxury and profuseness of the Romans, says, *There are few tables without Mentor:* that is, which were not made by him, or after his manner. And our Saviour says, in the parable of the rich man and Lazarus, *They have Moses and the Prophets*, meaning the books of Moses and the prophets. But under this sort of metonymy is included not only the agent, strictly so called, but also any means or instruments made use of in the doing of a thing, when put for the thing done. Thus, *polite literature*, is called *humanity*, because it cultivates and improves the human mind. And in that expression of Cicero, *Words move nobody but him who understands the tongue;* the word *tongue*, which is the instrument of speech, is put for *speech* or *language*. And in the like sense, *arms* are sometimes put for *war*, and the *sword* for *slaughter*. By the same kind of metonymy likewise any affection or quality is put for its effect. As when it is said, *the end of government is to maintain justice;* that is, *such mutual offices among men as are the effects of justice*. And so likewise in that of Cicero, *It is the business of magistrates to check the levity of the multitude*, by which he means tumults occasioned by their levity. Moreover, as human affections are attributed to the Deity in a metaphorical sense, so several parts of the human body are likewise ascribed to him by this kind of metonymy. Thus, his *hand* and his *arm* are used to express his power, as his *ear* and *eye*, his *care* and *providence*, these being the instruments of such effects in mankind. Metonymies of the final cause are those by which the end in doing a thing is put for the thing done. As when we say, *The watch is set*, meaning the *watchmen*, who are appointed for that purpose. And so likewise that expression, *to make an example*, as it signifies, *to punish*, in order to deter others from the like crimes by such an example. As also that of Virgil,

Phillis should garlands crop:

by which are meant *flowers* to make garlands.

The second kind of metonymy puts the effect for the efficient cause, whether the agent, or only the means and instrument. So Virgil calls the two Scipios *the destruction of Libya*, because they were the agents who effected it. And Horace compliments his patron Mæcenas with the titles of being *his guard and honour*; that is, his guardian, and the author of his honour. But when Cicero tells the citizens of Rome, that *the death of Clodius was their safety*, he means the occasion only of their safety. And elsewhere he calls that a *dark hope* and *blind expectation*, the effect of which was dubious and uncertain to those who entertained it. And in like manner, the sons of the prophets, when they were eating the pottage which Elisha had ordered to be set before them, cried out, *There is death in the pot;* that is, some *deadly thing*, as is presently after explained. And thus sweat, which is the effect of labour, is sometimes put for labour. As in the threat denounced against Adam, *In the sweat of thy face shalt thou eat bread*, that is, by labour in cultivating the ground. And, in allusion to this way of speaking, Antony the orator tells Crassus, the improvement of the style by constant exercise, as he prescribed, was a thing of much sweat." And *virtue is said to be gained by sweat*, that is, continued care and exercise in subduing the passions, and bringing them to a proper regulation. But in these two expressions there is likewise a metaphor, the effect of bodily labour being applied to that of the mind. In all these instances the effect is put for the efficient cause.

The third kind of metonymy is, when the subject is put for the adjunct. By subject here, in a large sense of the word, may be understood that wherein some other thing is contained, or about which it is conversant; as likewise the possessor with respect to the thing he possesses; and the thing signified, when put for the sign of it. Now, by the first of these ways of speaking, the seat of any faculty or affection is used for the faculty or affection itself. So it is usual to say, *a man of a clear head*, when we mean a clear mind or understanding; the seat of the mind being supposed to be in the head. And a person is said *to have a warm heart*, because the heart has been thought the seat of the affections. In like manner, the place where any actions are performed is put for the actions done in it. As when Cicero says, "Do not always think of the forum, the benches, the rostra, and the senate;" meaning the discourses which were usually made in those places. So likewise the country, or place of residence, is put for the inhabitants, as in that passage of Cicero: "And to omit Greece, which always claimed the pre-eminence for eloquence, and Athens, the inventress of all sciences, where the art of speaking was invented and perfected; in this city of ours, (meaning Rome), no studies have prevailed more than that of eloquence:" where the words Greece and Athens stand to denote the inhabitants of those places. And hither may also be referred those expressions in which the time is put for the persons living in it; as *the degeneracy of the present age, the virtue of former times*. In the second way above mentioned, the object is used for the person or thing employed about it: As when Cicero says, "In time of battle the laws are silent; where by *laws* he intends the *judges*, who pronounce sentence according to law. By the third of these ways, in which the possessor is put for the thing he possesses, we say, *to devour, destroy*, or *ruin a man*, meaning not his *person* but his *estate*. And mythologists explain the fable of Actæon by this trope, who is said to have been devoured by his dogs; for by dogs they understand flatterers and parasites, who consumed his estate and brought him to beggary. By the last way before recited, which puts the thing signified for the sign, statues and pictures are called by the names of the persons which they represent: as in that jest of Cicero upon his brother Quintus, when, as Macrobius relates, "being in the province which his brother had governed, and seeing a large portrait of part of his body, holding a shield, though Quintus was but a little man, he said, My half brother is bigger than my whole brother." The Popish doctrine of transubstantiation is founded upon an abuse of this trope. For when our Saviour, speaking of the bread and wine at that time before him, says, "This is my body, and this is my blood," his plain meaning is, they were the signs of his body and blood, the thing signified being put for the sign by this sort of metonymy. But the Papists take the expression literally, which must doubtless be very absurd:

absurd: since the words relate to the time then present, while Christ was yet living, and spoke them; when it was impossible for the bread and wine to be converted into his body and blood, it being evident to all who were present, that those elements, and his body, existed separately at the same time. But if the words are explained by this trope, the sense is plain and easy, and the way of speaking familiar to all writers. Whereas they who plead for the literal sense might with equal reason assert that those expressions above mentioned are to be taken literally, in which several parts of the human body, as the hand, the arm, the ear, and the eye, are ascribed to the Deity; or that, when our Saviour in a metaphorical sense calls himself *a vine*, and *a door*, these words were designed to be applied to him strictly and properly, and not by way of similitude only, as is the case in all metaphors.

The fourth kind of metonymy is that wherein the adjunct is put for the subject, which is done in the same variety of ways as the former. It is therefore a metonymy of the adjunct, when the thing contained is put for that which contains it. As when Virgil says, "They lie down upon purple;" that is, upon couches dyed with purple. And again, "They crown the wine;" meaning the bowl which contained the wine, it being the custom of the ancients to deck their bowls with garlands at their entertaiments. By these tropes likewise virtues and vices are put for the persons in whom they are found. As in that beautiful passage of Cicero, where, comparing the profligate army of Catiline with the forces of the state, he says, "On this side modesty is engaged, on that impudence; on this chastity, on that lewdness; on this integrity, on that deceit; on this piety, on that profaneness; on this constancy, on that fury; on this honour, on that baseness; on this moderation, on that unbridled passion; in a word, equity, temperance, fortitude, prudence, and all virtues, engage with injustice, luxury, cowardice, rashness, and all vices." And to this trope those expressions are to be referred, in which any thing is put for the object about which it is conversant. As in that saying of the wise man, "Hope deferred makes the heart sick;" where hope is put for the thing hoped for. And thus Suetonius calls the emperor Titus *the love and delight of mankind*, whose mild and obliging temper rendered him the object of those agreeable affections to all persons under his government. A third use of this trope is putting a thing for the time in which it was done. Thus we say of a person, *he has served so many campaigns*, meaning so many summers, that being the usual time in which armies are drawn out into the field. Lastly, by this metonymy, the sign is put for the thing it signifies; as, *the sceptre* for *the regal dignity*, and *the sword* for *the authority of the magistrate*.

56 Synecdoche explained.

III. *Synecdoche*. This is a trope by which either the whole of a thing is put for a part of it, or a part for the whole, so that the two things, whose ideas are presented to the mind in this trope, are internally related to each other: by which, as has been shown already, it is distinguished from all the other tropes. In a *synecdoche* the word retains its proper sense, and the expression is elliptical, as will appear by the several species of it, wherein the ellipsis in most of the examples is very obvious, and may with no great difficulty be supplied. Now a thing may be considered as a whole in three different respects, which logicians call an *universal*, *essential*, *and integral whole*. An universal whole is any genus with regard to its several species: as, an *animal* with respect to *mankind* and *brutes*, or *philosophy* with respect to the several *arts* and *sciences* comprised under it. An essential whole consists of matter and form; as, a *man* of *body* and *soul*. And an integral whole is any body or quantity, with respect to the several parts of which the matter of it is composed, and into which it may be divided: as, an *human body* with respect to its *several members*; or a *year*, as divisible into *months*, *weeks*, and *days*. And thus rhetoric is an integral whole in respect to the four parts that compose it; namely, invention, disposition, elocution, and pronunciation. So likewise any aggregate body, as a civil community, which is divisible into those who govern and are governed; or any army, consisting of the general and his soldiers. As a whole therefore, in each of these acceptations of the word, is frequently put for a part, and a part for the whole; hence arise six species or sorts of synecdoche.

The first of these puts the genus for the species.—Thus, virtue in general is sometimes used to denote some particular sort of virtue. As when Cicero mentions virtue as one of the four qualifications necessary in a general, he means greatness of mind. And so persons are often commended for instances of virtue shown in their conduct, which respect only some single virtue, as justice, temperance, or the like: And in this sense Cicero calls Clodius *a deadly animal*. So when our Saviour commissions his apostles to *preach the gospel to every creature*, the meaning is, *every rational creature*. And thus, likewise, *to talk to a person* sometimes denotes the same thing as to *blame* him, which is one way of talking.

The second kind of synecdoche puts the species for the genus. Thus *bread* denotes any kind of food; as when a person is said *to get his bread by his labour*. In the same way of speaking, *money* is put for any kind of wealth in general. And it is an usual expression to say, that *wine destroys more than the sword*; that is, than any *hostile arms*. And the legal form of banishment among the Romans was, to prohibit persons *the use of fire and water*; that is, *the most common and ordinary necessaries of life*, in which all others were included.

The third species of this trope is, when the essential whole is put for one of its parts; that is, either for the matter or form. Thus, in the evangelist, Mary Magdalen says, *They have taken away my Lord, and I know not where they have laid him*, meaning his *body*.—So it is usual to say of a deceased person, *He was buried at such a time*. And in the inscriptions of sepulchral monuments we frequently meet with this expression, *Here lies such a one*; that is, his *corpse*. Nor are instances uncommon in which the whole being is put for the form. Thus when Cicero says, *Those persons live, who have fled from the confinement of the body, as from a prison*; by *persons* must necessarily be understood their *souls*, which are here distinguished from and set in opposition to their *bodies*. And so Virgil represents Æneas as meeting with Dido and some of his Trojan friends in the infernal regions; by which are meant their *ghosts*.

The fourth kind of synecdoche is, when either the matter or form is put for the whole being. Thus *silver* and

Elocution.

and *gold* are used to signify money made of those metals; as when we say, *I have so much silver*, or *so much gold*. And the word *soul*, both in our own and other languages, is put for the *whole person*. So with us, *a merry soul*, and *a dull soul;* in Cicero, *dear souls;* and in Horace, *candid souls*, are all used in this tropical sense. But this way of speaking occurs nowhere more frequently than in the Sacred Writings. Thus, for instance, it is said, *All the souls which came with Jacob into Egypt*, meaning the *persons*. And again, *The soul that sinneth it shall die;* from which expression, and others of the like import, some persons, by not attending to the nature of this trope, have been erroneously led to infer that the soul is naturally mortal. But sometimes only part of the matter stands to express the whole essence or being. So we imitate the Latins in using the word *caput* or *head* to denote either a *person* or *thing*. For, as with them *lepidum caput*, so with us *a witty head*, signifies the same as *a man of wit*. And in the same sense, *so many head of cattle* means so *many entire cattle*.

By the fifth sort of synecdoche, the whole of any material thing or quantity, whether continued or discrete, is put for a part of it. So when Cicero says, *A war is kindled through the whole world*, in compliment to his country, he calls the Roman empire *the world*. And this expression is also used by historians. Thus Cornelius Nepos, speaking of the quarrel between Mark Antony and Augustus, tells us, *that each of them desired to be lord of the world*. And in like manner St Luke says, *There went out a decree from Cæsar Augustus, that all the world should be taxed.* So in St Paul's shipwreck, it is said, *They ran the ship aground*, that is, *the head of her*, for it is plain by what follows, that the stern was loose. And as to discrete quantity, our Saviour, using this trope, said he should be *three days and three nights in the heart of the earth.* Though he did not continue three whole days and nights in the grave, but only part of the first and third day, and the whole second day, with the two whole nights between the first and third day, according to our way of reckoning. For he was buried on Friday in the afternoon, and rested in the grave that night, with the following day, which was the Jewish Sabbath, and was risen on the morning of the next day. So that we must necessarily have recourse to this synecdoche which puts the whole for the part, to clear up that event.

By this kind of synecdoche, also, the plural number is sometimes put for the singular. Thus St Matthew says, *The thieves who were crucified with our Saviour reviled him:* though it is plain from St Luke, that only one of them did so. It may also be referred to this trope, when a certain number is put for an uncertain one. So it is an usual way of expression to say, *I have seen or done such a thing an hundred or a thousand times:* when perhaps so many are not really intended, but only in general some considerable number.

The sixth and last kind of synecdoche puts a part of any material thing or quantity for the whole of it. So we say of a man, *He shelters himself under such an one's roof;* that is, *in his house*. And of a fleet, that it *consists of so many sail;* meaning, *so many ships*. And by this trope, that is ascribed to a single person which was done by the assistance of others, and in conjunction with them: As when it is said, that *Hannibal killed forty thousand Romans at the battle of Cannæ;* For an army is an aggregate body, of which the general is the head, and consequently the chief part of it. And to this kind of synecdoche may also be referred such expressions in which the singular number is put for the plural: as if one should say, *A man is liable to be misled by the influence of irregular passions;* meaning *all men*, or *mankind in general*. Or when less than the real number is put for any round number: Thus some ancient writers, when they speak of the Grecian armada that came against Troy, call it a fleet of a *thousand ships;* though according to Homer's list, it contained 1186. And so likewise the Greek interpreters of the Old Testament are usually called the *Seventy;* whereas, in reality, they were seventy-two.

57 Irony defined and illustrated.

IV. *Irony*. This is *a trope in which one contrary is signified by another:* As if any one should say, *Well done;* when at the same time his design is to intimate that the thing was *ill done*. So that, by this manner of expression, the speaker appears to mean something contrary to the sense of the word he makes use of. Not that the word is changed from its usual signification; but by the circumstances attending the expression, we perceive the contrary to what is spoken is intended. Quintilian observes, that an irony may be known one of these three ways: "By the manner of pronunciation, or from the nature of the person or the thing. For (as he adds) where any of these does not suit with the words, it is plain the speaker intends the contrary. The irony is very plain from the manner of pronunciation in that passage of Terence, where Simo speaking to his servant by way of reproof, says, "You have taken great care indeed." From the circumstances of the person, when Cicero, addressing to Catiline, says, "He went to your companion, that *excellent man*, Marcus Marcellus." When he calls him an *excellent man*, it is evident he means the contrary: because no good man would be a companion of Catiline. And when he begins his oration for Ligarius with saying, "Cæsar, this is a *new* crime, and never heard of till now," the thing he is speaking of shows it to be an irony; for it was not new, as all who were present very well understood.

The subjects of irony are vices and follies of all kinds. And this way of exposing them is often more effectual than serious reasoning: For many persons, who, either from temper or want of reflection, cannot be moved by the force of an argument, are not proof against the poignancy of wit and raillery. And therefore we find the most grave and serious persons have not declined the use of this trope upon proper occasions. Socrates, whom the oracle pronounced the wisest man of his age, gave so much into it, that he got the name of *ειρων*, that is, the *droll*. In the Sacred Writings we have a remarkable instance of it in the prophet Elijah, where he challenges the priests of Baal to prove the truth of their deity: For it is said expressly, "He mocked them, and said, Cry aloud, for he is a god; either he is talking, or he is pursuing, or he is on a journey, or peradventure he sleepeth, and must be awaked." And Solomon takes the like method to expose the follies of youth by this ironical apostrophe, "Rejoice, O young man, in thy youth," with what

what follows, which is all ironical. Nay, our Saviour himself thought fit thus to reprove the Jewish doctors, when he says, "Full well ye reject the commandment of God, that ye may keep your own tradition:" Where, by the words *full well*, or, as it is in the original, καλως, it is very evident that a severe reprimand was intended.

An irony is used on a variety of occasions, as we shall show from some instances in Cicero. Sometimes he applies it in a way of jest and banter: As when he says, "We have much reason to believe the modest man would not ask him for his debt, when he pursues his life." At other times by way of insult and derision: Thus when he would represent the forces of Catiline as mean and contemptible, "O terrible war, (says he), in which this band of rakes are to march under Catiline! Draw out all your garrisons against this formidable body." Again, at other times, to give the greater force to his argument, he would seem, as it were, by this trope to recal and correct what he had said before; as in his oration for Milo: "But it is foolish in us to compare Drusus, Africanus, Pompey, and ourselves, with Clodius; all our calamities were tolerable, but no one can patiently bear the death of Clodius." Now the character of Clodius was so well known, that all who were present must be sensible he meant the contrary. And, to name no more, an irony is never used to greater advantage, than when it is followed immediately by something very stinging. Thus, speaking of Piso, he says, "You have heard this philosopher: he denies that he was ever desirous of a triumph." And then addressing himself to him, he immediately adds, "O wretch! when you destroyed the senate, sold its authority, subjected your consulate to the tribune, overturned the state, betrayed my life and safety for the reward of a province; if you did not desire a triumph, what can you pretend you did not desire?" This must effectually confound the false gravity at that time assumed by Piso.

Art. II. Secondary Tropes.

58 Secondary tropes similar in nature, though not in name, to the former ones.

Secondary tropes are so called, because they are all of the same nature with the former, and may be referred to some or other of them, though they have received different names.

They are chiefly eight in number; *Antonomasia*, *Communication*, *Litotes*, *Euphemism*, *Catachresis*, *Hyperbole*, *Metalepsis*, and *Allegory*. The three first of these are simple tropes, and may all be referred to a *Synecdoche*. But the five last are of a mixed or complex nature, and not confined to any one of the primary tropes; as will appear in treating upon them in order.

59 A common word often used by way of eminence for any thing remarkable.

I. A common or general word is sometimes used for the proper name of some particular thing or person which upon any account is eminent and remarkable. So we say, *He is gone to the city*, or *he came from the city*, that is, *London*. And by the *Scriptures*, we mean the *Bible*. So likewise, in speaking of persons, *the orator* is used for Cicero, *the poet* for Homer or Virgil, and *the philosopher* for Aristotle: and it is not unusual to say *the apostle*, when we mean St Paul. On the contrary, the proper names of things or persons are sometimes applied to any other of the same character. Thus we use the word *gospel* for any certain and undoubted truth. And *Carthaginian faith* proverbially stood for the greatest falsehood and deceit among the Romans. With the Greeks, *Hercules* signified a *strong man*, *Nestor* a *wise man*, and *Irus* a *beggar*; and the names of *Samson*, *Solomon*, and *Job*, now answer the like characters. Both these ways of expression are often very emphatical, and heighten the idea more than where things are expressed by their own name. To call a good orator *Cicero*, or an excellent poet a *second Virgil*, includes not only an encomium upon the arts themselves, but leads the mind to what is most perfect in them, and was peculiar to those persons. These forms of speech are called *antonomasia*, and come properly under a synecdoche; for in the former the whole is put for a part, and in the latter a part for the whole.

60 A change of persons common in oratory.

II. Nothing is more common with orators than a change of persons. Sometimes, to avoid envy, and prevent the imputation of pride, in assuming to themselves the praise of any laudable action, they ascribe it to their hearers, and do not say, *we*, but *ye did so and so*. At other times, when it is necessary to remind them of something which they have done amiss, or to caution them against some wrong step for the future; to prevent giving offence, they take it upon themselves, or at least join themselves with them, and do not say, *you have done this*, or *do not you do this*: but, *we have done it*, or *let us not do it*. And again, at other times, in compliment to their hearers, they join them as partners in the commendable actions or virtues of other persons; as when the whole body of the people is brought in to share the praise arising from the success of wise counsels or victorious arms. Such ways of speaking often occur both in Demosthenes and Cicero. They are called *communication*, and come properly under a synecdoche of the whole.

61 Litotes, where, by denying the contrary, more is meant than is expressed.

III. On the contrary, there is a mode of speech, in which, by denying the contrary, more is intended than the words express. This way of speaking is called *litotes*: and is often used for sake of modesty where a person is led to say any thing in his own praise, or to soften an expression which in direct terms might sound harsh or give offence. As if one should say, *I do not commend you for that*; meaning, *I greatly discommend*, or *blame you for it*: where more being understood than the words expressly denote, it is properly a synedoche of the part. Not that this manner of speaking is always to be so interpreted; but where it is not, there is no trope; which must be judged of by the circumstances of the discourse. But that it frequently is so used, might be easily shown from many instances; though it will be sufficient to mention two or three. Cicero speaking of Cotta, calls him *no mean orator*, whom he had just called *a very great orator*. And he says of Varro that "he pursued his studies not without industry; and afterwards gives him the character "of a man of the greatest application." Which passages, compared together, plainly show the import of those negative expressions. And a friend of Cicero, writing to him, begins his letter thus: "Although I am sensible the news I send you will not be very pleasant." This news was concerning the death of another friend of Cicero's; and there by the words *not very pleasant*, must, to be sure, be meant *very unpleasant and melancholy*; but he chose that expression in the beginning

Elocution.

beginning of his letter, as the softest and least shocking, the better to prepare him for the following account of what that news was. And in this way interpreters explain that passage in St Matthew: *And thou Bethlehem in the land of Judah art not the least among the princes of Judah;* where, by *not the least*, they understand the *greatest*, or *very great*, upon account of the honour it received by the birth of our Saviour, as the words immediately following plainly intimate.

62 Ungrateful things softened by agreeable words.

IV. When any displeasing or ungrateful thing is expressed by a more soft and agreeable word, it is called *euphemism*. And as the word made use of is either contrary to the proper word, or only different from it, it may be referred to different tropes. The Latins have a soft way of expressing their disregard to a person, by saying *valeat;* which we have borrowed from them, and say, *fare him well.* When the contrary being intended to what is expressed, it comes properly under an *irony*. And as the word *death* carries in it an idea that is disagreeable to human nature, instead of saying a person is dead, we often say *he is deceased*, or *departed;* which we have also taken from the Latins, who use the words *decessit* and *obiit* in the same sense. So that in both languages it comes under a synecdoche of the whole; to depart out of life being one sort of departure. But when the evangelist, speaking of Stephen, who was stoned to death, expresses it by saying, that *he fell asleep;* this is a beautiful metaphor, taken from the similitude between the death of a good man and sleep.

63 Catachresis or harsh tropes.

V. *Catachresis* signifies in general any harsh trope, though it is most commonly found in metaphors. It is principally used by poets, who make choice of it for novelty, or to enforce an expression, where the proper word does not seem strong enough. As when Milton, in describing the angel Raphael's descent from heaven, says, he

Sails between worlds and worlds;

where the novelty of the word enlivens the image more than if he had said *flies*. But it is sometimes found in the gravest authors, and even in the sacred writings. So we read of the *blood of the grape*. And Solomon says, *the horse-leech hath two daughters*. In all these instances the trope is a metaphor. But when St John says in the Revelations, *I turned to see the voice that spake to me*, it is here a metonymy of the adjunct; the word *voice* being put for the person who uttered it. In St Matthew we read of *Simon the leper;* not that he was then a leper, but had been so, and was cured; which is a *synecdoche* of the part. And when a criminal is said *to have had his reward*, that is, his punishment, it is an *irony*.

64 Hyperbole the boldest of all tropes.

VI. *Hyperbole* is the boldest of all tropes; for it exceeds the strict bounds of truth, and represents things either greater or less, better or worse, than they really are. But the representation is made in such a manner as not to impose on the hearers. For an *hyperbole* is not used to define or describe any thing accurately, but only to magnify or depress it in a considerable degree, when we either cannot or do not choose to represent it exactly. The excess in this trope is called *auxesis;* as when we say of any thing that is very high, *it reaches to the skies*. The defect, or contrary extreme, is termed *meiosis*. So we say of a very lean person, *he is nothing but skin and bones*, or *a mere skeleton*. It is principally metaphorical, but sometimes taken from other tropes. When Saul and Jonathan are said to have been *swifter than eagles, and stronger than lions*, the expression is founded in similitude, and is therefore a metaphor. When, instead of saying Cato was a very virtuous man, the historian calls him *the image of virtue;* it is an hyperbolical metonymy of the adjunct for the subject. And when we read in the Mosaic history *of cities fenced up to heaven*, there is a *synecdoche*. But if a man of weak sight be said *to be eagle-eyed*, it is an *irony*. Those hyperboles which are expressed comparatively, are commonly most emphatical, because they show a peculiarity in the excess. To say a thing is *as light as a feather*, carries the idea very far; but to say *it is lighter*, not only carries it still farther, but also heightens it, by leaving the mind at an uncertainty where to fix the limits.

65 Metalepsis, where two or more tropes are meant under one word.

VII. Sometimes two or more tropes and those of a different kind, are contained under one word; so that several gradations, or intervening senses, come between the word that is expressed, and the thing designed by it. And this is called a *metalepsis*. The contests between Sylla and Marius proved very fatal to the Roman state. Julius Cæsar was then a young man. But Sylla observing his aspiring genius, said of him, "In one Cæsar there are many Mariuses." Now in this expression there is a metalepsis. For the word *Marius*, by a *synecdoche*, or *antonomasia*, is put for any ambitious and turbulent person; and this again, by a *metonymy* of the cause, for the ill effects of such a temper to the public. So that Sylla's meaning, divested of these tropes, was, that Cæsar would prove the most dangerous person to the Roman state that ever was bred in it: which afterwards proved true in the event. So when Virgil, describing that part of the African coast where Æneas arrived with his ships, says, *A dark wood hung over it;* the word *dark*, by a metonymy of the effect, is put for *shady*, and that again by the same trope for *thick;* his meaning is, a *thick wood*. But the words of Dido, in the same poet, contain a larger gradation, when she says,

Happy, ah truly happy, had I been,
If Trojan ships our coasts had never seen.

In which expression first by a metonymy of the adjunct, the ships are put for the Trojans in the ships: and these, by a synecdoche of the whole, for Æneas, who was one of them; and again his arriving on the coast, by a metonymy of the cause, for her seeing him; and lastly, her seeing him, by the same trope, for the passion she had for him. So that her meaning is, she had been happy, if she had never entertained a passion for Æneas. This trope is more frequently to be met with in poets than in orators, as they take greater liberty in using distant allusions than is suited to that perspicuity of expression which is required in oratory. But as Quintilian has well observed, all the intermediate links of the chain in this trope are of no further use than to lead the mind gradually from the first to the last, the better to perceive their connection. As in the example last mentioned, relating to Dido, if we drop all the intervening steps, and connect the words expressed with what is directly intended, they will be found to contain a very remote cause put for the effect, which comes under

Elocution. der a metonymy. On the contrary, in the second example, where *dark* stands for *thick*, the effect is put for a remote cause. And the first, which is founded in a similitude of temper between Cæsar and Marius, belongs to a *metaphor*.

66
Allegory, a continuation of tropes through several sentences.

VIII. *Allegory*. As a metalepsis comprises several tropes in one word, so this is a continuation of several tropes in one or more sentences. Thus Cicero says, "Fortune provided you no field, in which your virtue could run and display itself:" where the words *field* and *run* are metaphors taken from corporeal things, and applied to the mind. And in another passage, speaking of himself, he says, "Nor was I so timerous, that after I had steered the ship of the state through the greatest storms and waves, and brought her safe into port, I should fear the cloud of your forehead, or your colleague's pestilent breath. I saw other winds, I perceived other storms, I did not withdraw from other impending tempests; but exposed myself singly to them for the common safety." Here the state is compared to a ship, and all the things said of it under that image are expressed in metaphors made use of to signify the dangers with which it had been threatened. And indeed allegories generally consist of metaphors; which being the most beautiful trope, a number of them well chosen and put together is one of the finest and brightest ornaments in language, and exceeds a single metaphor in lustre, as a constellation does a separate star. It is true, that allegories are sometimes found in other tropes; but this is very rare. In that known expression of Terence, the tropes are all metonymies: *Without Ceres and Bacchus, Venus grows cold;* that is, divested of the tropes, *Without meat and drink, love dies.* And Samson's riddle is made up of synecdoches: "Out of the eater came forth meat, and out of the strong came forth sweetness." But there is no small skill required in the right management of allegories. For care should be taken that the same kind of trope be carried through the whole, so as to compose one uniform and consistent set of ideas: otherwise they dress up a chimera, a thing that has no existence, and of which the mind can form no perception. And, as Quintilian says very justly, "to begin with a tempest and end with a fire, would be very ridiculous and unnatural." It is likewise very necessary that the allusions be all plain and evident, especially where the name of the thing alluded to is not expressed. These are called *pure allegories*. As that of Cicero: "So it happens, that I, whose business it is to repel the darts, and heal the wounds, am obliged to appear before the adversaries have thrown any dart; and they are allowed a time to attack us, when it will be not in our power to avoid the assault; and if they throw a poisonous dart, which they seem prepared to do, we shall have no opportunity to apply a remedy." The tropes here are all taken from military affairs, without any intimation what they are applied to. But that is plain from the context of the discourse. For he is speaking of the disadvantages he laboured under in defending his client against those of the opposite side, and so applies to the bar those terms which were proper to the field. But where the reference is not evident, it becomes a riddle: which is nothing else but an obscure allegory. To avoid this, therefore, the best writers generally use what they call *mixed allegories*, that is, such wherein the proper name of the thing is expressed, which the whole similitude respects. Of this kind is that in the speech of King Philip of Macedon, given us by Justin, where he says, "I perceive that cloud of a dreadful and bloody war arising in Italy, and a thunder-storm from the west, which will fill all places with a large shower of blood, wherever the tempest of victory shall carry it." The proper words *war*, *blood*, and *victory*, being joined to the tropes *cloud*, *shower*, and *tempest*, in this sentence, render the several parts of the similitude plain and evident. Quintilian thinks those allegories most beautiful, where the whole similitude is expressed, and those words, which in their proper sense relate to one of the two things between which the comparison is made, are allegorically applied to the other: As when Cornelius Nepos says of Atticus, "If that pilot gain the greatest reputation who preserves his ship in a boisterous and rocky sea; ought not he to be thought a man of singular prudence, who arrived in safety through so many and so great civil tempests? These are the allegories with which orators are chiefly concerned.

§ 2. *Of Figures*.

67
The term *figure* apparently borrowed from the stage.

This term seems to have been borrowed from the stage, where the different habits and gestures of the actors, suitable to the several characters they sustained, were by the Greeks called σχηματα, and by the Latins *figuræ*: And it is not unusual with us to say of a person, both with respect to his dress and action, that he makes *a very bad*, or *a very graceful figure*. And as language is the dress, as it were of our thoughts, in which they appear and are represented to others; so any particular manner of speaking, may, in a large sense of the word, be called its *figure*, in which latitude writers sometimes use it. But rhetoricians have restrained the sense of the word to such forms of speech as differ from the more common and ordinary ways of expression: as the theatrical habits of actors, and their deportment on the stage, are different from their usual garb and behaviour at other times. A *figure* therefore, in the sense it is used by rhetoricians, is *A mode of speaking different from, and more beautiful and emphatical than, the ordinary and usual way of expressing the same sense;* or, in other words, *That language which is suggested either by the imagination or the passions.* Now as the habits and gestures of our bodies are in a manner infinitely variable, so it is plain that the different forms of speech are almost innumerable. But every alteration from the common manner ought not to be esteemed a figure, nor deserves that character. It must contain some beauty, or express some passion, to merit a place among rhetorical figures, and be marked out for imitation.

The subject of *figure* seems to have been one of the last things which was brought into the place of oratory, in order to complete it. Aristotle, who treats so accurately upon other parts, says very little of this. But the Greek writers who came after him have abundantly supplied that deficiency. It is to them we owe the chief observations that have been made on this subject. They took notice of the several modes and turns of expression, observed their force and beauty, and gave them particular names by which they might be known and distinguished from each other. And indeed

Elocution. indeed they have treated the matter with such minuteness and subtility, that Quintilian seems, not without reason, to think they have multiplied figures to an excess. But though it was so late before they were taken notice of, and introduced into the art of speaking, yet the use of them in discourse was doubtless very ancient. The author of Homer's life, which some have ascribed to Plutarch, has shown, by examples taken out of him, that there is scarce a figure mentioned by rhetoricians, but is to be met with in that most ancient poet. And, if we consider the nature of speech, we shall easily perceive that mankind must have been under a necessity very early to introduce the use of *tropes* for supplying the want of proper words to express their simple ideas: so the like necessity must have put them upon the use of figures to represent their different passions; though both of them were afterwards increased, and improved in such a manner as to become the chief ornaments of language. The passions of men have been always the same; they are implanted in us by nature, and we are all taught to discover them by the same ways. When the mind is disturbed, we show it by our countenance, by our actions, and by our words. Fear, joy, anger, alter the countenance, and occasion different emotions and gestures of the whole body. And we know with what passion a man is affected, by hearing his words, though we do not see him. He does not express himself as he usually does at other times when cool and sedate. Objects appear to him in a different view, and therefore he cannot but speak of them in a different way. He interrogates, he exclaims, he admires, he appears, he invokes, he threatens, he recals his words, repeats them, and by many other different turns of expression varies his speech no less than his countenance, from his common and ordinary manner. Now as nature seems to teach us by these figurative expressions how to represent the different commotions of our minds, hence some have thought fit to call figures *the language of the passions*. And as these are given us, among other wise ends, to excite us the better to provide for our preservation and safety, this is done sometimes by force of arms, and at other times by discourse. And therefore Cicero very handsomely compares the conduct of an orator to the exercises of the palæstra: in which, as each combatant endeavours not only to defend himself, and attack his adversary, but likewise to do both with decency; so the principal weapons of an orator, as he represents them, are figures, which being no less the ornaments of language than images of our passions, answer all these purposes. Besides, figures chiefly distinguish the different kinds of style, furnish it with an agreeable variety, and often serve to represent things in a clear and forcible manner.

From this short account of the nature of figures, the advantage of them to an orator is very evident. They are a sort of natural eloquence, which every one falls into without attending to it, suitably to that temper of mind with which he is affected himself, and is desirous to affect others. In a cool and sedate discourse, such figures as convey our sentiments with the greatest strength and evidence are most proper. And there are others, which are suited to brighten and enliven more gay and sprightly objects. Others again are more peculiarly adapted to express the disorders and perturbations of the mind. To repeat the same thing again would many times be deemed a tautology and impertinent; but to do this when the mind is ruffled, is not only allowable, but the repetition renders it more strong and affecting. So likewise to interrogate, exclaim, or admire, under the influence of a passion, impresses the hearers, and disposes them to attention; whereas at another time perhaps such ways of speaking would scarce be consistent with prudence. There is a natural sympathy in men's minds, which disposes them to receive impressions from those with whom they converse. Thus one gay and pleasant companion gives a cheerfulness and vivacity to a whole company; whereas, on the contrary, one who is dull and phlegmatic damps the spirits of all about him, and affects them with the same gloomy temper. Figures are peculiarly serviceable to an orator for answering these different intentions. And as he finds them in life, from thence he must copy them; as a painter does the features of the countenance, and the several parts of the body; figures being to the one what lines and colours are to the other. The design of Catiline to destroy the Roman state and burn the city, is a story well known. There was an army drawn together at a proper distance to favour the undertaking; and others were left in Rome, who had their parts assigned them for burning the city, and destroying those who should escape the flames And, in a word, every thing was ready for putting in execution this horrid and barbarous scheme. So that nothing retarded it but the taking off Cicero, who was then consul, which was thought necessary to be done first. Cicero, upon information of the design against his life, finds means to prevent it, and the same day calls together the senate. And Catiline, who was a man of consummate boldness, had the confidence to appear in that assembly. Upon their meeting, Cicero opens to them the whole affair of the conspiracy, and the design against himself, in a most warm and pathetic harangue. In which he had two things in view; to raise the indignation of the senate against the conspirators, and particularly against Catiline; and, either by terrifying or exasperating him, to oblige him to leave the city. Now he does not begin his speech in his usual manner at other times, by addressing to his audience, bespeaking their favour and attention, or letting them gradually into the design of what he was about to say; but as Catiline was present, he immediately falls upon him with vehemence, in the following manner: "How far, Catiline, will you abuse our patience? How long will your fury insult us? What bounds will you set to your unbridled rage? Does neither the night-guard of the palace, nor the city-watch, nor the people's fear, nor the agreement of all good men, nor the meeting of the senate in this fortified place, nor the countenances and looks of this assembly, at all move you? Do not you perceive your designs are discovered, and that all who are present know of your conspiracy? Who of us, do you think, is ignorant of what you did the last night, and the night before, where you was, who was with you, and what you resolved on? O times, O manners! The senate knows this, the consul sees it; and yet this man lives! —lives? nay, comes into the senate, joins in the public counsels, observes and marks out each of us for destruction!" And in the same impetuous strain he proceeds through

through his whole speech, interspersing a great variety of the like strong and moving figures. And the discourse had its desired effect: for when Catiline stood up afterwards to make his defence, the whole senate was so inflamed, and their resentments against him rose so high, from what Cicero had said, that they had not patience to hear him speak; upon which he left both them and the city. Had Cicero, instead of venting his just indignation against the author of so barbarous and inhuman a design, in the manner he did, by figures suited to strike the passions of his hearers; had he, instead of this, attempted to reason with him, and told the story in a cold and lifeless manner, he would have exposed himself to the contempt of Catiline; and by leaving the senate little or nothing moved at what he said, prevented perhaps their coming to those speedy and vigorous resolutions which were necessary at so critical a juncture. Let us suppose him to have expostulated with Catiline in much the same words as before, but thrown into a different form, and divested of those pathetic figures. As thus: "Catiline, you have really abused our patience to a great degree. You have insulted us with your furious proceedings a long while. You seem to have fixed no bounds to your unbridled rage. Neither the night-guard of the palace, nor the city-watch, nor the people's fear, nor the agreement among good men, nor the calling together of the senate in this fortified place, nor the countenances and looks of this assembly, appear to move you in the least. I assure you we are all of us apprised of what you did the last night, and the night before, where you was, and who were with you, and what resolutions you came to. These are sad times, the age is very degenerate; that the senate should know all this, the consul see it; and yet that this man should live, come into the senate, hear all our debates, and mark us out to destroy us." You see the sense is entirely the same, and the words too in a great measure; so that there is little more than an alteration in the form of them. And yet who does not perceive how flat and languid such a way of talking must have appeared at that time? and how much it loses of that spirit and energy, which shows itself in Cicero's manner of expression? Had he delivered himself thus, it might indeed have made the senate look upon Catiline as an abandoned wretch, lost to all virtue and goodness, and perhaps have moved some to pity him on that account; as we are easily induced to compassionate persons in such circumstances, especially when descended from noble and virtuous ancestors, which was his case. But sure it would have been ill suited to fire their minds with that generous regard for their country, and the necessary precautions for its security, which the circumstances of the state then required. Nor would Catiline have been at all deterred by it, but rather encouraged in the prosecution of his designs, from the little effect a speech so managed must probably have had upon the minds of the senators. But Cicero knew very well that the passions of mankind are the springs of action: that it is many times not sufficient for an orator to convince their minds, by setting the truth in a clear light; but he must also raise their hopes, alarm their fears, inflame their anger, or excite some other suitable passion, before they will be brought to act with that zeal and fervour which the case may require. And as he was admirably well skilled in this art of touching the passions, he seldom fails to fix upon the proper methods of doing it, and makes choice of such figures and modes of speaking as in the strongest manner represent the emotions of his own mind. For every passion is not to be expressed by the same figures, any more than it is drawn by the same lines, or painted with the same colours. When Dido finds that Æneas is about to leave her, she uses all her arts to detain him. And as persons in great distress are seldom at a loss to express their condition in the most affecting way; she discovers her fear, anger, revenge, with the whole crowd of disorders which then possessed her mind, in a variety of moving figures, suited to raise the counter passions in his breast, as is finely represented by Virgil in that artful speech he has made for her, which we forbear to recite for no other reason but the length of it. But what particular figures are most accommodated to answer the several ends proposed by them, will best appear when we come to treat of them separately.

We shall therefore now proceed to lay down a few directions for the proper use of figures. And first they should always be accommodated to the sentiments, and rise in proportion to the images designed to be conveyed by them. So far as they are founded in reason, they are suited to impress the mind; but where the language outstrips the thought, though it may please the ear, and some weak persons may be carried away with a pomp of words, yet an intelligent hearer will soon see through the thin and airy dress. It is the sense which gives weight to the figure, as that by striking the imagination awakens the mind, and excites it to act in conformity to reason. Again, in the use of pathetic figures, it is generally better to be nervous than copious, that the images, by their closer union, may impress the mind with greater force and energy; though in such figures as are designed for ornament or illustration, a more diffusive way of painting is sometimes agreeable. But farther, the too frequent use of figures ought to be avoided. For what was observed in relation to tropes, is also true with respect to these; that a great number of them is apt to darken and obscure the style. And besides, Cicero's reflection in this case is very just, That "it is hard to say, what should be the reason, that those things, which most affect us with a sensible pleasure, and at first sight soonest move us, do likewise soonest cloy and satiate us." But that it is so, we find by common experience. Lastly, figures should be so interwoven in a discourse, as not to render the style rough and uneven, sometimes high and at other times low; now dry and jejune, then pompous and florid. In a word, they should rather seem to arise from nature than art; to offer themselves, than to be the effect of study; and to appear not like patches upon a face, but the agreeable beauty of a sound and healthful complexion. But of this we shall have occasion to speak more at large hereafter, in treating upon the different kinds or characters of style.

As to the division of figures, which is what remains to be considered, they are usually divided into two sorts, figures of words, and figures of sentences. The difference between them consists in this; that in the former, if you alter the words, or sometimes only the situation of them, you destroy the figure; but in the latter the figure remains, whatever words are made use of,

Elocution.

of, or in what manner soever the order of them is changed. Thus when the name of a person or thing is repeated, to intimate some known property or quality belonging thereto, it is a verbal figure called *place*. Cicero was a true patriot and hearty lover of his country. And therefore we shall use this figure in saying, that *at the time of Catiline's conspiracy Cicero appeared like Cicero*. The sense would remain the same, but the figure would be lost, if we should alter the words, and say, *at that time Cicero appeared like himself*. So when two or more sentences, or members of a sentence, end with the same word, it is called *epistrophe*; as when we say, *To lose all relish of life, is in effect to lose life*. But if only the order of the words be changed in the latter clause thus, *To lose all relish of life, is to lose life in effect*; the figure vanishes. And this is the nature of the verbal figures. But it is not so in figures of sentences: they continue the same, whatever alterations are made in the words. An orator sometimes thinks it proper to change the form of his discourse, and address himself to his audience, or an absent person, or else perhaps to introduce some other person as speaking to them whose words may be supposed to carry greater weight and authority with them than his own. The former of these is called *apostrophe*, and the latter *prosopœia* or *imagery*; which require no certain words or order of expression.

Art. I. Verbal Figures.

[67] Verbal figures distinguished into three sorts; with their various subdivisions.

These may be distinguished into three sorts, as they consist in a *deficiency* of words, a *redundancy*, or a *repetition*.

I. Of the first sort are *ellipsis* and *asyndeton*.

Ellipsis, is when one or more words are wanting in a sentence to complete the construction, and fully express the sense. This figure is often used in proverbial speeches: as when we say, *Many men, many minds*; that is, *have many minds*; and, *The more danger, the more honour*; that is, *gains more honour*. But where more is intended by such expressions than mere brevity, and especially when they are the effect of some passion, the figure receives another name, and is called *aposiopesis*, which is placed among the figures of sentences, where we shall consider it.

Asyndeton, is when the particles that connect the members of a sentence one with another are left out, to represent either the celerity of an action, or the haste and eagerness of the speaker. Thus Cæsar expresses his speedy conquest of Pharnaces: *I came, I saw, I conquered*. If he had inserted the copulatives, and said, *I came, and I saw, and I conquered*, it would have retarded the expression, and not given so full and just an idea of the swiftness of the action. In the last article we took notice of the vehement and impetuous manner in which Cicero attacked Catiline in his first oration, where his design was to fire the minds of the senate against him, and oblige him to leave the city, both which points he gained by that speech. The next day, therefore, when Catiline was gone, he calls together the body of the citizens, and, makes a speech to them, which in a sort of rapture or transport of mind he thus begins, by acquainting them with the departure of Catiline, *He is gone, departed, escaped, broke out*; intimating at the same time both the excessive rage in which Catiline left Rome, and the great pleasure with which he was himself affected on that account. This concise way of speaking adds likewise a considerable emphasis to an expression, and by bringing the several parts of a thing nearer together affects the mind with a greater force. Thus Cicero sets Cato's character in a very strong and beautiful light by the use of this figure. "Nature itself (says he) has made you a great and excellent man for integrity, gravity, temperance, magnanimity, justice, in a word, for all virtues."

II. The second sort of verbal figures is contrary to these, and consists in a redundancy or multiplicity of words; which are likewise two, *pleonasmus* and *polysyndeton*.

When we use more words than are necessary to express a thing, it is called *pleonasmus*. This is done sometimes for greater emphasis, as when we say, *Where in the world is he?* At other times it is designed to ascertain the truth of what is said: So the servant in Terence, when the truth of what he had related was called in question, replies, *It is certainly so; I saw it with these very eyes*.

When the several parts of a sentence are united by proper particles, it is called *polysyndeton*. This adds a weight and gravity to an expression, and makes what is said to appear with an air of solemnity; and by retarding the course of the sentence, gives the mind an opportunity to consider and reflect upon every part distinctly. We often meet with this figure in Demosthenes, which very well suits with the gravity of his style. So he encourages the Athenians to prosecute the war against King Philip of Macedon, from this consideration, that now "they had ships and men, and money, and stores, and all other things which might contribute to the strength of the city, in greater number and plenty than in former times." Every article here has its weight, and carries in it a proper motive to animate them to the war. But if you remove the copulatives, the sentence will lose much of its force.

III. The third kind of verbal figures consists in a *repetition*. And either the same word in sound or sense, is repeated; or one of a like sound, or signification, or both.

Of the former sort there are ten, called *antanaclasis*, *ploce*, *epizeuxis*, *climax*, *anaphora*, *epistrophe*, *symploce*, *epanalepsis*, *anadiplosis*, and *epanodos*. The two first of these agree in sound, but differ in sense; the eight following agree in both.

When the same word in sound but not in sense is repeated, it is called *antanaclasis*. This figure sometimes carries a poignancy in it; and when it appears natural and easy, discovers a ready turn of thought. As when a son, to clear himself of suspicion, assured his father *he did not wait for his death*; his father replied, *But I desire you would wait for it*. Here the word *wait* is taken in two different senses. It is likewise used on serious occasions, as in grave and moral precepts, which are apt to affect the mind with greater pleasure when delivered in an agreeable dress. As this: *Care for those things in your youth, which in old age may free you from care*: Where the word *care* in the former place signifies to *provide*, and in the latter *anxiety of mind*. And even our Saviour himself once uses this figure, when he says to one of his disciples, who

who desired to be dismissed from attending him, that he might go and bury his father; *Follow me, and let the dead bury their dead:* Where *dead* in one place denotes a *natural death*, and in other a *moral* or *spiritual death*.

Sometimes the name of some person or thing is repeated again, to denote some particular character or property designed to be expressed by it; and then it is called *ploce*. Thus Cicero says, *Young Cato wants experience, but yet he is Cato;* meaning he had the steady temper of the family. And so in the proverbial expression, *An ape is an ape, dress him ever so fine.*

68 When a word is repeated again with vehemence in the same sense, it is called *epizeuxis*. This figure shows the earnestness of the speaker, and his great concern of mind about what he says; and therefore has a natural tendency to excite the attention of the audience. It is suited to express anger, surprise, sorrow, and several other passions. As when Cicero would express his indignation against Antony for having been the chief instrument in bringing on the civil war, he says to him: *You, you, Antony pushed Cæsar upon the civil war.* And thus he tells Catiline in his first invective against him: *You live; and live, not to lay aside, but to pursue, your wicked design.* And when our Saviour would express his great concern and sorrow for the wickedness of the Jews, he does it in this pathetic manner: *O Jerusalem, Jerusalem, who killest the prophets.*

69 *Climax* is a beautiful kind of repetition, when the word, which ends the first member of a period, begins the second, and so through each member, till the whole is finished. There is a great deal of strength as well as beauty in this figure, where the several steps rise naturally, and are closely connected with each other. As in this example: *There is no enjoyment of property without government, no government without a magistrate, no magistrate without obedience, and no obedience where every one acts as he pleases.* But as Quintilian observes, this figure lies so open, that it is apt to look too much like art; for which reason he advises not to use it often. To prevent this, therefore, orators sometimes disguise it, by not repeating the same word which stood in the former member, but some other equivalent to it. As in the following instance of Cicero for Milo: "Nor did he commit himself only to the people, but also to the senate; nor to the senate only, but likewise to the public forces; nor to these only, but also to his power with whom the senate had entrusted the whole commonwealth.

70 When several sentences, or members of a sentence, begin with the same word, it is called *anaphora*. This is a lively and elegant figure, and serves very much to engage the attention. For by the frequent return of the same word the mind of the hearer is held in an agreeable suspense, till the whole is finished. "You do nothing (says Cicero to Catiline), you attempt nothing, you think nothing, but what I not only hear, but also see, and plainly perceive." It is frequently used by way of question; which renders it not only beautiful, but likewise strong and nervous. As at the beginning of the same speech: "Does neither the night-guard of the palace, nor the city-watch, nor the people's fear, nor the agreement of all good men, nor the meeting of the senate in this fortified place, nor the countenances and looks of this assembly, at all move you?" And in another of his orations: "What is so popular as peace, which seems to afford a pleasure, not only to beings endowed with sense, but even to inanimate nature? What is so popular as liberty, which even beasts as well as men seem to covet and prefer above all things? What is so popular as ease and leisure, for the enjoyment of which you and your ancestors have undergone the greatest labours?

Epistrophe is contrary to the former, and makes the repetition at the end of each member or sentence. As thus; "*Since concord was lost; friendship was lost, fidelity was lost, liberty was lost; all was lost.*" And Cicero, in the charge which he brings against Mark Antony before the senate, makes use of this figure, when he says, "Do you lament the destruction of three Roman armies? the author of that destruction was Antony. Do you bewail the loss of most eminent citizens? They have been taken from you by Antony. Is the authority of this order weakened? It is weakened by Antony." 71

Symploce takes in both these last figures. As in that of Cicero: "You would pardon and acquit him, whom the senate hath condemned, whom the people of Rome have condemned, whom all mankind have condemned." Here the several members both begin and end with the same word. We have a beautiful instance of it in St Paul, when he says, "Are they Hebrews? so am I. Are they Israelites? so am I. Are they the seed of Abraham? so am I." 72

When a sentence concludes with the word with which it began, it is called *epanalepsis*. As in that expression of Plautus, "Virtue contains all things; he wants no good thing who has virtue." The figure is the same, but the principle not so honest, in the advice which we find given by the miser in Horace, when he says, "Get money, if you can, honestly; but however, get money." This figure adds a force to an expression, when the principal thing designed to be conveyed is thus repeated, by leaving it last upon the mind. And it heightens the beauty of it, when the sentence has an agreeable turn arising from two opposite parts. As in Cicero's compliment to Cæsar: "We have seen your victory terminated by the war; your drawn sword in the city we have not seen." Hermogenes calls this a *circle*, because the sentence returns again to the same word, as that geometrical figure is formed by the orbicular motion of a line to the same point. 73

When the following sentence begins with the same word with which the former concluded, it is termed *anadiplosis* As in the following instance: *Let us think no price too great for truth; truth cannot be bought too dear.* So in that passage of St John: *He came to his own, and his own received him not.* This figure generally suits best with grave and solemn discourses. 74

Epanodos is the inversion of a sentence, or repeating it backwards, so that it takes in the two last figures; for it both begins and ends with the same word, and the same word is likewise repeated in the middle. This turn of expression has a beauty in it, and shows a readiness of thought. We have the following example of 75

Elocution. of it in Minutius Felix, where he is exposing the folly of the Egyptian superstition. "Isis (says he), with Cynocephalus and her priests, laments, bemoans, and seeks her lost son; her attendants beat their breasts, and imitate the grief of the unhappy mother; in a little time the son is found, upon which they all rejoice. Nor do they cease every year to lose what they find, or to find what they lose. And is it not ridiculous to lament what you worship, or to worship what you lament?" It serves likewise to illustrate and enforce the sense, by setting it in two opposite views. As in that expression of the prophet: "Wo unto them who call good evil, and evil good; who put darkness for light, and light for darkness!"

These figures which consist in a repetition of words of a like sound or signification, or both, are four; *paronomasia*, *homoioptoton*, *synonymia*, and *derivatio*; the two first of which respect words that are similar in sound only, the third in sense, and the last in both.

76 When two words very near in sound, but different in sense, respect each other in the same sentence, it is called *paranomasia*. As when we say, *After a feast comes a fast*; and, *A friend in need is a friend indeed.* We usually call it a *pun*, which when new, and appositely used, passes for wit, and serves to enliven conversation. Nor is it wholly to be excluded from grave and serious discourses: for a witty jest has many times had a better effect than a solid argument, and prevailed with those who could not be moved by close reasoning. And therefore Cicero and the best speakers have sometimes recourse to it upon weighty and solemn occasions, as will be shown hereafter in its proper place.

77 When the several parts of a sentence end with the same case, or tense of a like sound, this also is considered as a figure, and named *homoioptoton*. As thus: *No marvel though wisdom complain that she is either wilfully despised, or carelessly neglected: either openly scorned, or secretly abhorred.* This figure is esteemed most beautiful when the parts are all of the same length, or pretty near it; as it adds to the harmony of the period, and renders the cadency of the several members more musical from the just proportion between them. The Greek rhetoricians were much addicted to this figure, and Isocrates is particularly celebrated for it. But some of the best orators seem to have industriously avoided it, as carrying in it too much the appearance of art. And it is remarkable, that this figure appears nowhere so much in all the works of Demosthenes, as in an oration which he did not speak himself, but wrote for his friend Diodorus, a man of that taste, who was to pronounce it as his own.

78 The next figure above mentioned is *synonymia*. Now strictly speaking, synonymous words are those which have exactly the same sense. But there being few such, the use of the term is so far extended as to comprehend words of a near affinity in their signification, which in discourse are frequently put for one another. So, *to desire*, and *intreat*, are sometimes used as equivalent terms; whereas *to desire* is no more than to wish for a thing, and *to intreat* is to express that inclination in words. In like manner, *esteem* and *honour* are often taken for synonymous words, though they have not precisely the same sense, but one is the usual consequence of the other; for esteem is the good opinion we entertain of a person in our mind, and honour the outward expression of that opinion. When two or more such words come together, they constitute this figure. As when Cicero, speaking of Piso, says, "His whole countenance, which is the tacit language of the mind, has drawn men into a mistake, and deceived, cheated, imposed on those who did not know him." This figure sometimes adds force to an expression, by enlivening the idea; and it often promotes the harmony and just cadency of a sentence, which otherwise would drop too soon, and disappoint the ear.

When such words as spring from the same root, as *justice*, *just*, *injustice*, *unjust*, and the like, come together in the same sentence, they make the figure called *derivatio*. Cicero, observing the vanity of the philosophers who affected praise at the same time that they decried it, used this figure, when he says of them, "The philosophers set their names to those very books which they write for the contempt of glory; and are desirous to be honoured and applauded, even for what they say in contempt of honour and applause." This figure receives an additional beauty when repeated, especially in two opposite members; as, *He wished rather to die a present death, than to live a miserable life.* 79

Art. II. Figures *of* Sentences.

Of these, some are principally adapted for reasoning, and others to move the passions. 80

I. *Those suited for proof*, Which are six: *Prolepsis*, *hypobole*, *anacoinosis*, *epitrope*, *parabole*, and *antithesis*. Of figures of sentences; some are for reasoning and some for moving the passions.

Prolepsis or *anticipation*, is so called, when the orator first starts an objection, which he foresees may be made either against his conduct or cause, and then answers it. Its use is to forestal an adversary, and prevent his exceptions, which cannot afterwards be introduced with so good a grace. Though it has likewise a farther advantage, as it serves to conciliate the audience, while the speaker appears desirous to represent matters fairly, and not to conceal any objection which may be made against him. The occasions of this figure are various; and the manner of introducing it very different. Sometimes the orator thinks it necessary to begin with it, in order to justify his conduct, and remove any exceptions which may be made against his design. Cicero, for several years together, after he first began to plead, had always been for the defendant in criminal cases. And therefore, when he was prevailed with to undertake the accusation of Verres, he begins his oration with this apology for himself: "If any one present should wonder, that when for several years past I have so conducted myself as to defend many and accuse none, I now on a sudden alter my custom, and undertake an accusation: when he shall have heard the occasion and reason of my design, he will both approve of it, and think no person so proper to manage this affair as myself." And then he proceeds to give an account of the reasons which moved him to engage in it. At other times the objection is admitted as an exception to what has been said, but not so as to affect it in general. Thus, when Cicero has represented the advantages of literature and the polite arts, he starts this objection to what himself had said. "But some one will ask, whether those great men, the memory of whose glorious actions is delivered down to posterity, were acquainted with that sort of learning

Elocution. I so applaud?" To which he replies, "Indeed this can scarce be said of them all. However, the answer is easy. I have known several persons of excellent abilities, who, without learning, by the force of an extraordinary genius have been men of great virtue and solidity. Nay, I will add, that nature without learning, has oftener produced these qualifications, than learning without a genius. But yet it must still be owned, that where both these meet, they form something very excellent and singular." Again, at other times, the orator artfully represents the objection as something considerable and important, to give the greater weight to his answer when be has confuted it. Cicero, in his celebrated oration for the Manilian law, could not omit to take notice, that Lucullus had already gained several very considerable advantages over Mithridates. And therefore, having before described the war as very great and dangerous, apprehending these two accounts might appear somewhat inconsistent, and be liable to an objection, he puts it thus artfully himself: "But now, after what I have said of Lucullus, it may probably be asked, How then can the war be so great? be pleased to hear, for there seems to be very just reason for this question." And then he proceeds to show, from the power of King Mithridates at that time, his great abilities, long experience in military affairs, and fresh alliances, that the war was yet very great and dangerous. But sometimes, when the orator is sensible that what he has advanced lies open to an objection, he omits to make it in express terms; and yet proceeds to vindicate what he had said, as if it had been made. Thus, when Cicero had charged Verres with having plundered the inhabitants of Sicily of all their plate, jewels, and other valuable moveables, which he thought worth while to carry away; as the audience might imagine this to be scarce credible, he takes it for granted they thought so, and therefore immediately, adds, "As strange as this is, I affirm it positively, without any intention to aggravate the crime." And so he goes on to the proof of his assertion. But this figure is likewise made use of to guard against some objection, which the speaker apprehends may be made against what he designs to say. And thus Cicero uses it in his oration for Sextius. "My province (says he), as I speak last, seems to call for affection to my friend, rather than his defence; complaint, rather than eloquence; expressions of grief, rather than art. And therefore, if I shall express myself with more warmth, or greater freedom, than those have who spoke before me, I hope you will grant me all that liberty of speech which you judge reasonable to be allowed to an affectionate sorrow and just resentment." This figure requires great prudence and discretion in the management of it. The speaker must consider well the temper, bias, and other circumstances of his hearers, in order to form a right judgment what parts of his discourse may be most liable to exception. For to object such things, which the hearers would never have thought of themselves, is to give himself a needless trouble; and to start such difficulties, which he cannot afterwards fairly remove, will expose both himself and his cause. But as nothing gives an audience greater pleasure and satisfaction, than to have their scruples fully answered as they rise in their thoughts; so, on the contrary, be a discourse otherwise ever so entertaining and agreeable, if there be any doubt left upon the minds of the hearers, it gives them a pain that continues with them till it be removed. Elocution.

The figure *hypobole* or *subjection*, is not much unlike the former; and is, when several things are mentioned that seem to make for the contrary side, and each of them refuted in order. It consists of three parts, when complete; a proposition, an enumeration of particulars with their answers, and a conclusion.—Thus Cicero, upon his return from banishment, vindicates his conduct in withdrawing so quietly, and not opposing the faction that ejected him. "My departure (says he) is objected to me; which charge I cannot answer without commending myself. For what must I say? That I fled from a consciousness of guilt? But what is charged upon me as a crime, was so far from being a fault, that it is the most glorious action since the memory of man, (he means his punishing the associates of Catiline). That I feared being called to an account by the people? That was never talked of; and if it had been done, I should have come off with double honour. That I wanted the support of good and honest men? That is false. That I was afraid of death? That is a calumny. I must therefore say, what I would not, unless compelled to it, that I withdrew to preserve the city." When the objections are put by way of question, as in the example here given, they add a briskness and poignancy to the figure. All the parts of it are not constantly expressed. For thus Cicero in his defence of Plancius introduces his adversary objecting, and himself answering, "The people judged ill, but they did judge; they should not have done it, but they had a power; I cannot submit to it, but many very great and wise men have."—Both the proposition and conclusion are here omitted. 81

The next figure in order is *anacoinosis*, or *communication*; by which the speaker deliberates either with the judges, the hearers, or the adversary himself. Thus Cicero addresses the judges in his accusation of Verres: "Now I desire your opinion what you think I ought to do. And I know your advice will be, though you do not declare it, what appears to me necessary to be done." In another place we find him reasoning in this manner with the adverse party: "What could you have done in such a case, and at such a time: when to have sat still, or withdrawn, would have been cowardice? When the wickedness and fury of Saturnius the tribune had called you into the capitol; and the consuls, to defend the safety and liberty of your country; whose authority, whose voice, which party would you have followed, and whose command would you have chosen to obey?" This figure carries in it an air of modesty and condescension, when the speaker seems unwilling to determine in his own cause, but refers it to the opinion of others. It likewise shows a persuasion of the equity of his cause, that he can leave it to their arbitration; and serves very much to conciliate their minds, while he joins them, as it were with himself, and makes them of his party. And when the appeal is made to the adverse party, it is of considerable advantage, either to extort a confession, or at least to silence him. And therefore the sacred writers sometimes very beautifully introduce God himself thus expostulating with mankind; as the prophet Malachi, 82

Malachi, *A son honoureth his father, and a servant his master. If then I be a father, where is mine honour? and if I be a master, where is my fear?*

83 Another figure that comes under this head, is *epitrope* or *concession;* which grants one thing, to obtain another more advantageous. It is either real or feigned; and either the whole of a thing, or a part only, is granted. We shall consider each of these separately, and illustrate them with proper examples. Nothing more confounds an adversary, than to grant him his whole argument; and at the same time either to show that it is nothing to the purpose, or to offer something else which may invalidate it. *I allow*, says the claimant by will against the heir at law, *that no body was more nearly related to the deceased than you; that he was under some obligations to you; that you were in the army together: but what is all this to the will?* And thus Cicero in his defence of Ligarius, who was accused by Tubero for having joined with Pompey in the civil war between him and Cæsar: "You have, Tubero, what an accuser would most desire, the accused person confessing the charge; but so as to affirm, that he was of the same party with you and your excellent father. Therefore own first that it was a crime in yourself, before you charge it as such upon Ligarius." Sometimes the orator gives up some particular point that would well admit of a dispute, to gain something more considerable, which he thinks cannot fairly be denied him. In the affair of Roscius, where the proof depended upon circumstances, Cicero, who defended him, inquires what reason could be alleged for his committing so black a crime, as to kill his father. And after he has shown there was no probable reason to be assigned for it, he adds, "Well, since you can offer no reason, although this might be sufficient for me, yet I will recede from my right; and upon the assurance I have of his innocence, I will grant you in this cause what I would not in another. I do not therefore insist upon your telling me why he killed his father, but ask how he did it?" This appearance of candour and ingenuity in such concessions removes the suspicion of art, and gives greater credit to what is denied. We have an example of a feigned or ironical concession in Cicero's defence of Flaccus: where, interceding for him on the account of his former good services in the time of Catiline's conspiracy, he says in a way of irony, If such things are to be overlooked, "let us appease the ghosts of Lentulus and Cethegus; let us recal those who are in exile; and let us be punished for our too great affection and love for our country." By this artful insinuation, the orator, after he has used all his arguments to persuade his hearers, does as it were set them at liberty, and leave them to their own election; it being the nature of man to adhere more steadfastly to what is not violently imposed, but referred to his own free and deliberative choice. And to these feigned concessions may be referred such ways of reasoning, by which the orator both justifies a charge brought against him upon the supposition of its being true, and also proves that the charge itself is false. Thus Cicero, in his defence of Milo, represents the taking of Clodius, with which Milo was accused, as a glorious action; after he has shown that Milo's servants did it without the knowledge of their master.

84 *Parabole* or *similitude*, illustrates a thing by comparing it with some other, to which it bears a resemblance. Similitudes are indeed generally but weak arguments, though often beautiful and fine ornaments. And where the design of them is not so much to prove what is doubtful, as to set things in a clear and agreeable light, they come properly under the notion of figures. They are of two sorts; simple and compound. Those are called *simple*, in which one thing only is likened or compared to another, in this manner: *As swallows appear in summer, but in winter retreat; so false friends show themselves in prosperity, but all fly away when adversity approaches.* Compound similitudes are such, wherein one thing is likened or compared to several others; as thus: *What light is to the world, physic to the sick, water to the thirsty, and rest to the weary; that is knowledge to the mind.* The more exact the agreement is between the things thus compared, they give the greater beauty and grace to the figure.

Antithesis, or *opposition*, by which things contrary or different are compared, to render them more evident. 85 Thus Cicero says, "The Roman people hate private luxury, but love public grandeur." This is a very florid figure; and suited no less for amplification than proof. As in the following instance of Cicero, where, speaking of Pompey, he says, "He waged more wars than others had read; conquered more provinces than others had governed; and had been trained up from his youth to the art of war, not by the precepts of others, but by his own commands; not by miscarriages in the field, but by victories; not by campaigns, but triumphs." It is esteemed a beauty in this figure when any of the members are inverted, which some call *antimetathesis*. As where Cicero, opposing the conduct of Verres when governor of Sicily, to that of Marcellus who took Syracuse the capital city of that island, says, "Compare this peace with that war, the arrival of this governor with the victory of that general, his profligate troops with the invincible army of the other, the luxury of the former with the temperance of the latter; you will say, that Syracuse was founded by him who took it, and taken by him who held it when founded." To this figure may also be referred *oxymoron*, or *seeming contradiction:* that is, when the parts of a sentence disagree in sound, but are consistent in sense. As when Ovid says of Althea, that *she was impiously pious*. And so Cato used to say of Scipio Africanus, that "he was never less at leisure, than when he was at leisure; nor less alone, than when alone." By which he meant, as Cicero tells us, that "Scipio was wont to think of business in his retirement, and in his solitude to converse with himself." This is a strong and bold figure, which awakens the mind, and affords it an agreeable pleasure to find upon reflection, that what at first seemed contradictory, is not only consistent with good sense, but very beautiful.—The celebrated Dr Blair, whom we have more than once quoted in this article, has these observations on antithesis, or the contrast of two objects. "Contrast has always this effect, to make each of the contrasted objects appear in the strongest light. White, for instance, never appears so bright as when it is opposed to black, and when both are viewed together. Antithesis, therefore, may, on many occasions be employed to advantage, in order to strengthen the impression which we intend that any object should make. In order to render an antithesis more complete, it is always

Elocution. always of advantage that the words and members of the sentence, expressing the contrasted objects, be similarly constructed, and made to correspond to each other. This leads us to remark the contrast more, by setting the things which we oppose more clearly over against each other: in the same manner as when we contrast a black and a white object, in order to perceive the full difference of their colour, we would choose to have both objects of the same bulk, and placed in the same light. Their resemblance to each other, in certain circumstances, makes their disagreement in others more palpable. At the same time I must observe, that the frequent use of antithesis, especially where the opposition in the words is nice and quaint, is apt to render the style disagreeable. A maxim, or moral saying, properly enough receives this form; both because it is supposed to be the fruit of meditation, and because it is designed to be engraved on the memory, which recals it more easily by the help of such contrasted expressions. But where a string of such sentences succeed each other, where this becomes an author's favourite and prevailing manner of expressing himself, his style is faulty; and it is upon this account Seneca has been often and justly censured. Such a style appears too studied and laboured; it gives us the impression of an author attending more to his manner of saying things, than to the things themselves which he says." There is still another kind of antithesis, which consists in surprising us by the unexpected contrasts of things which it brings together; but it is such as is wholly beneath the dignity of an orator, or of grave compositions of any sort, and is fit only for pieces of professed wit and humour, calculated only to excite laughter or create ridicule.

86 The second kind of figures of sentences.

II. *Those suited to move the passions.* Which are 13; namely, *epanorthosis*, *paralepsis*, *parrhesia*, *aparithmesis*, *exergasia*, *hypotyposis*, *aporia*, *posiopesis*, *erotesis*, *ecphonesis*, *epiphonema*, *apostrophe*, and *prosopopeia*.

Epanorthosis, or *correction*, is a figure, by which the speaker either recals or amends what he had last said. It is used different ways. For sometimes one or more words are recalled by him, and others subjoined in their room; at other times, without recalling what has been said, somethingelse is substituted as more suitable. This is a very extensive figure, and made use of in addressing different passions. We have an instance of it in Terence's *Self-tormentor*, where the old man, whose extraordinary concern for the absence of his son gave occasion to the name of the play, thus bewails his condition to his neighbour. "I have an only son, Chremes. Alas! did I say that I have: I had indeed; but it is now uncertain whether I have or not." Here, to aggravate his misfortune, he recals a pleasing word, and substitutes another more affecting in its place. And Cicero, in his defence of Milo, speaking to the judges concerning Clodius, says, "Are you only ignorant what laws, if they may be called laws, and not rather torches and plagues of the state, he was about to impose and force upon us?" Again, in his defence of Plancius, he says, "What greater blow could those judges, if they are to be called judges, and not parricides of their country, have given to the state, than when they banished him, who when prætor freed the republic from a neighbouring war, and when consul from a civil one?" He is speaking there of Opimius. But in commending the moderation of Lucius Mummius, who did not enrich himself, but his country, by demolishing the wealthy city of Corinth, he thus recals his whole expression, and by giving it a new turn, heightens the compliment he designed him: "He chose rather (says he) to adorn Italy than his own house; though by adorning Italy his house seems to have received the greatest ornament." And sometimes the correction is made by substituting something contrary to what has been said before; as in the following passage of Cicero: "Cæsar (meaning Augustus), though but a youth, by an incredible and surprising resolution and courage, when Antony was most enraged, and we dreaded his cruel and pernicious return from Brundusium, at a time when we neither asked, nor expected, nor desired it (because it was thought impossible), raised a very powerful army of invincible veterans; to effect which he threw away his whole estate: Though I have used an improper word; for he did not throw it away, but employed it for the safety of the government." At other times, as has been said, the correction is made by adding a more suitable word, without any repetition of the former. Thus Cicero, after he has inveighed against the crimes of Verres, breaks out into this pathetic exclamation: *O the clemency, or rather wonderful and singular patience, of the Roman people!* He did not think the word *clemency* strong enough, and therefore adds *patience*, as better answering his design. The sudden and unexpected turn of this figure gives a surprise to the mind, and by that means renders it the more pathetic.

Paralepsis, or *omission*, is another of these figures, 87
when the speaker pretends to omit, or pass by, what at the same time he declares. It is used either in praise or dispraise. Thus Cicero, in his defence of Sextius, introduces his character in this manner, with a design to recommend him to the favour of the court: "I might say many things of his liberality, kindness to his domestics, his command in the army, and moderation during his office in the province: but the honour of the state presents itself to my view; and calling me to it, advises me to omit these lesser matters." But in his oration to the senate against Rullus the tribune, who had proposed a law to sell the public lands, he makes use of this figure to represent the pernicious effects of such a law, particularly with respect to the lands in Italy. "I do not complain (says he) of the diminution of our revenues, and the woeful effects of this loss and damage. I omit what may give every one occasion for a very grievous and just complaint, that we could not preserve the principal estate of the public, the finest possession of the Roman people, the fund of our provisions, the granary of our wants, a revenue entrusted with the state; but that we must give up those lands to Rullus, which, after the power of Sylla, and the largesses of the Gracchi, are yet left us. I do not say, this is now the only revenue of the state, which continues when others cease, is an ornament in peace, fails us not in war, supports the army, and does not fear an enemy. I pass over all these things, and reserve them for my discourse to the people, and only speak at present of the danger of our peace and liberties." His view here was to raise the indignation of the senate against Rullus, and excite them to oppose the law. There is a beautiful instance of this figure in St Paul's epistle to Philemon, where, after he has earnestly intreated him to receive again Onesimus his servant, who had run from him, and promised that if he

he had wronged him, or owed him any thing, he would repay it, he adds, *That I may not say, you owe even yourself to me.* Nothing could be a stronger motive to soften his displeasure against his servant, from a sense of gratitude to the apostle. Hermogenes has observed, that the design of this figure is to possess the minds of the audience with more than the words express, and that it is principally made use of on three occasions: either when things are small, but yet necessary to be mentioned; or well known, and need not to be enlarged on; or ungrateful, and therefore should be introduced with caution, and not set in too strong a light.

88 The next figure above-mentioned was *Parrhesia*, or *reprehension:* Not that whenever a person admonishes or reproves another it is to be esteemed a figure; but when it is done with art and address, and in such circumstances as render it difficult not to displease.—The orator therefore sometimes prepares his hearers for this by commending them first, urging the necessity of it, representing his great concern for them as his motive, or joining himself with them. Thus Cicero charges the senate with the death of Servius Sulpicius, for sending him to Mark Antony, under a very ill state of health. And his design in it was to bring them more readily into a motion he was about to make, that both a statue and a sepulchral monument might be erected to his memory at the public expence. "You (says he), it is a very severe expression, but I cannot help saying it; you, I say, have deprived Servius Sulpicius of his life. It was not from cruelty indeed (for what is there with which this assembly is less chargeable?), but when his distemper pleaded his excuse more than his words, from the hopes you conceived that there was nothing which his authority and wisdom might not be able to effect, you vehemently opposed his excuse, and obliged him, who always had the greatest regard for your commands, to recede from his resolution." Sometimes, indeed, the orator assumes an air of reproof, with a view only to pass a compliment with a better grace. As Cicero in his address to Cæsar, when he says, "I hear that excellent and wise saying from you with concern, That you have lived long enough, either for the purposes of nature, or glory: for nature, perhaps, if you think so: and, if you please, for glory: but, what is principally to be regarded, not for your country." It adds both a beauty and force to this figure, when it is expressed in a way of comparison. As in the following instance of Cicero: "But since my discourse leads me to this, consider how you ought to be affected for the dignity and glory of your empire. Your ancestors often engaged in war to redress the injuries of their merchants or sailors: how ought you then to resent it, that so many thousand Roman citizens were murdered by one message, and at one time? Your forefathers destroyed Corinth, the principal city in Greece, for the haughty treatment of their ambassadors; and will you suffer that king to go unpunished, who has put to death a Roman legate, of consular dignity, in the most ignominious as well as most cruel manner? See, lest, as it was their honour to leave you the glory of so great an empire, it should prove your disgrace not to be able to maintain and defend what you have received from them." By this figure an address is made to the more tender passions, modesty, shame, and emulation, the attendants of an ingenuous temper, which is soonest touched, and most affected, by a just reproof.

Another of these pathetic figures is *Aparithmesis*, or *enumeration*, when that, which might be expressed in general by a few words, is branched out into several 89
particulars, to enlarge the idea, and render it the more affecting. Cicero, in pleading for the Manilian law, where his design is to conciliate the love and esteem of the people to Pompey, thus enlarges upon his character: "Now, what language can equal the virtue of Cneius Pompey? What can be said either worthy of him, or new to you, or which every one has not heard? For those are not the only virtues of a general which are commonly thought so; labour in affairs, courage in dangers, industry in acting, despatch in performing, design in contriving; which are greater in him than in all other generals we have ever seen or heard of." And so likewise, when he endeavours to dispossess Pompey of the apprehension that Milo designed to assassinate him: "If (says he) you fear Milo; if you imagine that either formerly, or at present, any ill design has been formed by him against your life; if the soldiers raised through Italy (as some of your officers give out), if these arms, if these cohorts in the Capitol, if the centries, if the watch, if the guards which defend your person and house, are armed to prevent any attempt of Milo, and all of them appointed, prepared, and stationed on his account; he must be thought a person of great power, and incredible resolution, above the reach and capacity of a single man, that the most consummate general, and the whole republic, are in arms against him only. But who does not perceive, that all the disordered and sinking parts of the state are committed to you, to rectify and support them by these forces?" This might have been said in a few words, that such vast preparations could never be intended for so low a purpose. But the orator's view was to expose that groundless report, and shame it out of countenance. And soon after he endeavours to raise compassion for Milo under those prejudices by the same figure: "See how various and changeable is the state of human life, how unsteady and voluble is fortune, what infidelity in friends, what disguises suited to the times, what flights, what fears, even of the nearest acquaintance, at the approach of dangers." Had no address to the passions been designed here, fewer of these reflections might have been sufficient. The use of this figure in amplification is very evident from the nature of it, which consists in unfolding of things, and by that means enlarging the conception of them.

Exergasia, or *exposition*, has an affinity with the former figure: but it differs from it in this, that it consists 90
of several equivalent expressions or nearly such, in order to represent the same thing in a stronger manner; whereas the other enlarges the idea by an enumeration of different particulars. So that this figure has a near relation to synonymia, of which we have treated before under *Verbal Figures.* We have an instance of it in Cicero's defence of Sextius, where he says, "Those who at any time have excited the populace to sedition, or blinded the minds of the ignorant by corruption, or traduced brave and excellent men, and such as deserved well of the public, have with us always been esteemed vain, bold, bad, and pernicious citizens. But those who repressed the attempts and endeavours of such, or by their authority, integrity, constancy, resolution, and prudence, withstood their insolence, have been always accounted men of solidity, the chiefs, the leaders, and supporters

supporters of our dignity and government." Nothing more is intended by this passage, but to set the opposite characters of factious persons and true patriots in the strongest light, with a view to recommend the one, and create a just hatred and detestation of the other. So elsewhere he represents the justice of self-defence in no less different terms: "If reason (says he) prescribes this to the learned, and necessity to barbarians, custom to nations, and nature itself to brutes, always to ward off all manner of violence, by all possible ways; from their body, from their head, from their life; you cannot judge this to be a criminal and wicked action, without judging at the same time that all persons who fall among robbers and assassins must either perish by their weapons, or your sentence."—He is addressing here to the judges in favour of Milo. The warmth and vehemence of the speaker often runs him into this figure, when he is affected with his subject, and thinks no words, no expressions, forcible enough to convey his sentiments; and therefore repeats one after another, as his fancy suggests them. This flow of expression, under the conduct of a good judgment, is often attended with advantage; as it warms the hearers, and impresses their minds, excites their passions, and helps them to see things in a stronger light.

91 *Hypotyposis*, or *imagery*, is a description of things painted in such strong and bright colours, as may help the imagination of the hearers to conceive of them rather as present to their view, than described in words. It is peculiarly suited for drawing characters; and often affords the finest ornaments in poetry and history, as well as oratory. Nor is it less moving, but suited to strike different passions, according to the nature of the subject, and artful management of the speaker. Cicero has thus drawn the picture of Catiline, consisting of an unaccountable mixture of contrary qualities. "He had (says he) the appearance of the greatest virtues: he made use of many ill men to carry on his designs, and pretended to be in the interest of the best men; he had a very engaging behaviour, and did not want industry and application; he gave into the greatest looseness, but was a good soldier. Nor do I believe there was ever the like monster in the world, made of such jarring and repugnant qualities and inclinations. Who at one time was more acceptable to the best men, and who more intimate with the worst? Who was once a better patriot, and who a greater enemy to this state? Who more devoted to pleasures, who more patient in labours? Who more rapacious, and yet more profuse? He suited himself to the humours of all he conversed with: was serious with the reserved, and pleasant with the jocose; grave with the aged, and facetious with the young; bold with the daring, and extravagant with the profligate." Such a character of a man, when accompanied with power and interest, must render him no less the object of fear than detestation, which was the design of Cicero in this description. And elsewhere, in order to prevail with the senate to direct the execution of those conspirators with Catiline who were then in prison, he paints the most dismal scene of that horrid design in the strongest colours. "Methinks (says he) I see this city, the light of the world, and citadel of all nations, suddenly falling into one fire; I perceive heaps of miserable citizens buried in their ruined country; the countenance and fury of Cethegus raging in your slaughter, presents itself to my view." This figure is very serviceable to amplification, as we have formerly shewn in treating upon that subject. But no small judgment is required in the management of descriptions. Lesser circumstances should either be wholly omitted, or but slightly touched; and those which are more material drawn in their due proportion. Nature is as much the rule of the orator as of the painter, and what they both propose to imitate. And therefore, let a thought be ever so pleasing and beautiful in itself, it must not be introduced when foreign to the purpose, or out of its place, any more than a painter should attempt to alter nature when he proposes to copy it. This figure requires likewise a vigorous and lively genius. For the images in description can rise no higher than the conception of the speaker, since the idea must first be formed in his own mind before he can convey it to others; and agreeably to the clearness with which he conceives it himself, he will be able to express it in words.

Aporia, or *doubt*, expresses the debate of the mind with itself upon a pressing difficulty. A person in such a state is apt to hesitate, or start several things successively, without coming to any fixed resolution. The uneasiness arising from such a disorder of thought is naturally very moving. Of this kind is that of Cicero for Cluentius, when he says, "I know not which way to turn myself. Shall I deny the scandal thrown upon him of bribing the judges? Can I say the people were not told of it? that it was not talked of in the court, mentioned in the senate? Can I remove an opinion so deeply and long rooted in the minds of men? It is not in my power. You, judges, must support his innocence, and rescue him from this calumny." Orators sometimes choose to begin their discourse with this figure. A diffidence of mind at first is not unbecoming, but graceful. It carries in it an air of modesty, and tends very much to conciliate the affections of the hearers. Livy gives us a very elegant example of this in a speech of Scipio Africanus to his soldiers, when, calling them together after a sedition, he thus bespeaks them: "I never thought I should have been at a loss in what manner to address my army. Not that I have applied myself more to words than things; but because I have been accustomed to the genius of soldiers, having been trained up in the camp almost from my childhood. But I am in doubt what or how to speak to you, not knowing what name to give you. Shall I call you *citizens*, who have revolted from your country? *Soldiers*, who have disowned the authority of your general, and broke your military oath? *Enemies*? I perceive the mien, the aspect, and habit of citizens; but discern the actions, words, designs, and dispositions of enimies." 92

Sometimes a passion has that effect, not so much to render a person doubtful what to say, as to stop him in the midst of a sentence, and prevent his expressing the whole of what he designed; and then it is called *Aposiopesis*, or *concealment*. It denotes different passions; as anger, which, by reason of its heat and vehemence, causes persons to break off abruptly in their discourse. So the old man in Terence, when he was jealous that his servant obstructed his designs, uses this imperfect but threatening expression, *Whom, if I find*. And Neptune, when described by Virgil as very angry that the winds should presume to disturb the sea without his permission, after he has called them to him to know the reason of it, threatens them in this abrupt manner: 93

"Whom I—but first I'll lay the storm."

But Cicero, in writing to Atticus, applies it to express grief, where he says, "I know nothing of Pompey, and believe he must be taken, if he is not got on shipboard. O incredible swiftness! But of our friend—Though I cannot accuse him without grief, for whom I am in so much concern and trouble." And in a letter to Cassius he uses it to express fear, when he says to him, "Brutus could scarce support himself at Mutina; if he is safe, we have carried the day. But if—heaven avert the omen! all must have recourse to you." His meaning is, "If Brutus should be defeated."

94 The next figure is *erotesis* or *interrogation*. But every interrogation or question is not figurative. When we inquire about a thing that is doubtful, in order to be informed, this is no figure, but the natural form of such expressions. As if I ask a person, *Where he is going?* or *what he is doing?* But then it becomes figurative when the same thing may be expressed in a direct manner; but the putting it by way of question gives it a much greater life and spirit. As when Cicero says, "Catiline, how long will you abuse our patience? do not you perceive your designs are discovered!" He might indeed have said, *You abuse our patience a long while. You must be sensible your designs are discovered.* But it is easy to perceive how much this latter way of expression falls short of the force and vehemence of the former. And so when Medea says, *I could save; and do you ask if I can destroy?* Had she said, *I could save, and I can destroy*, the sentence had been flat, and very unfit to express the rage and fury in which the poet there represents her. This figure is suited to express most passions and emotions of the mind, as anger, disdain, fear, desire, and others. It serves also to press and bear down an adversary. Cicero frequently makes this use of it. As in his defence of Plancius: "I will make you this offer (says he), choose any tribe you please, and show, as you ought, by whom it was bribed; and if you cannot, as I believe you will not undertake it, I will prove how he gained it. Is this a fair contest? Will you engage on this foot? I cannot give you fairer play. Why do you dissemble? Why do you hesitate? I insist upon it, urge you to it, press it, require, and even demand it of you." Such a way of pushing an antagonist shows the speaker has great confidence in his cause; otherwise he would never lay himself so open, if he was not assured the other party had nothing to reply. This figure likewise diversifies a discourse, and gives it a beautiful variety, by altering the form of expression, provided it be neither too frequent, nor continued too long at once. And besides, the warmth and eager manner in which it is expressed, enlivens the hearers, and quickens their attention.

95 *Ecphonesis*, or *exclamation*, is a vehement extension of the voice, occasioned by a commotion of mind, naturally venting itself by this figure, which is used by Cicero to express a variety of passions. It often denotes resentment or indignation. Thus, after his return from banishment, reflecting on those who had occasioned it, he breaks out into this moving exclamation: "O mournful day to the senate, and all good men, calamitous to the state, afflictive to me and my family, but glorious in the view of posterity!" His design was to excite an odium against the authors of his exile, when recalled in so honourable a manner. And again, in his defence of Cælius: "O the great force of truth: which easily supports itself against the wit, craft, subtility, and artful designs of men!" He had been just showing the absurdity of the charge against Cælius, and now endeavours to expose his accusers to the indignation of the court. At other times it is used to express disdain or contempt. As when speaking of Pompey's house, which was bought by Mark Antony, he says: "O consummate impudence! dare you go within that house! dare you enter that venerable threshold, and show your audacious countenance to the tutelar deities which reside there!" Nor is it less suited to indicate grief, as when he says of Milo: "O that happy country, which shall receive this man! ungrateful this, if it banish him! miserable if it lose him!" And sometimes it serves to express admiration: as when, in compliment to Cæsar, he says, "O admirable clemency! worthy of the greatest praise, the highest encomiums, and most lasting monuments!" It has its use also in ridicule and irony. As in his oration for Balbus, where he derides his accuser, by saying, "O excellent interpreter of the law! master of antiquity! corrector and amender of our constitution!" The sacred writers sometimes use it by way of intreaty or wish. As the royal psalmist: "O that I had the wings of a dove, that I might fly away, and be at rest!" And at other times in triumph and exultation, as in that of St Paul: "O death, where is thy sting! O grave, where is thy victory!" It is frequently joined with the preceding figure *interrogation*; as appears in some of the instances here brought from Cicero. And it generally follows the representation of the thing which occasions it. Though sometimes it is made use of to introduce it, and then it serves to prepare the mind by exciting its attention. Thus Cicero, in his defence of Cælius, to render the character of Clodia more odious, at whose instigation he was accused, insinuates that she had before poisoned her husband; and to heighten the barbarity of the fact, and make it appear the more shocking, he introduces the account of it with this moving exclamation: "O heavens, why do you sometimes wink at the greatest crimes of mankind, or delay the punishment of them to futurity!"

Epiphonema, or *acclamation*, has a great affinity with 96
the former figure. And it is so called, when the speaker, at the conclusion of his argument, makes some lively and just remark upon what he has been saying, to give it the greater force, and render it the more affecting to his hearers. It is not so vehement and impetuous as exclamation, being usually expressive of the milder and more gentle passions. And the reflection ought not only to contain some plain and obvious truth, but likewise to arise naturally from the discourse which occasioned it, otherwise it loses its end. When Cicero has shown, that recourse is never to be had to force and violence, but in cases of the utmost necessity, he concludes with the following remark: "Thus to think, is prudence; to act, fortitude; both to think and act, perfect and consummate virtue." And elsewhere, after he has described a singular instance of cruelty and breach of friendship: "Hence (says he) we may learn, that no duties are so sacred and solemn which covetousness will not violate." This figure is frequently expressed in a way of admiration. As when Cicero has observed, that all men are desirous to live to an advanced age, but uneasy under it when

when attained, he makes this just reflection upon such a conduct: "So great is their inconstancy, folly, and perverseness!"

97 The next figure in order is *apostrophe*, or *address*, when the speaker breaks off from the series of his discourse, and adresses himself to some particular person present or absent, living or dead; or to inanimate nature, as endowed with sense and reason. By this means he has an opportunity of saying many things with greater freedom than perhaps would be consistent with decency if immediately directed to the persons themselves. He can admonish, chide, or censure, without giving offence. Nor is there any passion, but may be very advantageously expressed by this figure. When an orator has been speaking of any particular person, on a sudden to turn upon him, and apply the discourse to that person himself, is very moving; it is like attacking an adversary by surprise, when he is off his guard, and where he least expects it. Thus Cicero: "I desire, senators, to be merciful, but not to appear negligent in so great dangers of the state; though at present I cannot but condemn myself of remissness. There is a camp formed in Italy, at the entrance of Etruria, against the state; our enemies increase daily; but we see the commander of the camp, and general of the enemies, within our walls, in the very senate, contriving some intestine ruin to the state. If now, Catiline, I should order you to be seized and put to death, I have reason to fear, that all good men would rather think I had deferred it too long, than charge me with cruelty. But I am prevailed with for a certain reason not to do that yet, which ought to have been done long since." This sudden turn of the discourse to Catiline himself, and the address to him in that unexpected manner, must have touched him very sensibly. So, in his defence of Milo, expressing his concern if he should not succeed in it, he says, "And how shall I answer it to you, my brother Quintus, the partner of my misfortunes, who are now absent?" And elsewhere addressing to the soldiers of the Martian legion, who had been killed in an engagement with Mark Antony, he thus bespeaks them: "O happy death, which, due to nature, was paid to your country! I may esteem you truly born for your country, who likewise received your name from Mars; so that the same deity seems to have produced this city for the world, and you for this city." And in his oration for Balbus, he thus calls upon dumb nature to witness to Pompey's virtues: "I invoke you, mute regions; you, most distant countries; you seas, havens, islands, and shores. For what coast, what land, what place is there, in which the marks of his courage, humanity, wisdom, and prudence, are not extant? An appeal to heaven, or any part of inanimate nature, has something very sublime and solemn in it, which we often meet with in sacred writ. So the divine prophet: "Hear, O heavens! and give ear, O earth! for the Lord hath spoken." And in like manner, the prophet Jeremiah: "Be astonished, O ye heavens, at this." See APOSTROPHE.

98 *Prosopopeia*, or *the fiction of a person*: by which either an absent person is introduced speaking; or one who is dead, as if he was alive and present; or speech is attributed to some inanimate being. There is no figure, perhaps, which serves more or better purposes to an orator than this. For by this means he is enabled to call in all nature to his assistance, and can assign to every thing such parts as he thinks convenient. There is scarce any thing fit to be said, but may be introduced this way. When he thinks his own character is not of sufficient weight to affect his audience in the manner he desires, he substitutes a person of greater authority than himself to engage their attention. When he has severe things to say, and which may give offence as coming from himself; he avoids this, by putting them into the mouth of some other person from whom they will be better taken; or makes inanimate nature bring a charge, or express a resentment, to render it the more affecting. And by the same method he sometimes chooses to secure himself from a suspicion of flattery, in carrying a compliment too high. We meet with several very beautiful instances of this figure in Cicero; but an example of each sort may here suffice, beginning with that of an absent person, from his defence of Milo, whom he thus introduces as speaking to the citizens of Rome: "Should he, holding the bloody sword, cry out, Attend, I pray, hearken, O citizens, I have killed Publius Clodius; by this sword, and by this right hand, I have kept off his rage from your necks, which no laws, no courts of judicature, could restrain; it is by my means, that justice, equity, laws, liberty, shame, and modesty, remain in the city. Is it to be feared how the city would bear this action? Is there any one now, who would not approve and commend it?" And in his oration for Balbus, he introduces Marius, who was then dead, to plead in his defence: Can Balbus (says he) be condemned, without condemning Marius for a like fact? Let him be present a little to your thoughts, since he cannot be so in person; that you may view him in your minds, though you cannot with your eyes. Let him tell you, he was not unacquainted with leagues, void of examples, or ignorant of war." And again, in his first invective against Catiline, he presents his country as thus expostulating with himself, and upbraiding him for suffering such a criminal as Catiline to live. "Should my country (says he), which is much dearer to me than my life, should all Italy, all the state, thus address me, Mark Tully what do you do? Do you suffer him, whom you have found to be an enemy, who you see is to be at the head of the war, whom you perceive your enemies wait for in their camp as their general, who has been the contriver of this wickedness, the chief of the conspiracy, the exciter of slaves and profligate citizens, to leave the city, which is rather to bring him in, than let him out? Will not you order him to be imprisoned, condemned, and executed? What prevents you? The custom of our ancestors. But private persons have often punished pernicious citizens in this state. The laws relating to the punishment of Roman citizens? But traitors never had the rights of citizens. Do you fear the censure of posterity? Truly you make a very handsome return to the people of Rome, who have advanced you from an obscure condition so early to the highest dignity; if you neglect their safety to avoid envy, or from the apprehension of any danger. And if you fear censure; which is most to be dreaded, that which may arise from justice and fortitude, or from cowardice and treachery? When Italy shall be wasted by a war, cities plundered, and houses burnt, do you think then to escape the severest censure?" In the management of this figure, care should be

Elocution. be taken that what is said be always consistent with the character introduced, in which both the force and beauty of it consist.

In treating upon figures, we have hitherto considered them separately; but it may not be amiss to observe, that some expressions consist of a complication of them, and may come under the denomination of several figures, as well verbal as those of sentences, differently considered. Thus when Cicero says, "What, Tubero, did your drawn sword do in the Pharsalian battle? At whose side was its point directed? what was the intention of your arms?" As he speaks to Tubero, it is an apostrophe; as the expressions have much the same import, and are designed to heighten and aggravate the fact, it is *exergasia;* and as they are put by question, it is *interrogation.* So likewise, in his second Philippic, where he says, "What can I think? that I am contemned? I see nothing in my life, interest, actions, or abilities, as moderate as they are, which Antony can despise. Did he think he could easily lessen me in the senate? But they, who have commended many famous citizens for their good government of the state, never thanked any but me for preserving it. Would he contend with me for eloquence? This would be a favour indeed. For what could be a larger and more copious subject, than for me to speak for myself against Antony? His design was really this: he thought he could not convince his associates, that he was truly an enemy to his country, unless he was so first to me." There are three figures in this passage; *doubt*, *interrogation*, and *subjection.* And again, when he introduces Sicily thus addressing Verres in a way of complaint: "Whatever gold, whatever silver, whatever ornaments in my cities, dwellings, temples, whatever right of any kind I possessed by the favour of the senate and people of Rome; you, Verres, have plundered and taken from me." Here is a *prosopopeia*, joined with the verbal figure *anaphora*, as several members of the sentence begin with the same word. The like instances of complex figures frequently occur, and therefore we need not multiply examples of them here.

PARTICULAR ELOCUTION,

Or that part of Elocution which considers the several Properties and Ornaments of Language, as they are made use of to form different sorts of Style.

Chap. IV. *Of Style, and its different Characters.*

99 Particular elocution treats of style and its various characters.

The word *style* properly signifies the instrument which the ancients used in writing. For as they commonly wrote upon thine boards covered over with wax, and sometimes upon the barks of trees, they made use of a long instrument like a bodkin, pointed at one end, with which they cut their letters; and broad at the other, to erase any thing they chose to alter. And this the Latins called *stylus.* But though this be the first sense of the word, yet afterwards it came to denote the manner of expression. In which sense we likewise use it, by the same kind of trope that we call any one's writing his *hand.* Style, then, in the common acceptation of the word at present, is the peculiar manner in which a man expresses his conceptions by means of language. It is a picture of the ideas which rise in his mind, and of the order in which they are there produced. As to the reasons which occasion a variety of style, they are principally these.

Since both speech and writing are only sensible expressions of our thoughts, by which we communicate them to others; as all men think more or less differently, so consequently they in some measure differ in their style. No two persons who were to write upon one subject, would make use of all the same words. And were this possible, yet they would as certainly differ in their order and connection, as two painters, who used the same colours in painting the same picture, would necessarily vary their mixtures and disposition of them, in the several gradations of lights and shades. As every painter therefore has something peculiar in his manner, so has every writer in his style. It is from these internal characters, in a good measure, that critics undertake to discover the true authors of anonymous writings, and to show that others are spurious, and not the genuine productions of those whose names they bear; as they judge of the age of such writings from the words and manner of expression which have been in use at different times. And we may often observe in persons a fondness for some particular words or phrases, and a peculiarity in the turn or connection of their sentences, or in their transitions from one thing to another; by which their style may be known, even when they design to conceal it. For these things, through custom and habit, will sometimes drop from them, notwithstanding the greatest caution to prevent it.

There is likewise very often a considerable difference in the style of the same person, in several parts of his life. Young persons, whose invention is quick and lively, commonly run into a pompous and luxuriant style. Their fancy represents the images of things to their mind in a gay and sprightly manner, clothed with a variety of circumstances; and while they endeavour to set off each of these in the brightest and most glittering colours, this renders their style verbose and florid, but weakens the force and strength of it. And therefore, as their imagination gradually cools, and comes under the conduct of a more mature judgment, they find it proper to cut off many superfluities; so that by omitting unnecessary words and circumstances, and by a closer connection of things placed in a stronger light, if their style becomes less swelling and pompous, it is, however, more correct and nervous. But as old age sinks the powers of the mind, chills the imagination, and weakens the judgment; the style, too, in proportion usually grows dry and languid. Critics have observed something of this difference in the writings even of Cicero himself. To be master of a good style, therefore, it seems necessary that a person should be endowed with a vigorous mind and lively fancy, a strong memory, and a good judgment. It is by the imagination that the mind conceives the images of things. If the impressions of those images be clear and distinct, the style will be so too; since language is nothing but a copy of those images first conceived by the mind. But if the images are faint and imperfect, the style will accordingly be flat and languid. This is evident from the difference between such objects as are represented to our sight, and things of which we have only read or heard. For as the former generally make a deeper impression upon our minds, so we can describe them in a more strong and lively

lively manner. And we commonly find, that according as persons are affected themselves when they speak, they are able to affect others with what they say. Now persons are more or less affected with things in proportion to the impressions which the images of those things make upon the mind. For the same reason also, if the imagination be dull, and indisposed to receive the ideas of things, the style will be stiff and heavy; or if the images are irregular and disordered, the style will likewise be perplexed and confused. When things lie straight (as we say) in the mind, we express them with ease, and in their just connection and dependence; but when they are warpt or crooked, we deliver them with pain and difficulty, as well as disorder. A good fancy should likewise be accompanied with a happy memory. This helps us to retain the names of those things the ideas whereof are presented to the mind by the imagination, together with proper and suitable phrases to express them in their several connections and relations to each other. When the images of things offer themselves to the mind, unless the names of them present themselves at the same time, we are at a loss to express them, or at least are in danger of doing it by wrong and improper terms. Besides, variety is necessary in discourse to render it agreeable; and, therefore, without a large furniture of words and phrases, the style will necessarily become insipid and jejune, by the frequent return of the same terms and manner of expression. But to both these a solid judgment is highly requisite to form a just and accurate style. A fruitful imagination will furnish the mind with plenty of ideas, and a good memory will help to clothe them in proper language; but unless they are both under the conduct of reason, they are apt to hurry persons into many inconveniences. Such are generally great talkers, but far from good orators. Fresh images continually crowd in upon them, faster than the tongue can well express them. This runs them into long and tedious discourses, abounding with words, but void of sense. Many impertinences, if not improprieties, necessarily mix themselves with what they say; and they are frequently carried off from their point, by not having their fancies under a proper regulation. So that such discourses, though composed perhaps of pretty expressions, rhetorical flowers, and sprightly sallies of wit, yet fall very much short of a strong and manly eloquence. But where reason presides and holds the reins, every thing is weighed before it is spoken. The properest words are made choice of, which best suit the ideas they are designed to convey; rather than the most gay and pompous. All things are not said which offer themselves to the mind, and fancy dictates; but such only as are fit and proper, and the rest are dropped. Some things are but slightly mentioned, and others discoursed on more largely and fully, according to their different importance. And every thing is placed in that order, and clothed in such a dress, as may represent it to the greatest advantage. So that, in a word, the foundation of a good style is chiefly good sense. Where these qualities all meet in a considerable degree, such persons have the happiness to excel, either in speaking or writing. But this is not generally the case. Many persons of a vigorous and sprightly imagination, have but a weak judgement; and others much more judicious can think but slowly. And it is this, in a great measure, which makes the difference between speaking and writing well, as one or the other of these qualities is predominant. A person of a lively fancy, ready wit, and voluble tongue, will deliver himself off hand much better and more acceptably, than one who is capable, upon due premeditation, to discern farther into the subject, but cannot command his thoughts with the same ease and freedom. And this latter would have the same advantage of the other, were they both coolly to offer their sentiments in writing. Many things appear well in speaking, which will not bear a strict scrutiny. While the hearer's attention is obliged to keep pace with the speaker, he is not at leisure to observe every impropriety or incoherence, but many slips easily escape him, which in reading are presently discovered. Hence it is often found, that discourses, which were thought very fine when heard, appear to have much less beauty, as well as strength, when they come to be read. And therefore it is not without reason, that Cicero recommends to all those who are candidates for eloquence, and desirous to become masters of a good style, to write much. This affords them an opportunity to digest their thoughts, weigh their words and expressions, and give every thing its proper force and evidence; as likewise, by reviewing a discourse when composed, to correct its errors, or supply its defects; till by practice they gain a readiness both to think justly, and to speak with propriety and eloquence. But it is time to proceed to some other causes of the diversity of style.

Different countries have not only a different language, but likewise a peculiarity of style suited to their temper and genius. The eastern nations had a lofty and majestic way of speaking. Their words are full and sonorous, their expressions strong and forcible, and warmed with the most lively and moving figures. This is very evident from the Jewish writings in the Old Testament, in which we find a most agreeable mixture of simplicity and dignity. On the contrary, the style of the more northern languages generally partakes of the chillness of their climate. "There is (says Mr Addison *) a certain coldness and indifference in the phrases of our European languages, when they are compared with the oriental forms of speech. And it happens very luckily, that the Hebrew idioms run into the English tongue with a peculiar grace and beauty. Our language has received innumerable elegancies and improvements from that infusion of Hebraisms, which are derived to it out of the poetical passages in holy writ. They give a force and energy to our expressions, warm and animate our language, and convey our thoughts in more ardent and intense phrases than any that are to be met with in our own tongue. There is something so pathetic in this kind of diction, that it often sets the mind in a flame, and makes our hearts burn within us."

* *Spect.* N° 405.

Again, people of different nations vary in their customs and manners, which occasions a diversity in their style. This was very remarkable in the Attics, Asiatics, and Rhodians, and is often taken notice of by ancient writers. The Athenians, while they continued a free state, were an active, industrious, and frugal people: very polite indeed, and cultivated arts and sciences beyond any other nation: but as they had powerful enemies, and were exceedingly jealous of their liberties, this preserved them from wantonness and luxury. And their way of speaking was agreeable to their conduct; accurate and close, but very full and expressive.

Elocution. pressive. The Asiatics, on the other hand, were more gay, and loose in their manners, devoted to luxury and pleasure: and accordingly they affected a florid and swelling style, filled with redundancies and superfluities of expression. Indeed some of the ancients have attributed this looseness of style to their way of pursuing eloquence at first. For as they were put upon it by conversing with the Greek colonies who settled among them, they suppose, that, in imitating them, before they were masters of the language, they were often obliged to make use of circumlocutions, which afterwards became habitual, and very much weakened the force of their expressions, as it naturally would do. But one would think, if they were put to this necessity at first, when they found its ill effect, they might easily have amended it afterwards, as they grew better acquainted with the Greek language, had they been inclined so to do. The Rhodian style was a medium between the other two; not so concise and expressive as the Attic, nor yet so loose and redundant as the Asiatic. Quintilian says, it had a mixture of its author, and the humour of the people; and like plants set in a foreign soil, degenerated from the Attic purity, but not so wholly as to lose it. They first received it from Æschines, who being worsted in his famous contest with Demosthenes, retired thither, and taught rhetoric, which put them upon the study of eloquence.

The style of the same country likewise very much alters in different ages. Cicero tells us, that the first Latin historians aimed at nothing more than barely to make themselves intelligible, and that with as much brevity as they could. Those who succeeded them advanced a step farther; and gave somewhat a better turn and cadency to their sentences, though still without any dress or ornament. But afterwards, when the Greek language became fashionable at Rome, by copying after their writers, such as Herodotus, Thucydides, Xenophon, and others, they endeavoured to introduce all their beauties into their own tongue, which in Cicero's time was brought to its highest perfection. But it did not long continue in that state. A degeneracy of manners soon altered their taste, and corrupted their language, which Quintilian very much complains of in his time. The case was the same with respect to the Greek tongue; though that had the good fortune to continue its purity much longer than the Latin. Nor can any language be exempt from the common fate of all human productions; which have their beginning, perfection, and decay. Besides, there is a sort of fashion in language, as well as other things; and the generality of people are always fond of running into the mode. Perhaps some one, or a few persons, fall into a manner, which happens to please. This gives them a reputation; and others immediately copy after them, till it generally prevail. Cicero tells us, that the most ancient Greek orators whose writings were extant in his time, such as Pericles, Alcibiades, and others, were subtle, acute, concise, and abounded in sense rather than words. But another set that followed them, of which were Critias, Theramenes, and Lysias, retained the good sense of the former, and at the same time took more care of their style; not leaving it so bare as the former had done, but furnishing it with a better dress. After these came Isocrates, who added all the flowers and beauties of eloquence. And as he had abundance of followers, they applied these ornaments and decorations according to their different genius: some for pomp and splendour; and others to invigorate their style, and give it the greater force and energy. And in this latter way Demosthenes principally excelled. Now as each of these manners had its peculiar beauties, and generally prevailed in different ages, Cicero thinks this could not have happened otherwise than from imitation. And he attributes it to the same cause, that afterwards they sunk into a softer and smoother manner, not less exact and florid, but more cold and lifeless. If we take a view of our own tongue, Chaucer seems to have been the first who made any considerable atttempts to cultivate it. And whoever looks into his writings will perceive the difference to be so great from what it is at present, that it scarce appears to be the same language. The gradual improvements it has since received, are very evident in the writers almost of every succeeding age since that time; and how much farther it may still be carried, time only can discover. See LANGUAGE, *passim*: For the English *language* in particular, see N° 38; for the other European languages, as well as the Greek and Latin, see N° 27, &c.

Another cause of the variety of style arises from the different nature and properties of language. A difference in the letters, the make of the words, and the order of them, do all affect the style. So Quintilian observes, that the Latin tongue cannot equal the Greek in pronunciation, because it is harsher. The Latins want two of the softest Greek letters, υ and ζ; and use others of a very hard sound, which the Greeks have not, as *f* and *q*. Again, many Latin words end in *m*; a letter of a broad and hollow sound, which never terminates any Greek word; but ν does frequently, whose sound is much softer and sweeter. Besides, in the combination of syllables the letters *b* and *d* are often so situated, as to require too strong and unequal a force to be laid upon them, as in the words *obversus* and *adjungo*. Another advantage of the Greek tongue arises from the variety and different seat of the accents: for the Greeks often accent the last syllable, which both enlivens the pronunciation, and renders it more musical; whereas the Latins never do this. But the greatest advantage of the Greeks lies in their plenty and variety of words; for which reason they have less occasion for tropes or circumlocutions, which, when used from necessity, have generally less force, and weaken the style. But under these disadvantages, Quintilian seems to give his countrymen the best advice the case will admit of: That what they cannot do in words, they should make up in sense. If their expressions are not so soft and tender, they should exceed in strength; if they are less subtile, they should be more sublime; and if they have fewer proper words, they should excel in the beauty as well as number of their figures. If this account of Quintilian be just, that the Greek tongue does surpass the Latin in all these instances, it is certain that both of them have much greater advantages over some modern languages. The varying all their declinable words, both nouns and verbs, by terminations, and not by signs, contributes very much to the smoothness and harmony of their periods. Whereas in the modern languages, those small particles and pronouns which distinguish the cases of nouns and the tenses and persons of verbs, hinder the run of a period, and

and render the sound much more rough and uneven. Besides, the ancient languages seem to have a better and more equal mixture of vowels and consonants, which makes their pronunciation more easy and musical.

But the chief distinction of style arises from the different subjects or matter of discourse. The same way of speaking no more suits all subjects, than the same garment would all persons. A prince and a peasant ought not to have the same dress; and another different from both becomes those of a middle station in life. The style therefore should always be adapted to the nature of the subject, which rhetoricians have reduced to three ranks or degrees; the *low* or *plain* style, the *middle* or *temperate*, and the *lofty* or *sublime:* Which are likewise called *characters*, because they denote the quality of the subject upon which they treat. This division of style into three characters, was taken notice of very early by ancient writers. Some have observed it even in Homer, who seems to assign the *sublime* or magnificent to Ulysses, when he represents him as so copious and vehement an orator, that his words came from him *like winter snow*. On the contrary, he describes Menelaus as a *polite* speaker, but *concise* and *moderate*. And when he mentions Nestor, he represents his manner as between these two, not so high and lofty as the one, nor yet so low and depressed as the other; but smooth, even, and pleasant, or, as he expresses it, *more sweet than honey*. Quintilian observes, that although accuracy and politeness were general characters of the Attic writers; yet among their orators, Lysias excelled in the *low and familiar* way; Isocrates for his *elegancy, smoothness*, and the *fine turn of his periods;* and Demosthenes for his *flame and rapidity*, by which he carried all before him. And Gellius tells us, that the like difference was found in the three philosophers who were sent from the Athenians to Rome (before the Romans had any relish for the polite arts) to solicit the remittance of a fine laid upon them for an injury done to a neighbouring state. Carneades, one of those ambassadors, was *vehement and rapid* in his harangues; Critolaus, *neat and smooth;* and Diogenes, *modest and sober*. The eloquence of these orators, and the agreeable variety of their different manner, so captivated the Roman youth, and inflamed them with a love of the Grecian arts, that old Cato, who did all he could to check it by hurrying away the ambassadors, could not prevent their vigorous pursuit of them, till the study became in a manner universal. And the old gentleman afterwards learned the Greek language himself, when it became more fashionable. Which a noble writer of ours * represents as *a punishment upon him for his former crime*. It seldom happens that the same person excels in each of these characters. They seem to require a different genius, and most people are naturally led to one of them more than another: though all of them are requisite for an orator upon different occasions, as we shall show hereafter.

* *Lord Bacon.*

Chap. V. *Of the Low Style.*

100 The low style considered both as to thoughts and language.

This we shall consider under two heads, *thoughts* and *language;* in each of which the several characters are distinguished from one another.

I. And with respect to the former, as the subjects proper for this style are either common things, or such as should be treated in a plain and familiar way; so plain thoughts are most suitable to it, and distinguish it from the other characters. 101

Now, by plain thoughts, are meant such as are simple and obvious, and seem to rise naturally from the subject, when duly considered; so that any one, upon first hearing them, would be apt to imagine they must have occurred to himself. Not that this is really the case, but because the more natural a thing is, the more easy it seems to be; though in reality it is often otherwise; and the perfection of art lies in its nearest resemblance to nature. And therefore, in order to speak plainly and clearly upon any subject, it must first be duly considered, well understood, and thoroughly digested in the mind; which, though it require labour and study, yet the more a person is master of what he says, the less that labour will appear in his discourse. This natural plainness and simplicity, without any disguise or affectation, very much contributes to give credit to what is said. Nor is any thing more apt to impose on us, than the appearance of this, when artfully assumed. Cicero's account of the fight between Milo and Clodius, in which Clodius was killed, is a remarkable instance of this. "When Clodius knew (says he) that Milo was obliged to go to Lanuvium upon a solemn and necessary occasion, he immediately hastened from Rome, the day before, to assassinate him before Clodius's own house, as appeared afterwards by the event. And this he did at a time, when his turbulent mob in the city wanted his assistance; whom he would not have left but for the advantage of that place and season to execute his wicked design. But the next day Milo was in the senate, where he continued till they broke up; then went home; changed his dress; staid there some time till his wife was ready; and afterwards set forward so late, that if Clodius had designed to return to Rome that day, he might have been here by that time. Clodius, prepared for his design, met him on horseback, having no chariot, no equipage, no Greek attendants as usual; and without his wife, which was scarcely ever known: whereas Milo was in a chariot with his wife, wrapt up in a cloak, and attended by a large retinue of maid servants, pages, and other persons unfit for an engagement. He met with Clodius before his house, about five o'clock in the evening; and was presently assaulted from a higher ground by many armed men, who killed the coachman. Upon which, Milo, throwing off his cloak, leaped out of the chariot, and bravely defended himself: and those who were with Clodius, having their swords drawn, some made up to the chariot to attack Milo; and others, who now thought he had been killed, began to fall upon his servants who were behind. And of these, such as had courage, and were faithful to their master, some were killed; and others when they saw the skirmish at the chariot, and could do their master no service (for they heard Clodius himself say that Milo was killed, and really thought it was so), did that, not by their master's order, nor with his knowledge, nor when he was present, which every one would have his own servants to do in the like circumstances. I do not say this to fix any crime upon them, but only to relate what happened." His meaning is, they killed Clodius; which he avoids mentioning, to render what he says less offensive. Can any thing be told in a more plain and simple manner than this? Here is nothing said, but

Elocution. what in itself seems highly probable, and what one would imagine the fact might easily suggest to any ordinary spectator. But in this, both the art and skill of it consist. For in the whole account, as, on the one hand, Milo is so described as to render it highly improbable he could have any design at that time against Clodius; so on the other, no one circumstance is omitted which might seem proper to persuade the hearers that Clodius was the aggressor in that engagement. And yet, if we may believe Asconius, the quarrel was begun by some of Milo's retinue, and Clodius was afterwards killed by his express order. But as things are sometimes best illustrated by their opposites, we shall here produce a contrary instance of a very affected and unnatural way of relating a fact. Val. Maximus tells us of a learned man at Athens, who, by a blow which he received by a stone upon his head, entirely forgot all his learning, though he continued to remember every thing else. And therefore, as he says, since this misfortune deprived him of the greatest enjoyment of his life, it had been happier for him never to have been learned, than afterwards to lose that pleasure. This is the plain sense of the story. But now let us hear him relate it, "A man (says he) of great learning at Athens, having received a blow upon his head by a stone, retained the memory of all other things very perfectly, and only forgot his learning, to which he had chiefly devoted himself. The direful and malignant wound invading his mind, and as it were designedly surveying the knowledge reposited there, cruelly seized on that part of it in particular from which he received the greatest pleasure, and buried the singular learning of the man with an invidious funeral. Who since he was not permitted to enjoy his studies, had better never have obtained access to them, than afterwards to have been deprived of the delight they afforded him." What an unnatural way is this of relating such an accident, to talk of *a wound invading the mind*, and *surveying the knowledge reposited there*, and *cruelly seizing a particular part of it*, and *burying it with an invidious funeral*? There is nothing in the story could lead him to this, but an over-fondness to refine upon it in a very affected manner. But there are two properties of plain thoughts, one of which ought constantly to attend them in common with all thoughts, and the other is often necessary to animate and enliven this character.

The former of these is justness and propriety, which is what reason dictates in all cases. What Cicero says of the death of Crassus the orator, seems very just, as well as natural. "It was (says he) an affliction to his friends, a loss to his country, and a concern to all good men; but such public calamities followed upon it, that heaven seemed rather to have favoured him with death, than to have deprived him of life." This thought seems very just, and agreeable to the sentiments of a good man, as Crassus was; to choose death rather than to outlive the happiness of his country, to which he himself had so much contributed. Quintilian has a reflection upon a like occasion, which is not so just and becoming. It is upon the death of his only son, a youth of very uncommon parts, as he represents him; and for whose use he had designed his *Institutions of oratory*: but he died before they were finished. The passage is this: "I have lost him of whom I had formed the greatest hopes, and in whom I had reposed the greatest comfort of my old age. What can I do now? or of what farther use can I think myself to be, thus disappointed by heaven? What good parent will pardon me, if I can any longer study, and not condemn such resolution, if, thus surviving all my family, I can make any other use of my voice, than to accuse the gods, and declare that providence does not govern the world?" Allowance may be made for the sallies of passion, even in wise men, upon some shocking occasions; but when it proceeds to such a degree as to become impious, it is very indecent, as well as unjust. And all indecency is unnatural, as it is disagreeable to reason, which always directs to a decorum. That seems to be a very natural as well as just thought of Pliny the Younger, when he says, "The death of those persons always appears to me too hasty and unseasonable, who are preparing some lasting work. For persons wholly devoted to pleasures, live, as it were, from day to day, and daily finish the end for which they live; but those who have a view to posterity, and preserve their memory by their labours, always die untimely, because they leave something unfinished." We shall mention but one more instance; and that in a comparative view, to make it the more evident. The two sons of Junius Brutus, the first Roman consul, having been convicted of treason, in associating with Tarquin's party, were ordered, among others, to be put to death; and their father not only pronounced the sentence, but presided at the execution. This fact is mentioned by several of the Roman historians; and, as it carries in it not only the appearance of rigorous justice, but likewise of cruelty in Brutus, to have been present at the execution of his sons, they endeavour to vindicate him different ways. What Florus says seems rather an affectation of wit, than a just defence of the fact. "He beheaded them (says he), that being a public parent, he might appear to have adopted the whole body of the people." Nor does Val. Maximus come up to the case, who says, "He put off the father to act the consul; and chose rather to lose the sons, than be wanting to public justice." This might be a reason for condemning them; and would have been equally true, had he not been present at their execution. But Livy, whose thoughts are generally very just and natural, assigns the best reason which perhaps can be given for his vindication, when he says, "Fortune made him the executioner of the sentence, who ought not to have been a spectator." By saying *fortune made him* so, he represents it not as a matter of choice, like the other historians, but of necessity, from the nature of his office, which then obliged him to see the execution of that sentence he had himself before pronounced; as is the custom at present, in some popular governments.

The other property, which should often accompany plain and simple thoughts, is, that they be gay and sprightly. This, as has been said, is necessary to animate and enliven such discourses as require the low style. The fewer ornaments it admits of, the greater spirit and vivacity is requisite to prevent its being dry and jejune. A thought may be very brisk and lively, and at the same time appear very natural, as the effect of a ready and flowing wit. Such thoughts, attended with agreeable turns, are very suitable to this style; but care should be taken, lest, while fancy is too much indulged, the justness of them be overlooked. We shall give one instance, in which this seems to have been the case,

case, from a celebrated English work, where the ingenious writer endeavours to show the disadvantages of persons not attending to their natural genius, but affecting to imitate others in those things for which they were not formed. "The great misfortune (says he) of this affectation is, that men not only lose a good quality, but also contract a bad one; they not only are unfit for what they are designed, but they assign themselves to what they are unfit for; and instead of making a very good figure one way, make a very ridiculous one another. Could the world be reformed to the obedience of that famed dictate, *Follow nature*, which the oracle of Delphos pronounced to Cicero when he consulted what course of studies he should pursue, we should see almost every man as eminent in his proper sphere as Tully was in his. For my part, I could never consider this preposterous repugnancy to nature any otherwise, than not only as the greatest folly, but also one of the most heinous crimes; since it is a direct opposition to the disposition of providence, and (as Tully expresses it) like the sin of the giants, an actual rebellion against heaven." The advantages that arise from persons attending to their own genius, and pursuing its dictates, are here represented in a very lively and agreeable manner. But there is one thing asserted, which we fear will not hold; which is, that, *Could the world be reformed to that dictate,* "Follow Nature," *we should see almost every man as eminent in his proper sphere as Tully was in his.* For though doubtless persons would generally succeed best if they kept to this rule; yet different degrees of ability are often found, where the bias and inclination is the same, and that accompanied with equal labour and diligence. If this was not so, how happened it that no one came up to Tully in the art of oratory; especially in his own age, when there were the greatest opportunities for that study, and the highest encouragements were given to it, as it paved the way to riches, honours, and all the grand offices of the state? It cannot well be questioned but that there were other gentlemen, who had all the same advantages, accompanied with as strong a passion for this art, as Tully had, who yet fell much short of him in point of success. And experience shows, that the case has been the same in all other pursuits.

102 The language proper for this style.

III. But it is time to proceed to the other head, the *language* proper for this style. And here it may be observed in general, that the dress ought to be agreeable to the thoughts, plain, simple, and unaffected.

But the first thing that comes under consideration is elegance, or a proper choice of words and expressions; which ought always to suit the ideas they are designed to convey. And therefore when an ancient writer, speaking of *cruelty*, calls it *nævus crudelitatis*, the *blemish of cruelty;* and another, applying the same word to *ingratitude*, says *nævus ingratitudinis*, the *blemish of ingratitude;* that term does not sufficiently convey to us the odious nature of either of those vices, as indeed it was not their design it should. But otherwise, where the speaker has not some particular view in doing it, to sink too low is as much a fault as to rise too high. So to call ancient Rome *the mistress of Italy*, would as much lessen the just notion of the extent of her power, as the Roman writers aggrandise it when they style her *mistress of the world*. But purity, both in the choice of words and expressions, is never more necessary than it is here. This may be called *neatness in language*. And to be plain and neat at the same time, is not only very consistent, but the former can no other way recommend itself, than as joined with the latter. Besides, the fewer advantages any thing has to set it off, the more carefully they ought to be observed. Perspicuity is always to be regarded; and serves very much to keep up the attention, where other ornaments are wanting. Epithets should be sparingly used, since they enlarge the images of things, and contribute very much to heighten the style. Indeed they are sometimes necessary to set a thing in its just light; and then they should not be dropped. Thus, in speaking of Xerxes, it would be too low and flat to say, *He descended with his army into Greece.* Here is no intimation given of their vast and unparalleled numbers, which ought to be done. Herodotus says, his whole army, of sea and land forces, amounted to 2,317,000 and upwards. Therefore, unless the number be mentioned, the least that can be said is, that *he descended with a vast army.*

The next thing to be regarded is composition, which here does not require the greatest accuracy and exactness. A seeming negligence is sometimes a beauty in this style, as it appears more natural. Short sentences, or those of a moderate length, are likewise upon the whole best suited to this character. Long and accurate periods, finely wrought up with a gradual rise, harmonious numbers, a due proportion of the several parts, and a just cadency, are therefore improper, as they are plainly the effect of art. But yet some proportion should be observed in the members, that neither the ears be too much defrauded, nor the sense obscured. Of this kind is that expression of a Greek orator, blamed by Demetrius: *Ceres came readily to our assistance, but Aristides not.* The latter member of this sentence is too short; and by dropping so suddenly, both disappoints the ears, and is somewhat obscure. It would have been plainer and more agreeable thus, *but Aristides did not come.* As to order, the plainest and clearest disposition, both of the words and members of sentences, and what is most agreeable to the natural construction, best suits with this character. For one of its principal beauties is perspicuity. And a proper connection likewise of sentences, with a regular order in the dependence of things one upon another, very much contributes to this end. With regard to the collision of syllables in different words, for preventing either a hollowness or asperity of sound, greater liberty may be taken in this style than in the other characters. Here it may be allowed to say, *Virtue is amiable to all, though all do not pursue it.* But in a higher character, perhaps, in order to prevent the hollow sound of the words *though all*, a person would choose to vary the expression a little, and say, *though few pursue it.* So, *Xerxes' expedition*, may be tolerable here; but in the florid style, *the expedition of Xerxes* would sound much better.

The last thing to be considered, with respect to the language is dignity, or the use of tropes and figures. And as to tropes, they ought to be used cautiously; unless such as are very common, and by time have either come into the place of proper words, or at least are equally plain and clear. So in the instance mentioned above, Diodorus Siculus, speaking of the forces of Xerxes, calls them an *innumerable company*. Where, by

Elocution. by a *synecdoche*, he has chosen to make use of an uncertain number for a certain, as less liable perhaps to exception. Other examples might be given if necessary. And with regard to figures, as most of those which consist in words, and are therefore called *verbal figures*, serve chiefly to enliven an expression, and give an agreeable turn, they are often not improper for this character. Nor are figures of sentences wholly to be excluded, especially such as are chiefly used in reasoning or demonstration. But those which are more peculiarly adapted to touch the passions, or paint things in the strongest colours, are the more proper ornaments of the higher styles, as will be shown hereafter.

Upon the whole, therefore, pure nature, without any colouring, or appearance of art, is the distinguishing mark of the low style. The design of it is to make things plain and intelligible, and to set them in an easy light. And therefore the proper subjects of it are epistles, dialogues, philosophical dissertations, or any other discourses, that ought to be treated in a plain and familiar manner, without much ornament, or address to the passions. A freedom and ease both of thought and expression, attended with an agreeable humour and pleasantry, are its peculiar beauties that engage us. As we see persons of fashion and good breeding, though in the plainest habit, have yet something in their air and manner of behaviour that is very taking and amiable. Somewhat of the like nature attends this style. It has its difficulties, which are not so easily discerned but from experience. For it requires no small skill to treat a common subject in such a manner as to make it entertaining. The fewer ornaments it admits of, the greater art is necessary to attain this end. Lofty subjects often engage and captivate the mind by the sublimity of the ideas. And the florid style calls in all the assistance of language and eloquence. But the plain style is in a great measure stripped of those advantages; and has little more to recommend it, than its own native beauty and simplicity.

Chap. VI. *Of the Middle Style.*

103 This we shall treat in the same manner as we did the former, by considering first the *matter*, and then the *language* proper for it.

104 The middle style considered as to matter and language.

I. And as the subjects proper for this style are things of weight and importance, which require both a gravity and accuracy of expression; so fine thoughts are its distinguishing mark, as plain thoughts are of the low character, and lofty thoughts of the sublime. Now a fine thought may deserve that character from some or other of the following properties.

And the first property we shall mention is gravity and dignity. Thus Cicero in a speech to Cæsar, says, "It has been often told me, that you have frequently said, you have lived long enough for yourself. I believe it, if you either lived, or was born for yourself only." Nothing could either be more fit and proper, than this was, when it was spoken; or at the same time a finer compliment upon Cæsar. For the civil war was now over, and the whole power of the Roman government in the hands of Cæsar; so that he might venture to say he had lived long enough for himself, there being no higher pitch of glory to which his ambition could aspire. But then there were many things in the state that wanted redressing, after those times of disorder and confusion, which he had not yet been able to effect, and of which Cicero here takes an opportunity to remind him. We shall produce another example from Curtius. Philotas, one of Alexander's captains, having formed a conspiracy against him, was convicted of it, and put to death. Amintas, who was suspected of the same crime, by reason of his great intimacy with Philotas, when he comes to make his defence, among other things speaks thus: "I am so far from denying my intimacy with Philotas, that I own I courted his friendship. Do you wonder that we showed a regard to the son of Parmenio, whom you would have to be next to yourself, giving him the preference to all your other friends? You, Sir, if I may be allowed to speak the truth, have brought me into this danger. For to whom else is it owing, that those who endeavoured to please you, addressed themselves to Philotas? By his recommendation we have been raised to this share of your friendship. Such was his interest with you, that we courted his favour, and feared his displeasure. Did we not all in a manner engage ourselves by oath, to have the same friends, and the same enemies, which you had? Should we have refused to take this, which you, as it were, proposed to us? Therefore, if this be a crime, you have few innocent persons about you; nay, indeed none. For all desired to be the friends of Philotas; though all could not be so who desired it. Therefore, if you make no difference between his friends and accomplices, neither ought you to make any between those who desire to be his friends, and those who really were so." Could any thing be finer spoken, more proper, and becoming the character of a soldier, than this defence; especially to a prince of so great and generous a spirit as Alexander? There is something which appears like this in Tacitus with relation to the emperor Tiberius, but falls vastly short of it in the justness and dignity of the sentiment. Sejanus, his great favourite, and partner in his crimes, falling under his displeasure, was, like Philotas, put to death for a conspiracy. Now a Roman knight, who apprehended himself in danger on account of his friendship with Sejanus, thus apologizes for himself to the emperor, in the manner of Amintas: "It is not for us to examine the merit of a person whom you raise above others, nor your reasons for doing it. The gods have given you the sovereign power of all things, to us the glory of obeying. Let conspiracies formed against the state, or the life of the emperor, be punished; but as to friendships and private regards, the same reason that justifies you, Cæsar, renders us innocent." The turn of the expressions is not much different from that in the case of Amintas; but the beauty of the thought is spoiled by the flattery of complimenting Tiberius upon an excess of power, which he employed to the destruction of many excellent men. There is not that impropriety in the defence of Amintas, which is equally brave and just.

Another property of a fine thought is *beauty* and *elegance*. It is a fine compliment which Pliny pays to the emperor Trajan, when he says, "It has happened to you alone, that you was father of your country, before you was made so." Some of the Roman emperors had been complimented with the title of *father of their country*, who little deserved it. But Trajan had a long time refused it, though he was really so, both by his goo-

Elocution. good government, and in the esteem of his subjects, before he thought fit to accept of it. And Pliny, among other instances of the generosity of that prince, which he mentions in the same discourse, speaking of the liberty that he gave the Romans to purchase estates which had belonged to the emperors, and the peaceable possession they had of them, does it by a turn of thought no less beautiful than the former. "Such (says he) is the prince's bounty, such the security of the times, that he thinks us worthy to enjoy what has been possessed by emperors; and we are not afraid to be thought so." There is a sprightliness in this image, which gives it a beauty; as there is likewise in the following passage of the same discourse, where he says to Trajan, "Your life is displeasing to you, if it be not joined with the public safety; and you suffer us to wish you nothing but what is for the good of those who wish it." And of the same kind is that of Cicero to Cæsar, when he says, "You, Cæsar, are wont to forget nothing but injuries." It is a very handsome, as well as just reflection, made by Tacitus upon Galba's government, that "He seemed too great for a private man, while he was but a private man; and all would have thought him worthy of the empire, had he never been emperor." The beauty of a thought may give us delight, though the subject be sorrowful; and the images of things in themselves unpleasant may be so represented as to become agreeable. Sisigambis, the mother of Darius, after the death of her son, had been treated by Alexander with the greatest regard and tenderness, in whose power she then was. So soon as she heard therefore that he was dead, she grew weary of life, and could not bear to outlive him. Upon which Q. Curtius makes this fine reflection: "Though she had courage to survive Darius, yet she was ashamed to outlive Alexander."

The next property of a fine thought, which we shall mention, is *delicacy*. As, in the objects of our senses, those things are said to be delicate which affect us gradually in a soft and agreeable manner; so a delicate thought is that which is not wholly discovered at once, but by degrees opening and unfolding itself to the mind, discloses more than was at first perceived. Quintilian seems to refer to this, when he says, "Those things are grateful to the hearers, which, when they apprehend, they are delighted with their own sagacity; and please themselves, as though they had not heard, but discovered them." Such thoughts are not unlike the sketches of some pictures, which let us into the design of the artist, and help us to discern more than the lines themselves express. Of this kind is that of Sallust: "In the greatest fortunes, there is the least liberty." This is not often so in fact, but ought to be; both to guard against an abuse of power, and to prevent the effects of a bad example to inferiors. Pliny, speaking of the emperor Trajan's entry into Rome, says, "Some declared, upon seeing you, they had lived long enough; others, that now they were more desirous to live." The compliment is fine either way, since both must esteem the sight of him the greatest happiness in life; and in that consistency lies the delicacy of the thought. It was a fine character given of Grotius, when very young, on the account of his surprising genius and uncommon proficiency in learning, that *he was born a man:* As if nature, at his coming into the world, had at once furnished him with those endowments which others gradually acquire by study and application. Elocution.

The last property of a fine thought, which we shall take notice of, is *novelty*. Mankind is naturally pleased with new things; and when at the same time they are set in an agreeable light, this very much heightens the pleasure. Indeed there are few subjects, but what have been so often considered, that it is not to be expected they should afford many thoughts entirely new; but the same thought set in a different light, or applied to a different occasion, has in some degree a claim of novelty. And even where a thing hath been so well said already, that it cannot easily be mended, the revival of a fine thought often affords a pleasure and entertainment to the mind, though it can have no longer the claim of novelty. Cicero, in his treatise of an orator, among several other encomiums which he there gives to Crassus, says of him, "Crassus always excelled every other person, but that day he excelled himself." He means as an orator. But elsewhere he applies the same thought to Cæsar, upon another account; and with some addition to it. "You had (says he) before conquered all other conquerors by your equity and clemency, but to-day you have conquered yourself; you seem to have vanquished even victory herself, therefore you alone are truly invincible." This thought, with a little variation of the phrase, has since appeared in several later writers; and it is now grown common to say of a person, who excels in any way, upon his doing better than he did before, that he has outdone himself. The like has happened to another thought, which, with a little alteration, has been variously applied. It was said by Varro, *That if the Muses were to talk Latin, they would talk like Plautus.* The younger Pliny, applying this compliment to a friend of his, says, *His letters are so finely written, that you would think the Muses themselves talked Latin.* And Cicero tells us, *It was said of Xenophon, that the Muses themselves seemed to speak Greek with his voice.* And elsewhere, that *Philosophers say, if Jupiter speaks Greek, he must speak like Plato.* The thought is much the same in all these instances, and has been since revived by some modern writers.

125 The language of the middle style.

II. We shall now consider the *language* proper for the middle style. And in general it may be observed, that as the proper subjects of it are things of weight and importance, though not of that exalted nature as wholly to captivate the mind, and divert it from attending to the diction, so all the ornaments of speech, and beauties of eloquence, have place here.

And first with regard to elegance, it is plain that a different choice of words makes a very great difference in the style, where the sense is the same. Sometimes one single word adds a grace and weight to an expression, which, if removed, the sense becomes flat and lifeless. Now such words as are most full and expressive suit best with his character. Epithets also, which are proper and well chosen, serve very much to beautify and enliven it, as they enlarge the ideas of things, and set them in a fuller light.

The most accurate composition, in all the parts of it, has place here. Periods, the most beautiful and harmonious, of a due length, and wrought up with the most exact order, just cadency, easy and smooth connec-tion.

tion of the words, and flowing numbers, are the genuine ornaments, which greatly contribute to form this character.

But the principal distinction of style arises from tropes and figures. By these it is chiefly animated and raised to its different degrees or characters, as it receives a lesser or greater number of them; and those either more mild, or strong and powerful.

As to tropes, those which afford the most lively and pleasing ideas, especially metaphors, suit the middle character. It is a pretty remark, which has been made by some critics upon two verses of Virgil; one in his Eclogues, and the other in his Georgics. The former of these works is for the most part written in the low style, as the language of shepherds ought to be; but the latter in the middle style, suitable to the nature of the subject, and the persons for whom it was designed, the greatest men in Rome not thinking it below them to entertain themselves with rural affairs. Now in the Eclogue, as some copies read the verse, the shepherd, complaining of the barrenness of his land, says,

Infelix lolium et steriles nascuntur avenæ.

In English thus:

Wild oats and darnel grow instead of corn.

But in the Georgic, where the same sense is intended, instead of the proper word *nascuntur*, *grow*, the author substitutes a metaphor, *dominantur*, *command*, and says,

Infelix lolium et steriles dominantur avenæ.

That is in English;

Where corn is sown, darnel and oats command.

It was fit and natural for the shepherd to express his sense in the plainest terms; and it would have been wrong to represent him going so far out of his way, as to fetch a metaphor from government, in talking upon his own affairs. But in the Georgic, where the poet speaks in his own person, the metaphor is much more beautiful, and agreeable to the dignity of the work. This instance may show in some measure how the style is heightened by tropes, and the same thought may be accommodated to the several characters of style by the different manner of expression.

The like may also be said of figures either of words or sentences, in reference to this character; which admits of the finest descriptions, most lively images, and brightest figures, that serve either for delight, or to influence the passions without transport or ecstasy, which is the property of the sublime. This is indeed the proper seat of such embellishments, which support and make up a principal part of the middle or florid style. Having treated largely upon these in several preceding chapters, we shall here only briefly mention some of the most considerable.

106 Descriptions ornamental and pleasant.

Descriptions are not only a great ornament to a discourse, but represent things in a very lively and agreeable manner. In what a beautiful light has Cicero placed the polite arts and sciences, when, describing them from their effects, he thus represents to us the great advantages, as well as pleasure, which they afford to the mind? "Other studies neither suit with all times, nor all ages, nor all places; but these improve youth, delight old age, adorn prosperity, afford a refuge and solace in adversity; please at home, are no hinderance abroad; sleep, travel, and retire, with us." And they often affect us very powerfully, when they are addressed to the senses. Quintilian has painted the calamities of a city taken by storm in the brightest and strongest colours, which he represents by "Flames spreading themselves over the houses and temples, the cracking of falling buildings, and a confused noise from a variety of cries and shouts; some running they know not where, others in the last embraces of their friends; the shrieks of children, women, and old men unhappily reserved to such distress; the plundering of all places civil and sacred, the hurry and confusion in carrying off the booty, captives driven before their victors, mothers endeavouring to guard their infants, and quarrels among the conquerors where the plunder is largest." This seems to be a very natural, as well as moving, image of so dreadful a calamity.

107 Prosopopeia well fitted for this character.

Prosopopeia is another very strong and beautiful figure, very proper for this character. Seneca has a fine instance of it in his "Consolatory Letter to Marcia," upon the death of her son. After many arguments he had made use of to alleviate her grief, he at last introduces her father, Cremutius Cordus, as thus addressing to her: "Imagine your father (says he) from the celestial regions, speaking to you in this manner: Daughter, why do you so long indulge your grief? why are you so ignorant, as to think it unhappy for your son, that, weary of life, he has withdrawn himself to his ancestors? Are you not sensible what disorders fortune occasions everywhere? and that she is kindest to those who have least concern with her? Need I mention to you princes who had been extremely happy, had a more timely death secured them from impending evil? or Roman generals, who wanted nothing to consummate their glory but that they lived too long? Why then is he bewailed longest in our family who died most happily! There is nothing, as you imagine, desirable among you, nothing great, nothing noble; but, on the contrary, all things are mean, full of trouble and anxiety, and partake very little of the light which we enjoy." This advice was very suitable for a philosopher; and he seems to have chosen this way of introducing it, to enforce the argument drawn from the happiness of good men in a future state, from the testimony of a person who was actually in the possession of it.

108 Similitudes both ornamental and frequent here.

Similitudes and comparisons are another great ornament of this style, and oftenest found here. Nothing can be finer than the comparison between those two great orators, Demosthenes and Cicero, made by Quintilian, when he says, "Demosthenes and Cicero differ in their elocution; one is more close, and the other more copious; the former concludes more concisely, and the latter takes a larger compass; the one always with pungency, and the other generally with weight; one can have nothing taken from him, and the other nothing added to him; the latter has more of art, and the former more of nature. But this must be allowed to Demosthenes, that he made Cicero in a great measure what he was. For as Tully gave himself wholly to an imitation of the Greeks, he seems to me to have expressed the force of Demosthenes, the fluency of Plato, and the pleasantry of Isocrates." Similitudes, taken from natural things, serve very much to enliven the style, and

Elocution.

and give it a cheerfulness; which is a thing so common and well known, that we need not stay to give any instances of it.

109 Antithesis, has also a fine effect.

Antithesis, or opposition both in the words and sense, has often the like beautiful effect. There is an agreeable contrast in that passage of Seneca: "Cæsar does not allow himself many things, because he can do all things: his watching defends all others sleep, his labour their quiet, his industry their pleasure, his business their ease; since he has governed the world he has deprived himself of it." Had he said no more than only in general, that *Cæsar does not allow himself many things, because he can do all things*, it might have passed for a fine thought; but, by adding so many particulars, all in the same form of expression, and beginning each member with the same word, he has both enlarged the idea, and beautified the antithesis, by a bright verbal figure.

These, and such like florid figures, are sometimes found in historians, but oftener in orators; and indeed this middle character, in the whole of it, is best accommodated to the subjects of history and oratory.

Chap. VII. *Of the Sublime Style.*

110 The noblest and the most difficult part of an orator's province is the sublime.

The *sublime* is the most noble, as well as the most difficult, part of an orator's province. It is this principally which Cicero requires in his perfect orator, whom he could not describe in words, but only conceive of in his mind. And indeed, the noblest genius and greatest art are both requisite to form this character. For where nature has been most liberal in furnishing the mind with lofty thoughts, bright images, and strong expressions; yet without the assistance of art there will sometimes be found a mixture of what is low, improper, or misplaced. And a great genius, like a too rich soil, must produce flowers and weeds promiscuously, without cultivation. But the justest propriety, joined with the greatest strength and highest elevation of thought, are required to complete the true sublime. Art, therefore, is necessary to regulate and perfect the taste of those who are desirous to excel in this character.

In explaining the nature and properties of this character, we shall, as in the two former, consider first the *thoughts*, and then the *language*, in each of which it is distinguished from them.

§ 1. *Sublime, as it relates to Thoughts.*

111 Sublimity as it relates to thoughts.

Lofty and grand sentiments are the basis and foundation of the true sublime. Longinus therefore advises those who aspire at this excellence, to accustom themselves to think upon the noblest subjects. A mind that always dwells upon low and common subjects can never raise itself sufficiently to represent things great and magnificent in their full extent and proper light. But he who inures himself to conceive the highest and most exalted ideas, and renders them familiar to his thoughts, will not often be at a loss how to express them; for where proper words are wanting, by metaphors and images taken from other things, he will be able to convey them in a just and adequate manner. What is more common than for two persons to conceive very differently of the same thing from the different manner of thinking to which they have been accustomed? After the great battle in Cilicia, between Alexander and Darius, in which the latter was routed, he sent ambassadors to Alexander with proposals of peace, offering him half his kingdom with his daughter in marriage. Parmenio, one of Alexander's chief captains, says to him upon this occasion, "For my part, was I Alexander, I would accept of these conditions." "And so would I (replies that aspiring monarch), was I Parmenio." The half of so vast a kingdom at present, and a right of succession to the whole by marriage, was the highest ambition to which the thoughts of Parmenio could rise. But Alexander had vastly higher views; he aimed at nothing less than universal monarchy; and therefore such a proposal seemed much beneath his regard. Noble and lofty thoughts are principally those which either relate to divine objects, or such things as among men are generally esteemed the greatest and most illustrious.

Elocution.

Of the former sort is that of Homer, when describing the goddess Discord, he says, that she

Walks on the ground, and hides her head in clouds.

This stretch of thought, says Longinius, as great as the distance between heaven and earth, does not more represent the stature of the goddess, than the measure of the poet's genius and capacity. But such images, however beautiful in poetry, are not so proper for an orator, whose business it is to make choice of those which are suited to the nature of things and the common reason of mankind. When Numa the second king of Rome was settled in his government, and at peace with his neighbours, in order to soften the fierce and martial temper of his subjects, who had been always accustomed to war during the reign of his predecessor Romulus, he endeavoured to impress their minds with an awe of the Deity; and for that end introduced a number of religious ceremonies, which he pretended to have received from the goddess Egeria *. This must be esteemed an artful piece of policy at that time. But that sentiment is far more just and noble, with which Cicero endeavours to inspire the members of a community, in his treatise of Laws, when he says, that "Citizens ought first to be persuaded, that all things are under the rule and government of the gods; that every affair is directed by their wisdom and power; that the highest regard is due to them from men, since they observe every one's conduct, how he acts and behaves himself, and with what temper and devotion he worships them; and that they make a difference between the pious and impious." Persons under the influence of such a persuasion, could not fail of behaving well in society. And what he says to Cæsar is no less in this style, when, interceding for Ligarius, he tells him, that "men in nothing approach nearer to deity, than in giving life to men." And Velleius Paterculus, speaking of Cato, gives him this sublime character, "That he was more like the gods than men; who never did a good thing, that he might seem to do it."

* See Egeria.

The other kind of lofty thoughts mentioned above, are those which relate to power, wisdom, courage, beneficence, and such other things as are of the highest esteem among mankind. "Your fortune (says Tully to Cæsar) has nothing greater than a power, nor your nature

nature than a will, to save many." He subjoins this compliment to what we have just cited from him; and applies that to Cæsar, which was before only expressed in general, leaving him to draw the inference of his similitude to deity from the clemency of his nature. And elsewhere, as in a sort of transport for his success in defeating the conspiracy of Catiline, he thus bespeaks the Roman senate: "You have always decreed public thanks to others for their good government of the state, but to me alone for its preservation. Let that Scipio shine, by whose conduct and valour Hannibal was forced to leave Italy, and retire to Africa; let the other Scipio be greatly honoured, who destroyed Carthage and Numantia, two cities the most dangerous to this empire; let Lucius Paulus be in high esteem, whose triumphal chariot was adorned with Perses, once a most powerful and noble prince; let Marius be in eternal honour, who twice delivered Italy from an invasion and the dread of servitude; let Pompey's name excel all these, whose actions and virtues are terminated by no other bounds but the course of the sun;—yet among all their praises, there will still some place be left for my glory; unless indeed it be a greater thing to open for us new provinces to which we may resort, than to secure a place for our victorious generals to return in triumph." And Velleius Paterculus, as if he thought no encomium too high for this great orator, laments his unhappy fate in these lofty strains, addressed to M. Antony, by whose order he was put to death: "You have taken from Cicero old age, and a life more miserable than death under your government; but his fame, and the glory of his actions and words, you have been so far from destroying, that you have increased them. He lives, and will live in the memory of all ages; and while this system of nature, however constituted, shall remain (which scarce any Roman but himself conceived in his mind, comprehended by his genius, and illustrated with his eloquence), the praise of Cicero shall accompany it; and all posterity, while it admires his writings against you, will curse your treatment of him; and sooner shall mankind be lost to the world than his name." It was a noble reply of Porus the Indian king, when, after his defeat by Alexander, being brought before him, and asked *How he expected to be treated?* he answered, *Like a king.* And Valerius Maximus, speaking of Pompey's treatment of Tigranes king of Armenia after he had vanquished him, expresses it in a manner suited to the dignity and beneficence of the action, when he says, "He restored him to his former fortune, esteeming it as glorious to make kings as to conquer them."

But the true sublime is consistent with the greatest plainness and simplicity of expression. And, generally speaking, the more plain and natural the images appear, the more they surprise us. How succinct, and yet how majestic, is that expression of Cæsar upon his victory over Pharnaces? *I came, I saw, I conquered.* But there cannot be a greater or more beautiful example of this, than what Longinus has taken notice of from Moses. "The legislator of the Jews (says he), no ordinary person, having a just notion of the power and majesty of the Deity, has expressed it in the beginning of his laws in the following words: *And God said*—what? *Let there be light*; *and there was light. Let the earth be made*; *and it was made.*" This instance from the divine writer, and the character here given of him by that excellent critic, is the more remarkable, as he was himself a Pagan. And certainly no laboured description could raise in the mind a higher conception of the infinite power of the Deity, than this plain and short narration. To command nature itself into being by a *word*, represents it at once altogether boundless and unlimited.

It sometimes very much contributes to heighten the image of a thing, when it is expressed in so undetermined a manner, as to leave the mind in suspense what bounds to fix to the thought. Of this kind is that of Cicero, when he first raises an objection against the necessity of an acquaintance with polite literature in order to form a great man, and then answers it. The objection is founded upon the examples of several great and excellent persons among the Romans, who had raised themselves to the highest pitch of honour and dignity, and been very serviceable to their country, by the help of a good genius, without the advantage of much learning. In reply to which, he allows, that, where these are not united, nature or genius is of itself much preferable, and will carry a person further in the pursuit of great and noble designs, then learning without a genius; but that both are necessary to complete and perfect a truly great man. But we shall give what he says himself on this head, by which that property of a sublime thought we are now endeavouring to explain, will appear from his manner of expression: "I acknowledge (says he) that many persons of an exalted mind and virtue have, from a divine temper, without instruction, become moderate and grave; and I add likewise, that nature, without the assistance of learning, has frequently more contributed to honour and virtue, than learning where a genius has been wanting: But yet I must say, that where the direction and improvement of learning is added to a great and excellent genius, it is wont to produce something admirable and singular which I know not how to describe." He knew very well, that by leaving the minds of his hearers thus in suspense, they would form to themselves higher conceptions of what he intended, than from any idea he could convey to them in words. We may add to this another example from the same great orator, where he says, "Truly, if the mind had no views to posterity, and all its thoughts were terminated by those bounds in which the space of life is confined, it would neither fatigue itself with so great labours, nor be disquieted with so many cares and watchings, nor so often expose itself to death. But there is a certain active principle in every good man, which constantly excites his mind by motives of glory; and reminds him, that the remembrance of his name is not to end with his life, but extend itself to all posterity." Of the like nature is that of Milton, when he describes Satan as flying from hell in quest of our earth, then newly formed. For having represented that his wings failed him in the vast vacuity, he thus describes his fall:

Down he drops
Ten thousand fathom deep; and to this hour
Down had been falling, had not by ill chance
The strong rebuff of some tumultuous cloud,
Instinct with fire and nitre, hurried him
As many miles aloft.

Those

Elocution.

Those words, by which his fall is expressed,

And to this hour,
Down had been falling,

leave the mind in suspense, and unable to fix any bounds to the vacuity; and by that means raise a greater and more surprising idea of its space than any direct expression could have done. This image is very beautiful where it stands; but so much out of the common way of thinking, as to suit better with an epic poem than the discourse of an orator.

§ 2. *The Sublime, with regard to Language.*

112 Sublimity as to language. What we have to offer upon this subject will come under the three heads of *Elegance*, *Composition*, and *Dignity*; which comprehend all the properties of style.

113 I. *Elegance.* Those words and expressions chiefly contribute to form the sublime, which are most sonorous, and have the greatest splendour, force, and dignity. And they are principally such as these. Long words, when equally expressive, are rather to be chosen than short ones, and especially monosyllables. So to conquer or vanquish an enemy, carries in it a fuller and grander sound, than to beat an enemy. For which reason, likewise, compound words are often preferable to simple ones. So if we say, *Cæsar's army, when he was present, was always invincible;* this manner of expression has more of sublimity in it, than should we say, *Cæsar's army, when he was present, could never be conquered.* But the ancient languages have much the advantage of ours in both these respects; for their words are generally longer, and they are abundantly more happy in their compositions. The use of proper epithets does also in a particular manner contribute to this character. For as they denote the qualities and modes of things, they are as it were short descriptions; so that being joined to their subjects, they often greatly enlarge and heighten their image. Thus when the character of *divine poet* is given to Homer or Virgil, or *prince of orators* to Demosthenes or Cicero, it conveys to the mind a more sublime idea of them, than the bare mention of their name.

114 II. *Composition:* The force of which, as Longinus observes, is so great, that sometimes it creates a kind of sublime where the thoughts themselves are but mean, and gives a certain appearance of grandeur to that which otherwise would seem but common. But composition consists of several parts; the first of which, in the order we have hitherto considered them, is *period.* And here the case is much the same as with animal bodies, which owe their chief excellency to the union and just proportion of their parts. The several members, when separated from each other, lose both that beauty and force, which they have when joined together in a complete body. In like manner, sublimity arises from the several parts of a period so connected, as to give force, as well as beauty, to the whole. The periods therefore in this character should be of a proper length. If they are too short, they lose their just weight and grandeur, and are gone almost before they reach the ear; as, on the contrary, when they are too prolix, they become heavy and unwieldy, and by that means lose their force. But more especially, nothing superfluous ought to be admitted, which very much enervates the force of a sentence. We shall exemplify this in a passage from Herodotus, where he is giving an account of the famous battle at Thermopylæ between the Persians and Lacedæmonians. "Dieneces (says he) the Spartan, being told by a Trachinian, before the engagement with the Medes, that when the barbarians came to shoot their arrows, they would fly so thick as to obscure the light of the sun; he was so far from being terrified at this, that, despising their number, he replied, he "was pleased with what his friend told him, since if the sun was obscured, they should fight in the shade, and not in the sun." The sense here is great and noble, but the sublimity of expression is spoiled in a great measure by those last words, *and not in the sun*, which are wholly superfluous. Cicero was sensible of this, and therefore he omits that member in relating the same story, and says only: "A Spartan, hearing that one of the Persians should say in an insulting manner, that when they came to engage, they should not be able to see the sun, for the multitude of their darts and arrows, replies, Then we shall fight in the shade." By stopping here, he gives the sentence much more life and emphasis. The next thing to be considered in composition, is the order and disposition of the several words and members of a sentence. The different placing but of one or two words will sometimes wholly destroy the grandeur of a sentence, and make it extremely flat. "This public act (says Demosthenes) dispelled the danger which at that time, like a cloud, hung over the city." Let us vary the order a little, and read it thus: "This public act dispelled the danger, which like a cloud hung over the city at that time." What a different turn does the expression receive for the worse! The spirit and majesty of it are entirely lost. And in placing the several parts or members, they ought to be so disposed, that what is most weighty and important should stand last. So Tully says of Catiline, "We ought to return thanks to heaven, that we have so often escaped so odious, so frightful, so dangerous a plague of the state." A thing may be odious and frightful, and yet not dangerous; therefore he puts this in the last place, to give it the greater force, and make the deeper impression. Another thing to be attended to in composition, is the connection of the words with regard to the sound; that the pronunciation, in passing from one to another, may be most agreeable to the ear, and best suited to the nature of the subject. And as this is generally something grand and magnificent, such a contexture of them as will give the greatest force and energy to the expression is most proper for the sublime. Soft and languid sounds are very unsuitable to this character. They soothe and please the ear; but rather sink and depress the mind, than excite it to things great and noble. In this respect, therefore, our tongue, by its multitude of consonants, is more suitable for sublime discourses than some other modern languages, which abound with vowels.

III. The last head to be considered, is the proper use of tropes and figures, which is here so necessary, that the title of *dignity* seems to have been given to this part of elocution, from the assistance it more especially affords to this character. For if, as has been observed from Longinus, compositions will sometimes create a 115

Elocution. a sort of sublimity; this much oftener happens from the force and efficacy of some lively tropes and strong figures.

And as to *tropes*, bright metaphors are peculiarly suited to raise and animate the style. This is manifest from the nature of them, as they consist of contracted similies, reduced to a single word; which, if taken from things lofty and grand, must of consequence give a sublimity to the style. What can suggest to us a greater idea of the valour of Ajax, than Homer's calling him *the bulwark of the Greeks;* or of the Scipios, than when they are styled by Virgil, *the two thunderbolts of war.* A number of those, well chosen, contributes no less to the grandeur than to the beauty of discourse. Hyperbole sometimes gives the same force to an expression, if cautiously used; and so as not to exceed all appearance of truth. But the chief use of it is, where proper words will not express the just idea of the thing designed to be conveyed; and it may seem rather the offspring of necessity than choice. Of this nature is that of Herodotus, when speaking of the Lacedæmonians at Thermopylæ, he says, "They defended themselves with the swords they had left, and even with their hands and teeth, till the barbarians buried them under their arrows." It cannot be supposed strictly true, that so many arrows were thrown at them as to bury them; but having in the former part of the sentence represented their resolute defence in the strongest terms, by saying, that naked and without arms, they engaged armed men with their hands and teeth, the following hyperbole seems not unnatural, and to intimate nothing more than what was necessary to quell such obstinate resolution and courage.

As to *figures*, whether verbal or those which consist in the sense, the nature of this character will easily direct to such as are most proper. But with respect to the latter, poets take greater liberties in the use of them than would be allowed in an orator. As their images are often formed for pleasure and delight, so they carry in them more of rapture and transport. But the orator's use of them being to set things in a stronger and clearer light, they are more sedate and moderate. Besides, an orator scarce ever has occasion for such fictitious images as we often meet with in poetry; though his ought to appear as natural, and its painting as strong and lively. We shall just mention some of the chief of those figures which seem best suited for this purpose; though they are no less suited to the middle style, as has been shown already, when taken from subjects of an inferior nature.

116 1. *Description.* Of this Justin gives us a fine instance, in a speech of King Philip of Macedon, wherein he represents the necessity of falling upon the Romans, who at that time were engaged in a war with Hannibal. "I behold (says he) a cloud of a most dreadful and bloody war rising in Italy. I see a storm of thunder and lightning from the west, which will overspread all places with a vast shower of blood, into whatever country the tempest of victory shall drive it. Greece has undergone many violent shocks in the Persian, Gallic, and Macedonian wars; but these would all be found unworthy of regard, if the armies now engaged in Italy should march out of that country. I view the terrible and cruel wars which involve these nations through the courage of their forces, and skill of their generals. This rage and fury cannot cease by the destruction of one party, without the ruin of their neighbours. Indeed, Macedon has less reason to dread the savage conquerors than Greece; because more prepared, and better able to defend itself; but I am sensible, those who attack each other so impetuously will not confine their victories within those bounds, and that it will be our lot to engage the conquerors." So lively a picture of imminent and threatening danger must needs alarm the most timorous, and excite them to a resolution to defend their country, and all that was dear to them. Such images give life and vigour to a discourse, and being artfully interwoven with proper arguments, influence the mind, and carry it away by an irresistible force, so that the hearer is not barely left to conclude the certainty of the thing, but moved by it, as it were, from ocular demonstration. The images therefore of the orator ought to be drawn from real things, or at least such as are probable; for if they are wholly fictitious and incredible, as many poetical images are, they may give pleasure, but will not convince the mind, nor sway the passions.

2. *Enumeration* has some affinity with the former 117
figure; by which, if the several parts have each something grand in them, the whole, when brought together, and disposed in a just order, very much contributes to the sublimity. We shall produce an example of this from an English writer, containing a description of our globe, upon a survey of it after the general conflagration, which he represents in this strong light: "Such is the vanity and transient glory of this habitable world! By the force of one element breaking loose upon the rest, all the varieties of nature, all the works of art, all the labours of man, are reduced to nothing; all that we admired and loved before, as great and magnificent, is obliterated and vanished, and another form and face of things, plain, simple, and everywhere the same, overspreads the whole earth. Where are now the great empires of the world, and their great imperial cities? their pillars, trophies, and monuments of glory? Show me where they stood, read the inscription, tell me the victor's name. What remains, what impressions, what difference or distinction, do you see in this mass of fire? Rome itself, eternal Rome, the great city, the empress of the world, whose domination or superstition, ancient or modern, make a great part of the history of the earth, what is become of her now? She laid her foundations deep, and her palaces were strong and sumptuous; *she glorified herself, and lived deliciously, and said in her heart I sit a queen, and shall see no sorrow:* but her hour is come, she is wiped away from the face of the earth, and buried in everlasting oblivion. But it is not cities only, and the works of men's hands; the everlasting hills, the mountains and rocks of the earth, are melted as wax before the sun, *and their place is nowhere found.* Here stood the Alps, the load of the earth, that covered many countries, and reached their arms from the ocean to the Black sea. This huge mass of stone is softened and dissolved, as a tender cloud into rain. Here stood the African mountains, and Atlas with his top above the clouds. There was frozen Caucasus, and Taurus, and Imaus, and the mountains of Asia; and yonder, towards the north, stood the Riphean hills, clothed in ice and snow; all these are vanished, dropped away as the snow upon their

Elocution. their heads *." These particulars considered separately are all truly great and noble, and every way suited to the nature of the subject; but as they are here disposed, and rise in order, they both enlarge the idea, and heighten the image of that grand catastrophe.

* Burnet's Theory.

118 3. *Similitude:* which serves very much for beauty and ornament; and, when taken from great and sublime objects, adds a grandeur and magnificence to the things illustrated by it. We need go no farther for an example of this, than to the great critic so often mentioned already, who has treated upon the sublime in a style every way equal to the subject. He, then, comparing those two great works of Homer, his Iliad and Odyssey, thus describes them: "Homer composed his Iliad when his mind was in its full strength and vigour: the whole body of the poem is dramatic, and full of action: whereas the best part of the Odyssey is taken up in narrations, which seem to be the genius of old age. So that one may compare him in this latter work to the setting sun, which still appears with the same magnificence, but has no longer the same heat and force." And soon after, speaking of the Odyssey, he says, "That piece may be called, the reflux of his genius, which like the ocean ebbs, and deserts its shores." What nobler idea could possibly have been given of that great poet, than by those two similitudes of the sun and the ocean? And elsewhere, comparing those two great orators Demosthenes and Cicero, he shows the like sublimity of thought. "Demosthenes (says he) is sublime, in that he is close and concise; Cicero, in that he is diffuse and extensive. The former, by reason of the violence, rapidity, strength, and fury, with which he rages and bears all before him, may be compared to a tempest, and thunder; but the latter, like a great conflagration, devours and consumes all he meets, with a fire that is never extinguished, but wherever it advances continually gathers new strength."

119 4. *Antithesis,* or a sentence consisting of opposite parts, has often the same effect; as in the following instance of Cicero, where his view is to represent Pompey as a most consummate general. "Who (says he) ever was, or need be more knowing than this man? who from his childhood, and instruction at school, went into the army of his father, and learned the military art, in a very great war against the fiercest enemics: who, while yet a boy, became a soldier under the greatest general; and when but a youth was himself commander of a very great army: who has oftener engaged with the enemy in battle, than any other person with his adversary in private contests: has waged more wars than others have read, and conquered more provinces than others have wished to govern: whose youth has been spent in acquiring the art of war, not by the precepts of others, but his own commands; not by defeats, but victories; not by campaigns but triumphs."

120 5. *Apostrophe.* Among the articles charged against Demosthenes by his great adversary and rival Æschines, one was, that he had advised the Athenians to engage in a war against King Philip, wherein they had received a very great defeat. When Demosthenes comes to answer that part of the charge, he does not say, as he might, "You have not been misled, my fellow-citizens, in exposing your lives for the liberties and safety of Greece; you are not without the most illustrious examples of such conduct; for who can say these great men were misled, who fought for the same cause in the plains of Marathon?" But instead of expressing himself thus, he gives the matter quite a different turn; and in a sort of rapture, appealing to those brave defenders of their country, says, "No, my fellow-citizens, you have not done wrong, you have not; I protest by the ghosts of those great men who fought for the same cause in the plains of Marathon." By this appeal to those ancient worthies whose memories were in the highest esteem at Athens, that it was the cause, and not the success, which rendered their actions so glorious, he artfully corroborates his assertion in a way which he knew must have the greatest weight with his audience.

As the proper subjects of this character are either divine things, or such as are in the highest esteem and regard among mankind, which often require laudatory discourses, or panegyric; these naturally admit of all the ornaments and assistance of eloquence. Which, however, must be used with discretion; for when the mind is wrapt up in thought, and stretched to the utmost of its powers in the pursuit of some noble and sublime idea, it cannot attend to all the lesser fineries and niceties of language; but from its own vigour, and lively conception of things, will be led to express them in terms the most emphatical, and best suited to their nature. In such cases, therefore, the sublimity must appear rather from the elevation of the thought, attended with a simplicity of expression, than from the ornaments and dress of the language. These things seem more natural when the mind is relaxed, and employed upon lower objects. Though, upon the whole, grandeur and majesty of expression is the proper mark of this character with relation to the language, as beauty and splendour is of the middle style.

Chap. VIII. *Of the Style of an Orator.*

121 The *low*, *middle*, and *sublime* style requisite for an orator.

The style of an orator comprehends all the characters already explained, of *low*, *middle*, and *sublime*, as they are applied by him in the different parts of his province. For that the language must be suited to the nature of the subject, we have had occasion often to observe already; and the different view of the speaker or writer necessarily occasions a variety in the manner of expression. Now an orator has three things in his view; to prove what he asserts, to represent it in an agreeable light, and to move the passions. These are all necessary, we do not mean in the order wherein we have now mentioned them, but that the discourse may upon the whole have its desired effect upon the audience. For unless the mind be convinced of the truth of what is offered by solid and cogent arguments, neither will the most eloquent discourse afford a lasting pleasure, nor the most pathetic long influence the affections. Though, on the other hand, the hearers expect to be entertained at the same time they are informed; and, therefore, unless the language be agreeable to their taste, they will soon call off their attention, and think but meanly of the speaker. And unless both these are warmed and animated by a becoming pathos, the speaker may very probably miss of his end in bringing his audience over

Elocution. over to his sentiments. For bare conviction is not sufficient with many persons to excite them to action. They will acquiesce in the truth of a thing which they cannot contradict, or will not give themselves the trouble to examine; and at the same time remain unconcerned to prosecute it. And the pleasure of a florid discourse will of itself soon vanish, like the harmony of music, or the charms of a fine poem. And therefore to captivate his audience, secure them in his interest, and push them upon action, it is necessary for the orator to engage their affections: these are, as it were, the springs of the soul, which, managed by a skilful hand, move and direct it at pleasure. Now each of these parts of an orator's province requires a different style. The *low style* is most proper for proof and information; because he has no other view here but to represent things to the mind in the plainest light, as they really are in themselves, without colouring or ornament. The *middle style* is most suited for pleasure and entertainment, because it consists of smooth and well-turned periods, harmonious numbers, with florid and bright figures. But the *sublime* is necessary in order to sway and influence the passions. Here the orator calls in all the assistance both of nature and art; the most raised and lofty thoughts, clothed with the brightest and strongest colouring, enter into this character.

But as an orator has frequently each of these views in the same discourse, we shall first give a summary description of the several characters of style, which we have formerly discoursed on more at large; that, by placing them together in one view, the difference between them may be more plain and obvious: and then we shall proceed to show to what particular parts of a discourse each of them is more especially to be applied.

I. First, then, as shorter periods are proper in the *low style*, so less care is necessary in their turn and cadency. If a sentence now and then drop unexpectedly and disappoint the ear, or has something rough and harsh in its composition, it is no blemish in this character. For as it is suited to the manner of common discourse, an appearance of regard to the subject rather than the form of expression, is more becoming than any beauties of art. But the words should be well chosen and proper, suited to the ideas they are designed to convey; the expressions plain and clear, and the artificial ornaments few and modest. By *artificial ornaments*, are here meant *tropes* and *figures*; and they are called *artificial*, because they vary from the natural dress of language, either in the words or manner of expression: though they are often used by those who are wholly unacquainted with the rules of art; and particularly metaphors, which persons who have the least command of language frequently run into through mere necessity, for want of a sufficient stock of proper words to convey their ideas. The low style therefore admits of these: but care should be taken to choose such as have been rendered familiar by use, or at least where the similitude is very plain and evident. Bold or lofty metaphors, or where the allusion is dark and remote, ought to be avoided. Nor is the moderate use of the other tropes wholly disagreeable to this style. And the same thing is to be said with respect to verbal figures, or such as consist in the particular disposition of the sentence, so that if the form of it be changed, the figure is lost. Of these, such as come nearest to the natural way of expression are most proper for this style; and therefore those which consist in a jingle of words, arising from the same or like sound, are to be avoided, as carrying in them too much the appearance of art. Those likewise which consist in a repetition of the same word have often too great a force and vehemence for this mild and gentle character. And as to figures of sentences, which do not depend on the construction of words, but lie in the sense, many of them are too gay and sprightly, and others too rapid and impetuous, for the simplicity of the low style; so that only the more moderate and sedate ones are to be allowed a place here. It is therefore no wonder if persons are often mistaken in their notions of this character: the beauty of which consisting in a certain plainness and simplicity, without any thing in it but what seems natural and common, every one is apt to imagine he can readily be master of it, till by experience he finds the contrary. For the case is much the same here, as in persons of fashion and good breeding, whose behaviour and address is attended with that agreeable freedom and seeming negligence, which in appearance is very easy to express, but in reality is scarce imitable by others.

As the *middle style* is more adapted for pleasure and delight, it admits of all those beauties and ornaments which soothe and entertain the mind. It has more force and energy than the low style, but less than the sublime. Smooth and harmonious numbers, well turned periods, of a just length, delightful cadency, and accurate disposition of the words, are suited to this style. The most beautiful and shining tropes, which strike the fancy, and all those verbal figures which, by a repetition, similitude, or proportion of sounds, please and gratify the ear, help to form this character. The like is to be said as to figures of sentences: The most florid and beautiful, such as enumeration, description, similitude, and the like, are here the most proper.

But it is the *sublime style* which perfects the orator. This requires the most forcible and emphatical words, the boldest metaphors and strongest figures. In verbal figures, repetitions, synonyms, gradations, contraries, with others of a like force and energy, are chiefly employed here. But figures of sentences are the most considerable, and principally contribute to make up this character. Among these are similies taken from lofty subjects, prosopopœia, apostrophe, exclamation, epiphonema, aposiopesis, and others of a like nature. But due care must likewise be taken of the form, construction, and harmony of the periods; which seem best disposed, when long and short ones are intermixed. For though round and swelling periods carry in them something grand and majestic, yet many times they move too slow to strike the passions; whereas short ones are more acute and pungent, and by returning quick, awaken the mind, and raise the passions. But to render it complete, it must be supported with strong reason, grandeur of thought, and sentiments every way equal to the expression; without which it will be very liable to swell into bombast, and end barely in amusement.

II. Having given a short sketch of this part of the orator's furniture, we shall now go on to show where, and in what manner, he is to make use of it. This will

Elocution. will best appear by considering his principal view in each part of his discourse. Now the parts of a just oration (as we have formerly shown) are six; *Introduction*, *Narration*, *Proposition*, *Confirmation*, *Confutation*, and *Conclusion*. Not that all these are necessary in every discourse, but it is proper they should all be mentioned, that we may consider what style is fittest for them when they are necessary.

122 In the *Introduction*, the orator has three things before him; to gain the esteem of his hearers, to secure their attention, and to give them some general notion of his subject. To set out modestly is undoubtedly the most likely way to recommend himself. For to attempt to inflame an audience, before they are prepared for it, or see the reason of much warmth, is highly improper. A prudent speaker will, like Demosthenes, begin with temper, and rise gradually, till he has insensibly warmed his hearers, and in some degree engaged their affections in his favour. So that this part scarcely rises above the middle style. And if it carry in it an air of pleasantry and good-humour, it is generally the more apt to engage the attention.

123 The introduction is usually followed by the *narration*, or a recital of such things as either preceded, accompanied, or followed upon the subject under consideration. Now, as the qualities that recommend a narration are clearness, brevity, and probability; these sufficiently point out the style. Perspicuity arises from the choice of proper words, and such tropes as have been rendered most familiar by use; brevity requires moderate periods, whose parts are but little transposed; and a plain and simple dress, without ornament or colouring, is best suited to represent things probable: all which are the properties of the low style. And therefore Cicero says, *narrations come pretty near to our ordinary discourse*. Indeed, sometimes it is necessary not only to relate the facts themselves, but likewise to describe the manner in which they were performed. And then a further degree of art may be requisite to represent them with all their circumstances, and paint them to the mind in their proper colours.

124 The next part in order is the *proposition*, or subject of the discourse in which there can be no room for ornament. But as it is the basis and foundation of the orator's whole design, it ought to be laid down in the plainest and clearest terms, so as to leave no room for doubt or uncertainty what it is which he intends to discourse upon.

125 The next thing is *confirmation*, wherein the orator endeavours to maintain and defend his own cause, and to convince his hearers of the truth of it by reason and argument. Now the low style is certainly fittest for cool reasoning and debate. But the orator's method of reasoning often very much differs from that of the philosopher. The latter contents himself with the most plain and familiar manner of representing the truth, and thinks it sufficient if what he says be clearly understood. But the former, at the same time that he convinces the judgment, endeavours likewise to affect the passions, and that in a great variety of ways. So that in this part of the discourse the style is very different, according to the nature and circumstances of the case. Sometimes, while he is dwelling upon the proof of a thing, he talks coolly, and reasons with the sedateness of a philosopher; and where any part of his argument appears doubtful or obscure, he endeavours with the same even temper to explain and clear it up. But frequently he intermixes with his proofs all the arts of persuasion, and embellishes his reasons with the greatest ornaments and beauties of eloquence.

Confirmation is usually followed by *confutation*, in which the orator endeavours to enervate and overthrow all that has been advanced in favour of the opposite side of the question. But as the style is much the same here as in the former part, what has been said upon that may be sufficient for this likewise. 126

The last part above mentioned is the *conclusion*. This consists of two branches, *recapitulation*, and *address*. Recapitulation is a short recital of the several arguments, at the least the chief of them, which were before advanced in support of the cause; that, being brought together into a narrow compass, they may appear in a stronger light. Wherefore the language here ought rather to be forcible and strong than florid, because brevity and conciseness is a necessary quality. The other branch of the conclusion consists in an address to the passions, and is wholly persuasive; for which the speaker is now entirely at leisure. Indeed, this is often done occasionally in other parts of the discourse, particularly in the introduction and confirmation: But, as in the former of these, his view is principally to secure the good opinion of the hearers, and excite their attention; and in the latter to defend his own side of the question by reason and argument; when these two points are gained, he has nothing left but to prevail with them to fall in with his design, and declare for him. And the best way to attain this is, by engaging their passions in his interest. Hence, then, to use Quintilian's words, "All the springs of eloquence are to be opened. Now we are past the rocks and shallows, all the sails may be hoisted. And as the greatest part of the conclusion consists in illustration, the most pompous language and strongest figures have place here." 127

All the variety above mentioned, however, is not always necessary. Regard must be had to the nature of the subject, the time, place, persons, and other circumstances; by all which the style is to be regulated. To discourse in a lofty and grand way upon a common topic, or in a low and flat manner upon a sublime argument, are both equally injudicious. Cicero refers us to some discourses of his own, as instances of each kind. His oration for Cæcina, he says, is written in the low style, that for the Manilian law in the middle style, and that for Rabirius in the sublime; and his Actions against Verres, with some others, are patterns of the variety here mentioned. And he gives us a very comprehensive description of a perfect orator in very few words, when he says, "He is one who can speak upon a low subject acutely, upon a lofty subject with sublimity, and upon a moderate subject temperately." By which he means no more, than one who is master of the three characters here described, and knows when and how to use them. But although he mentions several among the Greeks, and some few among the Romans, who excelled in one or other of these different kinds; yet one who excelled in them all, he supposes never to have existed, except in the imagination. The reason perhaps

Pronunciation.

perhaps may be, because each of them seems to require a very different genius, so that it is scarce possible for the same person to succeed in them all. Since therefore it is so rare and difficult a matter to gain the command of each in any good degree, it is better perhaps for every one to pursue that which nature seems most inclined to, and to excel in it, than to strive against their genius. For every kind has its perfections; and it is more commendable to be master of one thing, than to do several but indifferently.

PART IV. OF PRONUNCIATION.

CHAP. I. *Of Pronunciation in general.*

128 Pronunciation a conformity of the voice and gesture to the subject.

PRONUNCIATION is also called *Action* by some of the ancients. Though, if we attend to the proper signification of each of these words, the former respects the voice, and the latter the gestures and motions of the body. But if we consider them as synonymous terms, in this large sense pronunciation or action may be said to be *a suitable conformity of the voice, and the several motions of the body, in speaking, to the subject matter of the discourse.*

The best judges among the ancients have represented this as the principal part of an orator's province, from whence he is chiefly to expect success in the art of persuasion. When Cicero, in the person of Crassus, has largely and elegantly discoursed upon all the other parts of oratory, coming at last to speak of this, he says: "All the former have their effect as they are pronounced. It is the action alone that governs in speaking; without which the best orator is of no value, and is often defeated by one in other respects much his inferior." And he lets us know, that Demosthenes was of the same opinion, who, when he was asked what was the principal thing in oratory, replied, action; and being asked again a second and a third time, what was next considerable, he still made the same answer. By which he seemed to intimate, that he thought the whole art did in a manner consist in it. And indeed, if he had not judged this highly necessary for an orator, he would scarce have taken so much pains in correcting those natural defects, under which he laboured at first, in order to acquire it. For he had both a weak voice, and likewise an impediment in his speech, so that he could not pronounce distinctly some particular letters. The former of which defects he conquered, partly by speaking as loud as he could upon the shore, when the sea roared and was boisterous; and partly by pronouncing long periods as he walked up hill; both of which methods contributed to the strengthening of his voice. And he found means to render his pronunciation more clear and articulate, by the help of some little stones put under his tongue. Nor was he less careful in endeavouring to gain the habit of a becoming and decent gesture; for which purpose he used to pronounce his discourses alone before a large glass. And because he had got an ill custom of drawing up his shoulders when he spoke; to amend that, he used to place them under a sword, which hung over him with the point downward. Such pains did this prince of the Grecian orators take to remove those difficulties, which would have been sufficient to discourage an inferior and less aspiring genius. And to how great a perfection he arrived in his action, under all these disadvantages, by his indefatigable diligence and application, is evident from the confession of his great adversary and rival in oratory, Æschines. Who, when he could not bear the disgrace of being worsted by Demosthenes in the cause of Ctesiphon, retired to Rhodes. And being desired by the inhabitants to recite to them his own oration upon that occasion, which accordingly he did; the next day they requested of him to let them hear that of Demosthenes; which having pronounced in a most graceful manner, to the admiration of all who were present, "How much more (says he) would you have wondered if you had heard him speak it himself!" By which he plainly gave Demosthenes the preference in that respect. We might add to these authorities the judgment of Quintilian, who says, that "it is not of so much moment what our compositions are, as how they are pronounced; since it is the manner of the delivery by which the audience is moved." And therefore he ventures to assert, that "an indifferent discourse, assisted by a lively and graceful action, will have greater efficacy than the finest harangue which wants that advantage."

The truth of this sentiment of the ancients concerning the power and efficacy of pronunciation, might be proved from many instances; but one or two may here suffice. Hortensius, a contemporary with Cicero, and while living next to him in reputation as an orator, was highly applauded for his action. But his orations after his death, as Quintilian tells us (for we have none of them now remaining), did not appear answerable to his character; from whence he justly concludes, there must have been something pleasing when he spoke by which he gained his character, which was lost in reading them. But perhaps there is scarce a more considerable instance of this than in Cicero himself. After the death of Pompey, when Cæsar got the government into his own hands, many of his acquaintance interceded with him in behalf of their relations and friends, who had been of the contrary party in the late wars. Among others, Cicero solicited for his friend Ligarius; which Tubero understanding, who owed Ligarius a grudge, he opposed it, and undertook to represent him to Cæsar as unworthy of his mercy. Cæsar himself was prejudiced against Ligarius; and therefore, when the cause was to come before him, he said, "We may venture to hear Cicero display his eloquence; for I know the person he pleads for to be an ill man, and my enemy." But, however, in the course of his oration, Cicero so worked upon his passions, that by the frequent alteration of his countenance, the emotions of his mind were very conspicuous. And when he came to touch upon the battle of Pharsalia, which had given Cæsar the empire of the world, he represented it in that moving and lively a manner, that Cæsar could no longer contain himself, but was thrown into such a fit of shivering, that he dropped the papers which

Pronunciation

which he held in his hand. This was the more remarkable, because Cæsar was himself one of the greatest orators of that age, knew all the arts of address, and avenues to the passions, and consequently was better prepared to guard against them. But neither his skill, nor resolution of mind, was of sufficient force against the power of oratory; but the conqueror of the world became a conquest to the charms of Cicero's eloquence; so that, contrary to his intention, he gave into his plea, and pardoned Ligarius. Now that oration is still extant, and appears exceedingly well calculated to touch the soft and tender passions and springs of the soul; but we believe it can scarce be discernible to any in reading it, how it should have had so surprising an effect; which must therefore have been chiefly owing to the wonderful address and conduct of the speaker.

The more natural the pronunciation is, it will of consequence be the more moving, since the perfection of art consists in its nearest resemblance to nature. And therefore it is not without good reason, that the ancients make it one qualification of an orator, that he be a good man; because a person of this character will make the cause he espouses his own, and the more sensibly he is touched with it himself, his action will be the more natural, and by that means the more easily affect others in the same manner. Cicero, speaking upon this subject, says, "It is certain that truth (by which he means nature) in every thing excels imitation; but if that was sufficient of itself in action, we should have no occasion for art." In his opinion therefore (and who was ever a better judge), art, in this case as well as in many others, if well managed, will assist and improve nature. But that is not all; for sometimes we find the force of it so great and powerful, that, where it is only counterfeit, it will for the time work the same effect as if it was founded in truth. This is well known to those who have been conversant with the representations of the theatre. In tragedies, though we are sensible that every thing we see and hear is feigned and counterfeit, yet such is the power of action, that we are oftentimes affected by it in the same manner as if they were all realities. Anger and resentment at the appearance of cruelty, concern and solicitude for distressed virtue, rise in our breasts; and tears are extorted from us for oppressed innocence, though at the same time, perhaps, we are ready to laugh at ourselves for being this decoyed. If art then has so great an influence upon us, when supported only by fancy and imagination, how powerful must be the effect of a just and lively representation of what we knew to be true and real?

How agreeable it is both to nature and reason, that a warmth of expression and vehemency of motion should rise in proportion to the importance of the subject and concern of the speaker, will further appear, by looking back a little into the more early and simple ages of the world. For the higher we go, the more we shall find of both. We shall give the observation of a very great man upon this head, in his own words. "The Romans (says he) had a very great talent this way, and the Greeks a greater. The eastern nations excelled in it, and particularly the Hebrews. Nothing can equal the strength and vivacity of the figures they employed in their discourse: and the very actions they used to express their sentiments, such as putting ashes on their heads, and tearing their garments, and covering themselves with sackcloth under any deep distress and sorrow of mind. I do not speak of what the prophets did to give a more lively representation of the things they foretold, because such figurative actions were the effect of divine inspiration. But even in other cases we find those people understood much better than we do how to express their grief, and fear, and other passions. And hence, no doubt, arose those surprising effects of eloquence, which we never experience now." Thus far this excellent writer. And what he says here with respect to the actions of the eastern nations, was in a good measure customary among the Greeks and Romans; if not entirely of the same kind, yet perhaps as vehement and expressive. They did not think language of itself sufficient to express the height of their passions, unless enforced by uncommon motions and gestures. Thus, when Achilles had driven the Trojans into their city with the greatest precipitation and terror, and only Hector ventured to tarry without the gates to engage him; Homer represents both King Priam and his queen under the highest consternation for the danger of their son. And therefore, in order to prevail with him to come into the city, and not fight with Achilles, they not only intreat him from the walls in the most tender and moving language imaginable; but he tears off his grey locks with his hands; and she, in a flood of tears, exposes her breasts, and adjures him by these paps which suckled him, to comply with their request. The poet knew very well, that no words of themselves could represent those agonies of mind he endeavoured to convey, unless heightened by the idea of such actions as were expressive of the deepest sorrow. And indeed this was anciently esteemed so requisite in an orator, that in matters of importance he was scarce thought to be in earnest who wanted it. In one of Cicero's orations, he does not stick to argue in that manner with his adversary. "Would you talk thus (says he) if you was serious? Would you, who are wont to display your eloquence so warmly in the danger of others, act so coldly in your own? Where is that concern, that ardour, which used to extort pity even from children? Here is no emotion either of mind or body: neither the forehead struck, nor the thigh, nor so much as a stamp of the foot. Therefore, you have been so far from inflaming our minds, that you have scarce kept us awake."

Dial. of Eloquence, p. 92.

As action therefore was judged so necessarily a qualification in an orator among the ancients, so they made use of several methods and expedients for the better attaining it. The principal of which we shall briefly mention.

Decency of pronunciation is a habit. And as all habits are gained by time, so the sooner they are learned, they are generally acquired with greater ease. For while persons are young, they are not only more flexible and capable of any particular bent, but they are likewise free from the trouble of encountering and subduing contrary habits, which doubles the labour, and increases the difficulty of attaining any laudable quality. Quintilian was very sensible of this in the case here before us; and therefore, in order to have persons trained up to it, he begins with them in their childhood, and descends so low as even to give directions how they should be taught to pronounce when they first learn to read. And he advises, that they should then be instructed where to suspend their voice, and make the proper pauses, Pronunciation. ses, both in distinguishing the several parts of the same sentence, and in separating one sentence from another; likewise when to raise or sink their voice, or give it a proper inflection; to be slower or faster, more vehement or sedate, as the nature of the things may require; and that the tone of their voice be always manly and grave, but at the same time mixed with an agreeable sweetness. These things may perhaps appear in themselves small; but if duly attended to, they will be found of considerable service to bring us to a just and proper pronunciation. For in every thing that is to be attained by practice, it is a great advantage to set out right at first.

The ancients likewise had persons whom they called *phonasci*, whose proper business it was to teach them how to regulate and manage their voice; and others, who instructed them in the whole art of pronunciation, both as to their voice and gestures. These latter were generally taken from the theatre, being some eminent experienced actors. So Quintilian, treating of the province of these persons, says, "The comedian ought to teach them how to relate facts, with what authority to advise, with what vehemence to express anger, and with what softness compassion." And speaking of gestures, he says, "He should admonish them to raise their countenance, not distort their lips, or stretch their mouths." With several other directions of the like kind. And we are told concerning the emperor M. Antoninus, usually called the philosopher, that *His first masters were Euphorio the grammarian, and Geminus the comedian.*

But though they made use of actors to instruct their youth in forming their speech and gestures, yet the action of an orator was much different from that of the theatre. Cicero very plainly represents this distinction in the words of Crassus, when, speaking of orators, he says, "The motions of the body ought to be suited to the expressions, not in a theatrical way, mimicking the words by particular gesticulations, but in a manner expressive of the general sense, with a sedate and manly inflection of the sides; not taken from the stage and actors, but from the exercise of arms and the palestra." And Quintilian says to the same purpose, "Every gesture and motion of the comedians is not to be imitated, nor to the same degree." They thought the action of the theatre too light and extravagant for the imitation of an orator; and, therefore, though they employed actors to inform young persons in the first rudiments, yet they were afterwards sent to the palestra, or schools designed on purpose, to teach them a decent and graceful management of their bodies. And such schools, as Quintilian informs us, were in use both among the Greeks and Romans: Just as of later ages children learn to dance, in some measure with the same intention.

Being thus far prepared, they were afterwards sent to the schools of the rhetoricians. And here, as their business was to cultivate their style, and gain the whole art of eloquence; so particularly to acquire a just and accurate pronunciation by those exercises, in which for that end they were constantly employed. And as the Greeks were most celebrated for their skill in all the polite arts, and especially oratory; the Roman gentry and nobility generally sent their sons abroad, and placed them under the tuition of some Grecian master, to instruct them in the art of speaking, and by that means to fit them for the service of their country, either in the courts of judicature or the senate. Thus Cicero was sent to Rhodes, to study under the famous Molo, and Brutus under Pammenes; Cæsar was going to the same place when taken by pirates; and Augustus afterwards studied there under Apollodorus.

Nor, after all this pains and industry, did they yet think themselves sufficiently qualified to take upon them the character of orators. But it was their constant custom to get together some of their friends and acquaintance who were proper judges of such performances, and declaim before them in private. The business of these persons was to make observations both on their language and pronunciation. And they were allowed the greatest freedom to take notice of any thing they thought amiss, either as to inaccuracy of method, impropriety of style, or indecency of their voice or actions. This gave them an opportunity to correct any such defects at first, before they became habitual. What effects might not justly be expected from such an institution! Persons trained up in this manner, with all those advantages, joined to a good natural genius, could not fail of making very complete orators. Though even after they came to appear in public, they did not lay aside the custom of declaiming. For Quintilian tells us, that *C. Carbo used to practise it daily in his tent.* And Augustus is reported to have continued it during the war of Mutina against M. Antony. Nor is it to be supposed, that so constant an attendance to this practice was only serviceable to them in their public performances; but it must necessarily affect their whole conduct, give them a freedom of speech, easiness of address and behaviour, and render them in all respects fine gentlemen as well as excellent orators. And from hence, perhaps, we may see less reason to wonder at the surprising effects of some of their discourses, when we consider what pains they took to arrive at those abilities.

Having thus far treated on pronunciation in general, we shall now proceed to consider the parts of it separately; which are *voice* and *gesture*.

Chap. II. *Of the Voice.*

Voice is one kind of sounds. Now the influence of sounds, either to raise or allay our passions, is evident from music. And certainly the harmony of a fine discourse, well and gracefully pronounced, is as capable to move us, if not in a way so violent and ecstatic, yet not less powerful, and more agreeable to our rational faculties. As the business of this chapter is to offer some considerations for the just and decent management of the voice, it may not be improper in the first place to observe in general what nature does when free and unconstrained. As persons are differently affected when they speak; so they naturally alter the tone of their voice, though they do not attend to it. It rises, sinks, and has various inflections given it, according to the present state and disposition of the mind. When the mind is calm and sedate, the voice is moderate and even; when the former is dejected with sorrow, the latter is languid; and when that is inflamed by passion, this is raised and elevated. It is the orator's business, therefore, to follow nature, and to endeavour that the tone of his voice appear natural and unaffected. And for this

119 Voice, a kind of sound which always influences the passions, either by raising or allaying them.

Pronunciation.

this end, he must take care to suit it to the nature of the subject; but still so as to be always grave and decent. Some persons continue a discourse in such a low and drawling manner, that they can scarce be heard by their audience. Others again hurry on in so loud and boisterous a manner, as if they imagined their hearers were deaf. But all the music and harmony of speech lies in the proper temperament of the voice between these extremes. In order to set this matter in a just light, it will be necessary to consider the principal affections or properties of the voice, and how they are to be regulated by an orator. Now these may all be referred either to *quantity* or *quality*.

The *quantity* of the voice consists in its *highness* or *lowness*, *swiftness* or *slowness*, and the intermediate degrees between them.

Every person who speaks in public should endeavour, if he can, to fill the place where he speaks. But still he ought to be careful not to exceed the natural key of his voice. If he does, it will neither be soft nor agreeable, but either harsh and rough, or too shrill and squeaking. Besides, he will not be able to give every syllable its full and distinct sound; which will render what he says obscure, and difficult to be understood. He should therefore take care to keep his voice within reach, so as to have it under management, that he may raise or sink it, or give it any inflection he thinks proper: which it will not be in his power to do if he put a force upon it, and strain it beyond its natural tone.

The like caution is to be used against the contrary extreme, that the voice be not dropped, and suffered to sink too low. This will give the speaker pain in raising it again to its proper pitch, and be no less offensive to the hearers. For though the music of speech consists in the variations of the voice, yet they must be gradual to render them pleasant. Such sudden and great changes at once are rather to be esteemed chasms in speaking than variations. Besides, as they often prevent the hearers from taking in the sense of what is said, it gives them no small uneasiness that they are obliged to stretch their attention. Many persons are too apt to be guilty of this, especially at the end of a sentence, by dropping the last word; which ought, in a particular manner, to be expressed distinctly, because the meaning of the whole sentence often depends upon it.

The medium between these two is a moderate and even voice. But this is not the same in all; that which is moderate in one would be high in another Every person, therefore, must regulate it by the natural key of his own voice. A calm and sedate voice is generally best; as a moderate sound is most pleasing to the ear, if it be clear and distinct. But this equality of the voice must also be accompanied with a variety, otherwise there can be no harmony; since all harmony consists in variety. Nothing is less pleasing than a discourse pronounced throughout in one continued tone of the voice, without any change or alteration. Besides, a variation of the voice is an ease to the speaker; as the body is relieved by shifting its posture. The equality, therefore, we are here speaking of admits a variety of inflections and changes within the same pitch. And when that is altered, the gradations, whether higher or lower, should be so gentle and regular as to preserve a due proportion of the parts and harmony of the whole, which cannot be done when the voice is suddenly varied with too great a distinction. And therefore it should move from one key to another, so as rather to glide like a gentle stream, than pour down like a rapid torrent, as an ingenious writer has well expressed it. An even voice is best fitted to keep the mind to close attention. And therefore, in subjects designed only for instruction, without any address to the passions, there is little room for a variety of voice. For the voice ought to agree with the style; and as upon such subjects this should be equal, moderate, and smooth, so should the other. Every thing, as we say, is beautiful in its season; and there is a certain propriety in things which ought always to be regarded. And, therefore, an affected variety, ill-placed, is as disagreeable to a judicious audience as the want of it, where the subject requires it. We may find some persons, in pronouncing a grave and plain discourse affect as many different tones, changes, and variations of their voice, as if they were acting a comedy; which is doubtless a very great impropriety. But the orator's province is not barely to apply to the mind, but likewise to the passions; which require a great variety of the voice, high, or low, vehement or languid, according to the nature of the passions he designs to affect. So that for an orator always to use the same tone or degree of his voice, and expect to answer all his views by it, would be much the same thing as if a physician should propose to cure all distempers by one medicine. From hence it is evident, that although various inflections and tones of the voice are requisite to make it harmonious and pleasing to the ear; yet the degree of it should differ according to the nature of the subject, and design of the speaker. And, as a perfect monotony is always unpleasant, so it can never be necessary in any discourse.

The next property of the voice above mentioned was *swiftness*. That some expressions ought to be pronounced faster and swifter than others, is very manifest. Gay and sprightly ideas should not only be expressed louder, but also faster, than such as are sad and melancholy. And when we press an adversary, the voice should be brisk and quick. But to hurry on in a precipitant manner, without pausing till stopt for want of breath, is certainly a very great fault. This destroys, not only the necessary distinction between sentence and sentence, but likewise between the several words of the same sentence; nay, and often occasions us to express our words by halves, while one is thrown so fast upon another, that we are not able to give each its full and just sound. By this means all the grace of speaking is lost, and in a great measure the advantage of hearing. For when the ears of the hearers cannot keep pace with the volubility of the speaker's tongue, they will be little the better for what he says. Besides, by not commanding his voice, and easing his breath at the proper pauses and points of distinction, he is often obliged to stop in the middle of a sentence; and so divides what should be continued, and joins what should be separated; which must necessarily destroy the sense, and confound his discourse. Young persons are very liable to this, especially at first setting out. And it often arises from diffidence. They are jealous of their performances, and the success they may have in speaking, which gives them a pain till it is over; and this puts them into a hurry of mind, which incapacitates them from governing their voice, and keeping it under that due

Pronunciation.

due regulation which perhaps they proposed to themselves before they began to speak. And the greater degree such persons have of a native and ingenuous modesty, accompanied with a laudable ambition to excel, they are commonly more exposed to this. For while, on the one hand, they are fired with an ardent desire to recommend themselves, and on the other are fearful of the event, this dubious state of mind is very apt to throw them off their guard, and run them into this excess. From which we may see the great advantage of having the voice well formed betimes; for when once it is become habitual to speak with justness and propriety, persons readily practise it without much attention or concern.

And as a precipitant and hasty pronunciation is culpable, so likewise, on the other hand, it is a fault to speak too slow. This seems to argue a heaviness in the speaker. And as he appears cool himself, he can never expect to warm his hearers, and excite their affections. When not only every word, but every syllable is drawn out to too great a length, the ideas do not come fast enough to keep up the attention without much uneasiness. For till the sense is completed, the mind is in suspense: and, if it be held long in that situation, it will of course flag and grow tired. Indeed, in some cases, it is requisite the pronunciation should be slower than in others; as in representing things great and difficult; or in expressing some particular passions, as admiration or grief. But the extreme we are now speaking of, is a slowness equally continuing through a whole discourse, which must necessarily render it flat and lifeless.

Now, to avoid either of the two extremes last mentioned, the voice ought to be sedate and distinct. And in order to render it distinct, it is necessary, not only that each word and syllable should have its just and full sound, both as to time and accent; but likewise that every sentence, and part of a sentence, should be separated by its proper pause and interval. This is more easy to be done in reading, from the assistance of the points; but it is no less to be attended to in speaking, if we would pronounce in a distinct and graceful manner. For every one should speak in the same manner as he ought to read, if he could arrive at that exactness. Now the common rule given in pausing is, that we stop our voice at a comma till we can tell one, at a semicolon two, at a colon three, and at a full period four. And as these points are either accommodated to the several parts of the same sentence, as the first three; or different sentences, as the last; this occasions the different length of the pause, by which either the dependence of what precedes upon that which follows, or its distinction from it, is represented. And, therefore, in the first three stops, the voice is rather to be suspended in different degrees or measures of time than entirely dropt, to shew that the sense is not yet completed. But between sentence and sentence we respire, and begin anew. So that in long periods, the voice should be favoured by beginning low and sedately, that it may hold to the end without respiration; or if it will not, the breath ought to be recovered without sinking the voice. For if once the voice drop for want of breath before the period be finished, not only the beauty, but likewise the sense of it, will be lost. Quintilian lays a great stress upon a due attention to these pauses; and says, "Though it may appear not so considerable in itself, yet all the other virtues of a good pronunciation are deficient without it."

Hitherto we have considered such properties of the voice as respect *quantity*, we come now to speak of its *qualities*. And the chief of these are *strength* or *weakness*, *clearness* or *obscureness*, *fulness* or *smallness*, *smoothness* or *roughness*. Now, one half of these is what every one would willingly choose, as he would wish to be free from the others. But it is not in our power to give ourselves what qualities of the voice we please; but only to make the best use we can of what nature has bestowed upon us. However, several defects of the voice are capable of being helped by care and proper means; as, on the other hand, the best voice may be greatly hurt by ill management and indiscretion. Temperance is a great preservative of the voice, and all excess is highly prejudicial to it. The voice must necessarily suffer, if the organs of speech have not their proper tone. And in order to their having this, they must be kept in due temperature; that is, they must neither be too moist nor too dry. If they abound with fluids, these will obstruct the clearness of the voice, and render it obscure and confused; and if they are parched with drought, the voice will be harsh and rough. Now all excesses, as well as some bodily indispositions, are apt to affect the organs one or other of these ways.

A strong voice is very serviceable to an orator, because if it want some other advantages, he is, however, capable to make himself heard. And if at any time he is forced to strain it, he is in less danger of its failing him before he has finished his discourse. But he who has a weak voice, should be very careful not to strain it, especially at first. He ought to begin low, and rise gradually to such a pitch as the key of his voice will well carry him, without being obliged to sink again afterwards. Frequent inflections of the voice will likewise be some assistance to him. But especially he should take care to speak deliberately, and ease his voice, by allowing due time for respiration at all the proper pauses. It is an extreme much less inconvenient for such a person rather to speak too slow, than too fast. But this defect of a weak voice is sometimes capable of being helped by the use of proper methods; as is evident from the instance of Demosthenes, before mentioned.

A voice is said to be *clear*, when the organs of speech are suited to give every single letter, and all the combinations of them in syllables and words, their proper and distinct sound. Such a voice is very pleasing and agreeable to the hearers; and no less an happiness to the speaker, as it saves him a great expence of spirits. For a moderate voice, if clear, will be as distinctly heard, as one much louder, if thick and obscure. Which is a great advantage to the speaker, because he can better keep his voice under command, and modulate it at pleasure, as the several parts and circumstances of his discourse may require. On the contrary, an obscure and confused voice is not always occasioned from a deficiency in the organ; but many times is the effect of custom and a bad habit. Some persons, either from want of due care in their education at first, or from inadvertency and negligence afterwards, run into a very irregular and confused manner of expressing their words; either by misplacing the accent, confounding the sound of the letters,

Pronunciation.

letters, or huddling the syllables one upon another, so as to render what they say often unintelligible. Indeed, sometimes this arises from a natural defect, as in the case of Demosthenes; who found a method to rectify that, as well as the weakness of his voice. But in faults of this kind, which proceed from habit, doubtless the most likely way to mend them is to speak deliberately.

A full voice is not the same as a strong or a loud voice. It fills the ear but it is often not pleasant. And therefore to render it so, as well as audible, it should be frequently varied. However, this seems better suited to the character of an orator, than a small and shrill voice; because it has something in it more grave and manly. And those who have the misfortune of a very small voice, should be cautious of raising it to too high a pitch, especially at once; because the sudden compressure of the organ is apt to occasion a squeaking and very disagreeable sound.

A soft and smooth voice is of all the most musical, especially if it be flexible. And, on the contrary, nothing is less harmonious than a voice that is harsh and rough. For the one grates as disagreeably upon the ear, as the other gives it pleasure and delight.

From the consideration of these several properties of the voice, we may conclude that to be the best, and fittest for an orator, which is moderate, distinct, firm, clear, and smooth, and withal easily flexible to the several degrees and variations of sound which every part of the discourse may require.

Chap. III. *Of Gesture.*

130
Gesture is the conformity of the motions of the countenance, &c. to the nature of the discourse.

By this is meant, a suitable conformity of the motions of the countenance, and several parts of the body, in speaking, to the subject-matter of the discourse. The word *gesture* is here used in a larger sense than is ordinarily done in common language. For we rarely make use of that word to denote the motions of the countenance, or any parts of it; but as these make a considerable part of our present subject, they must here be comprehended under this term.

It is not agreed among the learned, whether voice or gesture has the greater influence upon us. But as the latter affects us by the eye, as the former does by the ear, gesture in the nature of it seems to have this advantage, that it conveys the impression more speedily to the mind; for the sight is the quickest of all our senses. Nor is its influence less upon our passions; nay, in some instances it appears to act more powerfully. A cast of the eye shall express desire in as moving a manner as the softest language; and a different motion of it, resentment. To wring the hands, tear the hair, or strike the breast, are all strong indications of sorrow. And he who claps his hand to his sword, throws us into a greater panic than one who only threatens to kill us. Nor is it in some respects less various and extensive than language. Cicero tells us, he often diverted himself by trying this with Roscius the comedian; who could express a sentence as many ways by his gestures, as he himself by words. And some dramas, called *pantomimes*, have been carried on wholly by mutes, who have performed every part by gestures only, without words, in a way very intelligent, as well as entertaining to the spectators. Well, therefore, might Cicero call *action* (or gesture) *the language of the body*, since it is capable in so lively a manner to convey both our ideas and passions. But with respect to oratory, gesture may very properly be called the *second part of pronunciation*; in which, as the voice should be suited to the impressions it receives from the mind, so the several motions of the body ought to be accommodated to the various tones and inflections of the voice. When the voice is even and moderate, little gesture is required; and nothing is more unnatural than violent motion, in discoursing upon ordinary and familiar subjects. The motions of the body should rise therefore in proportion to the vehemence and energy of the expression, as the natural and genuine effect of it.

But as gesture is very different and various as to the manner of it, which depends upon the decent conduct of several parts of the body; it will not be amiss to consider more particularly the proper management of each of those parts. Now all gesture is either natural, or from imitation. By natural gesture we mean such actions and motions of the body, as naturally accompany our words, as these do the impressions of our minds. And these either respect the whole body, or some particular part of it. But before we enter upon this, give us leave just to observe, that it has been customary in all ages and countries, in making a set discourse before an assembly, to do it standing. Thus we read, that *Abraham stood up, and spake unto the children of Heth.* And it seems as if he sat down when he had ended his speech; because, immediately after the account of their answer, it is said again, that *Abraham stood up and bowed himself to the people of the land, the children of Heth.* In like manner Homer represents the Grecian princes, as standing up, when they made a speech, either to the army, or in their councils. So when Achilles has assembled the army, to inquire into the reason of the great plague which at that time raged among them, he rises up before he begins to speak, and sits down again when he has done. After him the prophet Calchas rises, and charges it upon Agamemnon; who rising up in a passion, does not refuse to comply with what Calchas proposed, but expresses his resentment at him for saying it. And upon another occasion both Agamemnon and Nestor do the same in council. And Cicero acquaints us, that when Lentulus had been charged in the senate as an associate with Catiline, he stood up to make his defence. Nor does the advantage of being better heard, seem to have been the only reason for so general an agreement in this posture; but it appears likewise to have been chosen, as the most decent and respectful. Sitting carries in it an air of authority, and is therefore a posture scarce used upon such occasions, unless perhaps where that is designed to be expressed by it. Wherefore it was a thing very much resented, that when Cæsar after he had got the power into his hands, once addressed the senate, either refused to rise, as some say, or as others, one of his friends held him down by his gown.

But though standing appears to be the most proper posture for speaking in public, yet it is very unbecoming for the body to be entirely without any motion like a statue. It should not long continue in the same position, but be constantly changing, though the motion be very moderate. There ought to be no appearance of stiffness, but a certain ease and pliableness, naturally suiting itself to every expression; by which

which means, when a greater degree of motion is necessary, it will appear less sudden and vehement: For as the raising, sinking, and various inflections of the voice must be gradual; so likewise should the motion of the body. It is only on some particular occasions that an hasty vehemence and impetuosity is proper in either case.

As to the several parts of the body, the head is the most considerable. To lift it up too high has the air of arrogance and pride; to stretch it out too far, or throw it back, looks clownish and unmannerly; to hang it downwards on the breast, shows an unmanly bashfulness and want of spirit: and to suffer it to lean on either shoulder, argues both sloth and indolence. Wherefore in calm and sedate discourse it ought to keep its natural state, an upright posture. However, it should not be long without motion, nor yet always moving; but gently turn sometimes on one side, and sometimes on the other, as occasion requires, that the voice may be heard by all who are present; and then return again to its natural position. It should always accompany the other actions of the body, and turn on the same side with them; except when aversion to any thing is expressed, which is done by stretching out the right hand, and turning the head to the left. The ancients erected a statue of Venus in this posture, who was called by the Greeks *αποςροφια*, and by the Latins *Verticordia*, and in English may be termed the *forbidding Venus*. But nothing is more indecent than violent motions and agitations of the head. And therefore when a witty writer, who is well known among us, would convey the most ridiculous idea of a pretender to knowledge, he expresses it thus:

> For having three times shook his head
> To stir his wit up, thus he said. HUDIBRAS.

But it is the countenance that chiefly represents both the passions and disposition of the mind. By this we express love, hatred, joy, sorrow, modesty, and confidence: by this we supplicate, threaten, soothe, invite, forbid, consent, or refuse; and all this without speaking. Nay, from hence we form a judgment not only of a person's present temper, but of his capacity and natural disposition. And therefore it is common to say, *such an one has a promising countenance*, or *that he promises little by his countenance*. It is true, this is no certain rule of judging; nor is it in the power of any one to alter the natural make of his countenance: however, it may put us upon endeavouring to gain the most pleasing aspect we can; since it is so natural for mankind to draw such conclusions from it: and some persons are so unhappy, as to render their countenance more disagreeable, than otherwise it would be, by ill habits.

But the several parts of the face bear their part, and contribute to the proper and decent motion of the whole. In a calm and sedate discourse, all the features retain their natural state and situation. In sorrow, the forehead and eyebrows lower, and the cheeks hang down. But in expressions of joy and cheerfulness, the forehead and eyebrows are expanded, the cheeks contracted, and the corners of the mouth drawn upwards. Anger and resentment contract the forehead, draw the brows together, and thrust out the lips. And terror elevates both the brows and forehead. As these are the natural signs of such passions, the orator should endeavour to conform to them.

But as the eyes are most active and significant, it is the advice of Cicero that the greatest care should be taken in their management. And he gives this reason for it, "Because other parts of the countenance have but few motions; whereas all the passions of the soul are expressed in the eyes, by so many different actions, which cannot possibly be represented by any gestures of the body, if the eyes are kept in a fixed posture. Common experience does in a great measure confirm the truth of this observation. We readily guess at a person's intention, or how he is affected to us, by his eyes. And any sudden change or emotion of the mind is presently followed by an alteration in the look. In speaking therefore upon pleasant and delightful subjects, the eyes are brisk and cheerful; as on the contrary, they sink and are languid in delivering any thing melancholy and sorrowful. This is so agreeable to nature, that before a person speaks, we are prepared with the expectation of one or the other from his different aspect. So likewise in anger, a certain vehemence and intenseness appears in the eyes, which, for want of proper words to express it by, we endeavour to represent by metaphors taken from fire, the most violent and rapid element, and say, in such cases, the *eyes sparkle*, *burn*, or are *inflamed*. In expressions of hatred or detestation, it is natural to alter the look, either by turning the eyes aside, or downwards. Virgil has very justly observed this: for when he describes Æneas meeting with Dido in the Elysian shades, and addressing her, he represents her disregard of him, by saying,

> Disdainfully she look'd; then turning round,
> Still fix'd her eyes unmov'd upon the ground.

She showed her resentment for his former treatment of her, by not vouchsafing to look on him. Indeed, the eyes are sometimes turned downwards upon other occasions, as to express modesty. And if at any time a particular object be addressed to, whatever it be, the eyes should be turned that way. And therefore Philostratus very deservedly ridicules a certain rhetorician as guilty of a solecism in gesture, who, upon saying, *O Jupiter!* turned his eyes downward; and when he said, *O Earth!* looked upward. A staring look has the appearance of giddiness and want of thought; and to contract the eyes, gives suspicion of craft and design. A fixed look may be occasioned from intenseness of thought, but at the same time shows a disregard to the audience; and a too quick and wandering motion of the eyes denotes levity and wantonness. A gentle and moderate motion of the eyes is therefore in common most suitable, always directed to some of the audience, and gradually turning from side to side with an air of respect and modesty, and looking them decently in the face, as in common discourse: Such a behaviour will of course draw an attention. As in conversation, when a person addresses us in an handsome and becoming manner, we presently put ourselves in a posture to give what he says a proper reception. But as all the passions are in the most lively manner expressed in the eyes, their motions ought to vary according to the different nature of these passions they are suited both to discover in the speaker, and convey to his hearers; since, as the quickest access to the mind is by the sight, a proper well-timed look will sometimes

Pronunciation

sometimes sooner effect this than it can be done by words; as in discharging a cannon we are struck with the light before we hear the sound.

As to the other parts of the body distinct from the head, the shoulders ought not to be elevated; for this is not only in itself indecent, but it likewise contracts the neck, and hinders the proper motion of the head. Nor, on the other hand, should they be drawn down, and depressed; because this occasions a stiffness both to the neck and the whole body. Their natural posture therefore is best, as being most easy and graceful. To shrug the shoulders has an abject and servile air; and frequently to heave them upwards and downwards is a very disagreeable sight.

A continued motion of the arms any way, is by all means to be avoided. Their action should generally be very moderate, and follow that of the hands, unless in very pathetic expressions, where it may be proper to give them a more lively spring.

The hands need never be idle. Quintilian seems to think them as necessary and powerful in action, as Cicero does the eyes. "The hands (says he), without which all gesture is lame and weak, have a greater variety of motions than can well be expressed; for they are almost equal to our words. Do not we desire with them, promise, call, dismiss, threaten, beseech, detest, fear, inquire, deny? Do not they express joy, sorrow, doubt, confession, penitence, measure, plenty, number, and time? Do not they excite, restrain, prove, admire, and shame? that in so great a variety of speech among all nations and countries, this seems to me the common language of all mankind." Thus far Quintilian. Now, all bodily motion is either upward or downward, to the right or left, forward or backward, or else circular. The hands are employed by the orator in all these, except the last. And as they ought to correspond with our expressions, so they ought to begin and end with them. In admiration, and addresses to heaven, they must be elevated, but never raised above the eyes; and in speaking of things below us, they are directed downwards. Side motion should generally begin from the left, and terminate gently on the right. In demonstrating, addressing, and on several other occasions, they are moved forward; and in threatening, sometimes thrown back. But when the orator speaks of himself, his right hand should be gently laid on his breast. When no other motion is necessary, the hands should be kept about as high as the breast, so as to make near a right angle with the arm. This is not only graceful, but likewise the most easy posture, and gives the least strain to the muscles. They should never be suffered to hang down, nor to loll upon the cushion or bar. The left hand should never move alone, but accommodate itself to the motions of the right. In motions to the left side, the right hand should not be carried beyond the left shoulder. In promises and expressions of compliment, the motion of the hands should be gentle and slow; but in exhortations and applause more swift. The hands should generally be open; but in expressions of compunction and anger they may be closed. All finical and trifling actions of the fingers ought to be avoided; nor should they be stretched out and expanded in a stiff and rigid posture, but kept easy and pliable.

Neither the breast nor the belly should be thrust out; which in itself looks ungainly, and hinders the free motion of the trunk; which ought not to be kept too stiff and upright, but easy and flexible, always suiting itself to the motions of the head and hands. The feet should continue steady, and not give the body a wavering and giddy motion by frequently shifting; though some persons fall into that habit without moving their feet. Curio, a Roman orator, as Cicero tells us, was addicted to this; which occasioned a friend of his once to pass a joke upon him, by asking, *Who that was talking out of a boat?* The jest is too plain to need explication; for every one knows the waving of a boat will give the body such a motion.

The gestures we have hitherto discoursed of, are such as naturally accompany our expressions. And we believe those we have mentioned, if duly attended to, will be found sufficient to answer all the purposes of our modern pronunciation. The ancients, indeed, used several more vehement actions and gestures than we are accustomed to; as we have formerly shown. Philip the Roman orator, as Cicero informs us, did not use to prepare his discourses; but spoke, as we say, *off-hand.* And he was wont to tell his friends, "he was never fit to talk till he had warmed his arm." He doubtless, therefore, used a more violent motion with his arms and hands than is common with us. And Cicero calls the arm projected *the orator's weapon.* Indeed, to extend or brandish the arm, carries in it an air of command and authority, which was not unbecoming the character of Philip, who was a person of the highest rank and quality. And therefore young orators, both among the Greeks and Romans, for a time used no motion of the arm, but kept it confined in their garment, as an argument of modesty, till age and experience allowed them to use greater freedom. Nor was it uncommon for the ancient orators to express the excess of their passions by tears. They thought nothing unbecoming that was natural: and judged it agreeable to the characters even of the bravest men, to be touched with a sense of humanity in great calamities: And therefore we find both Homer and Virgil make their greatest heroes shed tears on some occasions.

The other sort of gestures above mentioned are such as arise from imitation; as where the orator describes some action, or personates another speaking. But here great care is to be taken not to overact his part, by running into any ludicrous or theatrical mimicry. It is sufficient for him so to represent things of this nature, as may best convey the image of them in a lively manner to the minds of the hearers; without any such change either of his actions or voice as are not suitable to his own character.

Chap. IV. *Some particular Rules for the Voice and Gesture.*

131 Rules for the voice and gesture.

The subject of pronunciation is of so great importance to an orator, that it can neither be too clearly laid down, nor too strongly inculcated. If we inquire into the causes of that surprising power it has over us, and by what means it so strongly affects us, this may in some measure appear by reflecting on the frame and constitution of human nature. For our infinitely wise and great Maker has so formed us, that not only the actions of the body are subject to the direction of the mind, but we are likewise endowed with various passions.

Pronunciation.

passions and affections, that excite us to pursue those things which make for our happiness, and avoid others which are hurtful to us. And as we are made for society, we are also furnished with speech, which enables us to converse with one another. And such is the contrivance of our make, and influence of our minds upon the mechanism of our bodies, that we can not only communicate our thoughts to each other, but likewise our passions. For, as Cicero well observes, "Every motion of the mind has naturally its peculiar countenance, voice, and gesture; and the whole body, every position of the face, and sound of the voice, like the strings of an instrument, act agreeably to the impression they receive from the mind." Nor is this all: but as every one is differently affected himself, he is capable to make the like impressions upon others, and excite them to the same motions which he feels in himself. As when two instruments are set to the same pitch, the strings of the one being touched, produce in the other the like sound. This common sympathy in the human frame shows how necessary it is that an orator should not only in general be well acquainted with the rules of pronunciation, but likewise know how to use them as occasion requires; for a general knowledge of the rules of art is not of itself sufficient to perfect an artist, without a further acquaintance with the particular application of them to their several cases and circumstances. Thus, for instance, it is not enough for an orator to understand all the beauties and ornaments of language, and which of them are suited to form the several kinds of style, unless he can likewise accommodate each of those characters to their proper subject. And so likewise in pronunciation, he ought not only to know the several qualities of the voice, and proper gestures of the body, but also when and where to make use of them. For not only different subjects, but also different parts of the same discourse, and even particular expressions, often require a difference in the manner of pronunciation, both as to the voice and gesture. Having therefore treated on both these parts of pronunciation in general, it may not be amiss now to consider how they are to be applied in each of the two respects last mentioned.

We shall begin with the parts of a discourse, and treat of them in their natural order. And here the view and design of the speaker in each of them will easily help us to see the proper manner of pronunciation.

Let us suppose then a person presenting himself before an assembly, in order to make a discourse to them. It cannot be decent immediately to begin to speak so soon as ever he makes his appearance. He will first settle himself, compose his countenance, and take a respectful view of his audience. This prepares them for silence and attention. To begin presently, and hurry on, without first allowing either himself or his hearers time to compose themselves, looks as if he was rather performing a task than had any design to please them; which will be very apt to make them as uneasy till he has done, as he seems to be himself. Persons commonly form some opinion of a speaker from their first view of him, which prejudices them either in his favour, or otherwise, as to what he says afterwards. A grave and sedate aspect inclines them to think him serious; that he has considered his subject, and may have something to offer worth their attention. A haughty and forbidding air occasions distaste, as it looks like disrespect. A wandering giddy countenance argues levity. A dejected drooping appearance is apt to raise contempt, unless where the subject is melancholy. And a cheerful aspect is a proper prelude to a pleasant and agreeable argument.

To speak low at first has the appearance of modesty, and is best for the voice; which, by rising gradually, will with more ease be carried to any pitch that may be afterwards necessary, without straining it. However, some variation of the voice is always proper to give it an harmony. Nay, and sometimes it is not improper for an orator to set out with a considerable degree of warmth, expressed by such an elevation of the voice, and gestures of the body, as are suited to represent the emotions of his mind. But this is not ordinarily the case. We have some few instances of this in Cicero; as in his oration for Roscius Amerinus, where the heinousness of the charge could not but excite his indignation against the accusers. And so likewise in that against Piso, and the two first against Catiline, which begin in the same manner, from the resentment he had conceived against their persons and conduct.

In the narration, the voice ought to be raised to somewhat an higher pitch. Matters of fact should be related in a very plain and distinct manner, with a proper stress and emphasis laid upon each circumstance, accompanied with a suitable address and motions of the body, to engage the attention of the hearers. For there is a certain grace in telling a story, by which those who are masters of it seldom fail to recommend themselves in conversation. The beauty of it consists in an easy and familiar manner of expression, attended with such actions and gestures as are suited to the nature of the things related, and help to enliven each particular circumstance and part of the discourse.

The proposition, or subject of the discourse, should be delivered with a very clear and audible voice. For if this be not plainly heard, all that follows in proof of it cannot well be understood. And for the same reason, if it be divided into several parts or branches, they should each be expressed very deliberately and distinctly. But as the design here is only information, there can be little room for gesture.

The confirmation admits of great variety both of the voice and gestures. In reasoning, the voice is quick and pungent, and should be enforced with suitable actions. And as descriptions likewise have often a place here, in painting out the images of things, the orator should so endeavour to adapt both his voice, and the motions of his body, particularly the turn of his eyes, and action of his hands as may best help the imagination of his hearers. Where he introduces another person speaking, or addresses to an absent person, it should be with some degree of imitation. And in dialogue the voice should alter with the parts. When he diverts from his subject by any digression, his voice should be lively and cheerful; since that is rather designed for entertainment than instruction.

In confutation, the arguments of the adverse party ought first to be repeated in a plain and distinct manner, that the speaker may not seem to conceal, or avoid the force of them, unless they appear trifling and

and unworthy of a serious answer; and then a facetious manner, both of expression and gesture, may be the properest way to confute them. For to attempt to answer in a grave and serious manner, what is in itself empty and ludicrous, is apt to create a suspicion of its having more in it than it really has. So when Tubero, in his accusation of Ligarius before Cæsar, had made it part of his charge, that Ligarius was in Africa during some part of the civil war between Cæsar and Pompey; Cicero, in his answer, not thinking it deserved a serious reply, contents himself with barely mentioning it ironically. For thus he begins his defence of Ligarius: "Cæsar, my kinsman Tubero has laid before you a new crime, and till this day unheard of, that Q. Ligarius was in Africa." Every one must easily perceive, by the manner in which these words were pronounced, that the design of them was to make the charge appear ridiculous. But caution should be used not to represent any argument of weight in a ludicrous way, lest by so doing the speaker should more expose himself than his adversary.

In the conclusion, both the voice and gesture should be brisk and sprightly, which may seem to arise from a sense of the speaker's opinion of the goodness of his cause, and that he has offered nothing but what is agreeable to reason and truth; as likewise from his assurance that the audience agree with him in the same sentiments. In every undertaking that requires care and thought, persons are apt at first to be sedate and moderate; but when it is drawing to an end, and is near finished, it is very natural to appear more gay. If an enumeration of the principal arguments of the discourse be convenient, as it sometimes is, where they are pretty numerous, or the discourse is long, they ought to be expressed in the most clear and forcible manner. And if there be an address to the passions, both the voice and gesture must be suited to the nature of them, of which more will be said presently.

We proceed now to the consideration of particular expressions. And what we shall offer here, will be first in relation to single words, then sentences, and lastly the passions.

132 I. Even in those sentences which are expressed in the most even and sedate manner, there is often one or more words which require an emphasis and distinction of the voice. Pronouns are often of this kind; as, *This is the man.* And such are many words that denote the circumstances and qualities of things. Such as heighten or magnify the idea of the thing to which they are joined, elevate the voice; as *noble*, *admirable*, *majestic*, *greatly*, and the like. On the contrary, those which lessen the idea, or debase it, depress the voice, or at least protract the tone; of which sort are the words *little*, *mean*, *poorly*, *contemptible*, with many others, Some tropes likewise, as metaphors and verbal figures, which consist in the repetition of a single word, should have a particular emphasis. As when Virgil says of the river Araxes, *It disdained a bridge*. And Nisus of himself in the same poet, *I, I am the man;* where the repeated word is loudest. This distinction of words, and giving them their proper emphasis, does not only render the expression more clear and intelligible, but very much contributes to the variation of the voice, and the preventing a monotony. And the different pronunciation of these words will also require a peculiar gesture.

II. In sentences, regard should be had to their length, and the number of their parts, in order to distinguish them by proper pauses. The frame and structure of the period ought likewise to be considered, that the voice may be so managed as to give it the most musical accent. Unless there be some special reason for the contrary, it should end louder than it begins. And this difference of tone between the end of the former sentence and the beginning of the next, not only helps to distinguish the sense, but adds to the harmony of the voice. And that the last syllables of a sentence might become more audible and distinct, was doubtless one reason why the ancient rhetoricians dislike short feet at the end of a period. In an antithesis, or a sentence consisting of opposite parts, one contrary must be louder than the other. As, "*He is gone, but by a gainful remove, from* painful labour to quiet rest; *from* unquiet desires *to happy* contentment; *from* sorrow *to* joy; *and from* transitory time *to* immortality." In a climax or gradation, the voice should rise with it. So, "*There is no enjoyment of* property *without* government; *no* government *without a* magistrate; *no* magistrate *without* obedience; *no* obedience *where every one acts as he* pleases." And so in other gradations of a different form. As, "*Since* concord *was lost*, friendship *was lost*, fidelity *was lost*, liberty *was lost*, all *was lost.*" And again, "*You would pardon him whom the* senate *hath condemned*, *whom* the people of Rome *have condemned*, *whom* all mankind *have condemned.*" We might mention several other figurative expressions, which require a particular conformation and management of the voice; but these, we presume, with some others we shall have occasion to name presently when we come to the passions, may be sufficient to guide us in the rest. But that it may appear more evidently how necessary a different inflection and variation of the voice is in most sentences, give us leave to show how Quintilian illustrates it, by a passage which he takes from Cicero. The place is the beginning of Cicero's defence for Milo, and the words are these: "*Although I am apprehensive it may seem base to discover fear when I enter upon the defence of* a most courageous man, *and it may appear very indecent*, when Milo discovers more concern for the public safety than for his own, *not to show a greatness of mind equal to his cause*, *yet this new form of the court terrifies my eyes*, which cannot discern the ancient manner of the forum, and former custom of trials, *whatever way they look:* your bench is not surrounded with its usual attendants." This sentence consists of four members. And Quintilian supposes, that though these words are the beginning of a speech, and were accordingly expressed in a calm and submissive manner, yet that the orator used a great deal of variety in the pronunciation of their several parts. In the first member (as he imagines) his voice was more elevated in expressing the word, *a most courageous man*, than in those other parts of it, *I am apprehensive it may seem base*, and, *to discover fear*. In the second member he rose higher, in saying, *when Milo discovers more concern for the public safety than for his own;* and then again, as it were, checked himself in what follows, *not to show a greatness of mind equal*

Pronunciation. *equal to his cause.* The beginning of the third member carrying a reflection in it, was spoke with a different tone of the voice, *this new form of the court terrifies my eyes;* and the other part of it more loud and distinctly, *which cannot discern the ancient manner of the forum, and former custom of trials.* And the last member was still more raised and audible, *your bench is not surrounded with its usual attendants.* And it must be supposed, that while he was saying this, he cast his eyes round the assembly, and viewed the soldiers whom Pompey had placed there, which renders the expression still more grave and solemn. If this was the manner of the ancient orators, and they were so exact and accurate in expressing their periods, and the several parts of them, as we have reason to believe they were, it must have given a very great force, as well as beauty to their pronunciation.

134 III. That the passions have each of them both a different voice and action, is evident from hence; that we know in what manner a person is affected, by the tone of his voice, though we do not understand the sense of what he says, or many times so much as see him: and we can often make the same judgment from his countenance and gestures. Love and esteem are expressed in a smooth and cheerful tone: but anger and resentment, with a rough, harsh, and interrupted voice; for when the spirits are disturbed and ruffled, the organs are moved unequally. Joy raises and dilates the voice, as sorrow sinks and contracts it. Cicero takes notice of a passage in an oration of Gracchus, wherein he bewails the death of his brother, who was killed by Scipio, which in his time was thought very moving: "*Unhappy man* (says he), *whither shall I betake myself? where shall I go?* Into the capitol? *that flows with my brother's blood.* Shall I go home; *and behold my unhappy mother all in tears and despair?*" Though Gracchus had a very ill design in that speech, and his view was to excite the populace against their governors, yet (as Cicero tells us) when he came to this passage, he expressed himself in such moving accents and gestures, that he extorted tears even from his enemies. Fear occasions a tremor and hesitation of the voice, and assurance gives it strength and firmness. Admiration elevates the voice, and should be expressed with pomp and magnificence: *O surprising clemency, worthy of the highest praise and greatest encomiums, and fit to be perpetuated in lasting monuments!* This is Cicero's compliment to Cæsar when he thought it for his purpose. And oftentimes this passion is accompanied with an elevation both of the eyes and hands. On the contrary, contempt sinks and protracts the voice. In the dispute between Cicero and Cecilius, which of them should accuse Verres, Cicero puts this contemptuous question to him: "How are you qualified, Cecilius, for such an undertaking? I will not ask, when you ever gave a proof of it, but when you so much as attempted? Do you consider the difficulty of managing a public cause?" with much more to the same purpose. Though such kind of expressions require little gesture, yet sometimes a motion of the hand may not be improper, to signify disdain or aversion. We may suppose Cicero to have acted thus in his defence of Rabirius. For to show his assurance of his client's cause, having used this expression in a very audible manner, "I wish I had it to say, that Rabirius had with his own hand killed Saturninus, who was an enemy to the Roman state," some persons in the crowd began to raise a clamour, just as of later times hissing has been practised on the like occasions. Upon which Cicero immediately replies, "This noise does not disturb me, but please me, since it shows, though there are some weak persons, yet they are but few." Then presently after follows the expression we refer to: "Why do not you cease your clamour, since it only discovers your folly, and the smallness of your number?" All exclamations should be violent. When we address to inanimate things, the voice should be higher than when to animated beings; and appeals to heaven must be made in a loftier tone than those to men.

These few hints for expressing the principal passions may, if duly attended to, suffice to direct our practice in others. Though, after all, it is impossible to gain a just and decent pronunciation of voice and gesture merely from rules, without practice and an imitation of the best examples. Which shows the wisdom of the ancients, in training up their youth to it, by the assistance of masters, to form both their speech and actions.

But there is one thing which ought always to be attended to; namely, that persons should well consider their own make and genius, especially with respect to the passions. We seldom find, that any actor can excel in all characters; but if he performs one well, he is deficient in another: And therefore they are commonly so prudent as to confine themselves to such as best suit them. The case is the same in an orator; who should therefore keep within those bounds which nature seems to have prescribed for him. Some are better fitted for action than others, and most for some particular actions rather than others; and what fits well upon one would appear very awkward in another. Every one, therefore, should first endeavour to know himself, and manage accordingly. Though in most cases nature may be much assisted and improved by art and exercise. See Professor Ward's *System of Oratory.*

Oratory, Orb. ORATORY, among the Romanists, a closet or like apartment near a bed-chamber, furnished with an altar, crucifix, &c. for private devotions.

ORB, in *Astronomy*, denotes a hollow globe or sphere.

ORB, in tactics, is the disposing of a number of soldiers in circular form of defence. The orb has been thought of consequence enough to employ the attention of the famous Marshal de Puysegur in his Art of War, who prefers this position to throw a body of infantry in an open country, to resist cavalry, or even a superior force of infantry; because it is regular, and equally strong,

strong, and gives an enemy no reason to expect better success by attacking one place than another. Cæsar drew his whole army in this form, when he fought against Labienus. The whole army of the Gauls was formed into an orb, under the command of Sabinus and Cotta, when fighting against the Romans. The orb was generally formed six deep.

ORBIT, in *Astronomy*, the path of a planet or comet, or the curve that it describes in its revolution round its central body; thus, the earth's orbit is the curve which it describes in its annual course round the sun, and usually called the *ecliptic*. See ASTRONOMY, *passim*.

ORCADES, the *Orkney Islands*. See ORKNEY.

ORCHARD, a garden department, consigned entirely to the growth of standard fruit-trees, for furnishing a large supply of the most useful kinds of fruit. For the particular management of the orchard, see GARDENING.

In the orchard you may have, as standards, all sorts of apple-trees, most sorts of pears and plums, and all sorts of cherries: which four species are the capital orchard fruits; each of them comprising numerous valuable varieties. But to have a complete orchard, you may also have quinces, medlars, mulberries, service-trees, filberts, Spanish nuts, berberries; likewise walnuts and chesnuts; which two latter are particularly applicable for the boundaries of orchards, to screen the other trees from the insults of impetuous winds and cold blasts. All the trees ought to be arranged in rows from 20 to 30 feet distance, as hereafter directed.

But sometimes orchards consist entirely of apple-trees, particularly in the cyder-making counties, where they are cultivated in very great quantities in large fields, and in hedge rows, for the fruit to make cyder for public supply.

And sometimes whole orchards of very considerable extent are entirely of cherry-trees. But in this case, it is when the fruit is designed for sale in some great city, as London, &c. for the supply of which city, great numbers of large cherry orchards are in some of the adjacent counties, but more particularly in Kent, which is famous for very extensive cherry-orchards; many of which are entirely of that sort called *Kentish cherry*, as being generally a great bearer; others are stored with all the principal sorts of cultivated cherries, from the earliest to the latest kinds.

A general orchard, however, composed of all the before-mentioned fruit-trees, should consist of a double portion of apple-trees or more, because they are considerably the most useful fruit, and may be continued for use the year round.

The utility of a general orchard, both for private use and profit, stored with the various sorts of fruit-trees, must be very great, as well as afford infinite pleasure from the delightful appearance it makes from early spring till late in autumn: In spring the various trees in blossom are highly ornamental; in summer, the pleasure is heightened by observing the various fruits advancing to perfection; and as the season advances, the mature growth of the different species arriving to perfection, in regular succession, from May or June, until the end of October, must afford exceeding delight, as well as great profit.

Of the Extent, Situation, and Soil for the Orchard.—As to the proper extent of ground for an orchard, this must be proportioned, in some measure, to the extent of land you have to work on, and the quantity of fruit required either for private use or for public supply; so that an orchard may be from half an acre to 20 or more in extent.

With respect to the situation and aspect for an orchard, we may observe very thriving orchards both in low and high situations, and on declivities and plains, in various aspects or exposures, provided the natural soil is good: we should, however, avoid very low damp situations as much as the nature of the place will admit; for in very wet soils no fruit trees will prosper, nor the fruit be fine: but a moderately low situation, free from copious wet, may be more eligible than an elevated ground, as being less exposed to tempestuous winds; though a situation having a small declivity is very desirable, especially if its aspect incline towards the east, south-east, or southerly, which are rather more eligible than a westerly aspect; but a north aspect is the worst of all for an orchard, unless particularly compensated by the peculiar temperament or good quality of the soil.

And as for soil, any common field or pasture that produces good crops of corn, grass, or kitchen-garden vegetables, is suitable for an orchard; if it should prove of a loamy nature, it will be a particular advantage: any soil, however, of a good quality, not too light and dry, or too heavy, stubborn, or wet, but of a medium nature, of a soft, pliant temperature, not less than one spade deep of good staple, will be proper for this purpose.

Preparation of the ground.—The preparation of the ground for the reception of trees, is by trenching; or, if for very considerable orchards, by deep ploughing; but trench-digging, one or two spades, as the soil will admit, is the most eligible, either wholly, or only for the present in the places where the lines of trees are to stand, a space of six or eight feet wide, all the way in each row, especially if it be grass-ground, and intended to be kept in the sward; or if any under-crops are designed to be raised, the ground may be wholly trenched at first: in either case trench the ground in the usual way to the depth of the natural soil; and if in grass, turn the sward clean to the bottom of each trench, which, when rotted, will prove an excellent manure.

In planting orchards, however, on grass-grounds, some only dig pits for each tree, capacious enough for the reception of the roots, loosening the bottom well, without the labour of digging any other part of the ground.

The ground must be fenced securely against cattle, &c. either with a good ditch and hedge, or with a paling-fence, as may be most convenient.

Method of planting the Trees.—The best season for planting all the sorts of fruit-trees is autumn, soon after the fall of the leaf, from about the latter end of October until December; or indeed it might be performed any time in open weather from October until March.

Choose principally full standards, with straight clean stems, six feet high; each with a branchy well-formed head, of from two or three to four or five years growth; and let several varieties of each particular species be chosen, that ripen their fruit at different times, from the earliest to the latest, according to the nature of the dif-

Orchard.

ferent sorts, that there may be a proper supply of every sort regularly during their proper season. Of apples and pears in particular, choose a much greater quantity of the autumnal and late ripening kinds than of the early sorts, but most of all of apples; for the summer-ripening fruit is but of short duration, only proper for temporary service; but the later ripening kinds keep sound some considerable time for autumnal use; and the latest sorts that ripen in October, continue in perfection for various uses all winter, and several sorts until the season of apples come again.

Having made choice of the proper sorts, and marked them, let them be taken up with the utmost care, so as to preserve all their roots as entire as possible; and when taken up, prune off any broken or bruised parts of the roots, and just tip the ends of the principal roots, in general, with the knife on the under side with a kind of slope outward.

If the trees have been already headed, or so trained as to have branched out into regular shoots to form each a proper head, they must be planted with the said heads entire, only retrenching or shortening any irregular or ill-placed shoot that takes an awkward direction, or grows across its neighbours, or such as may run considerably longer than all the rest, &c.

The arrangement of the trees in the orchard must be in rows, each kind separate, at distances according to the nature of the growth of the different sorts; but for the larger growing kinds, such as apples, pears, plums, cherries, &c. they should stand from 25 to 30 or 40 feet every way asunder, though 25 or 30 feet at most is a reasonable distance for all these kinds.

Each species and its varieties should generally be in rows by themselves, the better to suit their respective modes of growth: though for variety there may be some rows of apples and pears arranged alternately, as also of plumbs and cherries; and towards the boundaries there may be ranges of lesser growth, as quinces, medlars, filberts, &c. and the outer row of all may be walnut-trees, and some chesnuts, set pretty close to defend the other trees from violent winds.

According to the above distances, proceed to stake out the ground for making the holes for the reception of the trees, which if made to range every way, will have a very agreeable effect, and admit the currency of air, and the sun's influence, more effectually.

But in planting very extensive orchards, some divide the ground into large squares or quarters, of different dimensions, with intervals of 50 feet wide between; serving both as walks, and for admitting a greater currency of air; in different quarters planting different sorts of fruit, as apples in one, pears in another, plums and cherries in others, &c. and thus it may be repeated to as many quarters for each species and its varieties as may be convenient.

As to the mode of planting the trees: A wide hole must be dug for each tree, capacious enough to receive all the roots freely every way without touching the sides. When the holes are all ready, proceed to planting, one tree in each hole, a person holding the stem erect, whilst another trims in the earth, previously breaking it small, and casting it in equally all about the roots, frequently shaking the tree to cause the mould to settle in close about all the smaller roots and fibres, and so as to raise the tree gradually up, that the crown of the roots may be but two or three inches below the general surface; and when the hole is filled up, tread it gently, first round the outside, then near the stem of the tree, forming the surface a little hollow; and then, if on the top of all be laid some inverted turf to the width of the hole, forming it with a sort of circular bank, three or four inches high, it will support the tree, and guard the roots from drying winds and the summer's drought: observing that each tree stand perfectly upright, and that they range exactly in their proper rows.

Method of improving the Fruit.—The following method is said to have been successfully employed, by a German clergyman, in promoting the growth of young trees, and increasing the size and flavour of the fruit in orchards. Having planted several young plum trees in an orchard, he covered the ground, for some years, around the trunks, as far as the roots extended, with flax-shows, or the refuse of flax when it is scutched or heckled; by which means these trees, though in a grass-field, increased in a wonderful manner, and far excelled others planted in cultivated ground. As far as the shows reached, the grass and weeds were choked; and the soil under them was so tender and soft, that no better mould could have been wished for by a florist.

When he observed this, he covered the ground with the same substance, as far as the roots extended, around an old plum-tree, which appeared to be in a languishing state, and which stood in a grass-field. The consequences were, that it acquired a strong new bark, produced larger and better tasted fruit, and that those young shoots, which before grew up around the stem, and which it was every year necessary to destroy, were prevented from sprouting forth, as the covering of flax-shows impeded the free access of air at the bottom of the trunk.

In the year 1793, he transplanted, from seed-beds, into the nursery, several fruit-trees; the ground around some of which he covered, as above, with flax-shows. Notwithstanding the great heat of the summer, none of those trees where the earth was covered with shows died or decayed, because the shows prevented the earth under them from being dried by the sun. Of those trees, around which the ground was not covered as before mentioned, the fourth part miscarried; and those that continued alive were far weaker than the former.

The leaves which fall from trees in autumn may also be employed for covering the ground in like manner; but stones, or logs of wood must be laid on them, to prevent their being dispersed by the wind. In grass land, a small trench may be made around the roots of the tree, when planted, in order to receive the leaves. If flax-shows are used, this is not necessary; they lie on the surface of the ground so fast as to resist the force of the most violent storm. The leaves which our author found most effectual in promoting the growth and fertility of fruit trees, are those of the walnut-tree. Whether it is, that, on account of their containing a greater abundance of saline particles, they communicate manure to the ground, which thereby becomes tender under them; or that they attract nitrous particles from the atmosphere; or that, by both these means, they tend to nourish the tree both above and below.

Those who are desirous of raising tender exotic trees from the seed, in order to accustom them to our climate, may,

may, when they transplant them, employ flax-shows with great advantage. This covering will prevent the frost from making its way to the roots; and rats and mice, on account of the sharp prickly points of the flax-shows, will not be able to shelter themselves under them.

ORCHESTRA, in the Grecian theatres, was that part of the *proscenium* or stage where the chorus used to dance. In the middle of it was placed the *Λογειον* or *pulpit*. The orchestra was semicircular, and surrounded with seats. In the Roman theatres it made no part of the *scena*, but answered pretty nearly to the pit in our playhouses, being taken up with seats for senators, magistrates, vestals, and other persons of distinction. The actors never went down into it. See THEATRE.

ORCHIA LEX, instituted by Orchius the tribune in the year of Rome 566. Its intention was to limit the number of guests that were to be admitted in an entertainment; and it is also enforced, that during supper, which was the chief meal among the Romans, the doors of every house should be left open.

ORCHIS, FOOLSTONES; a genus of plants belonging to the gynandria class, and in the natural method giving name to the seventh order *Orchideæ*. See BOTANY *Index*.

ORCUS, god of the infernal regions, the same with Pluto, so called from the Greek word *ορχος*, signifying a "tomb or sepulchre," or from *ορκος*, "an oath by the river Styx." The ancients gave this name to all the divinities of the infernal regions, even to Cerberus. There was a river of the same name in Thessaly, which took its rise from the marshes of the Styx, and the waters of which were so thick, that they floated like oil upon the surface of the river Peneus, into which they discharged themselves. This river probably suggested to the poets the idea of the infernal abodes, which they denominated *Orcus*. This deity has been confounded with Charon. He had temple at Rome.

ORDEAL, an ancient form of trial. See TRIAL.—It was an appeal to the immediate interposition of divine power, and was particularly distinguished by the appellation of *judicium Dei*; and sometimes *vulgaris purgatio*, to distinguish it from the canonical purgation, which was by the oath of the party. There were two sorts of it more common than the rest, at least in Europe; fire-ordeal, and water-ordeal. The former was confined to persons of higher rank, the latter to the common people. Both these might be performed by deputy; but the principal was to answer for the success of the trial; the deputy only venturing some corporal pain, for hire or perhaps for friendship.

That the purgation by ordeal, of some kind or other, is very ancient, admits not of a doubt; and that it was very universal in the times of superstitious barbarity, is equally certain. It seems even to have been known to the ancient Greeks; for in the Antigone of Sophocles, a person suspected by Creon of a misdemeanour, declares himself ready "to handle hot iron and to walk over fire" in order to manifest his innocence; which the scholiast tells us was then a very usual purgation. And Grotius gives us many instances of water-ordeal in Bithynia, Sardinia, and other places. It seems, however, to be carried to a greater height among the Hindoos, than ever it has been in any nation or among any people, however rude or barbarous; for in a paper of the Asiatic Researches communicated by Warren Hastings, Esq. we find that the *trial by ordeal* among them is conducted in *nine* different ways: first by the balance; secondly, by fire; thirdly, by water; fourthly, by poison; fifthly, by the Cosha, or water in which an idol has been washed; sixthly, by rice; seventhly, by boiling oil; eighthly, by red-hot iron; ninthly, by images.

I. Ordeal by the balance is thus performed. The beam having been previously adjusted, the cord fixed, and both scales made perfectly even, the person accused and a Pandit fast a whole day; then, after the accused has been bathed in sacred water, the *homa*, or oblation, presented to fire, and the deities worshipped, he is carefully weighed; and when he is taken out of the scale, the Pandits prostrate themselves before it, pronounce a certain *mentra* or incantation, agreeably to the Sastras, and, having written the substance of the accusation on a piece of paper, bind it on his head. Six minutes after, they place him again in the scale; and, if he weigh more than before, he is held guilty; if less, innocent; if exactly the same, he must be weighed a third time; when, as it is written in the *Mitacshera*, there will certainly be a difference in his weight. Should the balance, though well fixed break down, this would be considered as a proof of his guilt.

II. For the fire-ordeal, an excavation, nine hands long, two spans broad, and one span deep, is made in the ground, and filled with a fire of pippal wood: into this the person accused must walk barefooted; and, if his foot be unhurt, they hold him blameless; if burned, guilty (A).

(A) In Europe fire-ordeal was performed either by taking up in the hand, unhurt, a piece of red-hot iron, of one, two, or three pounds weight; or else by walking, barefoot and blindfold, over nine red-hot plough-shares, laid lengthwise at unequal distances; and if the party escaped being hurt, he was adjudged innocent; but if it happened otherwise, as without collusion it usually did, he was then condemned as guilty. However, by this latter method Queen Emma, the mother of Edward the Confessor, is mentioned to have cleared her character, when suspected of familiarity with Alwyn bishop of Winchester. The first account we have of Christians appealing to the fire-ordeal, as a proof of their innocence, is that of Simplicius, bishop of Autun, who lived in the fourth century. This prelate, as the story is related, before his promotion to the episcopal order, had married a wife, who loved him tenderly, and who, unwilling to quit him after his advancement continued to sleep in the same chamber with him. The sanctity of Simplicius suffered, at least in the voice of fame, by the constancy of his wife's affection; and it was rumoured about, that the holy man, though a bishop, persisted, in opposition to the ecclesiastical canons, to taste the sweets of matrimony: upon which his wife, in the presence of a great concourse of people, took up a considerable quantity of burning coals, which she held in her clothes, and applied to her breasts, without the least hurt to her person or her garments, as the legend says; and her example being followed by her husband with the like

Ordeal. III. Water-ordeal is performed by causing the person accused to stand in a sufficient depth of water, either flowing or stagnant, to reach his navel; but care should be taken that no ravenous animal be in it, and that it be not moved by much air; a brahman is then directed to go into the water, holding a staff in his hand; and a soldier shoots three arrows on dry ground from a bow of cane; a man is next despatched to bring the arrow which has been shot farthest; and, after he has taken it up, another is ordered to run from the edge of the water; at which instant the person accused is told to grasp the foot or the staff of the brahman, who stands near him in the water, and immediately to dive into it. He must remain under water, till the two men who went to fetch the arrows are returned; for, if he raise his head or body above the surface before the arrows are brought back, his guilt is considered as fully proved. In the villages near Benares, it is the practice for the person who is to be tried by this kind of ordeal, to stand in water up to his navel, and then, holding the foot of a brahman, to dive under it as long as a man can walk 50 paces very gently; if, before the man has walked thus far, the accused rise above the water, he is condemned; if not, acquitted (B).

IV. There are two sorts of trial by poison; first, the pandits having performed their homa, and the person accused his ablution, two *rettis* and a half, or seven barley-corns of *vishanaga*, a poisonous root, or of *sauc'hya*, that is, white arsenic, are mixed in eight *mashas*, or 64 *rettis*, of clarified butter, which the accused must eat from the hand of a brahman: if the poison produce no visible effect, he is absolved; otherwise condemned. Secondly, the hooded snake, called *nagga*, is thrown into a deep earthen pot, into which is dropped a ring, a seal, or a coin; this the person accused is ordered to take out with his hand; and, if the serpent bite him, he is pronounced guilty; if not, innocent.

V. Trial by the cosha is as follows: the accused is made to drink three draughts of the water, in which the images of the sun, of Devi, and other deities, have been washed for that purpose; and if, within 14 days, he has any sickness or indisposition, his crime is considered as proved.

VI. When several persons are suspected of theft, some dry rice is weighed with the sacred stone called *salgram*, or certain *slocas* are read over it; after which the suspected persons are severally ordered to chew a quantity of it: as soon as they have chewed it, they are to throw it on some leaves of *pippal*, or, if none be at hand, on some *b'hurja patra*, or bark of a tree, from Nepal or Cashmir. The man, from whose mouth the rice comes dry or stained with blood, is holden guilty; the rest is acquitted.

VII. The ordeal by *hot oil* is very simple: when it is heated sufficiently, the accused thrusts his hand into it; and, if he be not burned, is held innocent (C).

VIII.

---

like success, the silly multitude admired the miracle, and proclaimed the innocence of the loving pair. A similar trick was played by St Brice, in the fifth century. *Mosh. Eccl. Hist.* vol. ii.

(B) A very peculiar species of water-ordeal is said to prevail among the Indians on the coast of Malabar. A person accused of an enormous crime is obliged to swim over a large river abounding with crocodiles; and if he escapes unhurt, he is esteemed innocent.

At Siam, besides the usual methods of fire and water-ordeal, both parties are sometimes exposed to the fury of a tiger let loose for that purpose; and if the beast spares either, that person is accounted innocent; if neither, both are held to be guilty; but if he spares both, the trial is incomplete, and they proceed to a more certain criterion.

In Europe water-ordeal was performed, either by plunging the bare arm up to the elbow in boiling-water, and escaping unhurt thereby, or by casting the person suspected into a river or pond of cold water; and if he floated therein without any action of swimming, it was deemed an evidence of his guilt; but if he sunk, he was acquitted. It is easy to trace out the traditional relics of this water-ordeal, in the ignorant barbarity still practised in many countries to discover witches, by casting them into a pool of water, and drowning them to prove their innocence. And in the eastern empire the fire-ordeal was used for the same purpose by the emperor Theodore Lascaris; who, attributing his sickness to magic, caused all those whom he suspected to handle the hot iron: thus joining (as has been well remarked) to the most dubious crime in the world, the most dubious proof of innocence.

(C) This species of trial by ordeal is thus performed: The ground appointed for the trial is cleared and rubbed with cow-dung, and the next day at sunrise the *Pandit* worships Ganesa or the Hindoo Janus, presents his oblations, and pays adoration to other deities, conformably to the *Sástra*: then having read the incantation prescribed, he places a round pan of gold, silver, copper, iron, or clay, with a diameter of sixteen fingers, and four fingers deep, and throws into it one *sér*, or eighty *sicca* weight, of clarified butter or oil of *sesamum*. After this a ring of gold, or silver, or iron, is cleaned and washed with water, and cast into the oil; which they proceed to heat, and when it is very hot put into it a fresh leaf of *pippala*, or of *bilwa*: when the leaf is burned, the oil is known to be sufficiently hot. Then, having pronounced a *mentra* over the oil, they order the party accused to take the ring out of the pan; and if he take it out without being burned, or without a blister in his hand, his innocence is considered as proved; if not, his guilt. It is reported that this custom, with some slight variations, still prevails among the Indians on the coast of Malabar. The process there is said to begin after the accused person has been thoroughly washed in the presence of the prince of the country, the priests, &c.:—the pot is filled with boiling lead; and the accused must take the ring out three times successively. On the Malabar coast, this ordeal seems only to be used when the person is accused of a capital crime; for after the process the arm is bound with cloth and sealed; and after several days, being brought out publicly, and the arm inspected, if it is found burnt he is instantly put to death; if not, his accuser undergoes the same trial, and being burnt, forfeits his life.

Ordeal.

VIII. In the same manner they make an *iron ball*, or the *head of a lance*, red hot, and place it in the hands of the person accused; who, if it burn him not, is judged guiltless.

IX. To perform the ordeal by *dharmách*, which is the name of the *slóca* appropriated to this mode of trial, either an image, named *Dharma*, or the genius of justice, is made of silver, and another, called *Adharma*, of clay or iron, both of which are thrown into a large earthen jar; and the accused having thrust his hand into it, is acquitted if he bring out the silver image, but condemned if he draw forth the iron; or, the figure of a deity is painted on white cloth, and another on black; the first of which they name *dharma*, and the second *adharma*: these are severally rolled up in cow-dung, and thrown into a large jar without having ever been shown to the accused; who must put his hand into the jar, and is acquitted or convicted as he draws out the figure on white or on black cloth.

Though we have proceeded thus far, we have not exhausted Mr Hastings's communication. He goes on to show (to greater extent than our limits permit us to follow him) the manner in which each ordeal above mentioned was executed, giving examples, and unfolding other particulars of some importance in developing the nature of these barbarous customs. For these particulars, however, we must refer to the book itself. But as this subject unquestionably occupies an important department in the history of human superstition, we shall give the Indian law of ordeal from the same paper; when we shall introduce some further particulars concerning this extraordinary custom, which are not to be found in the above account, but which deserve to be noticed.

"1. The balance, fire, water, poison, the idol—these are the ordeals used here below for the proof of innocence, when the accusations are heavy, and when the accuser offers to hazard a mulct, (if he should fail):

2. Or one party may be tried, if he please, by ordeal, and the other must then risk an amercement; but the trial may take place even without any wager, if the crime committed be injurious to the prince.

3. The sovereign having summoned the accused while his clothes are yet moist from bathing, at sunrise, before he has broken his fast, shall cause all trials by ordeal to be conducted in the presence of *Bráhmans*.

4. The balance is for women, children, old men, the blind, the lame, *Bráhmans*, and the sick; for the *Súdra*, fire or water, or seven barley-corns of poison.

5. Unless the loss of the accuser amount to a thousand pieces of silver, the accused must not be tried by the red-hot ball, nor by poison, nor by the scales; but if the offence be against the king, or if the crime be heinous, he must acquit himself by one of those trials in all cases.

6. He who has recourse to the balance must be attended by persons experienced in weighing, and go down into one scale, with an equal weight placed on the other, and a groove (with water in it) marked on the beam.

7. 'Thou, O balance, art the mansion of truth; thou wast anciently contrived by deities: declare the truth, therefore, O giver of success, and clear me from all suspicion.

8. 'If I am guilty, O venerable as my own mother, then sink me down, but if innocent raise me aloft.' Thus shall he address the balance.

9. If he sink he is convicted, or if the scales be broken: but if the string be not broken, and he rise aloft, he must be acquitted.

10. On the trial by fire, let both hands of the accused be rubbed with rice in the husk, and well examined: then let seven leaves of the *Aswatt'ha* (the religious fig-tree) be placed on them, and bound with seven threads.

11. 'Thou, O fire, pervadest all beings: O cause of purity, who givest evidence of virtue and of sin, declare the truth in this my hand.

12. When he has pronounced this, the priest shall place in both his hands an iron ball, red-hot, and weighing fifty *palas* (D).

13. Having taken it, he shall step gradually into seven circles, each with a diameter of sixteen fingers, and separated from the next by the same space.

14. If, having cast away the hot ball, he shall again have his hands rubbed with rice in the husk, and shall show them unburned, he will prove his innocence. Should the iron fall during the trial, or should a doubt arise (on the regularity of the proceedings), he must be tried again.

15. 'Preserve me, O Varuna, by declaring the truth.' Thus having invoked the god of waters, the accused shall plunge his head into the river or pool, and hold both thighs of a man, who shall stand in it up to his navel:

16. A swift runner shall then hasten to fetch an arrow shot at the moment of his plunging; and if, while the runner is gone, the priest shall see the head of the accused under water, he must be discharged as innocent.

17. 'Thou, O poison, art the child of Brahmâ, steadfast in justice and in truth: clear me then from this heavy charge, and if I have spoken truly, become nectar to me.'

18. Saying this, he shall swallow the poison *Sárnga*, from the tree which grows on the mountain *Himálaya*; and if he digests it without any inflammation, the prince shall pronounce him guiltless.

19. Or the priest shall perform rites to the image of some tremendous deity; and, having bathed the idol, shall make the accused to drink three handfuls of the water that has dropped from it.

20. If in fourteen days after he suffers no dreadful calamity from the act of the deity or of the king, he must indubitably be acquitted."

The superstitious weakness of mankind, when left to themselves, is astonishing. There is indeed nothing so absurd but they may be made most firmly to believe, nor so impious but they will do. Nor can a more notorious instance of the truth of this assertion be

(D) A *pala* is four *carshas*, and a *carsha* eighty *racticás* or seeds of the *gungà* creeper, each weighing above a grain and a quarter, or correctly, $1\frac{5}{16}$ gr.

be possibly given than that of the trial by ordeal. The gross absurdity as well as impiety of pronouncing a man guilty unless he was cleared by a miracle, and of expecting that all the powers of nature should be suspended by an immediate interposition of Providence to save the innocent, when it was even presumptuously required, is self-evident. Yet the origin of it may be traced as well to necessity as to superstition. At the time in which it originated in England, as well as in other countries of Europe, it was no easy matter for an innocent person, when accused of guilt, to get himself cleared by the then established mode of trial. (See TRIAL). It was therefore natural for superstition to fly to Heaven for those testimonies of innocence which the absurdity of human laws often prevented men from obtaining in the ordinary way; and in this way doubtless did the trial by ordeal commence: and thus begun by necessitous superstition, it was fostered by impious priestcraft and unjust power. There was during all the processes great room for collusion and deceit; and there can be no question but it was often practised: it could not therefore on any account, or in any case, be a sign of innocence or of guilt.

Besides those particular methods of trial which we have already mentioned, there were some few more common in European countries; as the judicial combat —the ordeal of the cross—the ordeal of the corsned.

The judicial combat was well suited to the genius and spirit of fierce and warlike nations, and was, as we may reasonably expect, one of the most ancient and universal modes of trial. We know that it was exceedingly common in Germany in very remote ages. It was also used in some countries on the continent at pretty early periods: it is not, however, mentioned in any of the Anglo-Saxon laws; and it does not appear to have been much used in England till after the Conquest. There are, however, two remarkable instances of it upon record, which we shall give in the words of Dr Henry: "Henry de Essex, hereditary standard-bearer of England, fled from a battle in Wales, A. D. 1158, threw from him the royal standard, and cried out, with others, that the king was slain. Some time after, he was accused with having done this with a treasonable intention, by Robert de Montfort, another great baron, who offered to prove the truth of his accusation by combat. Henry de Essex denied the charge, and accepted the challenge. When all preliminaries were adjusted, this combat was accordingly fought, in the presence of Henry II. and all his court. Essex was defeated, and expected to be carried out to immediate execution. But the king, who was no friend to this kind of trial, spared his life, and contented himself with confiscating his estate, and making him a monk in the abbey of Reading.

"The priory of Tinmouth, in Northumberland, was a cell of the abbey of St Alban's. One Simon of Tinmouth claimed a right to two corrodies, or the maintenance of two persons in the priory, which the prior and monks denied. This cause was brought before the abbot of St Alban's and his court-baron, who appointed it to be tried by combat on a certain day, before him and his barons. Ralf Gubion, prior of Tinmouth, appeared at the time and place appointed, attended by his champion, one William Pegun, a man of gigantic stature. The combat was fought, Pegun was defeated, and the prior lost his cause; at which he was so much chagrined, that he immediately resigned his office. This judicial combat is the more remarkable, that it was fought in the court of a spiritual baron, and that one of the parties was a priest."

We need scarcely add, that this detestable form of trial was the foundation of the no less detestable crime of duelling, which so much disgraces our age and nation; which is defended only by ignorance, false honour, and injustice; which is a relick of barbarous superstition; and which was absolutely unknown to those brave and generous nations, the Greeks and Romans, which it is so much the fashion to admire, and who in this particular so well merit our imitation. See DUEL.

It was so much the custom in the middle ages of Christianity, to respect the cross even to superstition, that it would have been indeed wonderful if the same ignorant bigotry had not converted it into an ordeal; accordingly we find it used for this purpose, in so many different ways as almost to preclude description. We shall, however, transcribe, for the satisfaction of our readers, Dr Henry's account of it, and of the corsned: "In criminal trials, the judgment of the cross was commonly thus conducted. When the prisoner had declared his innocence upon oath, and appealed to the judgment of the cross, two sticks were prepared exactly like one another: the figure of the cross was cut on one of these sticks, and nothing on the other: each of them was then wrapped up in a quantity of fine white wool, and laid on the altar, or on the relicks of the saints; after which a solemn prayer was put up to God, that he would be pleased to discover, by evident signs, whether the prisoner was innocent or guilty. These solemnities being finished, a priest approached the altar, and took up one of the sticks, which was uncovered with much anxiety. If it was the stick marked with the cross, the prisoner was pronounced innocent: if it was the other, he was declared guilty. When the judgment of the cross was appealed to in civil causes, the trial was conducted in this manner: The judges, parties, and all concerned, being assembled in a church, each of the parties chose a priest, the youngest and stoutest that he could find, to be his representative in the trial. These representatives were then placed one on each side of some famous crucifix; and, at a signal given, they both at once stretched their arms at full length, so as to form a cross with their body. In this painful posture they continued to stand while divine service was performing; and the party whose representative dropped his arms first lost his cause.

"The corsned, or the consecrated bread and cheese, was the ordeal to which the clergy commonly appealed when they were accused of any crimes; in which they acted a very prudent part, as it was attended with no danger or inconveniency. This ordeal was performed in this manner: A piece of barley bread, and a piece of cheese, were laid upon the altar, over which a priest pronounced certain conjurations, and prayed with great fervency, that if the person accused was guilty, God would send his angel Gabriel to stop his throat, that he might not be able to swallow that bread and cheese. These prayers being ended, the culprit approached the altar, Ordeal.

altar, took up the bread and cheese, and began to eat it. If he swallowed freely, he was declared innocent; but if it stuck in his throat, and he could not swallow (which we may presume seldom or never happened), he was pronounced guilty."

There were besides these a variety of other ordeals practised in Christian countries, many of which retain the same names as among Pagans, and differ only in the mode of execution. In all nations of Christians where those trials were used, we find the clergy engaged in them. Indeed, in England, so late as King John's time, we find grants to the bishops and clergy to use the *judicium ferri, aquæ, et ignis*. And, both in England and Sweden, the clergy presided at this trial, and it was only performed in the churches or in other consecrated ground: for which Stiernhook gives the reason, *Non defuit illis operæ et laboris pretium; semper enim ab ejusmodi judicio aliquid lucri sacerdotibus obveniebat*. But, to give it its due praise, we find the canon law very early declaring against trial by ordeal, or *vulgaris purgatio*, as being the fabric of the devil, *cum sit contra præceptum Domini, Non tentabis Dominum Deum tuum*. Upon this authority, though the canons themselves were of no validity in England, it was thought proper (as had been done in Denmark above a century before) to disuse and abolish this trial entirely in our courts of justice, by an act of Parliament in 3 Hen. III. according to Sir Edward Coke, or rather by an order of the king in council.

It may still perhaps be a *postulatum* with some of our readers how the effects of these trials were evaded, and how it was possible to appear to do, what we know could not be really done, without material injury to the persons concerned: on this subject the learned historian whom we have already quoted, observes with regard to the ordeals in ancient Britain, which, *mutatis mutandis*, will answer for others, that, "If we suppose few or none escaped conviction who exposed themselves to those fiery trials, we shall be very much mistaken. For the histories of those times contain innumerable examples of persons plunging their naked arms into boiling water, handling red-hot balls of iron, and walking upon burning ploughshares, without receiving the least injury. Many learned men have been much puzzled to account for this, and disposed to think that Providence graciously interposed, in a miraculous manner, for the preservation of injured innocence. But if we examine every circumstance of those fiery ordeals with due attention, we shall see sufficient reason to suspect that the whole was a gross imposition on the credulity of mankind. The accused person was committed wholly to the priest who was to perform the ceremony, three days before the trial, in which he had time enough to bargain with him for his deliverance, and give him instructions how to act his part. On the day of trial, no person was permitted to enter the church but the priest and the accused till after the iron was heated, when twelve friends of the accuser, and twelve of the accused, and no more, were admitted, and ranged along the wall on each side of the church, at a respectful distance. After the iron was taken out of the fire, several prayers were said; the accused drank a cup of holy water, and sprinkled his hand with it, which might take a considerable time if the priest was indulgent. The space of nine feet was measured by the accused himself with his own feet, and he would probably give but scanty measure. He was obliged only to touch one of the marks with the toe of his right foot, and allowed to stretch the other foot as far towards the other mark as he could, so that the conveyance was almost instantaneous. His hand was not immediately examined, but wrapped in a cloth prepared for that purpose three days. May we not then, from all these precautions, suspect that these priests were in possession of some secret that secured the hand from the impressions of such a momentary touch of hot iron, or removed all appearance of these impressions in three days; and that they made use of this secret when they saw reason? Such readers as are curious in matters of this kind may find two different directions for making ointments that will have this effect, in the work here quoted *. What greatly strengthens these suspicions is, that we meet with no example of any champion of the church who suffered the least injury from the touch of hot iron in this ordeal: but when any one was so fool-hardy as to appeal to it, or to that of hot water, with a view to deprive the church of any of her possessions, he never failed to burn his fingers, and lose his cause."

* *DuCange, Gloss.* tom. iii. p. 397.

To this we shall add what the learned Beckmann has said concerning the imposition that was probably practised in the ordeal by fire. "I am not acquainted with every thing that concerns the trial by ordeal, when persons accused were obliged to prove their innocence by holding in their hands red-hot iron; but I am almost convinced that this was also a juggling trick of the popes, which they employed as might best suit their views. It is well known that this mode of exculpation was allowed only to weak persons, who were unfit to wield arms, and particularly to monks and ecclesiastics, to whom, for the sake of their security, that by single combat was forbidden. The trial itself took place in the church, entirely under the inspection of the clergy; mass was celebrated at the same time: the defendant and the iron were consecrated by being sprinkled with holy-water; the clergy made the iron hot themselves; and they used all these preparatives, as jugglers do many motions, only to divert the attention of the spectators. It was necessary that the accused person should remain at least three days and three nights under their immediate care, and continue as long after. They covered his hands both before and after the proof; sealed and unsealed the covering: The former, as they pretended, to prevent the hands from being prepared any how by art; the latter, to see if they were burnt.

Some artificial preparation was therefore known, else no precautions would have been necessary. It is highly probable, that during the three first days the preventive was applied to those persons whom they wished to appear innocent; and that the three days after the trial were requisite to let the hands resume their natural state. The sacred sealing secured them from the examination of presumptuous unbelievers; for to determine whether the hands were burnt, the three last days were certainly not wanted. When the ordeal was abolished, and this art rendered useless, the clergy no longer kept it a secret. In the 13th century, an account of it was published by Albertus Magnus, a Dominican monk

Ordeal, Order. monk (A). If his receipt be genuine, it seems to have consisted rather in covering the hands with a kind of paste than in hardening them. The sap of the *althæa* (marshmallow), the slimy seeds of the flea-bane, which is still used for stiffening by the hat-makers and silk-weavers, together with the white of an egg, were employed to make the paste adhere. And by these means the hands were as safe as if they had been secured by gloves.

"The use of this juggling trick is very old, and may be traced back to a Pagan origin. In the Antigone of Sophocles, the guards placed over the body of Polynices, which had been buried contrary to the orders of Creon, offered, in order to prove their innocence, to submit to any trial. We will, said they, take up red-hot iron in our hands, or walk through fire*.

* Vol. iii. 297.

ORDER, in *Architecture*, is a system of the several members, ornaments, and proportions of columns and pilasters; or a regular arrangement of the projecting parts of a building, especially the column, so as to form one beautiful whole. See ARCHITECTURE.

ORDER is also used for a division or class of any thing: thus the tribe of animals called *birds* is subdivided into six orders. See ORNITHOLOGY.

ORDER, in *Rhetoric*, is the placing of each word and member of a sentence in such a manner, as will most contribute to the force, beauty, or evidence of the whole; according to the genius and custom of different languages. With regard to order, we may observe in general, that, in English, the nearer we keep to the natural or grammatical order, it is generally the best; but in Latin, we are to follow the use of the best writers; a joint regard being always had to the judgment of the ear, and the perspicuity of the sense, in both languages.

ORDER is also used for a class or division of the members of the body of a state; with regard to assemblies, precedency, &c.

In this sense, order is a kind of dignity, which, under the same name, is common to several persons; and which, of itself, does not give them any particular public authority, but only rank, and a capacity of arriving at honours and employments.

To abridge this definition, order may be said to be a dignity attended with an aptitude for public employ. By which it is distinguished from an office, which is the exercise of a public trust.

In this sense, nobility is an order, &c. The clericate is also an order, &c.

ORDER is also the title of certain ancient books, containing the divine office, with the order and manner of its performance.

Roman order is that wherein are laid down the ceremonies which obtain in the Romish church. See RITUAL.

ORDER, in *Botany*, is a name given to a subdivision of plants in the Linnæan system. See BOTANY.

Order. ORDERS, by way of eminency, or *Holy ORDERS*, denote a character peculiar to ecclesiastics, whereby they are set apart for the ministry. See ORDINATION.

This the Romanists make their sixth sacrament.

In no reformed church are there more than three orders; viz. bishops, priests, and deacons. In the Romish church there are seven, exclusive of the episcopate, all which the council of Trent enjoins to be received, and believed, on pain of anathema.

They are distinguished into petty, or secular orders; and major, or sacred orders.

ORDERS, the petty, or minor, are for; viz. those of doorkeeper, exorcist, reader, and acolyth.

Those in petty orders may marry without any dispensation: in effect, the petty orders are looked on as little other than formalities, and as degrees necessary to arrive at the higher orders. Yet the council of Trent is very serious about them; enjoins that none be admitted into them without understanding Latin; and recommends it to the bishops, to observe the intervals of conferring them, that the persons may have a sufficient time to exercise the function of each order; but it leaves the bishops a power of dispensing with those rules; so that the four orders are usually conferred the same day, and only make the first part of the ceremony of ordination.

The Greeks disavow these petty orders, and pass immediately to the subdeaconate; and the reformed to the deaconate.

Their first rise Fleury dates in the time of the emperor Justinian. There is no call nor benefice required for the four petty orders; and even a bastard may enjoy them without any dispensation; nor does a second marriage disqualify.

ORDERS, sacred, or major, we have already observed, are three: viz. those of deacon, priest, and bishop.

The council of Trent, retrieving the ancient discipline, forbids any person being admitted to the major orders, unless he be in peaceable possession of a benefice sufficient for a decent subsistence; allowing no ordinations on patrimonies or pensions, except where the bishop judges it for the service of the church.

A person is said to be promoted to orders *per saltum*, when he has not before passed the inferior orders. The council of Constantinople forbids any bishop being ordained without passing all the degrees; yet church-history furnishes us with instances of bishops consecrated, without having passed the order of priesthood; and Panormus still thinks such an ordination valid.

Military ORDERS, are companies of knights, instituted by kings and princes, either for defence of the faith, or to confer marks of honour, and make distinctions among their subjects.

Religious ORDERS, are congregations or societies of monastics, living under the same superior, in the same manner, and wearing the same habit. Religious orders

(A) In his work *De Mirabilibus Mundi*, at the end of his book *De Secretis Mulierum*, Amstelod. 1702, 12mo, p. 100. Experimentum mirabile quod facit hominem ire in ignem sine læsione, vel portare ignem vel ferrum ignitum sine læsione in manu. Recipe succum bismalvæ, et albumen ovi, et semen psylli et calcem, et pulveriza, et confice cum illo albumine ovi succum raphani; commisce; ex hac confectione illineas corpus tuum vel manum, et dimitte siccari, et postea iterum illineas, et post hoc poteris audacter sustinere ignem sine nocumento.

ders may be reduced to five kinds; viz. monks, canons, knights, mendicants, and regular clerks. See MONK, CANON, &c.

Father Mabillon proves, that till the ninth century, almost all the monasteries in Europe followed the rule of St Benedict; and that the distinction of orders did not commence till upon the reunion of several monasteries into one congregation: that St Odo, abbot of Cluny, first began this reunion, bringing several houses under the dependence of Cluny: that, a little afterwards, in the 11th century, the Camaldulians arose; then, by degrees, the congregation of Vallombrosa; the Cistercians, Carthusians, Augustines; and at last in the 13th century, the Mendicants. He adds, that Lupus Servatus, abbot of Ferrieres, in the ninth century, is the first that seems to distinguish the order of St Benedict from the rest, and to speak of it as a particular order.

White ORDER denotes the order of regular canons of St Augustine. See AUGUSTINES.

Black ORDER denoted the order of BENEDICTINES.

These names were first given these two orders from the colour of their habit; but are disused since the institution of several other orders, who wear the same colours.

Gray ORDER was the ancient name of the CISTERCIANS; but since the change of the habit, the name suits them no more.

ORDERS, religious military, are those instituted in defence of the faith, and privileged to say mass; and who are prohibited marriage, &c.

Of this kind are the knights of Malta, or of St John of Jerusalem. Such also were the knights Templars, the knights of Calatrava, knights of St Lazarus, Teutonic knights, &c. See MALTA, TEMPLAR, &c.

Father Putignani accounts those military orders where marriage is not allowed, real religious orders. Papebroch says, it is in vain to search for military orders before the 12th century.

ORDERS, in a military sense, all that is lawfully commanded by superior officers. Orders are given out every day, whether in camp, garrison, or on a march, by the commanding officer; which orders are afterwards given to every officer in writing by their respective serjeants.

ORDINAL, a book containing the order or manner of performing divine service. See RITUAL.

ORDINAL Numbers, those which express order, as 1st, 2d, 3d, &c.

ORDINANCE or ORDONNANCE, a law, statute, or command of a sovereign or superior; thus the acts of parliament are sometimes termed *ordinances of parliament*, as in the parliament rolls. Though in some cases we find a difference made between the two; ordinances being only temporary things, by way of prohibition; and capable of being altered by the commons alone: whereas an act is a perpetual law, and cannot be altered by king, lords, and commons.

Coke asserts, that an ordinance of parliament differs from an act, as the latter can only be made by the king, and the threefold consent of the estates; whereas the former may be made by one or two of them.

ORDINANCE of the Forest, is a statute made in the 34th year of Henry I. relating to forest-matters.

In the French jurisprudence, ordinances are such laws as are established by the king's authority alone. All ordonnances begin with, *à tous presens, et à venir salut*.

ORDINARY, in general, signifies common, usual; thus, an ambassador, or envoy in ordinary, is one sent to reside statedly, and for a number of years, in the court of some foreign prince or state, in order to keep up a good understanding, and watch over the interest of his own nation.—This term is also applied to several officers in the king's household, who attended on common occasions. Thus we say, physician in ordinary, &c.

ORDINARY, in naval language, denotes the establishment of the persons employed by government to take charge of the ships of war, which are laid up in the several harbours adjacent to the royal dock-yards. These are principally composed of the warrant officers of the said ships, as the gunner, boatswain, carpenter, deputy-purser, and cook, and three servants. There is besides a crew of labourers inrolled in the list of the ordinary, who pass from ship to ship occasionally, to pump, moor, remove, or clean them, whenever it is necessary.

The term *ordinary* is also applied sometimes to the ships themselves; it is likewise used to distinguish the inferior sailors from the most expert and diligent. The latter are rated *able* on the navy books, and have higher pay than those who are rated *ordinary*.

ORDINARY, in common or canon law, means one who has ordinary or immediate jurisdiction in matters ecclesiastical, in any place. In this sense archdeacons are ordinaries, but the appellation is most frequently applied to the bishop of the diocese, who has of course the ordinary ecclesiastical jurisdiction, and the collation to benefices within such diocese. There are some chapels, chapters, abbeys, &c. exempted from the jurisdiction of the ordinary. The arsbbishop is ordinary of the whole province, to visit, and receive appeals from the inferior judicatures. The Romish writers on canon law call the pope by way of eminence *ordinary of ordinaries*, since by the Lateran council he has usurped the right of collating, by probation, to all benefices; in exclusion of the common collators.

ORDINARY of Assizes and *Sessions*, was a deputy of the bishop of the diocese, anciently appointed to give malefactors their neck-verses, and judge whether they read or not: also to perform divine service for them, and assist in preparing them for death. So the

ORDINARY of Newgate, is one who is attendant in ordinary upon the condemned malefactors in that prison, to prepare them for death; and he records the behaviour of such persons.

ORDINARY, or *Honourable ORDINARY*, in *Heraldry*, a denomination given to certain charges properly belonging to that art. See HERALDRY, Chap. III. sect. i.

ORDINATES, in *Geometry* and *Conics*, are lines drawn from any point of the circumference of an ellipsis, or other conic section, perpendicularly across the axis, to the other side. See *CONIC-Sections*.

ORDINATION, the act of conferring holy orders, or of initiating a person into the priesthood by prayer and the laying on of hands.

Ordination has always been esteemed a principal prerogative of bishops, and they still retain the function as as a mark of spiritual sovereignty in their diocese. Without ordination, no person can receive any benefice, parsonage, vicarage, &c. A person must be 23 years of age, or near it, before he can be ordained deacon, or have any share in the ministry; and full 24 before he can be ordained priest, and by that means be permitted to administer the holy communion. A bishop, on the ordination of clergymen, is to examine them in the presence of the ministers, who, in the ordination of priests, but not of deacons, assist him at the imposition of hands; but this is only done as a mark of assent, not because it is thought necessary. In case any crime, as drunkenness, perjury, forgery, &c. be alleged against any one that is to be ordained, either priest or deacon, the bishop ought to desist from ordaining him. The person to be ordained is to bring a testimonial of his life and doctrine to the bishop, and to give account of his faith in Latin; and both priests and deacons are obliged to subscribe the 39 articles.

The ordination of bishops is more properly and more commonly called *consecration.*

In the ancient discipline there was no such thing as a vague and absolute ordination; but every one was to have a church, whereof he was to be ordained clerk, or priest. In the twelfth century they grow more remiss, and ordained without any title or benefice.

The Council of Trent restored the ancient discipline, and appointed that none should be ordained but those who were provided of a benefice sufficient to subsist them. Which practice still obtains in England.

The council of Rome, in 944, ordered, that no ordinations shall be held, except on the first, fourth, seventh, and tenth months. In England, by can. 31. ordination days are the four Sundays immediately following the Ember-weeks; being the second Sunday in Lent, Trinity-Sunday, and the Sundays following the first Wednesday after September the 14th, and December the 13th. These are the stated times; but ordinations may take place at any other time, according to the discretion of the bishop or circumstances of the case.

Pope Alexander II. condemns *ordination per saltum,* as they call it; i. e. the leaping to a superior order without passing through the inferior.

Ordination is one of the sacraments of the church of Rome.

In the establishment of Scotland, where there are no bishops, the power of ordination is lodged in the presbytery, and by the Independents in the suffrage of the people. See Episcopacy, Presbyterians, and Independents.

ORDNANCE, a general name for all sorts of great guns used in war. See Gunnery.

Boring of Ordnance. Till within these 20 years, iron ordnance were cast with a cylindrical cavity, nearly of the dimension of the caliber of the piece, which was afterwards enlarged to the proper caliber by means of steel cutters fixed into the dog-head of a boring-bar-iron. Three side cutters equidistant were requisite to preserve the caliber straight and cylindrical; and a single cutter was used at the end of the bar to smooth the breech of the piece. In boring ordnance cast hollow, the piece was fixed upon a carriage that could be moved backwards and forwards in a direct line with the centre of a water-wheel; in this centre was fixed the boring-bar, of a sufficient length to reach up to the breech of the piece, or more properly to the further end of the caliber. The carriage with the piece being drawn backwards from the centre of the water-wheel to introduce the boring and finishing bars and cutters, it is then pressed forwards upon this bar by means of levers, weights, &c. and the water wheel being set a-going, the bar and cutters are turned round, and clean out and smooth the caliber to its proper dimensions.

Experience at last pointed out many inconveniences arising from the method of casting guns *hollow*, and widening the calibers by these boring bars. For the body of iron of the hollow-gun, being, at casting, in contact with the core that made the caliber within-side, and with the mould without-side, began to consolidate towards these sides in the first place, sooner than in the intermediate space, where of course the contraction of the iron takes place; by which means, all guns cast hollow become more or less spongy where they ought to have been most compact; and numberless cavities also were created round the cores, from stagnated air generated in them, which were too deep to be cut out by the boring.

To remedy these defects, iron ordnance is now universally cast solid, by which means the column of iron is greatly enlarged, and the grain more compressed; and the contraction of the iron becomes in the heart of the column, and consequently is cut out by the perforation for the caliber.

Guns are bored out of the solid reversely from the hollow method. The piece A is placed upon two standards BB, by means of two journeys, turned round by the water wheel C, the breech D being introduced into the centre of the wheel, with the muzzle towards the sliding carriage E, which is pressed forwards by a ratch F, and weights, in the same way as the gun-carriage was in the hollow-boring. Upon this sliding carriage is fixed, truly horizontal and centrical to the gun, the drill bar G, to the end of which is fixed a carp's tongue drill or cutter H; which, being pressed forward upon the piece whilst it is turning round, perforates the bore, which is afterwards finished with borers and cutters as the hollow guns were. The principal difficulty of perforating solid guns truly centrical, arises from the contraction of the iron above mentioned; which, resisting the drill unequally, tends to throw it out of the centrical line.

Plate CCCXC.

Office of Ordnance, an office kept within the Tower of London, which superintends and disposes of all the arms, instruments, and utensils of war, both by sea and land, in all the magazines, garrisons, and forts, in Great Britain. We have the following copious account of this establishment in Beatson's *Political Index*. In ancient times, before the invention of guns, this office was supplied by officers under the following names: the *bowyer*, the *cross bowyer*, the *galeator* or *purveyor of helmets*, the *armourer*, and the *keeper of the tents;* and in this state it continued till Henry VIII. placed it under the management of a master, a lieutenant, surveyor, &c. &c.

Some improvements have been since made; and this very important branch is now under the direction of the master general of the ordnance, having under him a lieutenant general, a surveyor general, a clerk, a storekeeper, a clerk of the deliveries, and a treasurer, with a very great number of inferior officers, employed in

Ordnance. in the Tower of London, at Woolwich, and in almost all the forts, garrisons, and principal ports in his majesty's dominions. The office of ordnance is divided into two distinct branches, the civil and the military; the latter being subordinate, and under the authority of the former. For the better understanding the business of the different officers, they shall be distinctly treated of, beginning with the principal one, viz.

Master General of the ORDNANCE is deemed the principal officer in the civil branch of the ordnance; yet he is always chosen from amongst the first generals in his majesty's service. His trust is very great, as in him is vested the sole power of storing all the military magazines in the king's dominions with proper munitions of war, and likewise to supply the royal navy with what they may need in his department, the parliament granting money in the most liberal manner for this purpose. He is colonel in chief of the royal regiment of artillery, at present consisting of four battalions; and he is invested with a peculiar jurisdiction over all his majesty's engineers employed in the several fortifications in his majesty's dominions; and to him they are all accountable for their proceedings, and from him they receive their particular orders and instructions, according to the directions and commands given by his majesty in council. As master general of the ordnance he has the appointment of almost all the inferior officers and servants. He has a secretary, and an under-secretary; and besides there is a secretary and a counsel to the board of ordnance.

Lieutenant General of the ORDNANCE receives all orders and warrants signed by the master-general, and from the other principal officers, and sees them duly executed, issues orders as the occasions of the state require, and gives directions for discharging the artillery when required at coronations, birth days, signal victories, and other solemn occasions. It is also his peculiar office to see the train of artillery, and all its equipage, fitted for motion, when ordered to be drawn into the field, or sent upon any particular service. He is colonel *en second* of the royal regiment of artillery, and has a secretary and several inferior officers and clerks under him.

Surveyor General of the ORDNANCE inspects the stores and provisions of war in the custody of the storekeeper, and sees that they are ranged and placed in such order as is most proper for their preservation. He allows all bills of debt, and keeps a check upon all labourers and artificers work; sees that the stores received be good and serviceable, duly proved and marked, as they ought to be, with the king's mark, taking to his assistance the rest of the officers and proof-masters. To assist him in the business of his office, he has under him the proof-master of England, and clerks, and other inferiors officers.

Clerk of the ORDNANCE, an officer whose function is to record all orders and instructions given for the government of the office; all patents and grants; the names of all officers, clerks, artificers, gunners, labourers, &c. who enjoy those grants, or any other fee for the same; to draw all estimates for provisions and supplies to be made, and all letters, instructions, commissions, deputations, and contracts for his majesty's service; to make all bills of imprest and debentures, for the payment and satisfaction of work done and provisions received in the said office; and all quarter books for the salaries and allowances of all officers, clerks, &c. belonging to the office; and to keep journals and ledgers of the receipts and returns of his majesty's stores, to serve as a check between the two accountants of the office, the one for money, and the other for stores. Ordnance ‖ Ordovices.

Storekeeper of the ORDNANCE takes into his custody all his majesty's ordnance, munitions and stores belonging thereto, and indents and puts them in legal security, after they have been surveyed by the surveyor-general, any part of which he must not deliver without a warrant signed by the proper officers: nor must he receive back any stores formerly issued till they have been reviewed by the surveyor, and registered by the clerk of the ordnance in the book of remains; and he must take care that whatever is under his custody be kept safe, and in such readiness as to be fit for service upon the most peremptory demand.

Clerk of the Deliveries of the ORDNANCE draws all orders for delivery of any stores, and sees them duly executed; charges by indenture the particular receiver of the stores delivered; and, in order to discharge the store-keeper, registers the copies of all warrants for the deliveries, as well as the proportions delivered.

Treasurer and Paymaster of the ORDNANCE receives and pays all moneys, both salaries and debentures in and belonging to this office. In his office are several clerks, ordinary and extraordinary, for the dispatch of business.

Office of ORDNANCE. Besides the principal officers already mentioned, there belong to this office two proof-masters; a clerk of the works; a purveyor for the land, and a purveyor for the sea; an architect; an astronomical observer; and other officers. The other part of this office, which is termed the military branch of the ordnance, is a chief engineer, who has under him two directors, four sub-directors, with an unlimited number of engineers in ordinary, engineers extraordinary, sub-engineers, and practitioner engineers.

ORDNANCE *Bills*, commonly called *ordnance debentures*, are bills issued by the board of ordnance on the treasurer of that office, for the payment of stores, &c. These are not payable at any certain time, and do not bear any interest, so that the discount upon them is often very high; but they are seldom much above two years in arrears.

ORDONNANCE, in architecture, is the composition of a building, and the disposition of its parts, both with regard to the whole and to one another; or, as Mr Evelyn expresses it, determining the measure of what is assigned to the several apartments. Thus ordonnance is the judicious contrivance of the plan or mould; as when the court, hall, lodgings, &c. are neither too large nor too small, but the court affords convenient light to the apartments about it; the hall is of fit capacity to receive company; and the bed-chambers, &c. of a proper size. When those divisions are either too great or too small, with respect to the whole, as where there is a large court to a little house, or a small hall to a magnificent palace, the fault is in the ordonnance. See ARCHITECTURE.

ORDONNANCE, in *Painting*, is used for the disposition of the parts of a picture, either with regard to the whole piece, or to the several parts, as the groups, masses, contrasts, &c. See PAINTING.

ORDOVICES, ancient Britons, of whom we have the following account in Henry's History of Great Britain. They lived "in that country which is now called

North Wales, and contains the counties of Montgomery, Merioneth, Caernarvon, Denbigh, and Flint. These Ordovices, or (as they are called by Tacitus) Ordeuices, are supposed to have been originally of the same tribe or nation with the Huicii of Warwickshire, who were under some kind of subjection to the Cornavii; but the Huicii of North Wales, being a free and independent people, were called Ordh Huici, or the free Huici. When they were invaded by the Romans, they showed a spirit worthy of their name, and fought with great bravery in defence of their freedom and independency. Though they received a great defeat from the Roman general Ostorius, in conjunction with the Silures, they maintained the war for a considerable time, until they were finally subdued, with great slaughter, by the renowned Agricola. It was probably owing to the nature of the country, and to the vicinity of Diva, now Chester, where a whole legion was quartered, that the Romans had so few towns or stations in the territories of the Ordovices. Mediolanum, which is mentioned by Ptolemy, was the capital of the nation, and was probably situated at Maywood, in Montgomeryshire. It was a place of some consideration in the Roman times, but was afterwards quite demolished by Edwin, king of Northumberland. Besides this, the Romans had a few other towns in this country; as Segontium, now Caernarvon; Conovium, now Conway; and Varæ, now Bodvary, which are all mentioned in the eleventh journey of Antoninus. The country of the Ordovices was comprehended in the Roman province which was called *Britannia Secunda*."

ORE, a mineral body, partly or entirely composed of metallic substances, in the natural state in which it exists in the earth. Metallic substances are found, either native, that is, pure, and uncombined with other substances, or alloyed with other metals, or combined with oxygen, or sulphur, or with acids; and thus it appears, that metals exist in ores, in four different states. 1. In the metallic state, when they are either pure, or combined with each other, as in the state of alloy. 2. In the state of an oxide. 3. Combined with sulphur in the state of sulphuret. And, 4. with acids, forming salts. For the particular description of ores, see MINERALOGY; and for the mode of their distribution in the earth, see GEOLOGY.

But ores are rarely found exactly in the state of combination now mentioned. It seldom indeed happens, that they are not mixed with various earthy minerals. As all metals are extracted from ores, it is of great importance to be acquainted, in the first place, with the materials of which they are composed, as they are obtained from the earth, with the view of ascertaining the nature and proportions of the various ingredients which enter into the composition; and in the second place, to know the simplest and easiest processes by which the metals may be separated, for the purposes of economy and manufactures. Hence, in the treatment of ores, two objects are in view. The first is their analysis, which is the province of the chemical philosopher; and the second is their reduction in the large way, which is the business of the metallurgist. The most improved methods for accomplishing each of these objects, will be detailed in the following treatise.

ORES, Reduction and Analysis of.

In the treatment of metallic ores, it has been already hinted, that two objects are in view: the one is to obtain a knowledge of the nature and proportions of their component parts; and the other is to be acquainted with the best methods of separating the metals which they contain, that they may be applied in their pure or uncombined state to useful purposes. In the following treatise, therefore, we shall keep in view the same objects: and under each of the metals we shall first detail the most improved methods of analysing its different ores; and, secondly, give a short account of the best and most approved processes that are employed in their reduction. The last object, however, refers only to some of the metals, others not being found in sufficient quantity, or not being applicable to useful purposes.

In this treatise we shall consider the metals in the same order in which they have been described under MINERALOGY, and to each metal we shall devote a particular chapter.

Chap. I. *Of the Ores of Platina.*

PLATINA, on account of its infusibility, density, and indestructibility, is one of the most important and useful of the metals yet known, and particularly for different chemical instruments and utensils, because there are few chemical agents whose effects it cannot resist. Platina is only found in the state of alloy, with rhodium and palladium, two of the newly discovered metals; and it is accompanied also with another alloy, iridium and osmium, also newly discovered metals, as well as with particles of iron, gold and some other substances. The discovery of these metals, and the importance of platina itself, have rendered the ores of this metal peculiarly interesting. We shall therefore in the present chapter, give a pretty full detail of the methods of analysing the ore, and of working it for the purposes of manufacture. These subjects will occupy the two following sections.

Sect. I. *Of the Analysis of the Ores of Platina.*

The whole of the platina which is brought to Europe, has been previously subjected to the process of amalgamation in South America; and hence it happens, that a small quantity of mercury remains in it, sometimes in very small distinct particles, but more commonly in a state of combination with gold, in the form of an amalgam. In treating the ores of platina, therefore, the first object is to separate the mercury, and the easiest process is to drive it off by means of heat, either in an open ladle, if it be not intended to collect the mercury, or in an earthen retort, if the object of the operator be to retain that metal. The platina remaining after the mercury is thus driven off, appears much yellower, because the particles of gold dispersed through it exhibit their peculiar colour. The ore is next to be spread out thin on a smooth table, and by means of a pair of common bellows, the lighter particles may be separated with tolerable

Platina.

lerable accuracy from the heavier ones. The lighter particles in the ore are found, on examination, to be minute crystals and fragments of quartz, and two kinds of iron ore, which are also in fragments, or in the form of small octahedrons. Some of the particles of iron are attracted by the magnet, forming the ore of iron called *magnetic iron-sand;* but others, which are not attracted by the magnet, give out, when roasted, a slight sulphureous odour.

The lighter particles being separated by mechanical action, the heavier particles are to be treated with a small quantity of slightly diluted nitro-muriatic acid, and by this means the whole of the gold is taken up, with a portion of iron, and a small quantity of platina and other ingredients. The gold may be thrown down from this solution by adding green sulphate of iron, and it may be purified by mixing it with nitre and borax. If the quantity of platina to be purified be considerable, it is an object worth the attention of the chemist, to separate and collect the gold, because the proportion of the latter contained in crude platina is not small. Proust obtained seven ounces of gold from a quantity of platina consisting of 100 ounces; and from another quantity of the same weight he separated not less than 13 ounces of gold*. It may be observed that the platina which is whitest, is found to be the richest in gold, and that the black varieties scarcely contain any at all.

* Ann. de Chim. xxviii. 146.

The gold being separated, the platina is next to be digested in nitro-muriatic acid, and excepting a black matter, the whole is dissolved. This black matter, when first observed, was supposed to be plumbago; but it appears from the discovery of Mr Tennant, to be a compound of two new metals, to which he has given the names of osmium and iridium. By adding muriate of ammonia to the nitro-muriatic solution, almost the whole of the platina is precipitated in the form of a yellow powder. This powder is a muriate of ammonia and platina, and it is nearly insoluble. The solution being next treated with zinc, the whole of its metallic contents, excepting the iron, are thrown down. The precipitate thus obtained is to be washed and digested in nitric acid much diluted. By this means the copper and lead with which crude platina is usually contaminated, are separated. The remainder is to be dissolved in nitro-muriatic acid; to the latter sollution add common salt, and evaporate the whole to dryness; the salt remaining contains the muriates of soda and of platina, palladium and rhodium; and as the salt of rhodium is found to be insoluble in alcohol, it may, by means of it, be separated from the former. The platina and palladium now remain in the alcoholic solution, and from this the greater part of the platina may be separated by means of muriate of ammonia; and after diluting the solution by adding prussiate of potash, a deep orange precipitate is obtained, which is palladium. By concentrating the remaining liquor, the platina may be precipitated by means of muriate of ammonia.

Sect. II. *Of the Methods of working Platina.*

Platina, on account of its peculiar properties in resisting great degrees of heat and the action of many of the most powerful chemical agents, is by far the most important and valuable of the metals yet known for the purpose of constructing various instruments and utensils which are found highly useful in chemical analysis. But the refractory nature of this metal has presented many difficulties, and has greatly exercised the ingenuity and skill of chemists and artists to rendered it malleable and capable of assuming the requisite forms. It has been observed that the largest and whitest grains picked out from crude platina have a considerable degree of malleability even when cold; but when they are heated, this property appears in greater perfection: and if two of these grains be brought into contact, and subjected to the highest degree of white heat, the stroke of a hammer will make them adhere more or less perfectly. In this way, a small mass of metal may be obtained by the union of a few grains. But it is obvious that the patience and dexterity required in this slow and tedious process will prevent it from being practically useful.

In the progress of experiments made on platina it was discovered that arsenic combined readily with that metal, and formed an alloy of easy fusibility. The great volatility of the arsenic, particularly when in contact with charcoal, gave reason to hope that the whole of it, by proper management, might be driven off, leaving the platina behind in a mass, and retaining its peculiar and characteristic properties. In this way different chemists succeeded in forming, of this alloy, crucibles and other chemical utensils, which were found to be less fusible than silver, and were capable of resisting many of the common chemical agents. The most successful method of rendering platina malleable, and working it by means of this alloy, was discovered by Jeanety, a Parisian silversmith, who long directed his attention to this object. An account of his method has been given by Berthollet and Pelletier, of which the following is an abstract*.

* Ann. de Chim. xiv. 20.

The crude platina being first ground in water, and washed for the purpose of separating the earthy matters, three half pounds of the metal, three pounds of white arsenic, and one pound of pearl ashes, are to be well mixed together. A crucible, capable of holding 20 pounds of this mixture, is then to be placed in a furnace of any convenient construction. When the crucible is thoroughly red hot, introduce one-third of the mixture, and continue stirring it with a rod of platina till it comes to a state of quiet fusion; then add another one-third, stirring it in the same manner till the fusion is completed, and afterwards add the remaining one-third, and apply a strong heat, so that the whole may become very fluid. Then withdraw the crucible, and when it has cooled gradually, break it up; a well formed metallic button will be found in it, covered by blackish brown scoriæ, which has a considerable action on the magnetic needle. The button, which is very brittle, being broken to pieces, is to be fused again with white arsenic and pearl ashes as before, and the metallic mass obtained from this second fusion is generally found to have no effect on the magnetic needle; but if this should not be the case, a third fusion in the same way becomes necessary.

The first step of the process is now completed. A flat-bottomed cylindrical crucible, about three inches and a half in diameter, is to be made thoroughly hot in a furnace, and charged with one pound and a half of the arsenicated platina, mixed with an equal weight of white arsenic, and one half pound of pot-ash; and when this mixture

Platina.

mixture has been completely fluid, the crucible is to be removed from the fire, and allowed to cool in a horizontal position, that the thickness of the cake of metal may be uniform. When the crucible is cold, it is to be carefully broken, and the scoriæ being removed, a cake of metal is obtained, well-formed and sonorous, weighing three ounces more than the arsenicated platina employed. The metal is now quite saturated with arsenic. It has been observed, that there is no inconvenience from incorporating too much arsenic, for it would appear that the full success and rapidity of the purification of the platina, are exactly in proportion to the quantity of arsenic with which it has been previously combined.

The mass of metal thus obtained, is placed in a muffle, and the heat is gradually increased, till the evaporation of the arsenic commence; after which the temperature is to be kept up as nearly as possible at the same degree, for the space of six hours, carefully watching not to increase it, lest the cake should be brought to a state of fusion. At the end of the six hours, the cake has usually become considerably porous; it is then to be withdrawn, and extinguished in common oil; after which it is returned to the muffle, by which means a further quantity of arsenic is drawn off; and this alternate heating and application of oil are to be continued till the arsenic no longer makes its appearance. In proportion as the arsenic is driven off, the fusibility of the mass diminishes, so that a greater degree of heat may be applied in the latter stage of the process. After having carefully burnt off at a high degree of heat the whole of the charcoal which is produced by the decomposition of the oil, the spongy cake of metal is to be digested in nitrous acid, and then edulcorated by repeated boiling in water. Three or more of the cakes are then to be placed in a crucible, and exposed to the highest degree of heat in a powerful furnace, and while they are thus rendered soft, an iron pestle let down upon them, will make them cohere; and being withdrawn from the crucible, they are to be heated to the utmost in a smith's fire, and carefully forged like iron on the anvil, into compact bars.

The cheapness of the process now detailed is the only advantage which it holds out, for the platina does not require to be previously dissolved in nitromuriatic acid; but it is to be observed, that the metal by this treatment is by no means perfectly pure; a small portion of arsenic and iron still adhering to it, and probably some lead and copper, which may have been accidentally mixed with the ore, while it contains the whole of the palladium, osmium, iridium, and rhodium; and thus contaminated, it is obvious, that it must be less capable of resisting the action of alkalies, and high degrees of heat without injury, than when it is brought to a state of greater purity. Accordingly, other processes for the purification of this valuable metal, have been contrived and practised.

The following is the processes proposed by Count Moussin Poushskin, to render platina malleable. 1. Precipitate the platina from its solution by muriate of ammonia, and wash the precipitate with a little cold water.

2. "Reduce it in a convenient crucible to the well-known spongy metallic texture, which wash two or three times with boiling water to carry off any portion of saline matter which may have escaped the action of the fire.

3. Boil it for about half an hour in as much water, mixed with one-tenth part of muriatic acid, as will cover the mass to the depth of about half an inch, in a convenient glass vessel. This will carry off any quantity of iron that might still exist in the metal.

Platina.

4. "Decant the acid water, and edulcorate or strongly ignite the platina.

5. "To one part of this metal take two parts of mercury, and amalgamate in a glass or porphyry mortar. This amalgamation takes place very readily. The proper method of conducting it is to take about two drams of mercury to three drams of platina, and amalgamate them together; and to this amalgam may be added alternate small quantities of platina and mercury till the whole of the two metals are combined. Several pounds may be thus amalgamated in a few hours, and in the large way a proper mill might shorten the operation.

6. "After the amalgam is completely produced, it must be quickly moulded in bars or plates, or any other forms that may be preferred; taking care that these moulded pieces should at least be half an inch in thickness, and of a proper length to manage them afterwards in the fire; it is also requisite that the mould should be perfectly even and smooth. Half an hour after the pieces are formed they begin to harden by the oxidation of the mercury, and change their brilliant metallic colour for a dull learden ore.

7. "As soon as the pieces have acquired a proper degree of hardness to be handled without danger of breaking, which commonly takes place in a little more than an hour, place them in a proper furnace, and keep them ignited under a muffle or in a small reverberatory. No other precaution is necessary in this operation, but that of not breaking the pieces during their transport. The mercury flies off during the heat, and the platina remains perfectly solid; so that, after being strongly ignited two or three times before the bellows, it may be forged, or laminated in the same manner as gold or silver; care being taken, at the commencement of the forging, or of passing it between rollers, not to apply too great a force till the metal has acquired all its density. It is almost superfluous to add, that in evaporating the mercury from large quantities of amalgam, a proper apparatus, such as in the silver amalgamation, must be employed, to receive the volatilized mercury; but for small quantities, where the loss of this metal is of no consequence, the furnace must have a proper chimney to carry off the metallic vapours. When the platina comes out of the first fire, its dimensions are about two thirteenth parts smaller every way than the original amalgam from the mould. The whole of this operation seems to be governed by the pressure of the atmosphere and the laws of cohesive attraction: for the air is driven out from between the molecules of the platina, which by their solution in mercury are most probably in their primitive and consequently uniform figure. It is very visible, and at the same time a very amusing phenomenon to observe, (during the process of ignition, which is performed in four or five minutes), how the platina contracts every way into itself, as if pressed by some external force."

The count then adds, "that, as soon as my amalgam of mercury is made, I compress the same in tubes of wood, by the pressure of an iron screw upon a cylinder of wood, adapted to the bore of the tube. This forces out the superabundant mercury from the amalgam, and renders

Platina.

renders it solid. After two or three hours I burn upon the coals, or in a crucible lined with charcoal, the sheath in which the amalgam is contained, and urge the fire to a white heat; after which I take out the platina in a very solid state, fit to be forged *."

* Nichol. Journ. ix. 65.

A simpler method for rendering platina malleable, at the same time not less effectual, has been proposed by Mr Knight. The following is an account of this method in the words of the author.

"To a given quantity of crude platina, I add fifteen times its weight of nitro-muriatic acid (composed of equal parts of nitric and muriatic acid) in a tubulated glass retort, with a tubulated receiver adapted to it. It is then boiled, by means of an Argand's lamp, till the acid has assumed a deep saffron colour; it is then poured off; and if any platina remain undissolved, more acid is added, and it is again boiled until the whole is taken up. The liquor, being suffered to rest till quite clear, is again decanted: a solution of sal-ammoniac is then added, by little and little, till it no longer gives a cloudiness. By this means the platina is thrown down in the form of a lemon-coloured precipitate, which having subsided, the liquor is poured off, and the precipitate repeatedly washed with distilled water till it ceases to give an acid taste; (too much water is injurious, the precipitate being in a certain degree soluble in that liquid): the water is then poured off, and the precipitate evaporated to dryness.

"So far my process is in a great measure similar to that which some others have also followed; but my method of managing the subsequent, and which are indeed the principal manipulations, will be found to possess many advantages over any that has yet been made public. The best process hitherto followed has been, to give the precipitate a white heat in a crucible, which in some measure agglutinates the particles; and then to throw the mass into a red-hot mortar, or any similar implement, and endeavour to unite them by using a pestle or stamper. But the mass is so spongy that it is hardly possible to get a single stroke applied to it before the welding heat is gone; and though by peculiar dexterity and address some have in this way succeeded, it has been found to require such innumerable heatings and hammerings, that most of those who have attempted it, have either failed entirely, or given it up as being too laborious and expensive. I have succeeded in obviating all these difficulties by adopting the following simple, easy, and expeditious method:—

"A strong, hollow, inverted cone of crucible earth being procured, with a corresponding stopper to fit it, made of the same materials, the point of the latter is cut off about three-fourths from the base. The platina, now in the state of a light yellow powder, is pressed tight into the cone, and a cover being fixed slightly on, it is placed in an air furnace, and the fire raised gradually to a strong white heat. In the mean time the conical stopper, fixed in a pair of iron tongs suitable for the purpose, is brought to a red or to a bright red heat. The cover being then removed from the cone, the tongs with the heated stopper is introduced through a hole in the cover of the furnace, and pressed at first gently on the platina, at this time in a state nearly as soft as dough, till it at length acquires a more solid consistence. It is then repeatedly struck with the stopper, as hard as the nature of the materials will admit, till it appears to receive no farther impression. The cone is then removed from the furnace, and being struck lightly with a hammer, the platina falls out in a metallic button, from which state it may be drawn, by repeatedly heating and gently hammering, into a bar fit for flatting, drawing into wire, planishing, &c.

"Besides the comparative facility of this process, it has the farther advantage of rendering the platina much purer than when red-hot iron is obliged to be had recourse to; for platina, when of a white heat, has a strong affinity for iron, and, with whatever care it may have been previously separated from that metal, will be found to have taken up a portion of it, when it is employed of a red heat, to serve to unite the particles of the platina. To the superior purity of platina, rendered malleable by the process before described, I attribute the greater specific gravity which I find it to possess, than that prepared by other methods. Having taken the specific gravity of about ten pennyweights of it, which I had previously passed repeatedly through a flatting mill, I found it to be 22.26†."

† Phil. Mag. vi. 2.

Another method, which has been successfully practised, was contrived by Mr Cock. The following is an account of his process. After the solution of the platina in nitro-muriatic acid, the liquor is filtered through clean sand, for the purpose of separating the black powder which floats in it. The clear solution is then decomposed by means of sal ammoniac; the yellow precipitate being collected, is to be moderately well washed in warm water and dried; and being distributed into saucers placed in a small oven, constructed for the purpose, in which they are to be exposed for a short time to a low red heat, that the platina may be brought to the metallic state, and the greater part of the sal ammoniac may be sublimed. When the platina, after this treatment, is withdrawn, it is in the form of a gray coloured, spongy mass; and in this state half an ounce of it is to be put into a strong iron mould, one inch and a half wide, and two and a half long. It is then to be compressed as strongly as possible, by striking with a mallet upon a wooden pestle accurately cut to fit the mould; another half ounce is then added, and treated in the same manner, till six ounces have been forced into the mould; a loose iron cover, just capable of sliding down the mould, is then laid upon the platina. This part of the process requires particular care; for if any material quantity of air be left in the mass, the bar into which it is formed is extremely apt to scale and be full of flaws in the subsequent operations. The pressure being properly made, the mould is to be taken to pieces, and the platina will be found in the form of a dense compact parallelopiped. It is next to be placed in a forge fire of charcoal, and heated to the most intense white heat, in order to drive off the muriate of ammonia which remains: this being done, it is to be quickly placed on a clear bright anvil, and gently hammered in every direction by a clean hammer. This is several times to be repeated, at the end of which the mass will be perfectly compact, and fit to be laminated or wrought in any other manner at the pleasure of the artist. It is to be observed, that while the platina is heating, it must be loose in the fire, for if it were held by the tongs, they would infallibly become welded to the platina, and by this means greatly damage it. When the platina is thus drawn down to a compact bar, it will be covered by a semivitreous crust,

somewhat

Gold.

somewhat reddish, chiefly proceeding from particles of the ashes melted down upon it, and extended by the hammer over its surface. To remove this, the bar, after being made red hot, is to be sprinkled over with glass of borax reduced to powder, and then kept at a white heat for a few minutes; it is to be plunged into diluted muriatic acid when moderately cool, by which the borax and other vitreous matters will be dissolved, and the platina with a perfectly clean white surface left behind *.

* *Aikin's Diction. of Chem.* &c. ii, 433.

Chap. II. *Of the Ores of Gold.*

Gold exists in nature only in the metallic state; but it is scarcely ever found perfectly pure, for it is alloyed in different proportions with silver, copper, tellurium, and some other metals. When it is alloyed with silver or copper, or even with both, the gold retains its ductility; but when combined with tellurium, its distinctive characters entirely disappear.

Sect. I. *Of the Analysis of the Ores of Gold.*

The method of analysing gold ores is very simple. The principal difficulty with which it is attended arises from the small proportion of this metal contained in the greater part, even of those ores which are considered as very rich. Native gold contains invariably, but generally in small proportion, silver or copper, and sometimes both, and the gangue is often a very hard quartz. In this case the following is an approved mode of proceeding. Reduce the ore to fine powder, mix it with six times its weight of carbonate of soda, or, what answers better, with four parts of carbonate of soda, and one of glass of borax: put the mixture into an earthen crucible, and melt it. Pour out the fused mass on a stone slab, and detach the small portion remaining in the crucible by means of a little diluted muriatic acid. Reduce the mass to coarse powder; put it into a flask with the muriatic solution; add strong muriatic acid, and apply a gentle heat. Continue the digestion, adding from time to time a little nitrous acid, till no farther action is produced, and the undissolved residue becomes of a pure white colour. Then pour off the liquor, wash the residue, and add the washings to the liquor.

1. After the insoluble residue is dried, expose it to the sun, and if it contain any muriate of silver, it will assume a purplish colour. When this is the case, let it be mixed with three times its weight of pearl-ash, and fused in an earthen crucible for five minutes. The silver will thus be reduced to metallic globules, and will be obtained pure by digesting it in muriatic acid, which combines with the earth and alkali, but does not act on the silver.

2. The nitro-muriatic solution is now to be carefully neutralized by means of soda or of potash; and a solution of green sulphate of iron is to be added, as long as any precipitate is formed. The precipitate thus obtained is gold, and this being carefully collected, is to be fused in a small crucible with nitre just in sufficient quantity to cover its surface.

3. The residual liquor, after being decomposed by the carbonate of an alkali, and the precipitate being well washed, is to be digested in liquid ammonia, to dissolve the copper. The ammoniacal solution being slightly supersaturated with muriatic acid, a rod of zinc being introduced, will precipitate the copper in the metallic state.

Auriferous pyrites. It appears that iron pyrites of a bronze yellow colour in masses, or in striated cubes, and hepatic pyrites, which are found in veins in primitive mountains, contain a quantity of pure gold, or of gold alloyed with silver, which is worth the trouble and expence of extracting it. A considerable proportion, not only of the American, but also of the Hungarian gold, is obtained from ore of this kind. The produce of the latter sometimes does not exceed a few grains of gold in the quintal, but occasionally the auriferous pyrites of the Hungarian mines yield not less than 450 ounces of gold in the quintal of the ore.

The following is the method of analysis to be followed in ores of this kind. The pyrites being reduced to powder, is digested in muriatic acid, occasionally adding a small portion of nitric acid, till every thing soluble is taken up. The residue, after being well washed and dried, is to be weighed, and exposed to a heat which is just sufficient to burn off the sulphur, the quantity of which is indicated by the loss of weight. The residue is again to be digested in nitro-muriatic acid, and this solution is to be added to the first. The earthy residue, which contains the silver in the state of muriate, is then to be fused with an equal weight of glass of borax, and three times the quantity of pearl ashes. By this process the silver is reduced, and may be separated from the alkali and the earth by means of muriatic acid very much diluted. The nitro-muriatic solution is to be neutralized by a fixed alkali, and if it be afterwards treated with nitrate of mercury prepared in the cold, the gold will be thrown down in the state of a brown powder. It may be reduced to the metallic state by fusing it with nitre. The oxide of iron which remains in solution, may be obtained in the usual way in the state of magnetic oxide.

Auriferous galena.—Galena, or the native sulphuret of lead, almost always contains a small portion of silver, and very often it is in such quantity as to be worth the trouble of extracting it. Galena sometimes has also combined with it a little gold as well as silver, and it is worked as one of the ores of gold. This is the case with some of the galena of Hungary, as that of Boicza yields $1\frac{1}{2}$oz. of alloy in the quintal, of which 31 parts are silver, and one of gold.

The analysis of auriferous galena is to be conducted nearly in the same way as the auriferous pyrites. The pulverised ore being digested in nitro-muriatic acid, the gold and the lead, and, if any are present, the iron and antimony, are taken up; leaving behind the earthy matters, as well as the sulphur and silver, which may be separated according to the method employed in the former process. By gradually evaporating the nitro-muriatic solution, a crystallized muriate of lead is obtained; and by again diluting the solution with water, the gold may be separated by adding nitrate of mercury.

The analysis of the ores of gold containing tellurium, will be given under the head of that metal.

Sect. II. *Reduction of the Ores of Gold.*

Many of the most profitable veins of gold are of trifling magnitude, but at the same time yield ample returns to the miner, although they are mixed with so large

Gold. large a proportion of stony matter and other impurities as would render the working of any other metal altogether unprofitable. This obviously arises from the great commercial importance of gold compared with other metals, which no doubt is owing as well to its rarity as to its peculiar properties. In the Hungarian gold mines, which are the richest yet known in the old continent, the attention of the miner is not merely limited to the strings of ore, but to the whole contents of the vein, which are usually extracted and raised to the surface in large masses. These masses are distributed to the workmen, who break them down, first with large hammers, and afterwards with smaller ones, till they are reduced to pieces of the size of a walnut. In the course of this process, every piece is carefully examined, and arranged according to its value. The smallest visible grain of native gold is separated from the quartz in which it is chiefly imbedded, and put by itself. The auriferous pyrites and galena are also put into separate heaps; even the small splinters that are detached in breaking down the masses, and the sand and mud of the mine, are all collected, washed, and sifted, and ranged according to their apparent richness. What has been rejected in the first examination, is re-examined by boys, whose labour is not of great value, and who pick out almost the whole that has been overlooked by the men, and arrange it in the same manner.

The native gold with the matrix attached to it, is again to be broken by hand into still smaller pieces, by which means other impurities and stony matters are separated. The ore is then introduced into a wooden box floored with cast-iron plates; and by the action of two or more heavy spars of oak, which are shod with iron, and alternately worked like the common stamping mill, it is reduced to a fine powder. This powder, which is called flour, is then removed into a vessel like a large bason, and is mixed with such a quantity of salt and water as will render it damp. The workman then takes a thin porous leather bag, introduces a quantity of mercury into it, and by a regular and continued pressure forces the mercury in very minute drops through the leather. In this divided state it falls upon the pulverized ore, and is immediately kneaded up with it, till the requisite quantity, which depends on the proportion of gold, has been added. After completing this part of the process, the next object is to incorporate the mercury and the gold. This is effected by rubbing the mixture together for some time by means of a wooden pestle. The mixture is then heated in a proper vessel, and subjected for three or four days, to the temperature of boiling water; and, lastly, the mixture is to be carefully washed by small parcels at a time, so that the earthy particles may be carried off by the water. The mercury combined with the gold, only remains behind, in the form of amalgam. A portion of this mercury is then separated by pressure in a leathern bag, and the remainder is driven off by distillation, leaving behind the gold, and silver with which it may be alloyed.

But a more complicated process is requisite in separating that portion of the gold which is invisibly dispersed in the pyrites, in galena, and other metallic substances, as well as the stony parts of the matrix. In the treatment and sorting already described, those ores are separated, not only according to their apparent richness, but they are arranged also according to the degrees of hardness. They are then carried to the stamping mill, of which the principal parts are, 1. The coffers or cisterns, in which the ore is reduced to powder, and through which a stream of water continually passes, and so managed as to be increased or diminished at pleasure: 2. The stampers, or vertical beams, which are shod with iron; and, 3. The axle, which is fixed horizontally, and one end of which works in a pivot, while the other is rivetted into the centre of a large water wheel. The mode of action of this apparatus is obvious. A stream of water falls upon the wheel, and turns it round, as well as the axle to which it is attached. The cogs, which are fastened to the axle, alternately raise the stampers to a given height, and then let them fall upon the ore placed in the coffers. And as the ore is sufficiently broken, it is carried by the stream of water continually passing through, out at the sides of the coffer into the labyrinths, where the stony and metallic contents of the ore are deposited, according to their specific gravity, nearer to or at a greater distance from the aperture. The coffer is a rectangular hole sunk below the level of the ground, and it is about five feet in length, two feet and sometimes less in width, and four feet deep. Five stampers are employed: they are strong oaken beams shod with iron, and weighing about 200 pounds each. They are placed side by side, at the distance of about $2\frac{1}{2}$ inches from each other.

When the ore is to be pounded, the first thing is to cover the bottom of the coffer with a flooring or pavement, composed of large pieces of the hardest and poorest part of the vein. These pieces are to be close set together, and a floor of this kind is found to answer better than an iron floor. The thickness of the floor is to be proportioned according to the degree of hardness of the ore to be pounded; for it is obvious that the higher it is, the smaller will be the space through which the stampers fall; and their momentum will therefore be proportionably diminished. One precaution must be invariably observed, that the part of the floor immediately under the middle stamper be about two inches lower than that below the stamper on each side, and that this again be an inch lower than that beneath the two outermost stampers.

After the coffer is thus prepared, the machinery is set in motion, a small stream of water being allowed to flow into the coffer. The ore is to be carefully thrown in, just below the middle stamper, or the proper quantity is supplied by means of a hopper. The ore being thus broken down by the middle stamper, is gradually delivered to the stampers on each side, where it is still farther reduced to powder, and from them it passes on to the two outermost stampers, where it is reduced to such a degree of fineness as to be for a time suspended in the water, and carried along with the stream through the openings at the ends of the coffer.

In stamping the ores of gold and silver, great attention is necessary, that no pieces of ore be subjected to the process that can be conveniently separated from the gangue by the hand; and that the ore be reduced to a coarse or fine powder, according to its nature. When native gold is dispersed in minute particles, in a hard siliceous matrix, it is found impossible to separate the whole of the metal, unless it be very finely pulverized; and in this case the ore may be reduced to fine powder, both on account of the great difference of the specific gravity of the two ingredients of the ore, and also because the siliceous particles, however minute, acquire no degree of tenacity, so as to adhere to the particles of gold. In stamping

Gold.

stamping ores of this kind, therefore, the coffers may be set very low, that the stampers may have the greater power, and a small stream of water only may be let in, that the current which passes out may carry with it only the smaller particles. But when the gold is dispersed in an indurated and ochrey clay, or in calcareous spar; if the ore in this case be not finely pulverized, a great proportion of the metal will be retained in the earthy matrix; and if the stamping be continued too long, the whole will be brought to a fluid mud, which will prevent the subsidence of the particles of gold. In the management of this part of the process, no small degree of skill and experience is requisite, to obtain the greatest produce of gold.

The reduction of the ore to grains of a uniform size, greatly facilitates the washing which follows the stamping, and yields a greater product of metal. This is effected by taking care that the ore, when first introduced into the coffer, shall fall under the middle stamper, and also by the velocity of the water wheel being properly regulated. When the motion of the stampers is too slow, loss of time is the only consequence; but when the motion is greatly accelerated, the water is violently thrown about, carrying with it to the apertures at the end of the coffer, pieces of the ore that are not sufficiently comminuted.

The ore being reduced to particles of a sufficient degree of fineness to be carried by the force of the water out of the coffer, passes into shallow channels of different dimensions. These channels or troughs, the whole series of which is called a labyrinth, are constructed of wood or stone, and communicate with each other at the extremities. The various parts of the ore are deposited in these channels, according to their specific gravities; the heaviest particles are detained in the first, and the lightest are carried along, and subside in the last and lowest. Each of the channels has a groove at its lowest extremity, and thus admits of being closed at pleasure by pieces of wood about an inch in height, which slide down upon each other. By varying the rapidity of the current through the channels, the heavy particles can be more accurately separated from the lighter ones, which is done by diminishing the slope, and increasing the width and length of the channels.

But with whatever care the first operation of the washing may be conducted, it is by no means sufficient to separate the whole of the sand from the ore. A second washing on tables, as they are called, is requisite. These tables are long wooden planes, which are considerably inclined, and are crossed at regular distances by narrow shallow grooves. A long wicker basket, or perforated wooden trough, filled with the washed ore, is fixed to the upper extremity of the table, and a small stream of water is admitted, which passing between the twigs of the basket, carries with it particles of the ore. These particles are either carried by the current off the table, or are deposited, according to their specific gravity, in the grooves, the heaviest particles subsiding first. In this way the auriferous ores of iron and copper pyrites, galena, &c. are sufficiently separated from the quartz and other stony matter, to be fit for the furnace; but for the ores of native gold, a third washing is necessary. This is performed in small quantities at a time, in a wooden vessel resembling in shape a common fire-shovel without a handle, but having the sides more elevated, and being furnished with two ears, by which it is held during the operation. The ore is put into this vessel, which is gently immersed in water, and a circular motion is communicated to it by a peculiar dexterity, which can only be acquired by practice. By this motion in the water the lighter particles are gradually thrown out of the vessel, and scarcely any thing remains behind but the gold, which is either amalgamated or fused with the addition of a little nitre, in an earthen crucible. Here it may be added, that the separation of the gold which is found in alluvial soil, or in the sands of rivers, is conducted precisely in the same way, only that it is not necessary to be subjected to the process of stamping previous to washing.

The produce of the proper auriferous ores is seldom of sufficient value to admit of the same attention in washing as native gold; and therefore it is always found, after this operation, mixed with a considerable proportion of earthy matters. When the metallic part is composed of pyrites, which is frequently the case, it may be useful, previous to the fusion of the ore, to give it a moderate roasting, for the purpose of expelling the greater part of the sulphur; but it must be observed, that this process is to be regulated by the quantity, and refractory nature of the stony part of the ore; because the sulphur in the subsequent fusion acts the part of a flux, and therefore the cleaner the ore, the more perfectly it may be roasted. This part of the process being completed, a little quicklime, as a flux, is added, and carefully mixed with the ore, and a portion of galena, according to the proportion of gold and silver contained in the pyrites, previously discovered by assaying it. This mixture is next to be introduced into a reverberatory furnace, which is to be raised to a red heat; and when the mixture begins to clot together, it is to be stirred from time to time, and kept at a temperature inferior to that of fusion, till part of the sulphur is expelled; and when this is accomplished, the fire is to be increased, so that the whole may be brought to a state of thin fusion, after which it is let out in the usual way, and received in a mould of sand. During the process of fusion, the iron having a very strong affinity for sulphur, recombines with that portion of which it had been deprived by the roasting, in consequence of the decomposition of the sulphurets of lead and copper with which it is mixed; and these metals, by their specific gravity, fall in drops through the vitreous ferruginous scoriæ, and carry with them the gold and silver, with which they unite at the bottom into a dense mass of metal. Thus it happens that the pig formed in the mould consists of two parts, which adhere to each other, but may be easily separated by the hammer. The superior and the larger portion, is a cellular mass of scoriæ, and the lower is a black, heavy, compact mass, containing the gold and silver, along with lead, copper, and a portion of sulphur and iron. It is again broken into pieces, and roasted and fused once or twice, till the whole of the sulphur and other impurities are separated, and nothing remains but the metallic substances.

In the farther treatment of the ores of gold, the object of the refiner is to separate it from the metallic substances with which it is alloyed. We shall now mention the different methods which are followed in separating the metals from gold with which it is usually alloyed.

1. *Separation*

Gold.

1. *Separation of gold from platina.*—As platina, like gold itself, is not susceptible of oxidation by exposure to heat and air, it cannot be separated by the process of cupellation; and platina having as little affinity for sulphur as gold itself, that substance, or the sulphurated metals, cannot be successfully employed for this purpose. It has been found that mercury combines more readily with gold than with platina, and from the knowledge of this circumstance a method has been devised of separating these metals. When the proportion of platina is so large, that the mass is brittle, it must be reduced to powder in a mortar; but if it be ductile, it may be reduced to small pieces by granulation. A quantity of mercury equal to seven or eight times the weight of the alloy, is then to be heated in an iron crucible, and raised to the boiling point. The alloy being first made red hot, is to be dropt in, and the whole kept for half an hour nearly at the same temperature. The mixture is then emptied into an iron mortar, and being covered with hot water, is to be carefully triturated for some hours, the water being renewed from time to time. In this way the gold combines with the mercury, and a considerable proportion of the platina will rise to the surface of the amalgam in the state of a black powder, which may be easily scraped off. In this way the alloy is to be purified as much as possible, and the superfluous mercury may be separated by straining through leather, and the amalgam is deprived of the remaining mercury by the process of distillation. The gold, which still holds a small quantity of platina, is now to be melted with three times its weight of silver; and the mixture being granulated, is to be parted by means of nitrous acid. It has been found (although it be a singular circumstance) that pure platina, or even when mixed with gold, is perfectly insoluble in this acid; but, when combined with a large proportion of silver, it is readily dissolved, and the solution is of a dark yellowish brown colour; and, therefore, by digesting this triple alloy of gold, platina, and silver, in nitrous acid, the silver and platina are dissolved, and the gold remains behind. But it may be necessary to ascertain whether the whole of the platina be separated. This is done by melting a few grains of the gold, after careful washing, with three times their weight of silver, and treating it as before with nitrous acid. If it contain one half per cent. or even a smaller proportion of platina, the acid will be perceptibly coloured, and this being the case, the process must be repeated again on the whole mass. But this is rarely necessary when the previous trituration with mercury has been carefully performed. By adding to the remaining nitrous solution, a solution of common salt, the silver will be precipitated, leaving the platina in the solution.

By the following method, which is still more compendious, gold may be separated from platina. The alloy is dissolved in nitro-muriatic acid, and the gold is precipitated by means of carbonate of soda, or a large quantity of green sulphate of iron, neither of which has the effect of decomposing the solution of platina. The precipitated gold being dried, and mixed with a little borax and nitre, is subjected to fusion, after which it will be found in a state of perfect purity.

2. *Separation of gold from silver.*—In ores in which the proportion of gold is small, the silver may be conveniently separated by means of sulphur. The alloy is first melted, and granulated, by pouring it into cold water, which is kept in constant agitation with a rod or wicker brush. From an eighth to a fifth of the granulated metal is reserved, and the remainder is carefully mixed with about one-eighth of its weight of powdered sulphur, which adheres readily to the moist grains. The mixture is introduced into a covered crucible, and kept for some time at a gentle heat, that the metal may be completely penetrated by the sulphur, after which the heat is increased till the whole mass is brought into fusion. This sulphuret of silver becomes a tough viscous fluid, which retains the particles of gold, and prevents them from subsiding. The mass being kept in fusion for about an hour, that the union of the sulphur and silver may be completed, and any excess may be burnt off, a third part of the reserved silver in grains is to be added, and when it is melted, is to be stirred with a wooden rod, that it may be accurately mixed with the other materials, and brought into contact with the gold, with which it immediately enters into combination. The fusion being continued another hour, a similar quantity of grained silver is to be added, and after a third hour has elapsed, the remaining third is introduced, and treated in the same manner. The crucible, which is now to be kept carefully covered, is to be exposed to a high temperature for three hours, while the melted mass is stirred from the bottom every half hour. At the end of this time the surface of the mass, instead of being dark brown, becomes whitish as the sulphur escapes, and some bright white drops of melted silver, about the size of pease, make their appearance. The fused mass is now to be poured into a greased cone; and when it is cold, it will be found to be composed of a mass of sulphuret of silver, resting upon a white metallic button, which is nearly equal in weight to the added silver, and contains the whole of the gold that originally existed in the entire mass. If it appears that any of the gold remains among the sulphuret of silver, it may be separated by fusion in an open crucible. By this process part of the sulphur is burnt off, and a corresponding quantity of silver is reduced to the metallic state, which being carefully mixed with the remainder, and repeatedly stirred with a piece of stick, the whole of the gold remaining in the silver, which is still sulphurated, will be attracted; and by being poured into a cone, will be collected at the bottom in a mass.

The silver containing the gold, which is collected in these two operations, being melted and granulated, is subjected to one or more repetitions of the same process, till the silver that remains is found to contain a sufficient proportion of gold, to render it worth while to proceed to the process of parting by means of aquafortis. The whole of the silver may be separated by means of sulphur; but when the proportion of gold is considerable, the sulphuret of silver always takes up a part of it, which cannot again be entirely separated without repeated fusions; and therefore, when the gold is equal to $\frac{1}{30}$th of the silver, a further purification by means of sulphur, will scarcely be found advantageous.

An ingenious and economical method of separating the gold from old gilt silver lace or wire, has been extensively practised in Saxony. This method proceeds on the principle, that the affinity of gold for copper, and of silver for lead, is much greater than the affinity which subsists between gold and silver; and it is conducted

Gold. ducted in the following manner. The alloyed metal is first granulated, and $\frac{1}{16}$ of it is mixed with $\frac{1}{8}$ its weight of litharge, and $\frac{1}{8}$ of sandiver. This is called the precipitating mixture. The next is mixed with $\frac{1}{8}$ of powdered sulphur, and is brought into fusion, which being complete, as will appear from the flashing at the surface, $\frac{1}{4}$ of the precipitating mixture is added at three different times, allowing an interval of five minutes between each time; and the fusion is then continued for ten minutes longer. Part of the sulphurated silver is taken out with a small crucible made red hot, and the remainder being poured into the melting cone, a quantity of metallic silver combined with the greatest part of the gold, subsides to the bottom. The sulphuret of silver is again melted, and the remaining part of the precipitating mixture is added as at first, and thus a second portion of gold alloyed with silver is obtained. But as the sulphuret still retains a small portion of gold, it is to be fused a third time; and a precipitating mixture, equal in weight to the former, but consisting of an alloy of equal parts of copper and lead, is to be added, and thus a third precipitate of gold holding silver is obtained, and the sulphuret is now deprived of the whole of its gold.

The different metallic masses thus obtained, are melted with $\frac{1}{8}$ of lead, then granulated, and treated in the same way as at first, with sulphur and the precipitating mixtures. The silver thus obtained being rich in gold, is first to be granulated, then mixed with $\frac{1}{16}$ of sulphur, and kept in fusion for about half an hour without any addition; and being poured into a cone, the sulphuret is separated from the metal, and this last is treated two or three times more with sulphur, in a similar manner. The metallic button obtained, which now appears of a yellow colour, is to be melted with one sixteenth of copper, then granulated, and mixed with one sixteenth of sulphur; and the mixture being first gently heated in a covered crucible, and kept in fusion for about a quarter of an hour, is poured into a cone, at the bottom of which the gold is collected of a brass colour, and about eighteen carats fine. The purification is afterwards completed by means of sulphuret of antimony, a process which will be afterwards described.

3. *Parting operation.*—When the proportion of the gold and silver, alloyed together, is such, that the former is not much less than one sixteenth, or greater than one fourth of the whole mass, the operation of *parting* may be followed. In this method the gold is separated from the silver by means of diluted nitric acid, or, as it is termed by manufacturers, *aquafortis*, which dissolves the silver, and leaves the gold untouched. The button of gold and silver is prepared for this process by flattening with the hammer, again heating it red hot, and slowly cooling to anneal it for the purpose of increasing its malleability. It is then to be extended into a small plate as thin as a wafer, by passing it between rollers of polished steel, again heated, but only to redness, and last of all rolled up in the form of a small loose coil or spiral, called a cornet. The annealing is useful in allowing the metal to be rolled up without cracking, and at the same time the freer action of the acid, in consequence of the texture of the metal being somewhat opened.

The cornet thus prepared is introduced into a pear-formed matrass, called a *parting-glass*, and three or four times its weight of pure nitric acid of 1.25 specific gravity are added; the mouth being slightly covered to keep out the dust, the glass is set on a sand bath, or over charcoal, to boil. As soon as it becomes warm, the acid begins to act on the silver, and dissolves it with the evolution of nitrous fumes. During the whole action of the acid, the cornet appears all over studded with minute bubbles, and when these discontinue, or run into one another, forming a few large ones, the action of the acid is nearly over. The process is usually completed in about fifteen or twenty minutes from the time that the acid begins to boil. The cornet now appears corroded throughout, and has lost during the solution the whole of the silver; and the remaining gold which is slender and brittle, retains the same spiral form. Indeed it is of considerable importance that it should not be broken, for much of the accuracy of the operation depends on having the gold in one piece and not in fragments.

The acid solution of silver, while yet hot, is next to be carefully poured off, and a portion of fresh acid, somewhat stronger, is to be added, to separate all the remains of silver; the boiling is to be repeated as before, but only for five or six minutes; it is then poured off and added to the former solution, and the parting-glass is filled with hot distilled water, to wash off the remains of the solution. The cornet, which is now of a brown colour and spongy texture, and has little of the metallic appearance, is taken out in the following manner. A small crucible is inverted over the mouth of the parting-glass, while it is yet filled with the distilled water, and the latter being rapidly inverted upon the crucible, the cornet falls softly through the water down the neck of the glass into the crucible, where it is deposited, and the water is carefully poured off. The crucible after being dried is next heated to redness under a muffle. The cornet contracts greatly in all directions, becomes of a firm texture, and resumes its metallic lustre; and after being brought to a red heat and cooled, it exhibits the appearance of a cornet of pure gold, having all the splendour, softness, and flexibility of this precious metal. By accurate weighing, the amount of the product is precisely ascertained, and thus the operation of parting is completed.

But if the proportion of gold amount to one third of the mass, it combines with part of the silver, and protects the latter by its insolubility from being acted on by the acid, so that in the process of parting, too great a proportion of gold in the alloy must be avoided; and farther, as the acid is expensive, unless the silver be rich in gold, this process, which is in many respects convenient, will not be found economical. In reducing the fineness of the alloy which is too rich in gold to be advantageously parted by itself, it will be the object of the refiner not to employ pure silver, but such as contains a small portion of gold; and at the same time it will be his study to save the quantity of acid.

The following is the usual method of conducting the process of parting. After selecting a proper quantity of rich and poor ingots of mixed metal, the whole is to be fused in an iron crucible; and being well mixed by frequent stirring, it is to be removed by a clean iron ladle, and granulated in cold water. The parting-glasses, which are nearly of the form of a truncated cone with a rounded bottom, are about twelve inches high and seven inches wide at the lower extremity, and they should be of equal thickness, well annealed, and free from any kind of flaws. About forty ounces of metal are introduced into each glass, and the nitrous acid, half saturated

ted with silver, is added till it stand two or three fingers breadth above the surface of the metal. Twenty or even more of these glasses are placed in a sand bath, and the heat, which should at first be moderate, is gradually increased till it nearly reach the boiling point about the time that the acid is saturated. The nitrate of silver is poured off, a new portion of stronger acid is added, and boiled as before till it is nearly saturated, when almost the whole of the silver is taken up, and what remains undissolved has the appearance of a brown mud, and consists of the gold finely divided with a small portion of silver. The acid again saturated is poured off, and a third portion of still stronger acid is added, which is kept at the boiling temperature till the evolution of nitrous gass ceases, and the bubbles are enlarged, which shews that all the silver is taken up. The acid is then decanted off, and reserved for the first part of a future process of the same kind; and the gold is repeatedly washed with fresh portions of hot water till the washings dropped on a polished copper plate produce no stain; and the powder, being dried and mixed with little nitre and borax, is fused, and is then in a state of purity.

To decompose the nitrate of silver with the view of procuring the pure metal, the solution is poured into a wooden vessel lined with copper, and in which are placed plates of copper that the silver may be precipitated from its solution in consequence of the greater affinity of the nitrous acid for the copper. The surface of the plates is to be cleared from time to time of the silver crust, that a fresh surface of copper may be exposed to the action of the acid, and the decomposition of the nitrate of silver may be promoted; after which the nitrate of copper formed in the solution is decanted off, the plates are scraped, and the silver being washed is fused with nitre, and is also obtained in a state of purity.

4. *Separation of gold from silver or other metals by sulphuret of antimony.*—All the common metals, excepting zinc, which come under the denomination of imperfect metals, may be separated from gold by this process; for as gold is incapable of combining with sulphur, and as the affinity of almost all the other metals for sulphur is stronger than that of antimony, it is sufficiently obvious, that an alloy of gold with any of these metals, as for instance gold and copper, being added to sulphuret of antimony, the sulphur will combine with the copper, and the antimony will form an alloy with the gold. When common crucibles are employed for this process, some previous preparation is necessary. A well burned crucible is selected, and soaked for two or three days in linseed oil, which is then to be cleared away from the inner surface till some finer powdered glass of borax dusted upon it shall just adhere, when it is to be put into a dry place for two or three weeks, after which it is fit for use.

The gold alloy is first melted in the crucible, and then about twice its weight of coarsely-powdered sulphuret of antimony is thrown in at two or three different times. At each addition the mixture froths and swells up, so that the crucible must be larger than the quantity contained, and great caution must be observed to prevent any bits of charcoal dropping into the crucible; for then the mass of melted matter would certainly flow over. When the mixture begins to sparkle on the surface, and appears to be perfectly fluid, it is to be poured into a melting cone which has been previously heated and greased, and the settling of the gold at the bottom is promoted by communicating a tremulous motion to the cone by means of slight blows. When the matter has become cold, it is removed from the cone by giving it a few blows in an inverted position. The mass is composed of an alloy of gold and antimony, covered with scoriæ consisting of the metal formerly alloyed with the gold now in combination with the sulphur or the antimony. But the gold still retains a little of its alloy, and from this it is to be freed; the same process is to be repeated not only a second, but even a third and fourth time, with a similar quantity of sulphuret of antimony. The metals from which gold may be advantageously purified by this process are iron, copper, tin, lead, and silver.

5. *Separation of gold from antimony.*—When the proportion of antimony exceeds that of the gold, the alloy is brittle. It must be reduced to small pieces, mixed with one-fourth its weight of sulphur, melted in a covered earthen crucible, and after the fusion is completed, poured into a melting cone previously heated and greased. When examined after being cooled, it will be found to consist of two parts, which may be easily separated by melting the alloy, exposing it to a high temperature, and at the same time directing a stream of air from a pair of bellows into the crucible which contains it. By this means the antimony is oxidated, and driven off in the form of white vapour. The gold having acquired a clear bright green colour, it is to be poured out and melted again in a small crucible with a little nitre. The remaining portions of antimony will be oxidated, and driven off from the gold as before. The small proportion of gold which remains attached to the sulphuret of antimony may be separated by bringing the whole mass into thin fusion, and precipitating part of the antimony by adding about one-fifth of its weight of iron filings. In this way the gold falls down in the form of alloy with the antimony, and it may be separated by means of the process described above.

Separation of gold from lead by cupellation.—This is the most economical method of separating gold from lead. The nature of the process of cupellation, and the method of conducting it, have been already described under CHEMISTRY, N° 2026. p. 682. But besides lead, other metals may be separated from gold, by employing that metal as a flux, the effects of which in scorifying and carrying down most of the imperfect metals, are such, that by the process of cupellation with lead, which is to be repeated according to the proportion of the alloy, and its affinity for the gold, almost every particle of the metals combined with it, may be separated. This method is usually followed where the proportion of alloy is but small; but when it is more considerable, some of the other methods are preferable. It is found however, that in the cupellation of pure gold with lead, it always retains a small portion of this metal, which affects its colour and ductility. But if the alloy to be purified, contain, beside lead, to the amount of one-twenty-fourth of the gold of copper, the whole of the lead may be separated, but scarcely any of the copper; and if it contain silver in a greater proportion than that of copper, the latter may be separated by the process of cupellation, and a little of the lead remains. But if the silver exceed

Gold.

exceed the gold, or be equal to it, the copper and lead may be entirely separated, while the gold and silver remain behind. From a knowledge of these facts, the refiners, in separating the base metals from gold, by the process of cupellation, add to the mixture a considerable proportion of silver. When the gold is alloyed with tin, cupellation with lead alone will not succeed, because the tin, with part of the lead, forms a spongy and refractory oxide, and floats on the surface of the fluid metal, and at the same time retains part of the gold. But as iron is found to combine with tin into an alloy that may be scorified by lead, the addition of iron filings during the process removes the difficulty.

The following table shews the quantity of gold which is got from the different countries of the old and new world, taken on an average, between the years 1790 and 1802.

Old Continent.	*Kilogrammes.*	
Siberia,	1700	
Africa,	1500	
Hungary,	650	
Saltzburg,	75	
Norway,	75	
Total of the Old Continent,	——	4000
New Continent.		
North America,	1300	
South America—		
Spanish possessions,	5000	
Portuguese possessions,	7500	
Total of the New Continent,	——	13800
		* 17800

* Brongniart, ii. 351.

The kilogramme being equal to 2lbs. 3oz. 5drs. avoirdupois, the whole amount is equal to about 39,285 pounds avoirdupois.

Chap. III. *Of the Ores of Mercury.*

The ores of mercury present less variety than those of many other metals; and on account of its peculiar properties, the management of its ores, whether for the purposes of analysis or reduction, is less complicated and difficult.

Sect. I. *Of the Analysis of the Ores of Mercury.*

To analyze the ore of native mercury, or native amalgam, it is to be digested in nitric acid of moderate strength; the mercury and silver, and bismuth, will be dissolved, and if the ore should contain a minute portion of gold, it will remain untouched in the form of a brown powder at the bottom of the solution. The nitrous solution is next to be gently evaporated till it is so far concentrated as to be on the point of crystallizing. It is then to be poured into a large quantity of pure water, by which means the most part of the bismuth will be separated, and a solution of common salt, or any other neutral muriate, being added to the filtered liquor, the silver and mercury will be precipitated in the form of muriate. After this is separated, add to the clear liquor some carbonated alkali, while any precipitation takes place; then boil the liquor, and separate the precipitate by filtration. The muriatic precipitate is next to be digested in nitro-muriatic acid moderately diluted, which takes up every thing excepting the muriate of silver, from which, after being washed and dried, the proportion of silver in the ore may be easily ascertained. The nitro-muriatic solution is now to be decomposed at a boiling heat, by a carbonated alkali, and the white precipitate thus obtained being added to the former carbonated precipitate, mix them with a little oil, or what answers better, sugar, and distil in a small coated glass retort. Raise it gradually to a red heat, and continue at that temperature while any mercury comes over. The residue in the retort consists of a little metallic bismuth and charcoal.

Mercury.

Native amalgam.—With the view of ascertaining the proportion of mercury and silver in this ore, Klaproth examined some of the garnet-like crystals from the quicksilver mines of Deux Ponts. Some pure crystals weighing $33\frac{1}{3}$ grains were introduced into a barometer tube of a larger diameter than usual, and closed at the lower end. This end was placed in sand, within a small crucible; heat was applied, and its intensity gradually increased to the degree of ignition. After cooling, he cut off the lower end of the tube, and found that it contained the silver, which had undergone ignition in its former crystalline form, and weighing 12 grains. On collecting the mercury which had been sublimed in the tube, he obtained 21 grains. Therefore since the deficiency of one third of a grain may be reckoned as a loss of quicksilver, the following will be the proportion of the parts in 100 of this crystallized amalgam of silver.

Silver,	36
Mercury,	64
	100

Cinnabar.—The analysis of cinnabar may be conducted in the following manner. The ore being reduced to a fine powder, is repeatedly digested in a mixture of 1 part of nitric acid, and 3 of muriatic, moderately diluted, by which every thing in the ore is dissolved excepting the siliceous earth and the sulphur. The residue being washed, dried, and weighed, is subjected to a red heat, and the remaining silex being deducted, the difference of weight shews the amount of the sulphur. The nitro-muriatic solution is next to be decomposed at a boiling heat, by carbonated alkali, and the precipitate obtained being mixed with a little lamp-black, and distilled, the mercury passes over in the metallic form. The residue in the retort consists of magnetic oxide of iron, and any accidental earth excepting silex that is contained in the ore, together with a little charcoal, which may be separated in the usual way.

Hepatic ores.—The hepatic ores of mercury, and such as contain bituminous substances, may be treated in the same way; but these ores are sometimes combined with a little silver, and therefore the matter which remains undissolved in nitro-muriatic acid, may be muriate of silver, as well as sulphur and silex. When the sulphur is burnt off, the residue is to be mixed with twice its weight of pearl-ash, and being strongly ignited in an earthen crucible, diluted muriatic acid is added, by which the alkali and the earth will be taken up, and the

Mercury.

the silver will remain behind in the form of small metallic grains.

Corneous ore of mercury.—To analyze this species of mercurial ore, let it be digested in a little distilled vinegar, by which the native mercury which is dispersed though the ore will be left behind. Add to the clear solution nitrate of barytes, by which the sulphuric acid will be separated in the state of sulphate of barytes; and this being removed, drop in nitrate of silver, by which the muriatic acid will be separated in the form of muriate of silver. The mercury now remains in solution in the state of nitrate, and being precipitated by means of iron, it is afterwards washed in muriatic acid, and thus appears in the metallic state. It may also be reduced to the metallic state by precipitating by carbonated alkali, and distilling the precipitate with a little lamp black.

A simple and easy process is followed in assaying the ore of mercury in the dry way. The ore to be examined is first to be reduced to powder, and carefully mixed with one-fourth of its weight of quicklime, and an equal portion of iron filings. It is then to be exposed to a red heat in an iron or earthen retort, as long as any mercury passes over into the receiver.

Sect. II. *Of the Reduction of the Ores of Mercury.*

A very simple process is followed for reducing the ores of mercury. The following is the method practised at the celebrated mines of Almaden in Spain. The pieces of pure cinnabar are first selected and separated from the ore, to be sold to painters and manufacturers of sealing-wax. The rest is sorted into three parts, of which the first is the richest, and is broken into pieces of a moderate size; the second, containing a smaller proportion of metal, is broken into smaller pieces; and the third consists of the dust and smaller fragments of the other two. These are kneaded up with clay, and being formed into bricks, are carefully dried in the sun. The furnace which is used for extracting the mercury is built in an oblong form, and is divided horizontally by an iron grate, into an upper and lower compartment, and near its top it communicates with a series of aludels. In charging the furnace, a stratum of flat rough stones is placed on the grate, intervals between each of the stones being left for the passage of the fire. A bed of ore of the second quality is laid on the stratum of stones, and then a stratum of the ore of the first quality, after which another of the second kind, and last of all a stratum of the third kind, which has been made up into bricks. A few faggots are then thrown into the lower cavity of the furnace, and lighted up; and a gentle fire is to be kept up by occasionally adding faggots for eight or twelve hours, according to the previous state of the ore with regard to moisture. After the moisture is separated, which is known by the vapour ceasing to be exhaled, the fire-place is filled again with faggots, and by the time they are consumed, a sufficient heat will be communicated to the ore, to allow the combustion to go on, by means of the sulphur which it contains, without requiring any more fuel. In the course of the next two days, while the sulphur burns slowly away, the mercury rises in the state of vapour, and passes into the aludels, where it is condensed. When the whole of the metal is extracted, the scoria is taken out of the furnace, and the aludels are emptied of their contents. But besides the mercury, they are found to contain a quantity of black matter like soot. This matter is easily separated by spreading the whole about on an inclined table, so that the mercury may run to the lower extremity, where it is collected in a channel, and the impure sooty matter remains behind.

Mercury.

The method of extracting mercury from its ores now described, is advantageous, on account of the simplicity of the apparatus, and the smaller expence of fuel; but it would appear that a portion of the mercury remaining in the ore is lost. There is besides a considerable loss in throwing away the soot, after separating the running mercury on the tables, not only because many of the globules of the metal itself are thrown away, but also the calomel, and cinnabar, which are found to be in considerable proportion, are wasted. Hence it has been recommended as a more profitable method, 1. To separate the sulphate of ammonia, which, according to the examination of Proust, forms part of the matter deposited in the aludels, and then by mixing what remains, with 12 or 15 per cent. of quicklime, distil it in an iron retort, by which means the whole of the running mercury would be obtained, as well as that which is produced by the decomposition of the calomel and cinnabar.

A more improved process is practised at the mines of Deux Ponts, and Idria. The ore, as it is brought out of the mine, is carefully sorted by the hand, and these parts that seem destitute of metal, are rejected. This process, although tedious and expensive, is found to be more advantageous than the older method of separating the cinnabar by washing, in which there is a great loss of metal. The ore being thus sorted, it is reduced to powder, and accurately mixed with one-fifth of quicklime, which has fallen to powder by exposing it to the air; but it ought to be observed that the quantity of quick lime is to be regulated by the proportion of cinnabar contained in the ore. The mixture being thus prepared, is introduced into iron retorts, which are capable of holding about 60lbs. weight. The retorts, to the number of 40 or 50, are fixed in a long furnace, and a glass receiver is attached to each, but it is not luted. A moderate heat is then applied for the purpose of driving off the whole of the moisture; and when this is done, the joinings of the vessels are to be closely stopt with tempered clay, and a full red heat is to be applied, and continued for seven or eight hours, at the end of which time the whole of the mercury will be volatilized, and condensed in the receiver. By this process it is found, that 100lb. of the ore yield from 6 oz. to 10 oz. of metal.

Chap. IV. *Of the Ores of Silver.*

The ores of silver present a considerable variety. Sometimes it is found in the metallic state in masses of from 30lbs. to 40lbs. weight, but it is oftener combined with sulphur in the state of sulphuret; with other metals, especially antimony, arsenic, iron, copper, lead, and bismuth; or with acids, as the carbonate and the muriatic, forming the carbonate and muriate of silver. The analysis and reduction of these different ores, it is scarcely necessary to observe, must be conducted according to the

Silver.

the nature and proportion of the ingredients which enter into the composition of the ore to be examined or reduced.

Sect. I. *Of the Analysis of the Ores of Silver.*

When a silver ore is to be examined, and the only object in view is to ascertain the proportion of silver it contains, the operation is usually conducted in the dry way. The ore is first roasted and reduced to powder; it is then mixed with litharge in proportion to the earthy matter combined with the ore, and quickly vitrified. The mass thus obtained is again reduced to powder, and being mixed with black flux, is to be fused in a crucible, with a sufficient degree of heat. By this process the lead of the litharge is revived, and collected at the bottom of the crucible, carrying with it the whole of the silver, as well as some of the other metals which may be combined with the ore. The button thus obtained is to be subjected to the process of cupellation, with the requisite quantity of pure lead, and in this way the base metals are scorified, and the silver remains behind in a state of purity, or combined only with the gold, which many of the ores of silver contain in small proportion. The gold is to be separated by some of the methods which we have already described, in treating of the ores of gold. This operation, in which the object only is to ascertain, as in this case, the quantity of silver, is called *assaying*. In the examination of ores in this view, more assays then one should always be performed, that an accurate and nearly invariable result may be obtained.

But in examining metallic ores, it is always more satisfactory to ascertain the whole of the ingredients of which they are composed. We shall therefore proceed to give an account of the best conducted analysis of the ores of silver.

Corneous silver ore.—The following is the analysis or this ore by Klaproth.

" Upon 200 grains of the corneous silver ore I poured three times their weight of pure nitric acid; but no action took place, either in the cold or in the heat of boiling; only a subtle brown red iron-ocbre was separated, which, being washed off from the remaining ore, and dried, amounted to four grains. Caustic ammonia, added to the nitric acid employed, precipitated five grains more of iron. When it was afterwards mixed with muriatic acid, only a pale milky colour was produced, but no real corneous silver ore deposited. It followed from this, that neither any free native silver, nor any portion of it mineralized by sulphur, had been contained in that ore. The horn-silver, after treatment with nitric acid, was reduced by twice its weight of salt of tartar, and yielded 133 grains of reguline silver.

" 1. For the purpose of finding out, more accurately, its constituent parts, I mixed 200 grains with 600 grains of the purest alkali prepared from tartar, and brought the mixture into the state of fusion in a glass retort, applying the necessary degree of heat. After refrigeration, I broke off the upper half of the retort, softened the fused mass, which was of a light-brown colour, with hot distilled water, filtered the whole, and edulcorated the residue.

" 2. This residue was then dissolved in nitric acid. The solution acquired a brown tinge, and the scum floating upon the liquor assumed the colour of bricks. When the argenteous parts were completely dissolved, there remained $8\frac{1}{2}$ grains of a brown-red powder, which imparted a golden yellow colour to the aqua regia, with which it was digested, and left a white residue behind. This last consisted of horn-silver, mingled with a slight portion of the gangue, or matrix of the ore, and afforded, on reduction, two grains more of silver. Caustic ammonia precipitated from the yellow solution seven grains of oxyded iron.

" 3. The nitric solution of the silver was precipitated by common salt; and the muriate of silver thus obtained weighed, after reduction by means of soda, $134\frac{1}{2}$ grains of reguline silver.

" 4. The fluid, left after the separation of the horn-silver, had a pale-yellow colour, owing to a portion of iron; which, precipitated by pure ammonia, weighed five grains.

" 5. After this, I proceeded to examine the saline mass, dissolved in distilled water, and separated from the silver, after the corneous ore had been fused with pure alkali. On saturating this mass with distilled vinegar, the solution was rendered turbid, and a loose white earth deposited, which, collected and dried, amounted to three grains and a half of argillaceous earth.

" 6. The alumina being separated, the solution was reduced to a dry salt by evaporation, and the alcohol, affused upon it, took up the acetite of pot ash. The neutral salt, which was left behind by this process, and which consisted of the mineralizing muriatic acid and the alkali employed, I dissolved in water, and obtained from it, by repeated evaporation and crystallization, $117\frac{1}{2}$ grains of muriate of potash.

" 7. In order to learn whether and in what proportion sulphuric acid, which by some writers has been mentioned as one of the constituent parts of the corneons silver ore, were really present in it, I again dissolved that salt in distilled water, and dropped into it liquid muriate of barytes. The mixture became turbid, exhibiting that appearance which indicates the presence of only a slight quantity of sulphuric acid. I continued to add the barytes, until no more turbidness appeared. The weight of the precipitate thus obtained was three grains: but, as in these three grains of sulphated barytes the acid cannot properly be estimated to be more than half a grain, I think this quantity is too trifling to be considered as one of the essential constituent parts of the corneous silver ore. But if that half grain of sulphuric acid be estimated equal to $1\frac{1}{2}$ grain of sulphur of potash, and be subtracted from the above $117\frac{1}{2}$ grains of digestive salt, or muriate of potash, there will remain of the latter only 116 grains, in which the concentrated muriatic acid amounts to 42 grains. Therefore,

" One hundred parts of this corneous ore contain

Silver,	67.75
Muriatic acid,	21
Oxide of iron,	6
Alumina,	1.75
Sulphuric acid	0.25
	96.75."

Red silver ore.—The following is the analysis of this ore, also by Klaproth.

" Upon

Silver.

"Upon 500 grains of bright, crystalline, red silver-ore, most finely pulverized, I poured six times their quantity of a mixture of equal parts of nitric acid of 1.350 specific gravity and distilled water. The phial was kept for several hours in a low digesting heat, so that the agency of the acid would be but moderate. I then diluted the solution with water; caused it to boil; and, after the residuum had subsided to the bottom, I decanted the clear solution. Upon the remaining pulverulent ore, a quantity of nitric acid and water, equal to the preceding, was again affused; and, in the same manner, proceeded with as at first. The ore appeared now to have been effectually decomposed; and for this reason the solutions, together with the residuum, were put on the filter, and the latter properly washed.

"The filtered nitric solution had no colour at all, having been very much diluted by the water by which the residue had been edulcorated. I subjected it to evaporation to $\frac{1}{8}$th part, and found the bottom of the evaporating glass vessel, after cooling, covered with copious, finely grained, resplendent, and heavy crystals of a gray white. To ascertain their nature, I procured, by a separate process, a quantity of a solution of the same red silver-ore, sufficient for this enquiry, and found that they were sulphate of silver. Being assured of this, I dissolved that sulphate by a proportionate quantity of water, assisted by heat, added it again to the nitric solution, and combined this last with muriatic acid, as long as any muriate of silver would precipitate; which, when collected, edulcorated, and dried, was found to weigh $391\frac{1}{2}$ grains.

"The fluid, from which the horn-silver had been thus separated, was then reduced to a smaller bulk, by distillation from a retort. This concentrated fluid became turbid, and left another grain of muriated silver on the filter. At this time it contained no other foreign substance, except a considerable portion of sulphuric acid.

"What remained undissolved by the nitric acid, consisted of an ash-gray, pretty loose, or flocculent powder, of 202 grains in weight. When this had been gently digested for half an hour, with a mixture of five parts of muriatic acid, mixed with one part of the nitric, and then diluted with half its quantity of water, there remained, after filtering, careful edulcoration, and drying, 65 grains; which were the sulphureous contents of the ore. When this residue had been gently heated, the sulphur deflagrated, leaving $6\frac{1}{2}$ grains of muriated silver behind. This sulphur, therefore, consisted of $58\frac{1}{2}$ grains.

"After the filtered solution had been evaporated in part, it was poured into a large quantity of water. By management, a white precipitate immediately ensued, which being separated by the filter, edulcorated, and dried, and lastly heated in a porcelain cup, gave 133 grains in weight. But I could not find the least trace of arsenic in it, though I had subjected it to all the trials deemed proper for discovering its presence. On the contrary, it was manifest, that this precipitate wholly consisted of oxide of antimony, quite of the same nature with that which is produced when muriatic solutions of antimony are precipitated by water. On exposing it to heat, a small portion of moisture still evaporated, attended with a muriatic smell, which was hardly perceptible. When again put on a test, and mingled with a third part of charcoal dust, the coaly powder was slowly consumed, by burning, without any arsenical smell, and left behind it the metallic oxide, possessed of a gray colour, and partly blended, partly covered, with a quantity of fine, gray-white, shining, acicular crystals, or the flowers of antimony, as they are called. But when it was fused in a covered crucible with tartar and powdered charcoal, it was completely revived into reguline antimony, which being blown off with the bellows, a bead of silver was left, weighing half a grain.

"The liquor also, from which the antimonial oxide was separated, contained free sulphuric acid. On this account, I put it into a retort, together with the nitric acid, from which the silver had been precipitated in the state of horn-silver, by means of muriatic acid, and continued the distillation until, at this temperature, nothing more would pass over; but, on raising the heat, thick white vapours had begun to rise. The fluid left behind in the retort was found upon trial, to be concentrated sulphuric acid. Upon diluting this last with water, and subsequent affusion of muriated barytes, the sulphate of barytes from thence produced, amounted, after edulcoration and desiccation, to 194 grains.

"Consequently, the constituent parts discovered by these researches, are, silver, antimony, sulphur, and sulphuric acid *."

* Essays.

Vitreous silver ore.—This has been also analyzed by Klaproth, according to the following method.

"1. If ductile vitreous silver ore be fused upon a piece of charcoal, by the assistance of the blow-pipe, its sulphur is quickly volatilized, and a button of pure silver remains. But it is otherwise with the brittle ore: for the bead left after the evaporation of the sulphur is brittle, and cannot be purified by the addition of borax. However, if a little nitrate of potash be added to the red-hot bead, it will destroy the portion of baser metal which it contains, and then the borate of soda causes it to yield a pure button of silver.

"2. One hundred grains of ore, previously levigated, were gently boiled in a sufficient quantity of nitric acid, diluted with an equal quantity of water. This operation was repeatedly performed, till the black colour of the powdered ore disappeared, and the insoluble portion had become of a loose texture, and had acquired a gray-yellow colour. When filtered and dried, this residue weighed 26 grains.

"3. On adding a solution of common salt to the above filtered solution, which had assumed a pale-greenish colour, a copious precipitate of horn-silver ensued, which, edulcorated and dried, gave $88\frac{1}{4}$ grains. Four parts of this afforded three of silver, by fusion with soda.

"4. The remaining solution was next combined with sulphate of soda; but neither any turbidness, nor any indication of the presence of lead, appeared. Upon this, caustic ammonia was affused to excess; and the gray precipitate, which then fell down, and which the volatile alkali could not again render soluble, weighed five grains. Urged by heat, it melted into a consistence like pap, at the same time that a weak arsenical smell was perceived. After this precipitate had been once more dissolved in nitric acid, the addition of soda caused it to yield a whitish yellow, alkaline sulphuret a dirty brown, and Prussian alkali a deep blue precipitate, liable to the attraction of the loadstone, after ignition. Therefore, it consisted of iron, with a slight trace of arsenic.

Silver.

"5. The proportion of copper, indicated by a blue colour, in consequence of the addition of ammonia, and which still remained in the solution, was but slight. For, after the solution had been saturated with sulphuric acid, polished iron immersed in it, was invested with so slight a coppery crust, that no copper to any amount could be collected.

"6. Those 26 grains, which continued insoluble in the nitric acid (2.), were digested in nitro-muriatic acid, till nothing appeared to remain but the mere sulphur. Its weight amounted to 13 grains; but after deflagration, it left behind it about one grain of quartzose matter of the mine.

"7. From this it is obvious, that 13 grains, or one-half of the above 26 grains, were held in solution by the nitro-muriatic acid; and these were precipitated entirely in the form of a white powder, upon the affusion of 20 parts of water. When ignited, this precipitate assumed a yellowish colour; but there was nothing either of arsenic, or any other volatile substance, perceivable. By combination with soda, it became reduced to pure reguline antimony; which, as such, admitted of being blown off, without leaving any residue, in its usual form of a thick white smoke, adhering to the contiguous bodies in the form of needle-shaped flowers (oxide) of antimony. Those 13 grains of oxided antimony are equivalent to ten grains of that matter in the reguline state *."

* *Essays.*

For the analysis of some of the other ores of silver, we must refer our readers to the ingenious and elaborate Essays of the sagacious Klaproth, from which we have extracted what is given above on this subject.

Sect II. *Reduction of the Ores of Silver.*

Although the ores of silver contain a larger proportion of extraneous matters than the ores of some other metals, the value of that metal being greater than that of many others, admits of greater expence in the processes employed for their reduction. The ores of silver are reduced either by fusion, or amalgamation.

Reduction of silver ores by fusion.—Native sulphuret of lead, or galena, commonly contains a portion of silver, and often in such quantity, as to make its separation from the lead a profitable undertaking. The proportion of silver contained in lead is very variable. The greatest produce of silver which we have heard of, was got from the lead ore of Craven in Yorkshire, which amounted to 230 ounces of silver in the ton of lead. The mines of Cardiganshire yielded formerly 80 ounces per ton; the Durham and Westmoreland mines afford lead, from which 17 ounces of silver are obtained upon an average per ton. The lead procured from the mines of Islay, one of the Western islands of Scotland, yielded, we have been informed, 40 ounces per ton; and the average produce of lead at the refinery at Poullaouen, in Brittany in France, is above 39 ounces of silver per ton. The following is the process carried on at the latter establishment, for separating the silver from the lead.

After the lead has been extracted from the ore, the object of the refiner is to obtain the silver in a separate state, which is dispersed through the mass of lead. This is performed by the process of cupellation on a large scale, or refining, as it is usually termed. The floor of the reverberatory furnace, in which the process is conducted, is horizontal, and it is lined with wood ashes and sand mixed together, and well beaten, and formed into a shallow bason, which is the cupel. There is an aperture at one side of the cupel, which forms a right angle with the flue by which the flame from the fireplace passes into the cavity of the furnace. Through this aperture the lead, brought to the state of litharge, runs; and opposite to it there is another aperture by which a blast of air is admitted. The top of the furnace has a circular aperture directly above, and corresponds in extent with the cupel, which may be shut up with a frame work of iron filled with bricks. When the furnace is ready, the cupel is lined with hay, and is then charged with about 177 quintals of lead, in bars or pigs, through the circular aperture, and the cover being put on, the fire is lighted up. In the course of six hours, the whole of the lead being melted, and brought to a red heat, a blast of air is directed upon the surface of the lead, and the ashes of the hay, and other impurities are removed with a wooden rake. The blast being continued for half an hour and more, the surface of the lead begins to be covered with a thick crust of oxide, which is scraped off, and is soon succeeded by another, but it is not till the surface has been cleared five or six times that the true litharge appears. When this is the case, the temperature is raised to a cherry red, and by the action of the blast, with the occasional aid of the workman, the litharge flows out through the aperture mentioned above. The intense heat volatilizes a considerable portion of lead, and so fills the interior of the furnace with vapour, that a person of experience only can discover what is going on in the cupel. At the end of 38 or 40 hours from the time that the fire is lighted, the contents of the cupel are reduced to about six quintals, and the litharge which comes over at this time is kept separate, because it contains a small portion of silver. At last the litharge ceases to flow, and the surface of the melted metal appears covered only by a thin pellicle. It then becomes gradually convex at the edges; the pellicle breaks up, and the surface of the metal appears quite bright. The blast is now to be turned off, the fire damped, and an aperture in the furnace, previously stopped with clay, is opened to admit a tin plate tube, through which a stream of water is poured into the cupel, in order to cool the metal rapidly, that it may be prevented from spirting, which would be the case, if this precaution were not observed at the moment of congelation. But the silver thus obtained is still contaminated with a portion of lead, from which it is freed by a second cupellation, which is performed in a moveable cupel containing about 700 or 800 ounces, and is placed in a small reverberatory furnace, which being heated about three hours, is charged with silver of the first cupellation. After the fusion of the silver, a proper working heat is kept up for four or five hours, when the refining is usually completed. The loss of lead by volatilization during the refining process is estimated at about eight per cent. When the quantity of litharge produced is large, it is reconverted into lead, by being returned into the reverberatory furnace, and treated in the same manner as the ore. This forms lead of the best and softest quality, because it is in a state of the greatest purity. And besides, the scoriæ that remain after the reduction of the ore, and the litharge, along

Silver. along with the old cupels, and the metallic soot which is deposited in the chimney of the furnace, are treated in a common blast furnace, and a considerable portion of lead is thus obtained.

A different practice is followed in the English refineries. A common reverberatory furnace, having the area perforated with a large oval hole to receive the cupel, is employed. The cupel is formed of six parts of well burnt bone ashes, and one of good fern ashes, mixed together, and moistened to a proper consistence. A quantity of this mixture is strewed to the depth of about two inches in an iron frame, which consists of a raised elliptical rim, with five broad bars rivetted to its bottom, so as to occupy nearly one-half of its area. The ashes are rammed down very close with a wooden beater, and particularly within the bars of the frame, as it is laid on a flat floor. More ashes are then added, and beaten carefully in, till the frame is quite full. By means of a sharp-edged spade, five inches square, a cavity is formed in the test for containing the melted metal, and at one end of the frame a semi-elliptical hole is cut through the breast, which latter is to be left of sufficient solidity and thickness. The test is now to be turned on its side, and dressed from all superfluous ashes adhering to the bottom, taking care that none shall be left flush with the bottom of the frame or cross bars, otherwise the test might be bulged, by fixing it at the bottom of the furnace. The rim being plastered with clay or moistened ashes, the test is placed upon the supporting cross bars, and fixed firmly with wedges against the bottom of the furnace, the breast being next to the feeding hole. A moderate heat is now applied, and gradually increased till the test be red hot; and when it ceases to emit steam from the under side, it is sufficiently dry. This previous preparation being completed, the following is the method of operation as it is described by Mr Sadler *.

"Lead previously melted in an iron pot is ladled into the test until the hollow part be nearly filled, the operator closes the feeding aperture, and increases the heat of the furnace until the surface of the lead is well covered with litharge; he then removes the door from the feeding hole, and with an iron rod, which has one end bent down at right angles about three inches, and made flat or chissel-shaped, scrapes the small gutter or channel until the litharge just flows into it; the blast from a pair of double bellows is then directed from the back part over the surface of the test, the litharge is urged forward, and flows from the gutter upon the floor of the refinery; the operation now goes forward, gradually adding lead as the escape of litharge makes it necessary, until the gutter is so worn down that the test does not contain more than an inch in depth of lead, the blast is then taken off, the gutter filled up with moistened ashes, and a fresh one made on the other side the breast; the test is again filled, though not so full as at first, and the operation carried on until this gutter also is worn down and the test contain from about 50 to 70 pounds of alloy. This quantity is run into an iron pot, and set by until a sufficient number of pieces have been collected to make it worth while to take off a plate of pure silver from them.

"The quantity of alloy left in the working off each test must depend in a great measure upon the quantity of silver which by estimation it is supposed to contain. A sufficient quantity of lead should always be left in the alloy to make it fuse easily in the iron pot.

"When the test is removed from the furnace and broken up, the litharge will be found to have penetrated to an inconsiderable but an equal depth in the ashes; that part not impregnated with litharge may be pulverized, mixed with fresh ashes, and again used for another test.

"The operation of taking off the silver pure differs in no respect from the foregoing, only more care is observed in the working, not to suffer the escape of any metallic particles with the litharge, as that would occasion considerable waste of silver. As the process advances, and the proportion of silver to lead increases, the litharge assumes a darker colour, a greater heat becomes necessary, and at last the brightning takes place; the interior of the furnace, which during the whole of the process had been very obscure and misty, clears up. When the operator observes the surface of the silver to be free from litharge, he removes the blast of the bellows, and suffers the furnace to cool gradually; as the silver cools many protuberances arise on the surface, and fluid silver is ejected from them with considerable force, which falling again on the plate, spots it very fantastically with small globules.

"The latter portions of litharge bring over a considerable quantity of silver with them; this is generally reduced by itself and again refined.

"The litharge as it falls upon the floor of the refinery is occasionally removed; it is in clots at first, but after a short time as it cools it falls for the most part like slaked lime, and appears in the brilliant scales it is met with in commerce: if it is intended as an article for sale, nothing more is necessary than to sift it from the clots which have not fallen, and pack it in barrels.

"If, on the contrary, it is intended to be manufactured into pure lead, it is placed in a reverberatory furnace, mixed with clean small-coal, and exposed to a heat just sufficient to fuse the litharge. The metal as it is reduced flows through an aperture into an iron pot, and is cast into pigs for sale. During the reducing, care is taken to keep the whole surface of the litharge in the furnace covered with small-coal.

"In some smelt works, instead of a reverberatory furnace for reducing, a blast furnace is made use of, on account of the greater produce, but the lead so reduced is never so pure as that made in the wind furnace. The oxides of the metals, which require a greater heat to reduce than the lead, are in the blast furnace generally reduced with it.

"The volatile oxides, as zinc, antimony, and arsenic, are mostly carried off by evaporation during refining; a considerable portion of the oxide of lead itself is carried off by evaporation, making the interior of the furnace so misty and obscure that a person unused to refining cannot see more than a few inches into it.

"A considerable portion of these oxides is driven by the blast of the bellows through the feeding aperture, and would be dissipated in the refining-house, to the great injury of the workmen's healths; to prevent their ill effects, the arch or dome over the feeding hole is erected to carry the fume into the stack of the furnace."

We shall now describe the method of treating the proper

* Nichol. Journ. xxv. 2.

Silver.

proper ores of silver, as it is conducted by Schreiber at Allemont in France. These ores are native silver, and the sulphuret of silver mixed with arsenical cobalt, pyrites, iron ochre, clay, calcareous spar, and some other earthy minerals. The silver being dispersed in very minute grains through the gangue, cannot be separated from the stony parts by washing. After the ore is picked by the hand, it is pounded dry in the stamping mill, and is reduced to the consistence of coarse sand. Roasting, previous to fusion, is not required; but the ore being refractory, it is found necessary to employ a flux composed of quicklime, scoriæ from a preceding fusion, and slag from the iron forges. To supply the proper quantity of lead, powdered galena, with the litharge and scoriæ furnished by the refinery, and with old cupels ground to powder, is added to the ore in such proportions that the lead, which is obtained by the fusion, may contain two per cent. of silver, allowing 20 per cent. of the lead at least to be lost by evaporation, or combining with the scoriæ. After being properly mixed, the materials are subjected to the heat of a powerful blast-furnace, with alternate charges of charcoal. The products of the fusion are lead combined with silver, a black, compact, sulphureous, semi-metallic substance which is called *matt*, and some scoriæ. The scoriæ thus obtained is neglected, excepting a certain proportion, which is reserved as a flux for the next parcel of ore. But the matt, which is tolerably rich in silver, is again melted with litharge, and the lead carries with it almost the whole of the silver; and although this second matt contain a portion of silver, it is not found worth while to subject it to a second fusion. After refining the lead procured by these operations, it is found to yield about two per cent. of silver. The process of cupellation is performed at a higher heat than usual, which it is supposed is necessary by the presence of a small portion of iron; but the consequence of employing this high temperature is to increase the waste of the metal by evaporation; for instead of seven or eight per cent. it amounts to no less than 20 per cent. And as every pound avoirdupois of the lead thus volatilized, contains from six to ten grains of silver, the loss in this process is very great. Perhaps it might be diminished by mixing a larger proportion of lead with the silver ore.

But other silver ores afford both lead and copper, and in this case a more complicated operation becomes requisite. In the first part of the process the poorest kinds of silver ore, or such as contain but a small proportion of copper and lead, and a great deal of stony matter, are to be mixed with the poorer pyritical ores, or such as contain little silver and copper, and a great deal of sulphur and iron. A portion of scoriæ obtained from a former process, and containing the oxides of lead and copper, with some silver, is added to this mixture by way of flux. The materials thus prepared being exposed to heat in a blast-furnace, re-act on each other, and enter into fusion. The stony matter is dissolved, and the melted mass separates into two distinct parts, of which the heaviest occupying the bottom of the furnace forms about one-fourth of the whole mass. This is called *matt*, and contains all the silver, with the greater part of the copper, most of the lead, iron, and sulphur, and generally zinc and arsenic. The slag which swims on the surface, as being the lighter portion, consists of the greater part of the sulphur, oxide of iron, and earthy matters; the small proportion of lead and copper is not worth the trouble of extraction.

To drive off part of the sulphur and other volatile impurities, the crude matt obtained in the preceding operation is roasted, and being mixed with one and a half times its weight of a richer kind of silver ore, and twice its weight of lead scoriæ, by way of flux, it is again fused, and thus a rich matt is procured, which may contain from nine to ten pounds of lead, from three to four pounds of copper, and from six to seven ounces of silver in the quintal, besides a quantity of scoriæ which holds a little silver, and which may therefore be successfully employed as a flux in subsequent fusions. This rich matt being roasted, is mixed with half its weight of litharge and scoriæ in equal proportions, and again subjected to fusion. The product of this fusion is a quantity of metallic lead, containing from six to eight ounces of silver in the quintal; a similar quantity of copper matt, which contains from 30 to 40 pounds of copper, and about four ounces of silver in the quintal; and lastly a quantity of scoriæ, which contains from six to 10 pounds of lead, and about 40 grains of silver in the quintal.

The copper matt of the above operation is next roasted, and fused with a quantity of lead and copper scoriæ, and the product obtained is black copper, which contains from 60 to 80 pounds of copper, and from five to ten ounces of silver in the quintal. This black copper being melted with litharge and scoriæ, the most part of the silver combines with the lead, and after one or two fusions, the copper is entirely freed, not only from the lead and silver, but also from the sulphur, iron, and other impurities.

Liquation.—The affinity between lead and silver is much stronger than the affinity between lead and copper. In consequence of this affinity, lead and silver are easily separated from copper, by being exposed to a moderate heat. This process is called *liquation* or *eliquation*. When the black unrefined copper, or copper matt, contains the proper proportion of silver for this operation, it is first used with lead or litharge, or with a mixture of the two, and an alloy consisting of copper, lead, and silver, is thus obtained. This is cast into moulds, so that the metallic product shall be in the form of round masses or loaves, which being set in a furnace on an inclined plane of iron, with a small channel grooved out, are exposed to a moderate red heat. By this process the lead melts, or, as it were, sweats out of the loaf, and carrying the silver along with it, on account of its stronger affinity for this metal, runs down the groove, while the copper remains behind as a dark red spongy mass. The lead containing the silver being subjected to the process of cupellation, the latter is obtained separate. But, in adopting this process, the proportion of the three metals must be attended to. The lead should not be more than four times the weight of the copper, otherwise the alloy becomes so fusible, that part of the copper will be melted and carried along with the lead and silver; or, if too great a degree of heat is applied, the whole loaf of liquation will be fused, and the process must again be repeated. The proportion of lead should at least be $2\frac{1}{2}$ times the quantity of copper, otherwise a considerable proportion of it, and also part of the silver, will remain in the loaf after heating. But as this process is now more rarely followed, we we shall not enter into any farther detail of the particulars connected with it.

Reduction of silver ores by amalgamation.—This process, by which silver ores are reduced, and which is now pretty generally followed in different parts of Europe, was first practised by the Spaniards in South America. The ores which are subjected to amalgamation, are such as contain only a small quantity of lead or copper; but it is of some importance that there should be a certain proportion of iron pyrites, and if this proportion be not naturally mixed with the ore, it is a good practice to supply the deficiency, by adding what is wanting to the dressed ore, so that the pyritical contents may, as nearly as possible, be in a certain proportion to the quantity of silver, which is to be ascertained by previously assaying a portion of the ore.

The ore being reduced to the consistence of coarse sand, is carefully mixed with common salt, in the proportion of eight or nine per cent. when the silver in the ore amounts to eight ounces per quintal; and when the latter amounts to 32 ounces, or even a greater proportion, from 10 to 12 per cent. of salt is to be added. The next process is roasting the ore, in which about three quintals are spread on the floor of a reverberatory furnace, and subjected to a moderate red heat. During the roasting the ore is to be turned twice or thrice, that every part of it may be equally exposed to the heat. The first charge being withdrawn, an experienced workman knows by its appearance whether the proportion of salt be too little or too much, and, as may be required, more salt or ore is added to the unroasted parcel. When the whole of the ore is roasted, it is ground in a mill, passed through sieves, by which it is made as fine as meal, and is then prepared for the proper process of amalgamation. This is performed in the following manner. A number of small barrels, which are made to revolve rapidly on their axes by means of machinery, or fixed tubs, either open or covered, having in the centre of each an instrument resembling a chocolate mill, which may be turned rapidly by similar machinery. The tubs or barrels are filled about one-third with water, and afterwards a sufficient quantity of roasted ore and mercury, in nearly equal proportions, is introduced, so that the whole may be of the consistence of thin mud. The machinery is put in motion, and continued without interruption for 30 or 48 hours, according to the nature of the ore, when the amalgamation is completed. About a quarter of an hour after the agitation of the matter in the barrels has ceased, the greater part of it falls to the bottom, and is withdrawn by opening a hole made for the purpose. The earthy residue is carefully washed by small portions at a time, and thus a good deal of the amalgam which, from being very minutely divided, could not sink through and mix with the rest, is recovered. The earth, however, if originally rich in silver, still retains a small proportion It is therefore dried, and being mixed with about 3 per cent. of salt, is again roasted, but at a higher temperature than at first; and the process of amalgamation being again repeated, the whole of the silver is extracted. The fluid amalgam is strained through a closely woven bag, and is thus separated into nearly pure mercury and a stiff amalgam; and the latter being subjected to distillation, the mercury is driven over, and the silver remains behind. The copper, which is combined with the silver, is separated by cupellation.

The process of amalgamation is thus explained. The greater part of the sulphur of the silver and pyrites is, by roasting, burnt off, and converted into sulphurous acid, which latter, as soon as it is formed, and assisted also by the affinity of the silver for muriatic acid, decomposes the common salt, forming a sulphate or sulphite of soda, while the muriatic acid combining with the silver, forms muriate of silver. In the amalgamation which follows, the mercury, being in great proportion, decomposes the muriate of silver, and is partly converted into calomel. Hence it appears, that the loss of mercury, which is sometimes very considerable in this process, arises, first, from the conversion of part of it into calomel; and, secondly, from the extremely minute division of another part, so that it is carried off in washing the earthy residue; but the proportion of the latter depends much on management.

By the following method silver may be separated from copper, according to Napione, without the expensive and complicated process of liquation. The mixed metal is melted; a quantity of sulphur is sprinkled over its surface, while the whole is stirred about with a stick by an assistant, so that the sulphur may combine with the copper into a matt, which floats above the metal, and is to be removed with a pair of tongs, previously moistening its surface with water, to make it solid. Another portion of sulphur is next to be stirred in, and the second matt produced is to be removed in the same manner. This process being repeated a sufficient number of times, the greater part of the copper is converted into matt, holding a small proportion of silver, while the remaining copper, which retains the most of the silver, originally diffused through the whole mass, becomes rich enough to be sent immediately to the refinery. In treating the matt, it is first to be reduced to powder, mixed with common salt and quicklime, in the proportion of 12 per cent. of each, roasted for 10 hours, amalgamated as before; and after three successive roastings and amalgamations, the whole of the silver may be extracted.

Chap.

Copper.

Chap. V. *Of the Ores of Copper.*

The ores of copper are very various. This metal is found native, in the state of oxide, in the state of sulphuret, and in that of salt, combined with carbonic, muriatic, phosphoric, and arsenic acids.

Sect. I. *Of the Analysis of the Ores of Copper.*

The analysis of the ores of copper, it is obvious, must vary, according to the nature of the substances with which they are combined; but as a great proportion of the ores of that metal are combined with sulphur or arsenic, when they are to be treated in the dry way, they are first roasted, for the purpose of expelling those substances. To effect this, the ore is mixed with about one half its bulk of charcoal powder, or fine saw-dust, and then subjected to a low red heat, on a flat tile or muffle, on which it should be thinly spread. The sulphur or the arsenic rises in fumes; and to accelerate the separation of these substances, the mixture should be frequently stirred, observing at the same time not to increase the heat to such a degree as to make the ore clot together, which is one of the objects in the use of the saw-dust or charcoal. When it appears that the fumes cease to rise, and the whole of the charcoal is burnt off, the part of the ore remaining is now in the state of oxide, but mixed with a quantity of sulphur or arsenic, which cannot be entirely separated by roasting, and with the earthy matters with which the ore was originally combined.

The next object is to reduce the oxides, thus obtained, to the metallic state; and in this process of reduction the oxide is exposed to a high temperature, in contact with some carbonaceous matter, and secluded from the air. It has been a common practice to add some alkaline matters by way of flux, to promote the fusion of the extraneous matters combined with the ore; but the experience and observation of more enlightened chemists have proved, that a portion of the metallic oxide is always dissolved by saline fluxes, so that by assays in the dry way with saline fluxes, a less proportion of metal than the ore really contains, is obtained from it. The loss, according to Klaproth, between the treatment of a copper ore in the dry way, and the same ore, in the moist way, amounted to no less than 9 per cent. To obviate this inconvenience, a flux is employed by some, composed of fusible glass, into which a large proportion of alkali and silica enters, without any metallic matter; or fluor spar, lime, and particularly borax. By the latter, a thinner fusion of the vitrifying mixture, than by an equal quantity of any other substance, is produced, so that a smaller proportion of borax than of the alkaline matters answers all the purposes of a flux; and thus the loss of the metallic oxide, by solution, is less.

But in reducing the pure oxides, or the carbonated oxides of copper, the method which is attended with scarcely any loss, is by subjecting them in contact with charcoal, in a covered crucible, to an intense heat. It is indeed in this way that the reduction of roasted copper ores is conducted on a large scale; but as these latter contain sulphur, arsenic, iron, and other impurities, the process must be many times repeated before the copper is brought to a malleable state.

In reducing the sulphurated ores of copper, a button of metal, of considerable purity, may be sometimes obtained by means of a single operation. The tedious process of roasting is avoided by adding to the ore two or three times its weight of nitre, and projecting it into a hot crucible. When thrown into the crucible, a deflagration takes place, in which the sulphur is burnt, and converted into sulphuric acid, which unites with the potash of the decomposed nitre. The metal being now freed from the sulphur, is in a state of complete oxidation by the nitric acid, and may be reduced by adding a flux of tartar and pitch, or other similar matters, and applying a strong heat for a sufficient length of time. But it seems to be more advisable to separate the metallic oxide after deflagration. This may be done by washing the mixture, after which the oxide is to be reduced by the proper flux.

In the analysis of copper ores in the moist way, the metal is obtained separate in three states; either in the metallic state, in the state of black oxide, or in that of green carbonate. If a polished piece of iron be introduced into an acid solution of copper, it is immediately covered with a coating of shining metallic copper, which is owing to a part of the iron being dissolved by the acid, and a corresponding portion of copper being separated from the solution. The whole of the copper may be precipitated in this way, and at last the solution contains only iron. The precipitate, which is in the form of ragged filaments, may be washed, dried, and weighed, so that the proportion of the metal in the ore examined may be ascertained. It may be added, that the precipitation is greatly promoted, by boiling for a short time, especially towards the end of the process, which produces the separation of the last portions of the copper; and it should be farther observed, that a perfect separation of copper from iron is obtained only when the solution is made in sulphuric or muriatic acid, and not in nitric acid. The method of separating copper from silver has been already mentioned. It may be separated from lead, by adding sulphate of soda to the solution, by which an insoluble sulphate of lead is obtained, and the copper remains behind. To separate copper from antimony, the oxides of copper and antimony are digested with nitric acid; the copper is dissolved, and the antimony is left. By immersing a piece of metallic tin in the solution, copper may be separated from tin; for by this means the copper only is precipitated. Arsenic is separated from copper by dissolving in nitrous acid, and adding acetate or nitrate of lead, which produces an insoluble arseniate of lead, and leaves the copper behind. In case there should be an excess of lead, the addition of sulphate of soda will throw it down in the form of insoluble sulphate. When nickel is combined with copper, it is usually conjoined with iron. Ammonia precipitates all the three metals; but, when added in excess, redissolves the nickel and copper. To obtain the latter separate, supersaturate with muriatic acid, and introduce a polished piece of iron, by which the copper is precipitated, and the nickel remains in the solution.

To ascertain the quantity of precipitated copper obtained from the examination of an ore, it is to be washed and dried, put into a small crucible, moistened with a drop or two of oil, and covered with borax. Thus prepared, it is subjected to strong heat for a few minutes, Copper. nutes, and a solid button of malleable copper is produced, which may be accurately weighed. But if the product of the analysis be in the state of green carbonate, which is obtained by adding carbonate of potash or soda to a solution of copper, the green precipitate, thus formed, is to be washed and dried at the temperature of boiling water. An hundred and eighty parts of this carbonate are equivalent to 100 of metallic copper. The quantity of copper obtained by analysis may be estimated also in the state of black oxide. If the green carbonate be boiled for a few moments in caustic potash, it shrinks and becomes a deep brownish black fine powder, which is a pure oxide of copper in its highest state of oxidation. One hundred parts of this oxide, after being well washed, and dried in a low red heat, for a minute or two, are constantly found to contain 80 parts of pure metallic copper.

We shall now give a few examples of the analyses of particular ores of copper.

Vitreous copper ore, or *sulphuret of copper from Siberia.*—The following is the mode of analysis of vitreous copper ore by Klaproth.

"1. Upon 200 grains of the ore, coarsely powdered, moderately strong nitric acid was affused, which attacked and dissolved them with frothing and extrication of red vapours. The solution was clear, and the sulphur alone in the ore was left behind, floating in the fluid, in gray, loose flocculi, without any other residue; which indicated that no antimony was present. The sulphur collected on the filter was heated in a small crucible to inflammation, and it burned with its peculiar odour, without any trace of arsenic; yet leaving a slight portion of oxidated iron and siliceous earth.

"2. The solution, which had a pure blue colour, was treated first with muriate, and then with sulphate of soda. But none of these, nor any other salt, rendered it turbid, or produced any other alteration; by which it appears, that this ore contains neither silver nor lead.

"3. To determine, with proper accuracy, the proportion of the constituent parts, I repeated the examination in the following manner Two hundred grains of the powdered ore were combined and heated with muriatic acid, to the degree of boiling. But as this alone manifested no action on it, I added nitric acid gradually, by drops, which exerted a strong attack in each instance. When the solution of the ore had been accomplished, I separated the fluid from the sulphur floating on the surface; and digested this last once more with a fresh quantity of muriatic acid, dropping into it some nitric acid, after which I collected it upon the filter. This sulphur, washed and desiccated, weighed $38\frac{1}{2}$grs. out of which, after its combustion, $1\frac{1}{2}$ grain of siliceous earth remained; so that the true amount of sulphur was 37 grains.

"4. The solution exhibited a glass-green colour. I divided it into two parts. Into one half polished iron was immersed, upon which the copper precipitated of a dendritical form, and pure metallic brilliance. It weighed $78\frac{1}{2}$ grains, when washed, and immediately desiccated in a moderate temperature.

"5. In order to ascertain the proportion of iron contained in the ore, I combined the other half of the solution with caustic ammonia added to excess of saturation. The precipitated iron remained behind, in the form of a subtle brown mud, which, collected on the filter, desiccated and ignited, weighed three grains. But as the iron is contained in the mixture of the ore, not in this calciform state, but in the reguline, which last is to the first in the proportion of 3 to 4, these three grains of oxidated iron give $2\frac{1}{4}$ of metallic iron to be added in the computation.

"Therefore, an hundred parts of the Siberian vitreous copper ore consist of,

Copper,	78.50
Iron,	2.25
Sulphur,	18.50
Silex,	0.75
	100.00†."

† Essays, i. 541.

Variegated copper ore.—This ore was analysed by Klaproth, in the following manner.

"1. One hundred grains of the pulverized ore were subjected to gentle digestion with nitric acid, whose action upon it was but moderate. From the residue, the sulphur was driven out by combustion. This residue, when a second time digested with nitric acid, dissolved in it, leaving only a slight portion of a red oxide of iron. On examining the solution, first by common salt, and then by Glauber salt, it continued limpid and unchanged.

"2. Upon 200 grains of the powdered ore, muriatic acid was affused, the mixture heated, and then combined in small portions with nitric acid. The solution, which was thus performed, had a brown colour while concentrated; but as soon as it was diluted with water, it acquired a green. The remaining sulphur was gray, tenacious, and spongy, and weighed 72 grains when dry. By slow combustion it left 35 grains, of which, after extraction by muriatic acid, five grains still remained behind. These lost one grain more of sulphur by burning, and the remaining four grains dissolved entirely in muriatic acid. Whence the quantity of sulphur amounted to 38 grains.

"3. The muriatic solution was divided into two equal parts; and the copper was precipitated from one of them by means of iron. It amounted to $69\frac{1}{2}$ grains.

"4. The other half was supersaturated with caustic ammonia, and the oxide of iron which fell down was collected. This, when moistened with linseed oil, and exposed to a low red heat, weighed 10 grains; which are equal to $7\frac{1}{2}$ grains of metallic or reguline iron.

"Thus, in 100 parts of this variegated copper ore from Norway were found,

Copper,	69.50
Sulphur,	19.
Iron,	7.50
Oxygen	4.
	100.00

"In supplying the deficiency in the sum of weights of the copper, iron, and sulphur, from the hundred, by putting oxygen in the account, I mean to characterize this last as a constant constituent part of variegated copper ore, producing in it those variegated colours: in the same manner, as in steel, in copper pyrites, and other

Copper. other metallic substances, the beginning of their oxidation is indicated by a similar diversity of colours.

"In the last-mentioned substances, however, the changeable colours are only owing to external causes; for which reason they present themselves only on the surface, when long exposed to air. On the contrary, the variegated copper ore is penetrated throughout its whole mass by the oxidating principle. This corresponds with the deficiency of weight to make up the sum of the fixed constituent parts of the ore here analysed; whereas no such loss is observable in the vitreous copper ore, treated and decomposed by the same method. It is on this account also, that the action of the nitric acid is less strong, and the disengagement of nitrous gas is less copious, in the variegated than in the vitreous copper ore *."

* Ibid. i. 545.

Malachite, or *carbonate of copper*.—Klaproth analysed a Siberian ore of this species, according to the following process.

"1. One thousand grains of compact reniform malachite, from the Turjin mines, on the Ural, were reduced to powder, and heated to complete redness in a small glass retort, connected with the pneumatic apparatus. Much carbonic acid gas was disengaged in this process, to the amount of 252 cubic inches, without reckoning that part which was absorbed by the water of the apparatus. This gas was entirely absorbed by lime water, at the same time that a proportionate quantity of carbonate or crude calcareous earth was produced. In the intermediate small receiver a moisture collected, weighing 78 grains, which, upon trial, proved to be pure water.

2. The pulverulent residue taken out of the retort appeared of a black colour, and weighed 716 grains. To serve for the following experiments, it was divided into four parts, at 179 grains each; and hence corresponding to 250 grains of rough malachite.

3. One hundred and seventy-nine grains of ignited malachite, combined with three times its quantity of black flux, were put into an assay crucible, without lining it, and covered with muriated soda. In this situation it was committed to the fire of the blast furnace, and when the coals had become red hot without the action of the bellows, it was kept melting for the space of 20 minutes. After cooling, it was observed that, in the broken retort, the whole mixture, under the covering of common salt, had run into an uniform, compact, and opaque mass, of the bright red colour of ordinary sealing-wax, and that no metallic button had been formed.

"It follows from this, that there was not carbone enough present to take up entirely the oxygen of the metallic oxide. Therefore the copper has, by means of this small remainder of oxygen still united with it, been brought into the state of red oxide of copper; and, as such, it has diffused itself uniformly through the alkaline salt.

"4. One hundred and seventy-nine grains of ignited malachite were mingled with three times their quantity of black flux, and one-tenth of powdered charcoal. When fused in this state, during 20 minutes, under a stratum of common salt, in an assay crucible not lined in the inside, they afforded a button of reguline copper, which had run well together, and weighed $136\frac{1}{2}$ grains.

"5. Another 179 grains of ignited malachite, mixed with thrice as many grains of black flux, and one-fifth part of their weight of colophony, and likewise fused for 20 minutes, under a cover of muriate of soda, in a crucible not secured by lining, yielded a well-melted button of reguline copper, weighing 138 grains.

"6. The remaining 179 grains of ignited malachite were, like the preceding, melted during the time of 20 minutes, under a cover of common salt. But the assay crucible had previously been lined with powdered charcoal, and the malachite mingled with an equal weight of calcined borax, with half its quantity of white glass, and one-fourth part of colophony, or boiled turpentine. By this process I obtained, indeed, a well-fused button of reguline copper; but with a considerable loss, as it weighed only $105\frac{1}{2}$ grains.

"In order to discover more accurately the constituent parts of the malachite, I performed the following experiments.

"7. One hundred grains of malachite, reduced to powder by trituration, were dissolved in nitric acid; which was effected without leaving any residue. The solution had a bright-blue colour, and was saturated to excess with caustic of ammonia; but the precipitate produced was entirely, and without turbidness, redissolved by the excess of the alkali. This shewed that the malachite here examined was perfectly free from iron, and similar admixtures.

"8. I combined 100 grains of triturated malachite with a sufficient quantity of sulphuric acid, previously diluted with five parts of water, and accurately weighed together with the vessel. After the malachite had been wholly dissolved, which was effected gradually, and with a moderately strong effervescence, the loss of weight, occasioned by the carbonic acid gas that was extricated, was found to consist of 18 grains.

"9. One hundred grains of the same powdered malachite were ignited, at a moderate heat, in a covered crucible. The black residue had lost $29\frac{1}{2}$ grains in weight. If from these be subtracted 18 grains for the carbonic acid, the remaining $11\frac{1}{2}$ grains of loss will consist of water.

"10. And lastly, 100 grains, which had been dissolved in diluted sulphuric acid, and precipitated by zinc, yielded 58 grains of pure copper.

"In consequence of these experiments, the Siberian malachite consists, in the 100, of,

Copper,	58.
Carbonic acid,	18.
Oxygen,	12.50
Water,	11.50
	100.00 *."

* Ibid. i. 550.

Muriate of copper.—This ore, when exposed upon charcoal to the action of the blow-pipe, gave to the flame a blue and green colour; the muriatic acid was soon driven off, and a metallic button of pure copper remained.

This ore of copper was examined and analyzed by Klaproth in the following manner. A portion of the ore being reduced to powder, and boiled with water, communicated no colour to the solution; and, with the addition of a solution of nitrate of silver, afforded a small quantity of a white precipitate which blackened

Copper. in the day light. This experiment shews, that the proportion of muriatic acid is too small to give a compound soluble in water.

" 1. One hundred grains of the elutriated mineral dissolved readily and quietly in nitric acrid affused in the cold. The solution possessed a pure blue colour, and deposited a little of a brown iron ochre, which, separated by filtering, weighed a grain and a half. It was then diluted with water, and treated with a nitric solution of silver. The precipitated muriate of silver, when edulcorated, dried, and melted at a moderate degree of heat, in a silver pan, weighed 64½ grains.

" One hundred parts of metallic silver yield by such combination 133 parts of muriated silver. But as this metal, to be rendered soluble in acids, takes up 12 per cent. of oxygen, these must be subtracted; so that of this increase of weight by 33 parts, there remain 20½ for the muriatic acid.

" These principles being laid down, the above 64½ grains of muriated silver will fix the proportion of the muriatic acid, contained in 100 parts of the ore, very nearly to 10 grains.

" 2. That I might be sure of having completely separated the muriatic acid from the nitric solution of this copper ore, I added the nitrated silver in a small degree of excess; and this silver I afterwards threw down with muriatic acid, and filtered it off. Which done, the copper was precipitated in the metallic state, by means of a piece of polished iron immersed in the solution. It amounted to 57½ grains when collected and carefully dried.

" The copper, however, is contained in the ore as an oxide. In this state its weight is increased 25 per cent. by the oxygen; which, for those 57.50 grains of metallic copper, just now mentioned, gives, by calculation, 14.38 grains.

" Now, since what is deficient from the first weight of the ore employed is to be considered for the greatest part as its water of crystallization, and since those 1½ grains of ferruginous ochre do not belong to the composition of the ore, the constituent parts of the muriated ore of copper may be said to be in the 100 as follows:

Oxide of copper,	73.
Muriatic acid,	10.1
Water of crystallization,	16.9
	* 100.0."

* Essays, ii. 158.

Phosphate of copper.—The following is the method of analysis adopted by Klaproth, in the examination of this ore.

" 1. Because this ore is very much intermixed with its quartzose matrix, I pulverized a portion of it, previously freed as much as possible from the stony matter, and ascertained the weight of quartz still united with it, by solution in nitric acid. The quartz amounted to 16 parts in 100 of the purified ore.

" On this consideration, I weighed 116 grains of the powdered ore, and poured nitric acid upon it. The mixture became of itself moderately warm. When the solution, assisted by a little heat, was thoroughly brought about, and by means of filtration freed from the undissolved quartzy matrix, it showed by its pure sky-blue colour, that it contained no iron.

" 2. After the small portion of the predominant acid had been saturated with potash, I added to the solution dissolved acetate of lead, until no farther precipitation took place. The precipitate was at first drenched for a while with weak acetic acid, then elixiviated with water, and at last perfectly dried in a low heat. It weighed 138 grains.

" That this precipitate was a combination of lead with phosphoric acid, of this I had myself assured by a previous experiment, made with another portion of the same fossil. It exhibited the phenomenon, which is peculiar to phosphated lead; namely, that under the blow-pipe it runs into a pearl, which in the very moment of fixation, rapidly assumes a garnet-like form with shining surfaces.

" Upon another portion of that precipitate, half its weight of sulphuric acid, sufficiently weakened with water, was poured and digested with it. The clear fluid, which had been filtered off from the generated sulphate of lead, and contained free phosphoric acid, was first half saturated with soda, and upon this perfectly neutralized with ammonia. By crystallization, it yielded microcosmic salt, or phosphate of soda and ammonia.

" 3. In order to discover the proportion of the phosphoric acid combined with those 138 grains of the precipitate mentioned before, I proceeded to the following experiment.

" I burned pure phosphorus under a large glass-bell, dissolved the obtained dry phosphoric acid in water, passed it through the filter, and reduced it by evaporation, in a sand heat, to a smaller volume. When towards the end of this process, flames of phosphorated hydrogen gas appeared, I added nitric acid by drops till no longer any red vapours were disengaged.

" Of this perfectly oxygenated unctuous liquid phosphoric acid, I diluted 100 grains with water, and neutralized the liquor with finely powdered white marble; of which 324 grains were employed. The mixture was evaporated to dryness, and the dry mass kept in a moderate red heat for half an hour. This ignited phosphate of lime weighed 256½ grains. In the 324 grains of marble employed in this experiment, the portion of lime, or pure calcareous earth, amounts to 178.20 grains, which if subtracted from the above 256.50 grains, determine the quantity of the phosphoric acid ingredient in that calcareous phosphate to be 78.30 grains.

" From these data, taken together, it now was rendered evident, that in those 138 grains of phosphated lead, which have been produced by the combination of lead with the phosphoric acid, constituting a component principle of the portion of the ore examined,—the concrete phosphoric acid amounts to 30.95 grains.

" 4. The remaining part of the solution, which yet contained the cupreous part of the ore, was first treated with sulphate of soda, to separate the small portion of lead it still held dissolved from a slight excess of acetated lead added in the process (2.). Which done, it was mixed with a little of uncombined sulphuric acid, and a piece of polished iron put into it to precipitate the copper, which I found to weigh 54.50 grains. But as this metal is contained in the ore in an oxidated state, which requires 25 per cent. of oxygen; there must 68.13 grains be reckoned for the oxide of copper.

Copper.

"One hundred grains of this phosphated ore of copper, therefore, consist of,

Oxide of copper.	68.13
Phosphoric acid,	30.95
	* 99.08."

* Ibid. ii. 162.

Arseniate of copper, or *needle-shaped copper ore*.—This ore was examined by Klaproth, according to the following process.

"1. Under the blow-pipe, upon charcoal, this ore detonates, emits a white arsenical smoke, and runs into small reddish-gray globules, which, when again fluxed with borax, yield a pure regulus of copper.

"2. A pure, massive specimen of this ore, weighing 50 grains, was kept in a porcelain crucible, during 15 minutes, in a moderate red heat. Its figure was not altered by the fire: but its dark olive colour was changed into a bright grass green, inclining to that of the siskin. Its weight was diminished by 1¼ grain.

"3. Nitric acid dissolves it quietly in the cold, and the solution possesses an undefiled blue colour. By the addition of nitrated silver, the mixture is not in the least rendered turbid. Acetate of barytes produces a precipitate which entirely disappears upon dilution with water. The affusion of dissolved acetate of lead, forms with this solution a white precipitate, which upon the charcoal emits arsenical vapours, and is reduced to metallic lead, when combined with an excess of ammonia, the precipitate falling down at first, is directly redissolved, no cloudiness left behind, and the deep-blue colour is restored to the liquor.

"4. Also by the acetic acid this ore is gradually dissolved. Upon the evaporation of the solvent, a dark-green salt of a dendritical form remains behind.

"5. One hundred grains of the acicular olive copper ore, which had previously been freed, by means of elutriation, from the admixed reddish iron ochre, soon dissolved in nitric acid, and without the application of heat. The solution, being accurately neutralized with carbonated potash, was combined with dissolved acetate of lead, until all precipitation ceased. The obtained precipitate, when edulcorated and dried in a raised temperature, weighed 133½ grains.

"6. To be more convinced that this precipitate was an arseniated lead, I drenched it with water, and digested it with half its weight of sulphuric acid. The liquor, separated by filtration, contained uncombined arsenic acid. I neutralized it with soda, and treated part of it with a solution of nitrated silver. This produced a copious precipitate of arseniated silver, which possessed the brick-red colour peculiar to it, emitted arsenical vapours upon the charcoal, and was readily reduced to pure silver. The remaining part of the solution, when mixed with liquid nitrate of iron, afforded the common whitish precipitate of arseniated iron.

"Now in order to ascertain, by means of a comparative experiment, the proportion of the acid of arsenic combined with the 133½ grains of the above precipitate (1.), I dissolved in water 100 grains of solid arsenical acid, and added to it a solution of acetated lead in small portions so long as any precipitate would appear. The arseniated lead then obtained weighed 297 grains after edulcoration and drying in a warm place. Hence it followed, that the quantity of concreted acid of arsenic combined with those 133½ grains of the precipitate, which the acid of arsenic contained in the ore had produced, must be estimated at 45 grains.

Copper.

"And to be more assured that all the arsenical acid had been separated from the nitric solution of the ore, I added a little more of acetated lead than would have been absolutely requisite. This was afterwards again precipitated as sulphate of lead, by adding sulphated soda, and filtered off. To the solution, thus freed from the last precipitate, I added uncombined sulphuric acid, and precipitated the copper, now disengaged from its mineralizing acid, by means of a polished piece of iron, in the metallic state. Thus I obtained of it 40½ grains.

"But since in the composition of the olive copper ore the copper is contained in the state of an oxide, it yet remained to discover the proportion of oxygen. To attain this end, I dissolved 200 grains of pure copper in nitric acid, diluted the solution with a sufficient quantity of water, and again precipitated the metal with a lixivium of caustic potash. The precipitate had a light blue colour; but after the mixture had stood a couple of days in a moderately warm place, that blue colour was changed into a brown. When separated by filtration, washed with a large quantity of water, and desiccated in a low heat, this precipitate amounted to 269 grains. Upon ignition it weighed only 250 grains, and appeared in the form of a very subtle, fully-black powder.

"Therefore, because according to this experiment, copper acquires an increase of 25 per cent. of weight by combining with oxygen, it is obvious, that for the above 40½ grains of metallic copper, we must put in the account 50.62 grains of oxidated copper.

"In consequence of this decomposition, 100 parts of the olive copper ore contain,

Oxid of copper,	-	50.62
Acid of arsenic,	-	45.
Water of crystallization,		3.50
		* 99.12."

* Ibid. ii. 150.

SECT. II. *Of the Reduction of the Ores of Copper.*

The processes employed for the reduction of copper ores in the large way are extremely simple. It scarcely ever happens, it has been remarked, that the same order in conducting the different reducing processes, even in cases where the quality of the ore is found to be the same, is observed at two works. The same remark, however, might probably be made with regard to other manufactories, where the same practical management being long established, and attended with ordinary success, its inconveniences or advantages are rarely investigated, with regard to the abridgement of labour, or the diminution of expence. We shall now describe the processes for the reduction of copper ores, which are followed in different places, by which our readers, who are interested in the subject, will be enabled to appreciate the advantages of each, or to suggest improvements of which they are susceptible; and with this view, we shall describe the operations for reducing copper ores which are followed in Cornwall, and in Anglesea.

Method

Copper.

Method of reducing copper ores in Cornwall.—The ore is first broken to pieces, of the size of a hazel nut. This operation is known by the name of *cobbing*. The richer pieces of ore are then picked out by the hand. The next operation is roasting, which is performed in large reverberatory furnaces, 16 feet long, and 14 feet broad. The bottom of the furnace is composed of fire bricks, covered with sand, two feet thick. This sand becomes a semivitrified mass by the intense heat. The height of the chimney is from 40 to 50 feet, the draught of which is so strong, that the sulphur and arsenic, separated during the roasting, are carried almost entirely through it. The ore is introduced through a kind of funnel, and spread to the thickness of a foot over the bottom of the furnace. The fuel is placed at the anterior part of the furnace, so that the flame must pass over the surface of the ore as it is directed by the current of air towards the chimney. The ore is roasted in this furnace with a dull red heat for 12 hours, and is frequently stirred with an iron rake, to expose fresh surfaces to the flame.

The ore being sufficiently roasted, is carried to another furnace, nine feet long by six wide, where it is exposed to a fusing heat, without addition, except that of a little calcareous sand, when the slag does not rise freely. It is raked out at the end of every four hours, when it is of the consistence of soft dough, and is introduced into oblong moulds, a little water being sprinkled upon it, to make it sink down. The slag being raked off, a fresh quantity of calcined ore is introduced into the furnace, and the copper is tapped off by a hole in its side, which had been stopped up with wet clay mixed with one-fourth part of new coal, which prevents the clay from becoming so hard as to render it difficult to open the hole by means of an iron pick. As the rough copper flows from the furnace, it is conducted by a gutter into a large bucket, suspended by chains in a well, through which a stream of water is passing. The metal, as it falls into the water, is granulated, without explosion or danger, and is afterwards taken out by raising the bucket.

But in this state the copper is very impure, being quite brittle, and mixed with arsenic and sulphur, which can only be separated by other processes. For this purpose it is again melted, and granulated two or three times. Each time a slag is thrown up in the furnace; but as it contains some copper, it is not, like the first slag, rejected, but worked over and over again with new charges of calcined ore. The nature of the ore must determine the number of fusions and granulations. After the granulation, the mass is melted and cast into pigs, which have a blistered appearance on the surface. These are again broken up, and melted and roasted several times, by which the metal becomes purer, and is then cast into iron moulds, after which it is carried to the refining furnace; and being again melted with the addition of some charcoal, it is brought to such a degree of purity as to bear the hammer, and be fit for the market. In this way, by repeated calcination and fusion, the common ores of copper are freed from arsenic, sulphur, and earthy matters, and brought to the metallic state. Here it is proper to add, that where there is variety of ores, no small degree of judgment is requisite in sorting and distributing them for the furnace, that the more fusible ores being mixed with such as are more refractory, will render the poorer ores, by the addition of a portion of the richer, worth the working.

Copper.

Method of reducing copper ores in Anglesea.—The ore, which is the sulphuret of copper, is broken into small pieces, and exposed to heat in a kiln, which is close covered. A little fire is applied to the mass of ore in different places, by which the whole is gradually kindled. The kiln is furnished with flues, which open into a long, close, pent-house gallery, for the purpose of collecting the sulphur, which rises in the state of vapour to the top of the kiln, passes through the flues into the long gallery, where it is slowly condensed, is afterwards taken out, and farther prepared for sale. The mass of ore, after it is once kindled, burns of itself for about six months, and in this time the sulphur chamber is four times cleared out. The improved sulphur chambers are constructed in the form of lime kilns, having the ore at the bottom, and the sulphur subliming at the top. The richer part of the roasted ore is exported without being subjected to any other preparation, but the poorest part is melted on the spot, and contains, besides a great deal of sulphur, many other impurities. The smelting houses consist of a range of large reverberatory furnaces, having chimneys above 40 feet high, thus producing a very strong current of air. Thirty one of these furnaces are arranged side by side under the same roof. The fuel, which is coal, is burnt on a grate at the anterior part of the furnace, and the flame is carried over the ore placed on the bottom of it, by the draught of air. Twelve hundred weight of roasted ore is introduced into the furnace, mixed with a small portion of coal dust. Here the ore is melted, and brought to an impure regulus, and when it is sufficiently fused, it is drawn off into earthen moulds. Each charge of the furnace is worked off in about five hours, and yields about half a hundred weight of rough copper, which after being farther purified, affords about 50 per cent. of pure metal.

In reducing copper ores at Neusol in Hungary, lead is employed in the refining part of the process. The rough copper is spread out on the rough bed of a furnace, and after being six hours in fusion, a quantity of lead, in the proportion of from six to eight per cent. of the copper, is thrown in. This immediately begins to vitrify, and form a thick scoria, along with the impurities of the copper. The scoriæ are successively removed, till the whole is separated, and the copper is purified. The scoriæ retain a portion of the copper, and are employed in a future operation. The process continues from ten to twelve hours, with fifty quintals of raw copper.

Some of the fine copper ores contain such a proportion of silver as to render it worth while to extract the metal. In the different roastings and fusions which are employed to bring the copper to a state of purity, the silver always remains combined with it, so that it must be separated by another process. The method of separating silver from copper has been already described, in treating of the reduction of the ores of silver.

The springs which are found in copper mines, or flow from rocks which afford copper ores, are often so strongly impregnated with blue vitriol or native sulphate of copper, as to yield a considerable quantity of this metal. It is obtained by the following process. Large, square open pits, are formed of rammed clay, two or

Iron.

three feet deep. Into these pits the vitriol water is pumped; a quantity of refuse iron is thrown in, which being allowed to remain for a considerable time, the iron is dissolved by its stronger affinity for the acid, and the copper being separated, is precipitated in the form of brown mud. After the water appears to be exhausted of the copper, the oxide of copper collected at the bottom is raked out, and being dried in the sun, may be reduced in the usual way. This material which is the richest employed in obtaining metallic copper, yielding fifty per cent. although contaminated with some iron and clay, is rarely smelted, excepting along with the poorer ores, some of which do not afford more than five per cent. of pure metal.

The plates of copper of a fine red colour, usually known by the name of *rosette copper*, are made by a particular management. When the metal is found to be in a state of sufficient purity, the surface while in fusion is well scummed, and allowed to cool till it is just ready to fix. At this time the workman brushes it over with a wet broom, by which the surface is immediately fixed, and a thin plate is separated from the metal below, which is still in a fluid state. The plate thus produced is taken off and thrown into water, where it becomes of a high red colour. The same operation is repeated and continued successively till the whole of the fluid metal is converted into thin irregular plates of the above description.

Chap. VI. *Of the Ores of Iron.*

The ores of iron, which present a considerable variety, are reduced, on account of the refractory nature of this metal, with no small difficulty. The most powerful agents must be employed for this purpose. And as the construction of furnaces is a matter of the greatest importance in the smelting of iron ores, we were led, when treating of that subject, to enter into a pretty full account of the processes themselves; to this account the reader is referred for information on the methods followed in the reduction of these ores. The present chapter therefore will be only occupied in giving an abridged view of their analysis.

Sect. I. *Of the Analysis of Iron Ores.*

Native Iron.—In analysing this ore, it may be dissolved in diluted nitric acid; the lead may be separated by adding sulphate of soda, thus forming an insoluble sulphate of lead; the oxides of iron and copper may be precipitated by means of caustic fixed alkali at a boiling heat; the addition of caustic ammonia will dissolve the copper, and the iron will remain behind.

Pyrites.—Iron pyrites is either magnetical, or is destitute of this property. When the ore is magnetical, it may be either proper magnetical pyrites, or common pyrites with a mixture of magnetic iron, either in the metallic state, or in that of black oxide. If the magnetism be owing to black oxide mixed with common pyrites, no hydrogen gas will be produced by digesting it in muriatic acid; and if metallic iron and pyrites be combined together, the gas obtained will be hydrogen gas: but if the ore examined be magnetic pyrites, the gas evolved by muriatic acid will be sulphurated hydrogen. The following analysis is applicable to both species of pyrites. 1. After reducing the pyrites to a very fine powder, let it be digested in nitric acid of moderate strength, and boiled almost to dryness; then add a fresh portion of acid, and repeat this process till the whole sulphur is converted into sulphuric acid. 2. Pour off the liquor, edulcorate the undissolved residue, and add the washings to the liquor. 3. Add to this carbonate of soda to a slight excess, and separate the precipitate, if any take place. 4. After neutralising the residual liquor by a little nitrous acid, it may be decomposed by muriate of barytes, which is to be added while any precipitate takes place. A hundred parts of this precipitate indicate 14.5 of sulphur in the ore. 5. The insoluble residue (2.) is next to be digested with caustic soda, and being evaporated to dryness and slightly ignited, the precipitate (3.) is to be added, and the whole dissolved in muriatic acid, and boiled nearly to dryness. By the affusion of water the silica will be left in the state of a white insoluble powder. 6. Mix the muriatic solution with ammonia in slight excess, and the alumina and oxide of iron will be precipitated together, leaving the lime, if there should be any, in the solution, from which it may be obtained in the state of carbonate, by a mild alkali. 7. The iron and alumina may be separated by boiling in nitric acid, which leaves the metallic oxide untouched, or by digestion in caustic potash or soda, which produces a similar effect.

Magnetic Iron Ore, Specula Iron Ore, and *Red Iron Ore,*—are composed chiefly of oxide of iron, with an accidental quantity of silica and alumina. These ores are with difficulty acted on by acids alone. In conducting the analysis, therefore, 1. The ore is to be reduced to a fine powder, and heated in a silver crucible, with caustic soda in solution. When the whole moisture is evaporated, the remaining matter is to be ignited to a low degree for a few minutes; next dissolve the whole contents of the crucible in diluted muriatic acid; evaporate the solution nearly to dryness, and boil the residue in distilled water, acidulated with a little muriatic acid, and the silica will remain behind undissolved. 2. The solution being considerably reduced by evaporation, add caustic soda to a slight excess, and boil it upon the precipitate which is thus obtained. This precipitate, after being edulcorated, is pure oxide of iron, and being heated with a little wax, it may brought to the state of magnetic oxide, one hundred parts of which indicate seventy-three of metallic iron. In this way the quantity of iron in the ore may be estimated. 3. The alkaline solution contains the alumina, which may be separated by muriate of ammonia, and after being washed and ignited, its quantity may be ascertained.

Black Iron Ore, and Brown Iron Ore.—Besides the ingredients contained in the former species, these ores are combined with a portion of manganese; the precipitate obtained, therefore, is a mixture of the oxides of iron and manganese. These oxides may be separated by dissolving them in muriatic acid, and adding to the hot solution caustic soda, drop by drop, till the liquor becomes colourless, or till the precipitate thrown down at each addition of the alkali begins to be white. In this way the oxide of iron is precipitated, while that of the manganese remains in solution The iron being removed, the oxide of manganese may be obtained, by continuing the addition of soda till no farther precipitate is produced. The two oxides may also be separated by adding

succinate

3

Iron. succinate of soda to the muriatic solution, by which means the iron is precipitated, and the manganese remains in solution.

Sparry Iron Ore.—This ore of iron, which is supposed to contain carbonic acid, the oxides of iron and manganese, lime, magnesia and barytes, in the state of carbonate, with a small portion of silica and alumina, may be examined according to the following analysis. 1. Digest the ore reduced to very fine powder, in muriatic acid, with a little nitric acid: a slight effervescence takes place, and the loss of weight indicates the quantity of carbonic acid driven off. 2. The insoluble portion of the ore, after being twice or thrice digested in muriatic acid, is silica. 3 The muriatic solutions and washings, being mixed together, are to be concentrated by evaporation, and decomposed at a boiling heat, by adding caustic soda in excess. 4. Boil the precipitate and supernatant fluid together for a short time, the alumina only will be dissolved. 5. The insoluble portion is next to be well washed and ignited, and being once abstracted with nitric acid, the lime, barytes, and magnesia, will be dissolved, leaving behind the oxides of iron and manganese. 6. To separate the oxides, digest the mixture with a gentle heat in diluted nitric acid, with the addition of a small bit of sugar; the manganese is dissolved, and the remaining oxide of iron may be brought to the magnetic state, by heating it with wax. 7. The nitrate of manganese may be precipitated by carbonate of soda, and after washing and drying it at a heat below redness, pure carbonate of manganese is obtained, one hundred parts of which indicate fifty-five of metallic manganese. 8. To the nitric solution (5.), a good deal diluted with water, add sulphuric acid as long as any precipitate is formed. The sulphate of barytes thus obtained being removed, the other earths may be thrown down by means of the carbonate of an alkali; they are again dissolved in diluted sulphuric acid, and the sulphates of lime and magnesia thus produced, being precipitated by alcohol, may be separated from each other by cold water. In this way the sulphate of magnesia is dissolved, with only a very inconsiderable quantity of the sulphate of lime.

Argillaceous iron ore, bog iron ore, blue earthy and green earthy iron ores,—are chiefly composed of the oxides of iron and manganese, phosphate of iron, silica, alumina, and lime. The analysis of these ores may be conducted according to the following process. 1. After the ore is reduced to powder, and ignited, abstract it two or three times with nitric acid; pour off the acid, and wash the residue with a small portion of strong nitric acid. 2. Add the acids together, evaporate nearly to dryness, wash the residue with cold water; the phosphate of iron remains behind. 3. Ignite the insoluble residue (1.) with caustic soda, and separate the silica as in a former analysis, by muriatic acid. 4. Mix the nitric and muriatic liquors, boil them with an excess of caustic soda, and the alumina will be dissolved, while the metallic oxides and lime are precipitated. 5. After ignition, abstract the compound precipitate with nitric acid; the lime is now dissolved, and nothing remains but the oxides of iron and manganese, which may be separated according to the preceding analysis.

Arseniate of Iron.—This ore is found to contain oxides of iron and copper, with arsenic acid, besides a portion of silica, and sometimes lime. It was analysed by Mr Chenevix, according to the following process. Being reduced to powder, and subjected to less than a red heat, the water of crystallization is driven off; the residue is next boiled with caustic potash, and the alkaline solution being separated by filtration, is to be neutralized with nitric acid. The addition of nitrate of lead affords a precipitate of arseniate of lead, one hundred parts of which indicate thirty-three of arsenic acid. Muriatic acid is next to be added to the residue, which is insoluble in potash; the iron and copper are thus dissolved, and the silica remains behind. By supersaturating the muriatic solution with ammonia, the oxide of iron will be precipitated, and the oxide of copper will remain in solution by the alkali.

But, for practical purposes, we shall give a short view of the simpler methods of assaying the ores of iron, which are chiefly employed in manufacture, with the view of ascertaining the quantity of metal to be obtained from them, when treated in the large way. Among the older metallurgists it was usual to employ active saline fluxes in assaying the ores of iron; but as the metallic part of the ore can only be brought into fusion at a very high temperature, the same degree of heat effects the vitrification of the earthy matters, when aided by lime and bottle glass, so that the use of borax, or alkaline salts, which are more expensive, may be dispensed with.

To assay the richer varieties of magnetic iron ore, particularly iron sand, reduce them to a fine powder, add one-twelfth of charcoal, or double the quantity of fine saw dust, and expose the mixture in a covered crucible for an hour to the heat of a powerful wind furnace. After this the iron will be found at the bottom of the crucible, in the form of an irregular button, and covered with a small portion of cellular scoriæ. This process will be sufficient where the quantity of earthy matter is small; but as the common magnetic iron ore contains a considerable portion of silica, a flux of the following materials may be necessary. For every eight parts of ore take eight of bottle glass, six of limestone or chalk, and one of charcoal; mix the whole carefully together with the ore, and expose the mixture to heat as in the former case. If the operation have succeeded, a button of iron will be found at the bottom of the crucible, covered by a compact, vitreous, greenish slag.

As the specular iron ore generally contains a portion of sulphur, from the admixture of pyrites, it must be roasted at a moderate red heat, till the sulphureous odour is no longer perceptible; then to eight parts of the ore, add eight of bottle glass, six of chalk, and one twelfth of charcoal, and treat the mixture as before. The red, brown, and black iron ores, may be assayed in the same way.

Sparry iron ore may be assayed without roasting, by reducing it to powder, and placing it in a crucible lined with a mixture of charcoal and clay, and then covering it with about one-fourth of its weight of calcined borax.

In assaying argillaceous and bog ores of iron, they are first to be roasted, and then mixed with eight parts of bottle glass, seven of chalk, and one and a half of charcoal, to eight parts of ore, and subjected to fusion in an unlined crucible. It is scarcely necessary to observe, that the proportion of chalk may be diminished in treating

Lead.

ing those varieties of ore which contain calcareous earth in considerable quantities.

Sect. II. *Of the Reduction of the Ores of Iron.*

In treating of the construction of furnaces, the proper form and management of which are of the utmost importance in extracting the metal from the ores of iron, we were led to enter pretty fully into the nature and effects of the smelting process, or the method of reducing iron ores. We shall not, therefore, resume the subject in this place. See Furnace.

Chap. VII. *Of Lead.*

In the present chapter we shall first give an account of the most improved methods of analysing the ores of lead; and secondly, treat of the best methods of reducing or smelting these ores.

Sect. I. *Of the Analysis of Lead Ores.*

The analysis of the ores of lead is less difficult than that of the other metals of which we have just now treated; and when accuracy is wanted, the humid way of analysis is to be preferred. The method of separating lead from silver has been already noticed, as well as that by which it is separated from iron and copper. The same process as that employed for separating iron and copper from lead, may be followed with regard to the separation of lead from tin, cobalt, and zinc. We shall now give an account of the analysis of particular lead ores.

Galena, or *sulphuret of lead*.—This species, which is the most common ore of lead, was analysed by Vauquelin, by the following process*. 1. Three hundred parts of the ore, reduced to powder, were roasted; and lost, during the process, twelve per cent. 2. Three hundred parts of the same ore were heated with nitric acid very much diluted; a strong odour of sulphurated hydrogen was perceived, and the solution of the lead being completed and filtered, there remained on the filter pure silica, which being heated to redness and cooled, weighed fifty grains, or 16.67 parts per cent. 3. The solution of lead in nitric acid being decomposed by means of sulphate of soda, and the sulphate of lead precipitated being washed and dried, weighed 250 grains, or 63.1 of metallic lead per cent. 4. After the sulphate of lead was separated, ammonia was added, and a precipitate of oxide of iron was obtained, which being subjected to a red heat, weighed ten grains, or was equal to 3.33 per cent. 5. Carbonate of potash being added to the residual liquor, threw down nine grains of carbonate of lime, which is equal to three per cent. The sulphuret of lead thus analyzed, afforded in one hundred parts,

* *Jour. des Mines*, N° lxviii. p. 157.

Sulphur,	12.
Silica,	16.67
Metallic lead,	63.1
Oxide of iron,	3.33
Carbonate of lime,	3.
Loss,	1.9
	100.00

To assay galena in the dry way, it is to be mixed after roasting with three times its weight of black flux, covered with salt, and melted. A button of lead will be found at the bottom of the crucible, but the silver and other metals which existed in the ore, are still combined with the metallic lead.

Sulphuret of lead, antimony and copper.—An ore of this kind was analysed by Mr Hatchett, by the following process. Two hundred grains of the ore were heated in a matrass, with two ounces of muriatic acid, and nitric acid was very slowly added, till the whole exhibited a moderate effervescence. Being gently heated for an hour, the solution assumed a green colour, and a quantity of sulphur which floated on the surface, being collected, digested separately with a little muriatic acid, and washed and dried, weighed thirty-four grains; and as it burnt entirely away without any residuum, in a red earthen cup, it was perfectly pure. The solution with the muriatic acid, in which the sulphur had been washed, was first boiled, and afterwards mixed with six pints of boiling distilled water, to which it communicated a milky appearance. It was filtered while hot, and the filter washed with another portion of boiling water. The white precipitate, which was oxide of antimony, was dried in a sand bath, and weighed sixty-three grains. When the liquor with the washings cooled, some crystals of muriate of lead were deposited. The liquor was afterwards evaporated nearly to dryness, and a few drops of sulphuric acid were added, to separate the lead which remained in solution. The residue being again dissolved in boiling water, was entirely decomposed by sulphate of soda, and the sulphate of lead thus obtained being added to the former portion, was washed and dried on a sand bath. It weighed. 120 grains.

The liquor, which was now bluish green, assumed a deep blue colour by the addition of ammonia; a small portion of the oxide of iron was separated, which, when dried and heated with wax, became magnetic, and amounted to 2.4 grains. The liquor, after being evaporated nearly to dryness, was boiled with a strong solution of potash, till it was nearly dry, and the residue being washed with water, a black oxide of copper remained; which, after being dried, weighed thirty-two grains.

White lead ore, or *carbonate of lead*.—The white tabular lead ore, from Leadhills in Scotland, was analysed by Klaproth, according to the following process.

"1. One hundred grains of it, in pure specimens, and previously triturated to a powder, were by small portions introduced into a mixture of 200 of nitric acid with 300 grains of water, and put in equilibrium upon the balance. The ore dissolved readily, and with a strong effervescence, without leaving any residue. By the carbonic acid that escaped, there was a loss of 16 grains of weight.

"2. The solution, which was clear and colourless, was diluted with water, and a cylinder of zinc put into it. After 24 hours, the whole of the lead had shot into beautiful metallic laminæ, which collected, washed, and both quickly and carefully dried, to the end that no oxidation might take place, afforded 77 grains of lead in the reguline state, which correspond with 82 grains of oxidated lead.

"Consequently, the constituent parts of this tabular and

Lead.

and carbonated white lead ore, bear to each other the following proportion:

Oxide of lead,	-	82.
Carbonic acid,	-	16.
Water,	- - - -	2.
		† 100."

† Essays, ii. 132.

Green lead ore, or *phosphate of lead*.—The following is an example of the method of analysing this species of ore, adopted by Klaproth.

"1. An hundred grains of this ore, in very pure specimens, left on solution in dilute nitric acid one half grain of the quartzose matrix behind; which I separated and replaced by an equal quantity of pure ore. The colourless solution, treated with nitrate of silver, yielded 10 grains of muriated silver: which indicates 1.54 of concrete muriatic acid, contained in 100 of the ore.

"2. In the next instance, the ingredient lead was separated by means of sulphuric acid. The collected sulphate of lead, after gentle ignition, weighed $104\frac{1}{2}$ grains; for which 77.10. grains of oxidated lead must be put in the account.

"3. When after this the nitric solution had been freed, by nitrated barytes, from the portion of sulphuric acid added to excess, and subsequently treated with ammonia so far, that the acid still predominated, I continued adding a solution of acetated lead, till no more turbidness was effected. The generated phosphate of lead, when collected and exposed to a gentle red heat, proved to weigh 85 grains; and consequently, the proportion of the phosphoric acid must have been 19 grains.

"4. The remaining fluid was mixed with muriatic acid, the mixture evaporated to dryness, and extracted with ardent spirit. The residue, after completely evaporating the spirit, was again dissolved in water, and treated with Prussian alkali. A precipitation of prussiated iron ensued, which indicated the amount of oxide of iron 10 grains.

"From the results of this decomposition it follows, that the constituent parts of green lead ore, and their proportion to each other, are:

Oxide of lead,	-	77.10
Phosphoric acid,	-	19.
Muriatic acid,	- -	1.54
Oxide of iron,	-	0.10
		† 97.74"

† Ibid. ii. 125.

Red lead ore, or *chromate of lead*.—In analysing this ore, Vauquelin adopted the following simple process. Equal weights of the ore reduced to fine powder, strong muriatic acid, and distilled water, were digested together at a moderate temperature, and stirred from time to time. The chromate of lead is thus decomposed, and converted, for the most part, to muriate of lead, which is of a white colour. When the acid has ceased to act, pour off the liquor, add fresh muriatic acid, diluted as before with an equal quantity of water, and to the amount of about one fourth of the former quantity, and digest till the whole of the orange-coloured particles among the white muriate disappear. This liquor is to be added to the former, along with the washings; the whole is to be heated, and placed in a cool place for a few days, that the small portion of muriate of lead which it holds in solution, may be deposited; and this being removed, add very gradually oxide of silver, precipitated from its solution in nitric acid by caustic potash, till the last portions assume a red purple colour. In this way the whole of the muriatic acid is separated, and the liquors contain only chromic acid, which is deposited by slow evaporation in the form of small, prismatic, ruby red crystals. The quantity of muriate of lead obtained by this process being ascertained, will shew the quantity of metallic lead contained in the ore.

Lead.

Yellow lead ore, or *molybdate of lead*.—Klaproth analysed this ore in the following manner.

"1. A hundred grains of the crystals were carefully freed from the adhering calcareous earth and ochre of iron, and then finely pulverized. They were then dissolved in muriatic acid, assisted by heat, alternately affusing upon them the acid, and a large quantity of water. In this instance a trace of siliceous earth, though scarcely discernible, appeared.

"2. The greatest part of muriate of lead, generated in the process, was deposited in fine needles, even before the solution had completely grown cold. The supernatant clear fluid was then poured off, reduced to a smaller volume by evaporation, and freed from the muriated lead, which still separated. The muriated metal, collected with care, and briskly desiccated, weighed $74\frac{1}{2}$ grains. By dissolving it in hot water, and steeping into the solution a polished piece of iron, the lead precipitated upon this last in fine lamellæ, and in the metallic state.

"3. But in order to find more accurately what proportion this muriated lead might bear to pure oxide of lead, I made the following experiment.

"Two hundred grains of lead, cut into shreds, were dissolved in 300 grains of nitric acid, diluted with 10 ounces of water, and, with the assistance of digestion, in a boiling heat. The solution was then divided into two parts.

"*a*. Into one half I dropped muriated acid, as long as it produced any turbidness; evaporating afterwards the mixture to the most perfect dryness of the residue. The muriate of lead here produced weighed 133 grains.

"*b*. From the second half of the nitric solution I precipitated the oxide of lead by dissolved caustic potash. This oxide, when edulcorated and briskly dried till it began to turn yellowish, amounted to 115 grains.

"From this it followed that those $74\frac{1}{2}$ grains of muriated lead, obtained from 100 grains of the yellow molybdate of lead (2.) are equal to 64.42 grains of pure oxide of lead.

"4. The concentrated muriatic solution of molybdena, which had a blue colour, was mixed with nitric acid, and lodged in a sand bath for farther evaporation. Being thus circumstanced, it was again divested of its blue colour, and a yellow oxide of molybdena separated. But when the evaporation had been carried on to complete dryness, I collected and weighed the remaining lemon-yellow oxide of molybdena; and found it amount to $34\frac{1}{4}$ grains.

"Wherefore, one hundred parts of the purest crystals of the yellow lead ore, from Carinthia, contain,

Oxide

Lead.

Oxide of lead,	64.42
Oxide of molybdena,	34.25
	* 98.67."

* Ibid. i. 358.

Sulphate of lead.—This ore of lead was analysed by Klaproth according to the following process.

"1. One hundred grains of tabular sulphate of lead from Wanlockhead, in select pure specimens, lost $2\frac{1}{4}$ grains, by being heated in a covered crucible. When finely pulverized and ignited in a platina crucible with 400 grains of carbonate of potash, they yielded a brownish yellow, moderately concrete mass. Upon this substance, previously triturated, water was affused and heat applied to promote the solution of the soluble parts. As in the case of the preceding fossil, so in this, an oxide of lead deposited from the liquor, which, when washed, dried, and moderately ignited, weighed $70\frac{1}{2}$ grains. Diluted nitric-acid took the whole of it up, without the assistance of heat, and afforded a clear solution, from which the lead has been precipitated in the reguline state, by means of zinc. The metallic lead, thus obtained, when collected, washed and quickly dried, amounted to $65\frac{1}{2}$ grains.

"2. In order to ascertain the quantity of sulphuric acid contained in the alkaline solution, it was combined with nitric acid added to super-saturation in some degree, and, in the next instance, treated with acetate of barytes. By this management sulphate of barytes was formed and precipitated, to the amount of 76 grains, after being heated to redness, which indicates $25\frac{1}{4}$ grains of concrete sulphuric acid.

"According to this decomposition, an hundred parts of this tabular sulphate of lead consist of,

Oxide of lead,	70.50
Sulphuric acid,	25.75
Water of crystallization,	2.25
	†98.50."

† Ibid. ii. 130.

Sect. II. *Of the Reduction of the Ores of Lead.*

Galena is by far the most abundant ore of lead, and indeed almost the only ore which is subjected to the process of reduction. The treatment of this ore of lead in this way is very simple. The first object in dressing the ore, is to separate the extraneous matters or impurities, such as iron pyrites, blende, calcareous spar, quartz, &c. The purer part of the ore is broken to pieces about the size of a hazel nut, and washed from any earthy matters which adhere to it, and then it is ready to be smelted. A ton, or a greater quantity, of the ore, is spread on the floor of a common reverberatory furnace with a low arch, and with the flame of pit coal it is quickly brought to a red heat; being, during this time, occasionally stirred with iron rakes, to expose fresh surfaces to the action of the heat. When it begins to assume the consistence of paste, the heat is lowered, and kept at a dull red, till the whole of the sulphur is nearly driven off; when the heat is increased, and the ore brought to perfect fusion. The mass consists of two fluids the upper being a vitreous slag, and the lower metallic lead. The fire is now damped, and a few spadefuls of quicklime thrown in, by which the scoriæ become suddenly solid, and are removed to the side of the furnace. The tap hole is now opened, and the lead runs into moulds, in which oblong masses or pigs, about 60 pounds each, are formed. After the lead has run out of the furnace, the hole is again closed, the scoriæ are replaced in the bed; and the heat being raised to a glowing red, they are soon melted. The greater part of the lead separates from the slag, and collects in a mass at the bottom. The scoriæ become solid with the addition of a little lime, and the lead is let off into the mould. The second scoriæ still contain a portion of lead, from six to eight per cent.; but as it is not worth the expence of extracting, it is thrown away. It is found that the first running of lead is the best; the second, which is obtained from the scoriæ, being considerably harder, on account of a greater proportion of iron combined with it.

The process which is followed, at least in most parts of Scotland, is somewhat different from that now described, particularly in the previous preparation of the ore. The masses of ore, as it is brought from the mine, being separated from any adhering impurities, are reduced to small pieces, well washed, and then pulverised. In this state it is ready for the smelting process, which till of late was usually performed in an open furnace.

In some mining countries there is a considerable proportion of white lead ore mixed with the galena; doubts have been entertained whether it be profitable to retain this ore, even although it contain a large proportion of metal, because in the reverberatory furnace it is vitrified immediately on the appellation of the heat, and acting as a powerful flux, the whole is brought into fusion before the sulphur be entirely separated; so that the proportion of scoriæ in this case is greatly augmented, with very little increase in the produce of lead.

Tin.

Chap. VIII. *Of the Ores of Tin.*

There is no great variety of the ores of tin. It is usually found in the state of oxide, or in that of sulphuret, when it is also combined with copper, and a small proportion of iron.

Sect. I. *Analysis of the Ores of Tin.*

Before treating of the analysis of the ore of tin, we shall first describe a very simple process for assaying it. The ore is first reduced to the consistence of coarse sand, and separated from the stony matters by washing. If it appear, by subjecting a grain or two to the action of the blow-pipe, that it contains arsenic, 200 grains of the ore mixed with a little charcoal, are to be roasted in a calcining test at a low red heat, till the whole of the arsenic is driven off. The residue is withdrawn, mixed with a little pitch and fine saw-dust, introduced into a crucible lined with charcoal, and after a cover is luted on, placed in a large furnace, whose heat is to be raised to a bright red. In about 20 minutes the reduction is completed, the crucible is removed, and a button of metallic tin is found at the bottom, covered with a little scoriæ. But if the ore should contain no arsenic, the previous process of roasting is unnecessary.

Tin-stone.—The best method of analysing the ores of tin, is that contrived by Klaproth, by means of the fixed alkalies, which was conducted according to the following process.

"1.

Tin.

"1. One hundred grains of tin-stone from Alternon, in Cornwall, previously ground to a subtle powder, were mixed in a silver vessel with a lixivium containing 600 grains of caustic potash. This mixture was evaporated to dryness in a sand heat, and then moderately ignited for half an hour. When the gray-white mass, thus obtained, had been softened while yet warm, with boiling water, it left on the filter 11 grains of an undissolved residue.

"2. These 11 grains, again ignited with six times their weight of caustic potash, and dissolved in boiling water, left now only $1\frac{1}{4}$ grain of a fine yellowish-gray powder behind.

"3. The alkaline solution (1. and 2.), which was in some degree colourless, was saturated with muriatic acid. A brilliant white, tender oxide of tin was thrown down, giving to the mixture a milky appearance. This precipitate, re-dissolved by an additional quantity of muriatic acid, was precipitated afresh by means of carbonated soda. When lixiviated and dried in a gentle heat, it acquired the form of bright yellowish transparent lumps, having in their fracture a vitreous lustre.

"4. This precipitate, being finally powdered, soon and entirely dissolved in muriatic acid, assisted by a gentle heat. Into the colourless solution, previously diluted with from two to three parts of water, I put a stick of zinc; and the oxide of tin, thus reduced, gathered around it in delicate dendritic laminæ of a metallic lustre. These, when collected, washed, and fused, under a cover of tallow, in a capsule placed upon charcoal, yielded a button of pure metallic tin, weighing 77 grains.

"5. The above-mentioned residue of $1\frac{1}{4}$ grain, left by the treatment with caustic potash (2.), afforded with muriatic acid a yellowish solution; from which, by means of a little piece of zinc introduced into it, one half grain of tin was still deposited. Prussian alkali, added to the remainder of the solution, produced a small portion of a light-blue precipitate; of which, after subtracting the oxide of tin now combined with it, hardly one-fourth of a grain remained, to be put to the account of the iron contained in the tin-stone, here examined.

"In these experiments, (excepting only a slight indication of silex, amounting to about three-fourths of a grain), no trace has appeared, either of tungstenic oxide, which some mineralogists have supposed to be one of the constituent parts of tin-stone, or of any other fixed substance. Therefore, what is deficient in the sum, to make up the original weight of the fossil analysed, must be ascribed to the loss of oxygen; and thus the constituent parts of pure tin-stone from Alternon are to each other in the following proportion:

Tin,	77.50
Iron,	0.25
Silex,	0.75
Oxygen,	21.50
	100.00*."

* Essays, i. 523.

The analysis of grained tin ore, or wood tin, may be conducted in the same way as the former.

Tin pyrites.—The following is the process which Klaproth adopted in the analysis of this species of tin ore.

"1. Two drams of finely triturated tin pyrites were treated with an aqua regia, composed of one ounce of muriatic and a half ounce of nitric acid. Within 24 hours the greatest part of the metallic portion was dissolved in it, without application of heat; while the sulphur rose up, and floated on the surface of the menstruum. After the mixture had been digested upon it for some time in a low sand heat, I diluted it with water, and filtered it. It left 43 grains of sulphur on the paper, still, however, mixed with metallic particles. When the sulphur had been gently burnt off on a test, there still remained 13 grains; of which eight were dissolved by nitro-muriatic acid. The remaining part was then ignited with a little wax; upon which the magnet attracted one grain of it.—What remained was part of the siliceous matrix, and weighed three grains.

"2. The solution of the metallic portion (1.) was combined with carbonate of potash; and the dirty green precipitate, thus obtained, was re-dissolved in muriatic acid, diluted with three parts of water. Into this fluid a cylinder of pure metallic tin, weighing 217 grains, was immersed. The result was, that the portion of copper contained in the solution, deposited itself on the cylinder of tin; at the same time that the fluid began to lose its green colour, from the bottom upwards; until, after the complete precipitation of the copper in the reguline state, it became quite colourless.

"3. The copper thus obtained weighed 44 grains. By brisk digestion in nitric acid, it dissolved, forming a blue tincture, and left one grain of tin behind, in the character of a white oxide. Thus the portion of pure copper consisted of 43 grains.

"4. The cylinder of tin, employed to precipitate the copper, now weighed 128 grains; so that 89 grains of it had entered into the muriatic solution. From this, by means of a cylinder of zinc, I re-produced the whole of its dissolved tin, which was loosely deposited on the zinc in a tender dendritical form. Upon being assured, that all the tin had been precipitated, I collected it carefully, lixiviated it cleanly, and suffered it to dry. It weighed 130 grains. I made it to melt into grains, having it previously mixed with tallow, and under a cover of charcoal dust, in a small crucible; which done, I separated the powder of the coal by elutriation. Among the washed grains of tin, I observed some black particles of iron, which were attracted by the magnet, and weighed one grain. Deducting this, there remain 129 grains for the weight of the tin. By subtracting again from these last, those 89 grains, which proceeded from the cylinder of tin employed for the precipitation of the copper (2.) there remained 40 grains for the portion of tin contained in the tin pyrites examined. Hence, including that one grain of tin, which had been separated from the solution of the copper (3.), the portion of pure tin contained in this ore amounts to 41 grains. An hundred parts yielded,

Sulphur,	25
Tin,	34
Copper,	36
Iron,	2
Earthy matters,	13
	100*."

* Ibid. i. 527.

Sect.

Tin.

Sect. II. *Of the Reduction of the Ores of Tin.*

Tin stone, or vein tin, as it is called in Cornwall, contains a large proportion of stony matters. It is first broken by hammers into pieces of the size of a hen's egg, when it is ready for the operation of stamping, which is performed in the way already described for the ores of gold, excepting that there are only three stampers. A tin plate about a foot square, and pierced with holes to admit a moderate sized knitting-needle, is inserted in front of the trough, and that surface of the plate with the rough extremities of the holes is on the inside, by which the holes are prevented from being plugged up with the ore. As the ore is reduced to the proper fineness, it passes with the water through the holes into the labyrinth, where it is collected, and after being washed on a wooden table, when it is ready for roasting. In this state it has a considerable proportion of copper and iron pyrites, and is called black tin. After being calcined at a low red heat for several hours, in a large reverberatory furnace, the ore comes out of a bright ochrey red colour, owing to the decomposition and oxidation of some of the metallic substances; but the oxide of tin, when the operation is properly conducted, remains unaltered. The ore is washed a second time, to separate the remaining impurities; and the water which is impregnated with sulphate of copper, is retained and decomposed by means of old iron.

The reduction of the ore is the next step in the process. Seven cwt. of roasted ore, with one fifth of its bulk of small coal, are introduced into a reverberatory furnace, which is about seven feet long, and $3\frac{1}{2}$ wide. No lime, or indeed flux of any kind is required. A brisk heat is kept up for about six hours; the tin sinking down as it is reduced, and covered with black scoriæ. The furnace is now tapt, and the metal flows into a shallow pit. When the whole of the metal has run out, the scoriæ are removed from the furnace, and a fresh charge is made. The metal in the pit throws up a slag, rich in metal, which is immediately returned into the furnace; and after the melted tin has cooled a little, it is taken out with iron ladles, and poured into granite moulds. Each charge affords on an average from four to five cwt. of metal; but as the first scoriæ are not entirely free from metal, they are again stamped and washed, and mixed with a new parcel of roasted ore. The pigs of tin are next put into a small reverberatory furnace; where, without any addition, they are subjected to a very gentle heat; the purest part of the tin melts first, and is drawn off, forming what is called common grained tin; the other part contains some copper, arsenic and iron, which is brought to a state of fusion, and cast into pigs, forming common tin.

Stream tin ore, which is peculiar to Cornwall, is prepared for the furnace by reducing it to powder, and passing it through wire sieves, which have 16 meshes in the square inch. A blast furnace is employed, which is about seven feet high, and is supplied with air from two cylinders washed by an overshot water wheel. The method of managing the furnace, after being fully heated, is the following. Three or four shovels full of ore, and two or three half bushels of charcoal, without any kind of flux, form a charge with which the furnace is fed at short intervals. There is a small channel at the bottom of the furnace, through which the reduced tin is constantly flowing into a pit below, and the slag which accompanies it is removed from time to time, and returned into the furnace. When the pit is full, the melted metal is removed into an iron boiler three feet in diameter, having a small fire under it, to keep the metal in fusion. Two or three large pieces of charcoal are then placed upon the tin, and forced to the bottom by means of an iron instrument resembling a wheel, with a long handle fixed in the axle. This produces a violent ebullition, and a little slag, before mixed with the metal, rises to the surface, and is removed. In a minute or two the metal is tried, as it is called, by taking up a ladleful, and returning it again into the mass; when, if it assume a bright silver-like appearance, and a uniform consistence, the purification is complete. When cool to the proper degree, it is removed into the moulds, where it is formed into pigs of two or three cwt. Stream tin ore yields from 65 to 75 per cent. of the best and purest tin *.

* Aikin's Diction. of Chem. &c. ii.

Bismuth.

Chap. IX. *Of the Ores of Bismuth.*

Bismuth is found in the metallic state, accompanied by native silver, blende, and galena, some other metals, and earthy substances. It is also met with in the state of oxide, and also in the state of sulphuret.

Sect. I. *Of the Analysis of the Ores of Bismuth.*

In conducting the analysis of the ores of bismuth, previous roasting is not requisite. The native bismuth, or oxide of bismuth, dissolves readily in nitrous acid, diluted with about one third of water, and either in the cold, or with a moderate heat; but boiling is necessary for the sulphuret, to precipitate the sulphur, and dissolve the bismuth. The greater part of the nitrate of bismuth may be precipitated from the solution, and separated from the metals with which it is usually alloyed, by adding a large quantity of water. But to separate the bismuth totally, evaporate the clear liquor which remains over the precipitated oxide to a small bulk, so as to retain in solution the nitrates of the other metals. Add muriatic acid by drops, as long as any white cloud is formed. This last precipitate consists of the remaining portion of the oxide of bismuth, mixed with muriate of silver, if the ore examined contain any of that metal. Then add a few drops of strong nitric acid, which dissolves the bismuth, and leaves the silver; and to this portion of the nitrate of bismuth add water, which separates the whole by precipitation. To ascertain whether the solution contains any silver, expose the precipitate by muriatic acid to the light, which will become of a bluish or slatey colour, if any silver has been dissolved; but if not, the pure white colour remains unaltered. As the oxide of bismuth is composed of 81.3 per cent. of metal, and 18.7 of oxygen, the proportion of metal in the ore may be precisely ascertained by weighing it. The other metals held in solution by the nitrous acid, which are chiefly lead, iron, copper and cobalt, may be separated in the usual way.

Sect. II. *Of the Reduction of the Ores of Bismuth.*

The low degree of heat at which bismuth is fusible, renders

Bismuth. renders the reduction of the ores of this metal a very simple process. In the treatment of the native metal, and the oxide, the weight of the ore of black flux is put into a crucible along with it, covered with salt, to about a finger's breadth, and melted for 5 minutes with a brisk fire; when it is cold, the bismuth is found in a clean button. The flux employed by others is one part of borax, and the same quantity of powdered glass, to two of the ore, and the fusion is effected in a crucible lined with charcoal. With the oxide, a little oil, rosin, or charcoal, should also be mixed. Previous roasting is necessary in the treatment of the sulphuret of bismuth, to separate the sulphur; the other part of the treatment is the same with that now described.

But in the large way, the ores of bismuth are reduced merely by heating them along with burning fuel. Sometimes a shallow hole is made in the ground, and filled loosely with pieces of wood and bushes, and after the fire is kindled, the ore reduced to small pieces is thrown in; and sometimes the stump of a hollow pine tree is filled with wood and ore alternately, and set on fire; the bismuth separates from its matrix, and collects in a mass at the bottom.

Chap. X. *Of the Ores of Zinc.*

The ores of zinc are, the native carbonate, or common calamine, the oxide of zinc, and the sulphuret.

Sect. I. *Analysis of the Ores of Zinc.*

On acount of the great volatility of zinc, it cannot be examined in the dry way, or subjected to assay, without particular precaution. In assaying blende, or the sulphuret of zinc, the ore, after being bruised, is to be carefully separated from particles of galena, or other impurities. It is then to be roasted, and the sulphur being driven off, to be reduced to fine powder, mixed with half its weight of charcoal, introduced into an earthen retort, to which a tube is fitted. The retort being exposed to a strong heat in a wind furnace, for three quarters of an hour, is to be gradually cooled, and on breaking it, the zinc is found in the neck, in metallic drops. The object may be accomplished in another way. Prepare the ore as before, and having mixed it with charcoal, let it be stratified in a crucible, with its own weight of copper clippings; and having luted on a perforated cover, subject it for nearly an hour to a low white heat. Allow it to cool, and examine and wash the contents. The globules of brass formed are thus easily separated from the other impurities, and the excess of weight of the brass above the copper, indicates the quantity of zinc given out by the ore.

Blende, or *sulphuret of zinc*.—This ore is found to contain not only zinc and sulphur, but sometimes iron, lead, copper, and arsenic, with silica, alumina, and a portion of water. It may be analyzed by the following process:

1. Introduce into a small coated glass retort, 200 grains of ore reduced to powder, and let it be gently ignited for a quarter of an hour. The fluid collected in the receiver will be found to be water.

2. Digest another portion of ore in repeated quantities of diluted nitric acid, till every thing soluble is taken up; wash the residue; weigh and ignite it; the loss of weight indicates the quantity of sulphur which is burnt off. Zinc.

3. Digest the residue in a little nitro-muriatic acid, till the insoluble portion becomes quite white, which is pure silica.

4. Add to the nitric solution (2.) a few drops of sulphate of soda; evaporate gently, and continue to add sulphate of soda while a precipitate is formed, and after being evaporated nearly to dryness, digest in diluted muriatic acid; the sulphate of lead remains behind.

5. Add together the nitro-muriatic solutions (3, 4.); decompose by carbonate of soda, and digest the precipitate in caustic ammonia; the zinc and copper are thus dissolved.

6. Let the ammoniacal solution (5.) be saturated with muriatic acid; boil it, and add caustic soda, while a precipitate takes place: this is the brown oxide of copper.

7. Oxide of zinc now only remains in the soda solution, which is to be saturated with muriatic acid, and decomposed by carbonate of soda. The precipitate obtained after ignition is oxide of zinc.

8. The residue which was insoluble in ammonia (5.), is to be treated repeatedly with nitric acid, and digested in caustic soda. Oxide of iron, contaminated slightly with arsenic, remains insoluble.

9. Having saturated the soda solution (8.) with nitric acid, add nitrate of lead, till no farther precipitate is formed; the precipitate is arseniate of lead.

10. And to the residual liquor, add first, sulphate of soda, to separate any nitrate of lead that may remain; filter the liquor, decompose it by carbonate of ammonia; the precipitate, washed and ignited, is pure alumina.

Calamine, or *carbonate of zinc*.—The ores of this species contain, besides the carbonate of zinc, the carbonates of lead, iron, and lime. The following is the mode of analysis.

1. The ore reduced to powder is to be dissolved in diluted nitric acid; the loss of weight during the solution indicates the quantity of carbonic acid. Neutralize the solution with caustic soda, evaporate gently, and add from time to time a few drops of sulphate of soda while any precipitate is formed.

2. Having thus cautiously brought it nearly to dryness, digest it in highly rectified alcohol, and afterwards in a little cold water, which will take up every thing but the sulphates of lead and lime.

3. These may then be separated by digestion in sulphuric acid very much diluted, which will take up the sulphate of lime, leaving the sulphate of lead pure.

4. Neutralize the muriatic solution by soda, and evaporate nearly to dryness; then add alcohol to the residue, which will throw down the sulphate of lime with a little sulphate of soda, which latter may then be washed away by a little cold water.

5. The alcoholic solution (2.) after evaporation to dryness, may be digested in caustic ammonia, which will take up the oxide of zinc, and leave behind the oxide of iron.

6. The alkaline solution, after being slightly supersaturated with muriatic acid, is to be decomposed by a perfectly carbonated alkali, by which the zinc is pro-

Zinc.

cured in the state of carbonate; and this, after edulcoration, being dissolved by sulphuric acid, and the solution ignited in a platina crucible, affords dry sulphate of zinc, containing 50 per cent. of oxide of zinc.

7. Thus, all the constituent parts are ascertained except the water: to determine the proportion of this, take a fresh parcel of the ore, weigh it, and then ignite it for half an hour, note the loss of weight, and transfer the residue into muriatic acid; if while it dissolves in this fluid it gives out any gas, let the loss of weight be noted; then add together the losses by ignition and solution; deduct from the sum the known weight of the carbonic acid, and the residue is water.

SECT. II. *Of the Reduction of the Ores of Zinc.*

The ore being reduced to small pieces, and the different impurities being separated, it is next calcined in a reverberatory furnace at a moderate red heat, and if the ore be calamine, the carbonic acid is driven off, and if blende, it is deprived of its sulphur. After this it is washed, and the metallic oxide being separated from the earthy parts, it is dried, and carefully mixed with about one-eighth of its weight of charcoal, by grinding the ingredients together in a mill, and is now ready for the smelting process. This is performed in a circular furnace, in which are fixed six large earthen pots, about four feet high and nearly of the shape of oil jars. An iron tube is inserted into the bottom of each pot, and, passing through the arched floor of the furnace, terminates in a vessel of water placed beneath, while the other end of the tube rises within the crucible to a few inches of the top. The crucibles are then filled with the mixture of the ore and charcoal, to the level of the tube, the cover of each is carefully luted on, and an intense heat is to be kept up for several hours. The zinc, as the process of reduction goes on, rises in the form of vapour to the top of the pot; but as it cannot escape, it descends through the iron tube, passes into the water, and is condensed in small drops. The globules are afterwards fused, and cast into the form of ingots, when it is fit for the market.

But as common zinc contains a little of other metals, as copper, lead, arsenic, iron, and manganese, which impair its quality, these impurities are partially separated by melting the zinc in a crucible, and stirring into it, with a stick or earthen rod, a mixture of sulphur and fat; by the latter the zinc is preserved from oxidation, and the sulphur combines with all the other metals except the zinc, and converting them into sulphurets, they rise to the top in the form of scoriæ, which may be removed. This process is to be repeated as long as any scoriæ appear. The method of purifying zinc proposed by Proust, is simple distillation in an earthen retort. The zinc passes over, and the oxides of the other metals remain behind. But it is supposed that the arsenic or lead cannot be separated in this way.

CHAP. XI. *Of the Ores of Antimony.*

NATIVE antimony is a very rare production; the most common ore of antimony is the sulphuret; but it is also sometimes found in the state of oxide.

Antimony.

SECT. I. *Of the Analysis of the Ores of Antimony.*

Gray ore of antimony, or sulphuret of antimony.—As the sulphurets of antimony are the principal ores of this metal, we shall only describe the process by which the analysis of these ores may be conducted.

1. Five hundred grains being reduced to fine powder, are to be digested with 1500 grains of pure nitric acid of specific gravity 1.25, and 1000 grains of water, for half an hour, at 150° Fahrenheit; then add a quantity of pure water, equal to the rest of the fluid; mix the whole well together, and pour off the liquor as soon as it becomes clear. This consists of the nitrates of silver, lead, and copper, and perhaps a little iron dissolved in an excess of acid. By simple boiling and filtration, the iron is separated in the state of red oxide.

2. Add to the solution muriate of soda, while any precipitate takes place, and let the whole stand till the supernatant liquor becomes clear; the precipitate is pure muriate of silver.

3. The solution (2.) is next to be saturated with potash or soda, and concentrated by evaporation to one-third of its bulk. The addition of caustic ammonia in excess throws down the lead in the state of oxide, and the copper remains in solution.

4. Acidulate slightly the solution (3.) with nitrous acid; add carbonate of potash, by which the green oxide of copper will be precipitated, and being subjected to a low red heat, is reduced to the state of brown oxide, of which 100 parts indicate 85 of metal.

5. The portion of ore (1.) which was insoluble, is next to be digested at a degree of heat below boiling, with successive portions of nitromuriatic acid, composed of nitric acid, as long as any thing is taken up. The different solutions are then mixed, concentrated by evaporation, and poured into a large portion of pure water; a precipitate immediately takes place, which is the white oxide of antimony, which, after being separated and washed, is to be mixed with twice its weight of crude tartar and a little nitre, and then exposed to a full red heat, which in a few minutes reduces it to the metallic state.

6. The solution (4.) contains now a little sulphuric acid and iron, with some earthy matters. By adding nitrate of barytes while any precipitate is produced, the quantity of acid may be ascertained, and then adding caustic potash in excess, which, assisted by a boiling heat, will precipitate the iron, and retain the alumina and silica.

7. The insoluble residue (6.) contains sulphur and earth; it is decomposed by a red heat, the sulphur being dissipated, and the earth remains.

SECT. II. *Of the Reduction of the Ores of Antimony.*

The ore of antimony, which is found in sufficient quantity to be employed in the process of reduction in the large way, is the sulphuret, the analysis of which has now been detailed. The ore being separated from the greater part of the stony matters which adhere to it, is placed on the bed of a reverberatory furnace, and covered with charcoal powder; and being brought to a low red heat, the sulphuret enters into fusion, and the earthy

Antimony. earthy parts floating on the surface, are removed with a rake. The melted part is cast into the form of large cakes, and is the crude antimony of the shops.

The metal is obtained in a state of purity from the crude antimony, or sulphuret, by different processes. The following is recommended as one of the best, and most frequently practised. The sulphuret being reduced to small pieces, is strewed thinly on the floor of a reverberatory furnace, to drive off the sulphur. The heat at first must not exceed that of the melting point of tin, otherwise the antimony will melt. A lambent blue flame is observed over the surface of the ore, which proceeds from the combustion of the sulphur; the metal is deprived of its lustre, and is converted into a grayish oxide. In the course of some hours, by carefully stirring the ore, and cautiously increasing the temperature, as the fusibility diminishes, it at last ceases to give out sulphureous vapours, and can bear a moderate red heat without melting. After the roasting, the ore is removed from the fire, and is found changed into an ash-gray oxide, weighing from 30 to 36 per cent. less than the sulphuret, but it is not yet entirely free from sulphur. To reduce the oxide, mix it with half its weight of crude tartar, and subject to a full red heat in a covered crucible. The oxide is decomposed by the carbonaceous part of the tartar, and the antimony, reduced to the metallic form, is collected at the bottom of the crucible. A small proportion, however, still remains, dissolved by the sulphuret of potash, formed by the alkaline base of the tartar and the sulphur of the oxide. The quantity of metal which is thus obtained in the large way, amounts to 66 or 70 per cent. of the oxide employed. The loss, however, would be greater, if the ore has not been properly roasted.

The reduction is effected also by another process, which is supposed to be more economical. The roasted oxide is mixed with oil or fat, and a little powdered charcoal, and then introduced into a crucible; and as the metal begins to appear, powdered nitre, in the proportion of an ounce to a pound of oxide, is gradually injected, after which the whole mass is brought to thin fusion, affording a pure metal, and in greater proportion than in the usual way.

The only other process which we shall mention, for reducing sulphuret of antimony, is that by means of some of the other metals, for which the sulphur has a greater affinity than for the antimony. Proceeding on this principle, iron, copper, lead, silver, and tin, may be employed in the process; but as iron is not only more effectual, but also cheaper, it is preferred. The antimony obtained by this process, was formerly called *martial regulus*, not only on account of the iron being used in the preparation, but, not improperly, on account of a small portion of that metal which still adheres to it. The proportions recommended are the following: Eight ounces of small iron nails are heated in a crucible almost to whiteness; 16 ounces of crude or roasted sulphuret of antimony, coarsely pounded, are then added: the crucible is covered, and the fire kept up; and in a few minutes, when the whole is melted, three ounces of nitre are to be added: after a slight detonation has taken place, the whole is brought to perfect fusion. It is then put into an iron cone previously heated and greased, and as the mass becomes solid, the sides of the cone are struck, to promote the precipitation of the metal. When cold and weighed, a mass of antimony is obtained, equal to about 20 ounces of the sulphuret employed, covered with alkaline ferruginous scoriæ, from which it is easily separated by a blow of the hammer.

Cobalt. But the metal is not yet entirely free from iron and sulphur; to purify it still farther, therefore, it is to be remelted, two ounces of crude antimony, and three of nitre being added; and when the detonation has ceased, it is poured into a cone, and the metal is separated as before, from the scoriæ. Fuse the metal again; project upon it three ounces of nitre; separate the purified metal from the scoriæ; remelt with a strong heat, projecting gradually three ounces of nitre, and immediately pour it into a cone. About eight ounces of a beautiful stellated regulus, covered with yellowish white scoriæ, are thus obtained.

Chap. XII. *Of the Ores of Cobalt.*

Cobalt exists usually in a state of combination with arsenic and sulphur, or in the state of oxide. Scarcely any of its ores are free from arsenic and iron. Nickel is also sometimes abundantly mixed with the ores of cobalt, and occasionally a little manganese and copper.

Sect. I. *Of the Analysis of the Ores of Cobalt.*

White and gray cobalt ores, consisting chiefly of arsenic and cobalt, may be examined in the dry way, according to the following process, which, however, is not to be considered as very perfect. The ore is to be mixed with charcoal or saw-dust, and roasted to drive off the arsenic. The oxide after calcination is mixed with four times its weight of an equal mixture of carbonate of potash and tartar, and heated intensely, at the temperature which is required for melting cast-iron. A button of metallic cobalt is found beneath the scoriæ, which are always of a deep blue, or nearly black colour, owing to the combination of part of the oxide of cobalt. A hundred grains of this ore, treated by Klaproth according to this process, yielded 44 grains of metallic cobalt; but if the ore contained iron, copper, or nickel, it must have been alloyed with these metals, and perhaps not entirely free from arsenic.

But the analysis may be conducted with more accuracy according to the following process by Tassaert *.

1. With a view to ascertain the quantity of arsenic, he digested 100 parts of cobalt ore with diluted nitric acid. The whole was dissolved in a few hours, and deposited, on cooling, white crystalline grains. By evaporation more crystals were deposited; the whole collected and dried, weighed 56 parts, and, excepting three parts, the whole was sublimed. These 53 parts are oxide of arsenic, and indicate 49 per cent. of metal in the ore.

2. Three hundred parts of the ore digested with four times as much nitric acid, afforded a rose-coloured solution. After partial evaporation, and with the addition of water and heat, a pale-red precipitate (1) was formed, leaving a rose-coloured solution. The solution being boiled with an excess of potash, afforded an oxide of cobalt, which was rose coloured, and then green, and when dried in a red heat, black. The amount was 85 parts.

* Ann. de Chim xxviii. p. 9.

5 3. These

Cobalt.

3. These 85 parts, dissolved in nitro-muriatic acid, gave, with the addition of pure ammonia, a black precipitate, which, excepting a small portion, was again dissolved by an excess of alkali. The undissolved portion treated again with nitro-muriatic acid and ammonia, was reduced to four parts, and appeared to be oxide of iron.

4. The rose-coloured precipitate (2.), which was a mixture of arseniate of cobalt and iron, being decomposed by caustic potash in excess, afforded a precipitate, which weighed, after being dried, 100 parts.

5. The 100 parts (4.) being again dissolved in nitric acid, and the solution being partially evaporated, and then diluted with water, gave a precipitate of 27 parts of oxide of iron, and left a clear solution of cobalt.

6. The nitrate of cobalt (5.) was decomposed by ammonia; and the precipitate redissolved by an excess of the alkali, excepting an insoluble oxide of iron, amounting to 15 parts. The solution was then added to the ammoniated cobalt (3.).

7. The insoluble precipitates of oxide of iron (3. 5. and 6.) were then mixed and examined. With borax they gave a blue glass, indicating a portion of cobalt still combined. They were then dissolved in nitro-muriatic acid, precipitated by ammonia, and the wet precipitate was introduced into acetic acid, which at first dissolved the whole, but by boiling and evaporation nearly to dryness, four times successively, the oxide of iron became insoluble, while the cobalt remained in solution, and as it was more freed from iron, it assumed more of a fine rose colour. The solution of acetate of cobalt was supersaturated with ammonia, and the solution of ammoniated cobalt was added to the different portions of the same, obtained in former experiments. To expel the ammonia, the whole solution was boiled, and, by adding potash, the whole oxide of cobalt, was precipitated, which being washed and dried, amounted to 133 parts. The oxide being reduced in a crucible lined with charcoal, afforded pure metallic cobalt, of specific gravity 8.538.

8. To determine the quantity of sulphur, 100 parts of the ore were separately boiled with 500 of nitric acid, and diluted with water, to separate the whole of the oxide of arsenic that deposited spontaneously. The sulphur was now converted into sulphuric acid; nitrate of barytes was added, and a precipitate of sulphate of barytes was formed, the quantity of which being ascertained, the proportion of sulphur might in this way be estimated.

Sect. II. *Of the Reduction of the Ores of Cobalt.*

As cobalt in the metallic state is not applied to any useful purpose, the reduction of its ores in this view is not an object of manufacture. But as it is extensively employed in the state of oxide, to give a fine blue colour to glass, porcelain, &c. we shall here give a short account of the method of preparing the ores for this purpose. When the oxide of cobalt is simply mixed, after calcination, with a quantity of vitrifiable earth, it is then known by the name of *zaffre*, and it is in the form of a brown, gritty powder; but if it be melted with a quantity of vitrifiable matters, it yields a glass of a very deep blue colour, which being reduced to a fine powder, constitutes the smalt of commerce.

Preparation of zaffre.—This substance is chiefly prepared in the large way, in different parts of Germany, but particularly in Saxony, and the following is the method of its preparation. The furnace employed is somewhat like a baker's oven, and is so constructed, that the flame of wood may be reverberated on all sides. The cobalt ore is placed on the hearth of the furnace, and by the action of the flame soon becomes red hot; a dense arsenical vapour arises, which is conducted through a horizontal wooden square trough or chimney, some times 100 fathoms long. In this chimney the arsenic is chiefly condensed, yet it is said, that some of the vapours, on account of their great volatility, escape. The calcination is continued till the exhalation of vapours nearly ceases: the ore is then reduced to powder, calcined a second time, again ground, and passed through a fine sieve. The powder is then mixed with two parts of powdered flint or quartz, after which it is moistened, and packed into barrels, where it acquires a great degree of hardness. This is the zaffre of commerce, in the state in which it is exported; the exportation of the simple coloured oxide being prohibited under heavy penalties, it is said that the flints are added with a view to conceal the real nature of the substance.

Preparation of Smalt.—This is also sometimes called zaffre, and when reduced to a very fine powder, it is called *azure blue*. It is prepared with about equal parts of calcined cobalt ore, potash, and ground flints. This mixture is first fritted, and afterwards made into glass, in pots like those of the glass-house. Eight or ten hours are required for its fusion. When the blue colour is perfect, the fused matter is taken out with iron ladles, and dropt into cold water, which makes it crack in all directions, so that it is easily reduced to fine powder. This operation is performed in a mill of very hard stone, inclosed in a wooden case. In the preparation of the smalt by the above process, a portion of bismuth, which usually accompanies the ores of cobalt, is found. Above it there is also a mixed alloy of iron, copper, and arsenic.

Chap. XIII. *Of the Ores of Nickel.*

Nickel.

Nickel, as it is found in the state of ore, is usually combined with arsenic and sulphur, copper and iron, or with oxygen, in the form of oxide.

Sect. I. *Of the Analysis of the Ores of Nickel.*

When the ore contains, beside nickel, arsenic, sulphur, copper, and iron, with which it is usually accompanied, cobalt, silver, and bismuth, with some earthy matters, the analysis may be conducted according to the following process.

1. The ore being reduced to an impalpable powder, is to be two or three times digested in nitric acid, considerably diluted, after which every thing soluble will be taken up. During the process, nitrous gas is given out.

2. The insoluble part consists mostly of sulphur and silica, which after being dried, weighed and heated, the sulphur burns off, and the difference of weight before and after ignition, indicates its amount. The residue, after boiling in a little nitrous acid, is pure silica.

3. Saturate the two nitrous solutions (1. and 2.) with pure

Manganese.

pure soda, evaporate considerably, and pour the solution into cold distilled water; the oxide of bismuth is precipitated.

4. Add muriate of soda by drops to the filtered solution, while any precipitate is formed, which is the muriate of silver.

5. Evaporate the solution nearly to dryness, boil it with strong nitric acid while nitrous gas is given out; red oxide of iron is precipitated during the process.

6. Remove the oxide of iron, saturate the liquor with soda, and add nitrate of lead while any precipitate takes place. This is the arseniate of lead, which may be separated by filtration.

7. Decompose the nitrous solution by carbonate of soda: digest the washed precipitate in liquid ammonia; the oxide of iron mixed with alumina, is left behind, and may be separated by caustic fixed alkali.

8. Let the ammoniacal solution be slightly supersaturated with nitric acid, and a polished bar of iron introduced; in this way the copper will be separated: then decompose the liquid by carbonate of soda, and digest the precipitate in ammonia, and the iron employed in separating the copper will be removed.

9. The solution now contains only nickel and cobalt. Let it be evaporated till the excess of ammonia be expelled. This is the case when the vapour ceases to discolour moist turmeric paper. Then add pure potash or soda to the solution largely diluted, while any precipitation takes place. The precipitate is the oxide of nickel. The cobalt now only remaining in the solution, may be separated in the usual way. To reduce the oxide of nickel, mix it with glass of borax and a small quantity of carbonaceous matter, and then subject it in a crucible to the most powerful furnace heat. A button of pure nickel is thus produced.

As the ores of nickel are not very abundant, and as this metal is little employed for purposes of manufacture, the reduction of its ores does not extend beyond chemical analysis, which we have now detailed.

Chap. XIV. *Of the Ores of Manganese.*

Manganese usually exists in the state of oxide, combined with a small proportion of iron, or in the state of carbonate, and sometimes in that of sulphuret.

Sect. I. *Of the Analysis of the Ores of Manganese.*

Radiated gray ore of manganese.—This ore was analysed by Klaproth according to the following process.

"Two hundred grains of the ore, in grossly broken crystals, were heated to a thorough redness in a small coated glass retort, connected with the pneumatic apparatus. The gas collected amounted only to nine grains, upon deducting the common air of the apparatus; but shewed by the lively combustion of an iron wire confined in it, that it was pure oxygen gas.

"2. In the small intermediate hollow glass sphere of the apparatus, a considerable quantity of moisture has condensed, which weighed 14 grains, and was pure water.

"3. The manganese, having sustained that ignition, weighed 181 grains. The external lustre of the crystals was very much diminished, and their gray colour turned blackish.

"One hundred parts of this ore have, consequently, been decomposed into,

Black oxide of manganese	90.50
Water,	7.
Oxygen gas,	2.25
	99.75 "†

† Essays, ii. 245.

As manganese is chiefly employed for economical purposes, in the state of oxide, the reduction of its ores forms no object of manufacture.

Chap. XV. *Of the Ores of Molybdena.*

For an account of the treatment of the ores of molybdena, which exists in the state of sulphuret and in that of oxide only, see Chemistry; see also the analysis of the molybdate of lead, in the chapter on lead, in this article.

Chap. XVI. *Of the Ores of Arsenic.*

Arsenic is found native, when it is alloyed with a small portion of iron, and sometimes also with a little gold or silver; in the state of sulphuret, or in the state of oxide.

Sect. I. *Of the Analysis of the Ores of Arsenic.*

The method of analysing the ores of arsenic by Bergman, has been already given under Arsenic in the article Chemistry, as well as the method of subliming the metal in close vessels, to obtain it in a state of purity. The following is recommended as a successful process for preparing this metal for nice chemical purposes. Mix a quantity of arseniate of potash with about $\frac{1}{8}$ part of charcoal, and let it be sublimed in a close glass vessel, slowly heated to redness. The metallic arsenic thus obtained is in the form of beautiful brilliant crystals.

Sect. II. *Preparation of White Arsenic and Orpiment.*

White arsenic.—In the large way, this is prepared, by roasting the arsenical ores, previously ground to powder, and mixed with charcoal or saw dust, at a low red heat for several hours. The roasted ore is then subjected to a second sublimation, according to the following method; which is practised in Bohemia. The vessels in which the sublimation is performed, are strong square boxes of cast iron furnished with conical heads, which are closely luted with clay. These boxes are arranged in a spacious brick area, which is heated by flues proceeding from two furnaces, placed a little below them. When the impure arsenic has become red hot, it is removed into the boxes by 15 pounds at a time, where it is brought into fusion, and about an hour after begins to sublime into the conical head. When the arsenic ceases to rise, another quantity is introduced into the vessel, and treated in the same way. These additions are continued till about 150 pounds of arsenic have been thus treated in each vessel; a period of about 12 hours is requisite for the sublimation of the whole quantity. When the vessels are cold, the conical head is taken off, and the sublimed arsenic is broken off with hammers, at the same time any impurities that adhere to it are separated, for a second operation.

Orpiment.—

Arsenic.

Orpiment.—This substance is prepared in the same manner, and with the same apparatus, but the arsenic is previously mixed with half its weight of sulphur. In both cases a uniform red heat should be kept up during the operation, so that the materials in the lower vessel may be always in fusion; and when these materials are of any tolerable degree of purity, almost the whole is sublimed.

As the remaining metals have yet been found only in very small quantity, the reduction of their ores is not an object of much importance. A short account of the method of analysing them will be found under CHEMISTRY, and the characters of the ores, with their constituent parts, will be found under MINERALOGY. See also ASSAYING, CHEMISTRY, and DECOMPOSITION CHEMICAL, in the SUPPLEMENT.

For the account of an elaborate analysis of the ores of tellurium, see Klaproth's Essays, ii. 1.

Orellana || Orestes.

ORELLANA, FRANCIS, the first European, as is commonly thought, who discovered the river of the Amazons. In 1539, he embarked near Quito, upon the river Coca, which farther down takes the name of Napo. From this he fell into another large river; and, leaving himself entirely to the direction of the current, he arrived at Cape North, on the coast of Guiana, after sailing nearly 1800 leagues. Orellana perished 10 years after, with three vessels which had been intrusted to him in Spain, without being able to find again the mouth of this river. In sailing down the river, he met with some armed women, against whom an Indian cacique had told him to be on his guard; and he thence named it *the river of the Amazons*.

ORENSE, an ancient town of Spain, in the kingdom of Galicia, with a bishop's see, famous for its hot baths, is seated at the foot of a mountain, on the river Minho, over which there is a handsome bridge of one arch. W. Long. 7. 27. N. Lat. 42. 16.

ORESTES, in *Ancient History*, a son of Agamemnon and Clytemnestra. When his father was cruelly murdered by Clytemnestra and Ægisthus, young Orestes was saved from his mother's dagger by means of his sister Electra, called by Homer *Loadicea*, having been privately conveyed to the house of Strophius, who was king of Phocis, and who had married a sister of Agamemnon. He was tenderly treated by Strophius, who carefully educated him with his son Pylades. The two young princes soon became acquainted, and from their familiarity arose the most inviolable attachment and friendship. When Orestes came to years of discretion, he visited Mycenæ, and avenged his father's death by assassinating his mother Clytemnestra and her adulterer Ægisthus. Various accounts are given of the way in which these murders were committed. After their commission, however, he was acknowledged king of Mycenæ; but being tormented by the Furies, a punishment which the ancients always thought followed parricide, he exiled himself to Argos, where he was still pursued by the vengeful goddesses. Apollo, however, purified him, and he was acquitted by the unanimous opinion of the Areopagites, whom Minerva herself instituted on this occasion, according to the narration of the poet Æschylus, who flatters the Athenians in his tragical story, by representing them as passing judgment even upon the gods themselves. According to Pausanias, Orestes was purified of the murder, not at Delphi, but at Trœzene, where still was seen a large stone at the entrance of Diana's temple, upon which the ceremonies of purification had been performed by nine of the principal citizens of the place. There was also at Megalopolis, in Arcadia, a temple dedicated to the Furies, near which Orestes cut off one of his fingers with his teeth in a fit of insanity. These different traditions are confuted by Euripides, who says that Orestes, after the murder of his mother, consulted the oracle of Apollo at Delphi, where he was informed that nothing could deliver him from the persecutions of the Furies, if he did not bring into Greece Diana's statue, which was in the Taurica Chersonesus, and which, as it is reported by some, had fallen down from heaven. This was an arduous enterprise. The king of Chersonesus always sacrificed on the altars of the goddess all such as entered the borders of his country. Orestes and his friend were therefore both carried before Thoas the king of the place, and they were doomed to be sacrificed. Iphigenia, Orestes's sister, was then priestess of Diana's temple, and it was her office to immolate these strangers. The intelligence that they were Grecians delayed the preparations, and Iphigenia was anxious to learn something about a country which had given her birth. She even interested herself in their misfortunes, and offered to spare the life of one of them, provided he would convey letters to Greece from her hand. This was a difficult trial: never was friendship more truly displayed, according to the words of Ovid, *ex Pont.* 3. *el.* 2.

Ire jubet Pylades carum moriturus Orestem.
Hic negat; inque vicem pugnat uterque mori.

At last, however, Pylades gave way to the pressing intreaties of his friend, and consented to carry the letters of Iphigenia to Greece. These were addressed to Orestes himself; and therefore these circumstances soon led to a discovery of the connections of the priestess with the man whom she was going to immolate. Iphigenia was convinced that he was her brother Orestes; and when the cause of their journey had been explained, she herself resolved with the two friends to fly from Chersonesus, and to carry away the statue of Diana. Their flight was discovered, and Thoas prepared to pursue them; but Minerva interfered, and told him that all had been done by the will and with the approbation of the gods. Some imagine that Orestes came to Cappadocia from Chersonesus, and that there he left the statue of Diana at Comana. Others contradict this tradition; and Pausanias thinks that the statue of Diana Orthia was the same as that which had been carried away from the Chersonesus. Some again suppose that Orestes brought it to Aricia in Italy, where Diana's worship was established. It was after this that Orestes ascended the throne of Argos, where he reigned in perfect security, married Hermione the daughter of Menelaus, and gave his sister to to his friend Pylades. The marriage of Orestes with Hermione is also a matter of dispute among the ancients. All are agreed that she had been promised to the son of Agamemnon; but Menelaus had married her to Neoptolemus the son of Achilles, who had shown himself so truly interested in his cause during the Trojan war. The marriage of Hermione with Neoptolemus displeased Orestes; he remembered that she had been early promised to him; he was therefore determined to recover her by force or artifice. This he did by procuring the assassination of Neoptolemus. According to Ovid's epistle of Hermione to Orestes, Hermione had always been faithful to her first lover, and even it was by her persuasions that Orestes removed her from the house of Neoptolemus, for she was dissatisfied with the partiality of Neoptolemus for Andromache, and her attachment for Orestes was increased. There are, indeed, various opinions likewise about this: he, however, certainly managed to secure her affections, and retired to his kingdom of Argos. His old age was crowned with peace and security, and he died in the 90th year of his age, leaving his throne to his son Tisamanes by Hermione. Three years after, the Heraclidæ recovered the Peloponnesus, and banished the descendants of Menelaus from the throne of Argos. Orestes died in Arcadia, as some say, by the bite of a serpent: and the Lacedæmonians, who had become his subjects at the death of Menelaus, were directed by an oracle to bring his bones to Sparta. They were some time after discovered at Tegea, and his stature appeared to be seven cubits, according to the traditions mentioned by Herodotus and others. The friendship of Orestes and of Pylades became proverbial: and the two friends received divine honours among the Scythians, and were worshipped in temples.

ORFA, a considerable town of Diarbeck (anciently Mesopotamia) in Asia, very pleasantly situated, and well fortified. It formerly belonged to Persia; but is now in the Turkish dominions, and is a place of very good trade. It has a stately castle standing on a hill, which makes a great show at a distance. They pretend to show the well where Rachel watered her father's camels when Jacob met her, and they call it *Abraham's well*. E. Long. 37. 45. N. Lat. 36. 20.

ORFFYREUS's WHEEL, in *Mechanics*, is a machine so called from its inventor, which he asserted to be a perpetual motion. This machine, according to the account given of it by Gravesande, in his Oeuvres Philosophiques, published by Allemand, Amst. 1774, consisted externally of a large circular wheel, or rather drum, 12 feet in diameter, and 14 inches deep; being very light, as it was formed of an assemblage of deals, having the intervals between them covered with waxed cloth, to conceal the interior parts of it. The two extremities of an iron axis, on which it turned, rested on two supports. On giving a slight impulse to the wheel, in either direction, its motion was gradually accelerated; so that after two or three revolutions it acquired so great a velocity as to make 25 or 26 turns in a minute. This rapid motion it actually preserved during the space of two months, in a chamber of the landgrave of Hesse, the door of which was kept locked, and sealed with the landgrave's own seal. At the end of that time it was stopped, to prevent the wear of the materials. The professor, who had been an eye-witness to these circumstances, examined all the external parts of it, and was convinced that there could not be any communication between it and any neighbouring room. Orffyreus however was so incensed, or pretended to be so, that he broke the machine in pieces, and wrote on the wall, that it was the impertinent curiosity of Professor Gravesande, which made him take this step. The prince of Hesse, who had seen the interior parts of this wheel, but sworn to secrecy, being asked by Gravesande, whether, after it had been in motion for some time, there was any change observable in it, and whether it contained any pieces that indicated fraud or deception, answered both questions in the negative, and declared that the machine was of a very simple construction.

ORFORD, a town of Suffolk in England, 88 miles from London, situated between two channels, where the river Ore, after having joined the Ald, falls into the sea. It was once a populous town, with a castle; of which, and of a nunnery near the quay, there are still some ruins. The towers of the castle and its church are a sea-mark for colliers, coasters, and ships that come from Holland. There is a light-house at Orford-Nesse, which is also of great use to seamen, and is a shelter for them when a north-east wind blows hard upon the shore. The town was incorporated by Henry III. has a mayor, 18 portmen, 12 chief burgesses, a recorder, a town-clerk, and two serjeants at mace. Though it sent members to parliament, in the 26th of Edward I. yet it had no more elections till the reign of Edward IV. It still sends two members to parliament, and has the title of an *earldom*. There are still remaining the ruins of an holy house, where the seamen's wives used to pray for the safety of their husbands. By the withdrawing of the sea, it has been deprived of its chief advantage, for it now deserves not the name of a harbour. It had the honour to give title of earl to the brave admiral Russel, which, after being many years extinct, was revived in the person of Sir Robert Walpole. The population in 1811 amounted to 737. E. Long. 1. 40. N. Lat. 52. 15.

ORGAL, among dyers, denotes the lees of wine dried.

ORGAN, in general, is an instrument or machine designed for the production of some certain action or operation; in which sense the mechanic powers, machines, and even the veins, arteries, nerves, muscles, and bones of the human body, may be called *organs*.

ORGAN, in *Music*, denotes the largest and most harmonious of all wind-instruments; on which account it is called the *organ*, *ὀργανον*, the instrument, by way of excellence; chiefly used for playing a thorough bass, with all its accompaniments.

That organs are the invention of remote antiquity has been argued, and seems now to be generally allowed; but the particular time and country in which the discovery was made appears to be lost amidst the ruins of time. In ancient authors there are a variety of passages where mention is made of the organ, but it is at least possible that an instrument is meant very different from that which now goes by the same name. From St Augustin's commentary on the 4th verse of the 150th Psalm we learn, that the Greeks had another name for those instruments in which bellows were employed; that the name *organ* was appropriated to this particular instrument merely from the usage of the Latin tongue; and that it was indifferently given to all instruments used to accompany the voice in concert. We mention this, not because we doubt of the antiquity

Organ. antiquity of the organ, but merely to show that the time of its invention cannot be determined by the era of the authors where its name occurs. As the following observation, extracted from a periodical work which has long been in deserved esteem with the public, are intended to ascertain its early use, we submit them, without commentary, to the judgment of our readers. Gent. Mag. Cassiodorus has described our organ in a few words, lib. 1. Epis. 45. Praising that art, which makes *Organa extrancis vocibus insonare, et peregrinis flatibus complet, ut musica possit arte cantare.* And the emperor Julian has given an exact description of it in an epigram which may be found in the *Anthologia*, b. i. ch. 86. In his time these instruments were in such request, that Ammianus Marcellinus, b. xiv. ch. 6. complains that they occasioned the study of the sciences to be abandoned. However, those musical instruments whose melody is produced by wind, had been known at Rome long before. Witness that agreeable poem of Capa, which for its elegance has been ascribed to Virgil; where we find that the musician introduces the wind into her pipes by means of a pair of bellows, which she holds under her arms and blows. In the hydraulic organ, the water moves the air, instead of bellows. Cornelius Severus, in his *Etna*, has given an exact description of it (A). And though there were two kinds of hydraulic and pneumatic instruments, the first of which played by the inspiration and action of bellows, and the other by the action of water, it is certain, nevertheless, that both of them were pneumatic, being inspired by the wind. And Heron of Alexandria, in his Pneumatics, has treated of Hydraulics as belonging to pneumatics. This Heron lived in the time of Ptolemy Euergetes, king of Egypt. When Suetonius says, that Nero *Organa hydraulica novi et ignoti generis circumduxit*, he did not mean that they were unknown at Rome before Nero, but that those of Nero were of a new construction. Those were the hydraulics of a new fabric, which he exhibited to the people at the public games, as Seutonius relates a little after. Heliogabalus, one of the worthy successors of Nero, like him was fond of these hydraulics; and Alexander Severus, his cousin and successor, had the same inclination. Claudian, who lived some time after, has left us this elegant description of them:

Et qui magna levi detrudens murmura tactu
Innumeras voces segetis moderatur aënæ;
Intonet erranti digito, penitusque trabali
Vecte laborantes in carmina concitat undas.

This very construction which is observed in the pipes of an organ, gradually decreasing in magnitude, has been represented in an epigram of Optatianus Porphyrius, who lived in the time of Constantine. This epigram, which is quoted in Pithon's collection of ancient epigrams, is composed of verses of an unequal length, successively increasing. This corresponds with those words of the old scholiast on Juvenal, sat. 8. ver. 270. *Tunicâ Galli utuntur in sacris in modum organi utrinque decrescentibus virgulis purpureis.*

On the whole, then, the antiquity of organs, or of instruments of a very similar nature, can scarcely be disputed; but nothing very particular respecting the time, place, or manner, of the invention can possibly be determined from those incidental observations which occur in the writings of the ancients (B). It appears indeed to have been borrowed by the Latins from the Greeks, but not to have been in general use till the eighth century; and it has been affirmed, that, in France, it was not known till the time of Louis *le Debonair*, i. e. A. D. 815, when an Italian priest taught the use and construction of it, which he himself had learned at Constantinople. By some, however, it has been carried as far back as Charlemagne, and by others as far as Pepin. Bellarmine says that the organ began to be used in the service of the church about the year 660, as Platina relates out of the Pontifical: for when Pope Vitalian reformed the singing of the Roman church, he added to it organs in order to support and embellish it. Ammonius thinks, however, that this happened after the year 820, in the time of Louis the Pious. Perhaps the learned Bingham is our surest guide in determining this point. He positively asserts † that there were no such things as organs

† Origines Sacræ.

(A) Which is thus translated by Mr Jabez Hughes:

As in an organ *, first the rushing air
A mass of waters does before it bear;
And then the waters, in their turn, we find
Drive through the hollow pipes the vanquish'd wind;
Which strongly from its strait confinement sent,
Comes loudly rattling through the narrow vent:
Still as the waters press, the spirits sound,
And spread the bubbling symphony around.
So air and water meet, &c.

* Organon Hydraulicon.

It is by no means certain that Cornelius Severus was the author of this poem, though it is published under his name by Le Clerc. Seneca's authority, on which the Younger Scaliger founds his opinion, enforces no such conclusion. He only says, that "Severus was not discouraged from writing on this subject, by its having been already treated by Ovid and Virgil." Barthius, in his notes on Claudian, refers it to Manilius, and in his *Adversaria* to some Christian writer. By others it has been ascribed to Virgil, and by Scaliger, the father, to Quintilius Varus. But though it is less clear and methodical than Virgil, and though it has been much mutilated by time, it certainly was penned by a masterly and truly poetical hand.

(B) Vitruvius describes an organ in his 10th book; and St Jerome mentions one with 12 pair of bellows, which might be heard a thousand paces, or a mile; and another at Jerusalem which might be heard at the Mount of Olives.

Organ.

organs in use in the ancient church; and that though church-music was as old as the apostles, instrumental music was not so. He also says that it was the general opinion of the learned in his days, that organs were not introduced into churches till after the time of Thomas Aquinas, A. D. 1250; and for this opinion, as far as the authority of Aquinas will go, we have a positive proof; for in his sermons we find these words: "Our church does not use musical instruments, as harps and psalteries, to praise God withal, that she may not seem to Judaize (C)." From hence it has reasonably been concluded, particularly by the learned Gregory †, that they were not used in churches in his time. Mr Wharton has also observed that *Marinus Sanutus* (who flourished A. D. 1290) first introduced wind organs into churches; from this circumstance he derived the name *Torcellus*, the name for organ in the Italian language. About this same time Durandus in his *Rationale* speaks of them as generally received in the church; and he, in Mr Gregory's opinion, is the first author who takes notice of it. These authorities are strong, and the opinions founded on them by the learned render them still more convincing: it appears, however, from the testimony of Gervas the monk of Canterbury, who flourished A. D. 1200, that organs were introduced upwards of 100 years even before that time; for in his description of Lanfranc's church, as it was before the fire in 1174, he has these words, "*Crux australis supra fornicem* organa *gestare solebat*." We do not say that this invalidates the reasoning of the learned Bingham; of that our readers are to judge, and in forming their judgments they will be determined by the credit of the testimonies which are here opposed to each other. If we suppose that of Gervas the strongest, and in opposition to the other conclude from it, that organs were introduced into England long before the 13th century, it will give some countenance to an opinion which prevails pretty generally, viz. that in Italy, Germany, and England, they became frequent about the 10th century. See MUSIC, p. 493. But however we are disposed to determine this matter (which is in itself but of little consequence), it is certain that the use of the organ was very common in the latter ages of the church, and the propriety of it was undisputed. In the last century, however, during the civil wars, organs were removed from the churches in England; and so generally reprobated, that, at the Restoration, there could scarce be found either organists, organ builders, or singers (D).

† Bingham, ubi supra.

The organs in Germany (says Dr Burney) in magnitude, and the organists in abilities, seem unrivalled in any other part of Europe, particularly in the use of pedals. In Marpurg's Essays, vol. iii. there is a minute account of a variety of organs in Germany; of all which the longest pipe of the manuals is 16 feet long, and of the pedals 32. One of the largest organs in Germany, but which Marpurg has omitted in his list, is at Gorlitz in Upper Lusatia. It would be to no purpose to enlarge our article with a more minute account of the state of organic music in different parts of the world; in various parts of the article MUSIC, observations connected with this subject will be found, and to that we must refer. We may particularly notice, for the perusal of those who wish for further information on this subject, the observations which have been made on organs in the *History of* MUSIC, at p. 493. We need scarcely refer to the life of Handel, which all our readers who are fond of music of any kind, particularly sacred, have undoubtedly perused.

The church organ consists of two parts; the main body, called the *great organ;* and the positive or *little organ*, which forms a small case or buffet, commonly placed before the great organ. The size of an organ is generally expressed by the length of its largest pipe: thus they say, an organ of 8, 16, 32 feet, &c. The organ in the cathedral church at Ulm in Germany is 93 feet high and 28 broad: its largest pipe is 13 inches diameter, and it has 16 pair of bellows.

Plate CCCXCI. fig. 1.

The several parts of the church-organ are as follows: HIH is the sound-board; which is composed of two parts, the upper board or cover HHH, and the under board HI, which is much thicker than the other; each of these consists of several planks laid with their edges to each other, and joined very close together. In the under side of the lower board there are made several channels, which run in the direction LL, MM, &c. and are continued as far as there are stops in the organ, and come almost to the edge HK. These channels are covered over very close with parchment or leather all the way, except a hole that is commonly at the fore end next HK, upon which a valve or puff is placed. These channels are called *partitions*. When this valve or flap is shut, it keeps out the air, and admits it when open. On the upper side of the lower board there are likewise cut several broad square channels, lying cross the former, but not so deep as to reach them; these lie in the direction LN, PQ, &c. To fit these channels, there are the same number of wooden sliders or registers *f, f, f,* &c. running the whole

(C) The lawfulness of using organs in churches, has, however, been ably defended by an appeal to the use which the Jews made of instruments of music in divine service; and with much reason; for were the use criminal in us, as was asserted by many well-meaning men of the last century, and as it is still thought by some in this, it would unquestionably have been equally unlawful for the Jews. The Christians in Aquinas's time, however, acted wisely in avoiding the use of them, if by so doing they would have given offence to their weaker brethren. For though they are highly ornamental, and in some churches may be productive of good effects, yet the use of them is far from being essential, and may be easily dispensed with.

(D) Organs have never yet been used in the establishment of Scotland, since that became Presbyterian; but they are used in Holland, where that form of church-government also obtains. Bishop Horne, in a sermon which he preached at the opening of the new organ at Canterbury in 1784, says that he believes some Presbyterian dissenters in England have adopted it in their places of worship. See his Sermon, p. 8.

Organ. whole length; and these may be drawn out or thrust in at pleasure. The number of these is the same as that of the stops in the organ.

IKKK is the wind-chest, which is a square box fitted close to the under side of the lower board, and made air-tight, so that no air can get out but what goes through the valves along the partitions.

VV are the valves or puffs which open into the wind-chest; they are all inclosed in it, and may be placed in any part of it, as occasion shall require. One of these valves, with the spring that shuts it, and the wire that opens it, is represented by fig. 2. Fig. 2.

C, D, E, F, &c. are the keys on which the fingers are placed when the organ is played: these keys lie over the horizontal bar of wood W, in which are stuck an equal number of wire-pins z, z, on which keys are fixed; and the keys move up and down on the bar, as on a centre. There is another bar, against which the keys fall when put down, and which is here marked 3: on this also are several wires, which go through the keys, to guide them; and on this bar a list is fastened to hinder the keys from knocking against the wood.

The keys are made to communicate with the valves several ways, as we shall now describe. First, *s*, *s*, *s*, are the key-rollers, moving on the pivots *t*, *t*: these rollers lie horizontally, one above another, and are of such a length as to reach from the valve to the key: *a*, *a*, *a*, are arms or levers fixed to the key-rollers; *w*, *w*, the valve-wires fixed to the arms *a*, *a*, and to the valves V, and go through the holes *h*, *h*, in the bottom of the wind-chest: *b*, *b*, *b*, are likewise arms fixed to the key-rollers: *d*, *d*, *d*, the key-wires, fixed to the arms *b*, *b*, and to the keys C, D, E. Now, when the end of any one of the keys C, D, E, is put down, it pulls down the arm *b*, by the wire *d*, which turns about the roller *s* with the arm *a*, that pulls down the wire *w*, which opens the valve that is shut by the spring as soon as the pressure is taken off the key. In this construction there must be a worm spring fastened to the key, and to the bar W on the further side, to keep down the end 5 of the key.

Another method of opening the valves is thus: *x y*, *x y*, are slender levers, moveable on the centres 1, 1; 5 *x*, 5 *x*, are wires going from the further ends of the keys to the ends *x* of the levers; *y* V, *y* V, are other wires, reaching from the ends *y* of the levers, through the holes *h*, to the valves V. So that putting down the key C, D, &c. raises the end 5, which thrusts up the end *x* of the lever, by the wire 5 *x*; this depresses the end *y* of the lever, which pulls down the wire *y* V, and opens the valve V.

A third way of opening the valve is this: At the end of the key *b*, is a lever, 8, 9, moving in the centre 7. This makes, with the key, a compound lever. From the end 9, a wire goes to the valve. Now the putting down the end 6 of the key, raises the end 8, which depresses the end 9, of the lever 8, 9, pulls down the wire, and opens the valve. There is only one of these drawn in the scheme, and but a few of the others, to avoid confusion.

R, R, are the rollers, to move the sliders, by help of the arms *c f*, *c f*, which are fixed horizontally in these rollers: *k e*, *k e*, are also levers fixed in the rollers; *l e*, *l e*, are the handles, which lie horizontally, and pass through the holes *l l*; they are fastened to the lever *k c*, being moveable about a joint at *e*. Organ.

Now, any handle *l p*, being drawn out, pulls the end *e* towards *l*, which turns about R *k*, along with the arm *c f*; and the end *f* pulls out the slider *f g*; and when *p* is thrust in, the arm *c f* likewise thrusts in the slider *f g*.

Upon the several rows of holes which appear on the top of the upper board, there are set up an equal number of rows of pipes. The pipes of an organ are of two kinds; the one has a mouth like a flute, the other with reeds. The first, called *pipes of mutation*, consist, (1.) of a foot AABB (fig. 3.), which is a hollow cone, that receives the wind that is to sound the pipe: (2.) To this foot is fastened the body of the pipe BBDD. Between the foot and the body of the pipe is a diaphragm or partition FEF, that has a long but narrow aperture, by which the wind comes out; over this aperture is the mouth BBC, whose upper lip C, being level, cuts the wind as it comes out. Fig 3.

The pipes are of pewter, of lead mixed with a twelfth part of tin, and of wood. Those of pewter are always open at their extremities: their diameter is very small, and their sound very clear and shrill. Those of lead mixed with tin are larger; the shortest are open, the longest quite stopped; those of a mean size are partly stopped, and have beside a little ear on each side the mouth, to be drawn closer or set further asunder, in order to raise or lower the sound. The wooden pipes are square, and their extremity is stopped with a valve or tampion of leather. The sound of the wooden and leaden pipes is very soft; the large ones stopped are commonly of wood, the small ones of lead. The longest pipes give the gravest sound, and the shortest the most acute: their lengths and widths are determined by a fixed proportion to their sounds; and their divisions are regulated by a rule, which is called the *diapason*. The longest has commonly 16 feet; but in very large organs it has 32 feet. The pedal tubes are always open, though made of wood and of lead. Whatever note any open pipe sounds, when its mouth is stopped, it will sound an octave lower; and a pipe of twice its capacity will likewise sound an octave lower.

A reed-pipe consists of a foot AABB (fig. 4.), that carries the wind into the shallot or reed CD, which is a hollow demi-cylinder, fitted at its extremity D, into a sort of mould, by a wooden tampion G. The shallot is covered with a plate of copper KKLL, fitted at its extremity II, into the mould, by the same wooden tampion. Its other extremity KK is at liberty: so that the air entering the shallot makes it tremble or shake against the reed; and the longer that part of the tongue IL, which is at liberty, is made, the deeper is the sound. The mould II, that serves to fix the shallot or reed, the tongue, tampion, &c. serves also to stop the foot of the pipe, and make the wind go out wholly at the reed. Lastly, in the mould is soldered the tube HH, whose inward opening is a continuation of that of the reed: the form of this tube is different in different ranks of pipes. The degree of acuteness or gravity in the sound of a reed pipe, depends on the length of the tongue, and that of the pipe CK, taken from the extremity of the shallot to the extremity of the tube. The quantity or intention of the sound depends on the width of the reed, Fig 4.

the

Engraved by W.D. Lizars Edinburgh.

the tongue, and the tube; as also on the thickness of the tongue, the figure of the tube, and the quantity of wind. To diversify the sounds of the pipes, a valve is added to the port-vent, which makes the wind go out in fits or shakes. In fig. 1. X represents a flute-pipe of wood, Z a flute-pipe of metal, Y a trumpet-pipe of metal. The pipes, to prevent them from falling, pass through holes made in boards, placed upon the upper board.

The pipes are made to communicate with the wind-chest in the following manner. There are holes bored that go through the upper and lower boards, and through the slider (when it is drawn out), into the partition below; so that any pipes placed upon those holes will then communicate with the partition, which by its valve, communicates with the wind-chest. But when the slider is thrust in, its holes do not answer to those in the upper and lower boards; therefore, the communication is stopped, so that no wind can get to the pipe.

To every large organ there must be at least two pair of bellows, which are marked in fig. 1. by TU, TU.
Plate CCCXCI. O, O, are the handles, moving upon the axis *n n*, *n n*. Each of these bellows consists of two boards, the lowest of which is immoveable; and in this there is a valve *r*, opening inwards, and a tube leading to it, called the *conveying tube*. There is also a hole in this under board, from which a tube leads to the port-vent, which is a square tube marked 4, rising upward, and inserted into the under side of the wind-chest at 2. In the tube leading to the port-vent, there is a valve that opens towards the port-vent, and suffers the air to go up the port-vent, but not to return. Now the handle Θ being pulled down, raises the upper board T, and the air enters through the valve *r*; and when the handle is let go, the weight of the upper board, which carries three or four pounds to every square foot, continually descending, drives the air through the port-vent to the sound-board: and as the bellows work alternately, one pair is constantly descending, which occasions a continual blast through the port vent. In chamber organs there is but one pair of bellows; but they are formed of three boards, in the manner of a smith's bellows, and so have a continual blast. All the internal structure of the organ is concealed from the sight by the front of the instrument, which stands upon the part between the numbers 3 and 6 (fig. 1.).

In every organ, the number of partitions LL, MM, &c. there are in the sound-board (fig. 1.), that of the valves VV, that of the rollers *s s*, or of the levers *x y* or 8 9 and their wires, and that of the keys ABC, &c. must be always equal. Large organs have commonly four or five sets of keys, beside those that belong to the pedals or large pipes, the stops to which are played by the feet; said to be the invention of Bernard, a German, about the year 1400. These command certain pipes, which, to increase the harmony, are tuned below the diapason. The keys of an organ are usually divided into four octaves; which are, the first sub-octave, second sub-octave, middle octave, and first octave. Each octave is divided into 12 stops or frets, of which seven are black and five white: the former mark the natural notes, and the latter the artificial notes, that is, flats and sharps. The number of keys, therefore, when there are four octaves, must be 48. Some organists add one or more stops to the first and second sub-octaves. The pedals have two or three octaves, at the option of the organist; so that the number of stops is indeterminate. The keys are placed between GG (fig. 1.), but the scheme could not contain them all. There are also as many handles *l*, *l*, &c. rollers RR, &c. sliders *f*, *f*, &c. as there are stops upon the organ; and it must be observed, that between the sliders *f*, *f*, &c. there are as many sliders on the right hand, and the same number of handles and rollers, and other rows of pipes placed between LN, PQ, which could not be expressed in the figure.

The least pipes and partitions are placed toward the middle of the organ, and the greatest on the outside. The stops of an organ have various denominations, according to the sounds they are to produce; some of which are diapason, principal, fifteenth, twelfth, tearce, cornet, trumpet, French horn, vox humana, flute, bassoon, cremona, &c. The foreign organs, especially those of Germany, have many more: particularly that in the abbey church of Weingarten, a town in the Upper Palatinate, which has 66 stops, and contains no fewer than 6666 pipes. The organ at Haerlem is said to have 60 stops, many of them but little known to the English workmen, and distinguished by names that express the sound which they produce.

When this magnificent instrument is played, the handle O of the bellows is first put down, which raises the upper board T, and gives room for the air to enter by the valve *r*. Then the other handle O is put down: In the mean time the board T, belonging to the first handle, descending, and shutting the valve *r*, drives the air through the other valve, up the port-vent, and into the wind-chest. Then drawing out any handle, as that of the flute-stop *p l*, which draws out the slider *f g*, all the pipes in the set LN are ready to play, as soon as the keys C, D, E, &c. are put down: therefore if the key D be put down, it opens the corresponding valve *m* V, through which the air enters into the pipe X, and makes it sound. In the same manner any other pipe in the set LN, will sound when its key is put down: but no pipe, in any other set, will sound till the slider be drawn out by its corresponding handle.

Among the modern improvements of the organ, the most remarkable are the swell and the tremblant: the former, invented by an English artist, consists in a number of pipes placed in a remote part of the instrument, and inclosed in a kind of box, which being gradually opened by the pressure of the foot, increases the sound as the wind does the sound of a peal of bells, or suppresses it in like manner by the contrary action. The tremblant is a contrivance by means of a valve in the port-vent, or passage from the wind-chest, to check the wind, and admit it only by starts; so that the notes seem to stammer, and the whole instrument to sob, in a manner very offensive to the ear. There is a tremblant in the organ at the German chapel in the Savoy. See Hawkins's *History of Music*, and Burney.

Hydraulic ORGAN, denotes a musical machine that plays by water instead of wind. Of these there are several in Italy, in the grottoes of vineyards. Ctesebes of Alexandria, who lived in the time of Ptolemy Euergetes, is said to have invented organs that played by compressing the air with water, as is still practised. Archimedes

medes and Vitruvius have left us descriptions of the hydraulic organ.

In the cabinet of Queen Christina is a beautiful and large medallion of Valentinian, on the reverse whereof is seen one of these hydraulic organs; with two men, one on the right, the other on the left, seeming to pump the water which plays it, and to listen to its sound. It has only eight pipes, placed on a round pedestal. The inscription is PLACEA SPETRI, if it be not wrong copied, which we suspect to be the case.

ORGASM, οργασμος, denoting violence or turgescency; formed from οργαω, *turgeo*, "I swell," an ecstasy or impetuous desire of coition, occasioned by turgescency of the seminal vessels, which are no longer able to restrain their contents. The ancients also extend orgasm to the other humours, and even excrements, which being accumulated, and coming to ferment, demand excretion. Quincy uses orgasm for an impetuous or too quick motion of the blood or spirits; whereby the muscles are distended with an uncommon force.

ORGIA, feasts and sacrifices in honour of Bacchus, held every third year, and chiefly celebrated by wild distracted women, called *Bacchæ*. The chief solemnities were performed in the night, to conceal, perhaps, their shocking impurities; and a mountain was generally chosen as the place of celebration. They were instituted by Orpheus; and from him are sometimes called *Orphica*. Authors are not agreed as to the derivation of the word; but if we consider the frantic proceedings of the Bacchanalians, οργη, *furor*, bids fair for the true etymology. See BACCHANALIA.

Orgia, according to Servius, was a common name for all kinds of sacrifices among the Greeks, as *ceremoniæ* was amongst the Romans.

ORGUES, in the military art, are thick long pieces of wood, pointed at one end, and shod with iron, clear one of another; hanging each by a particular rope or cord, over the gateway of a strong place, perpendicularly, to be let fall in case of the approach of an enemy.

Orgues are preferable to herses, or portcullices, because these may be either broke by a petard, or they may be stopped in their falling down: but a petard is useless against an orgue; for if it break one or two of the pieces, they immediately fall down again and fill up the vacancy; or if they stop one or two of the pieces from falling, it is no hindrance to the rest; for being all separate, they have no dependence upon one another.

ORGUES, is also used for a machine composed of several harquebuss or musket barrels bound together, by means whereof several explosions are made at the same time. It is used to defend breaches and other places attacked.

ORGYA, οργυια, an ancient Grecian measure containing six feet.

ORIBASIA, a genus of plants belonging to the pentandria class, and in the natural method ranking under the 47th order, *Stellatæ*. See BOTANY *Index*.

ORIBASUS, a celebrated physician, greatly esteemed by the emperor Julian, in whose reign he flourished. He abridged the works of Galen, and of all the most respectable writers on physic. This was done at the request of the emperor. He accompanied Julian into the east, but his skill proved ineffectual in attempting to cure the fatal wound which his benefactor had received. After Julian's death he fell into the hands of the barbarians.

ORICHALCUM, or AURICHALCUM, a metallic substance resembling gold in colour, but very inferior in value. It was well known to the old Romans, who often took advantage of its resemblance to gold: for some sacrilegious characters, who could not resist the temptation of taking gold from temples and other public places, chose to conceal their guilt by replacing it with orichalcum. It was thus that Julius Cæsar acted when he robbed the capitol of 3000 pounds weight of gold; in which he was followed by Vitellius, who despoiled the temples of their gifts and ornaments, and replaced them with this inferior metal. It has been a matter of dispute with philosophers and others, what this metal could be, or how it was procured or made; it is probable at least that it was greatly analogous to our brass, if not wholly the same with it (See BRASS). The value of our brass is much less than that of gold, and the resemblance of brass to gold, in colour, is obvious at first sight. Both brass and gold, indeed, are susceptible of a variety of shades of yellow; and, if very pale brass be compared with gold, mixed with much copper, such as the foreign goldsmiths, especially, use in their toys, a disparity may be seen; but the nearness of the resemblance is sufficiently ascertained in general, from observing that substances gilded with brass, or as it is commonly called *Dutch leaf*, are not easily distinguished from such as are gilded with gold leaf.

The Romans were not only in possession of a metallic substance, called by them *orichalcum*, and resembling gold in colour, but they knew also the manner of making it, and the materials from which they made it were the very same from which we make brass. There are, indeed, authors of great repute who think very differently; and who consider the art of making brass as an invention wholly modern. Thus M. Cronstedt does not think it just to conclude from old coins and other antiquities, that it is evidently proved that the making of brass was known in the most ancient times *; and the authors of the French Encyclopedié assure us, that our brass is a very recent invention (A). It appears, however, from Pliny's Nat. Hist. lib. xxxiv. § 2. and from the concurring testimony of other writers, that orichalcum was not a pure or original metal; but that its basis was copper, which the Romans changed into orichalcum by means of *cadmia*, a species of earth which they threw upon the copper, and which it absorbed. It has indeed been contended, that the cadmia of Pliny was native arsenic; an opinion which scarcely merits confutation, but which must appear extremely groundless, when we reflect

* Miner. p. 218.

(A) Art. Orichalque.—"The vessels here called brazen, after ancient authors, cannot have been of the materials our present brass is composed of; the art of making it is a modern discovery." See *Laughton's History of Ancient Egypt*, p. 58.

reflect that it is impossible to make either brass or copper from arsenic, and that Pliny expressly calls it a *stone* from which brass was made. The testimony of Ambrose bishop of Milan, in the 4th century, and of Primasius bishop of Adrumetum, in Africa, in the 6th, and of Isidorus bishop of Seville in the 7th, all seem to confirm Pliny's account. We may therefore safely conclude that the Romans knew the method of making brass by mixing *cadmia* or *calamine* with copper; yet it is probable they were not the inventors of this art; but that they borrowed it from some other country. It appears from a variety of testimonies that brass was made in Asia, in a manner very similar to that at Rome; and a variety of places are mentioned in that extensive country where it was commonly made; and it is supposed by some that in India, as well as in other parts of Asia, it was made in the remotest ages.

With respect to orichalcum, it is generally supposed that there were two sorts of it, one factitious, the other natural. The factitious, whether we consider its qualities or composition, appears to have been the same with our brass. As to the natural orichalcum, there is no impossibility in supposing, that copper ore may be so intimately blended with an ore of zinc, or of some other metallic substance, that the compound, when smelted, may yield a mixed metal of a paler hue than copper, and resembling the colour of either gold or silver. In Du Halde's history of China, we meet with the following account of the Chinese white copper. "The most extraordinary copper is called *de-tong*, or white copper: it is white when dug out of the mine, and still more white within than without. It appears by a vast number of experiments made at Pekin, that its colour is owing to no mixture; on the contrary all mixtures diminish its beauty; for, when it is rightly managed, it looks exactly like silver: and were there not a necessity of mixing a little *tutenag*, or some such metal with it, to soften it and prevent its brittleness, it would be so much the more extraordinary, as this sort of copper is perhaps to be met with nowhere but in China, and that only in the province of *Yun-nan**." Notwithstanding what is here said, of the colour of this copper being owing to no mixture, it is certain that the Chinese white copper, as brought to us, is a mixed metal; so that the ore from which it is extracted must consist of various metallic substances, and from some such ore it is possible that the natural orichalcum, if ever it existed, may have been made. But, notwithstanding that the existence of natural orichalcum cannot be shown to be impossible, yet there is some reason to doubt whether it ever had a real existence or not.

* *Phil. Trans.* vol. i. p. 16.

We know of no country in which it is found at present; nor was it anywhere found in the age of Pliny; nor does he seem to have known the country where it ever had been found. He admits, indeed, its having been formerly dug out of the earth; but it is remarkable, that in the very passage where he is mentioning by name the countries most celebrated for the production of different kinds of copper, he only says in general concerning orichalcum, that it had been found in other countries, without specifying any particular country. Plato acknowledges, that orichalcum was a thing only talked of even in his time; it was nowhere then to be met with, though in the island of Atlantis it had been formerly extracted from its mine. The Greeks were in possession of a metallic substance, called *orichalcum*, before the foundation of Rome; for it is mentioned by Homer and by Hesiod; and by both of them in such a manner as shows that it was then held in great esteem. Other ancient writers have expressed themselves in similar terms of commendation; and it is principally from the circumstance of the high reputed value of orichalcum that authors are induced to suppose the ancient orichalcum to have been a natural substance, and very different from the factitious one in use at Rome, and probably in Asia, and which it has been shown was nothing different from our brass.

But this conclusion cannot be validly drawn from their encomiums upon it; for at whatever time the method of making it was first discovered, both its novelty and scarceness, joined to its utility, would enhance its value, at least there can be no absurdity in supposing, that when first introduced it was greatly prized, even though it be granted that it possessed no other properties than such as appertain to brass.

Respecting the etymology of the word there is great diversity of opinions. Those who write it *aurichalcum* think it is composed of the Latin word *aurum*, "gold," and the Greek χαλκος, "brass or copper." The most general opinion is, however, that it is composed of 'ορος, "a mountain", and χαλκος, alluding perhaps to its being found in mountains or mountainous countries. The above account is chiefly extracted from a paper in the second volume of Memoirs of the Literary and Philosophical Society of Manchester, written by the present bishop of Landaff, Dr Watson, and communicated by Dr Percival. To this paper then we refer our readers who desire a more copious account of it. To the above two etymological meanings of the word we shall subjoin the following, mentioned by the learned bishop, and which, in our opinion, is equally well founded, and certainly as ingenious, as the other two.

The Hebrew word *Or*, *Aur*, signifies light, fire, flame; the Latin terms *uro*, "to burn," and *aurum*, "gold," are derived from it, in as much as gold resembles the colour of flame: and hence it is not improbable, that orichalcum may be composed of an Hebrew and Greek term, and that it is rightly rendered, *flame-coloured copper*. In confirmation of this, it may be observed, that the Latin epithet *lucidum*, and the Greek one φαεινον, are both applied to orichalcum by the ancients. See also *Beckmann*, *Hist. of Invent.* iii. 71.

ORIFICE, the mouth or aperture of a tube, pipe, or other cavity.

ORIGANUM, Origany or *Marjoram*, a genus of plants belonging to the didynamia class, and in the natural method ranking under the 42d order, *Verticillatæ*. See Botany *Index*.

ORIENT, a town and harbour of France, in the department of Morbihan, in the bottom of the bay of St Louis. Since the year 1720, a handsome town has been built here, where the French East India Company had large magazines. It was formerly a free port. The number of inhabitants in 1800 was 19,922. The English attempted to become masters of it in 1746, but miscarried. W. Long. 3. 16. N. Lat. 47. 45.

ORIENTAL Philosophy. See Philosophy.

ORIGEN, one of the most celebrated ecclesiastical writers, greatest geniuses, and most learned men of the

Origen. the primitive church, during the third century, was born at Alexandria in the year 185: and was surnamed *Adamantus*, either from his indefatigable application to study, or from the firmness he discovered amidst the torments he suffered for the faith. Leonidas, his father, trained him at home with great care, and made him apply to the study of the Holy Scriptures from his infancy, in which he made surprising progress. The son's inclination and turn suited exactly with the father's design; for he pursued his studies with a most extraordinary zeal and ardour: and, being endued with a quick apprehension and a strong imagination, did not content himself with that sense which at first presented itself, but farther endeavoured to dive into mysterious and allegorical explications of the sacred books. He would sometimes even puzzle his father, by too much soliciting him for recondite meanings; which obliged the good man to reprehend him a little, and withal to advise him not to attempt to penetrate too far in the study of the Holy Scriptures, but to content himself with their most clear, obvious, and natural sense. Hence it appears, how early he was seized with that *furor allegoricus*, as a learned modern calls it, that rage of expounding the Scriptures allegorically, which grew afterwards to be even a distemper, and carried him to excesses which can never be excused (A). He had afterwards in philosophy Ammonius the celebrated Christian philosopher, and St Clement of Alexandria for his master in divinity. At 18 years of age he succeeded that great man in the office of catechist; an important employment, which consisted in teaching divinity, and expounding the Scriptures. Leonidas his father had suffered martyrdom the year before, during the persecution of Severus in 202; and Origen had shown such eagerness to follow his father to martyrdom, that his mother was obliged to hide his clothes to prevent his going abroad. Origen had a great concourse of auditors who attended his school, some of whom were of the faithful, and the others pagans. He confirmed and strengthened the first in their faiths, and converted most of the others; and there were such a number of martyrs amongst his disciples, that it might be said, that he kept rather a school of martyrdom than of divinity. He taught the doctrines of Christianity to the girls and women as well as to the men; and taking in a too literal sense what Christ says of becoming voluntary eunuchs, castrated himself to prevent his deserving or suffering scandal. He took a voyage to Rome in 211, in the beginning of Caracalla's reign, under the pontificate of Zepherinus. At his return he published many works, by which he acquired an extraordinary reputation, that drew to him a great number of auditors. But Demetrius, bishop of Alexandria, conceiving a jealousy of him, endeavoured by various pretences to injure him. At length Origen went to Antioch, whether the empress Mammæa had sent for him to hear him discourse on the Christian religion. He did not however stay long there, but returned to Alexandria, where he continued to teach till the year 228, when he left that city, and travelled into Achaia. In that journey he went into Palestine, and was ordained by the bishops of that province at 42 years of age. His being ordained by foreign bishops, without the permission of Demetrius, renewed that prelate's resentment against him; on which Origen hastily returned to Alexandria, to endeavour to mollify him: but Demetrius drove him from thence in 231, and caused him to be excommunicated, and even deposed in a council held in Egypt. Origen then retired to Cæsarea in Palestine, where he raised a celebrated school, and had St Gregory Thaumaturgus, and a great number of other persons who were illustrious for their virtue and learning, for his disciples. He afterwards travelled to Athens; and then, at the desire of Firmilianus, staid some time at Cæsarea in Cappadocia; whence he was invited into Arabia, to convince and bring back to the truth Beryllus bishop of Bostra; who maintained that the Word had no existence before his incarnation. Origen had the happiness to make him sensible of his mistake; and some years after was sent for into Arabia by an assembly of bishops, to dispute against the Arabians, who maintained that the souls of the dead remained in a state of insensibility till the general resurrection. At length the seven persecutions of the Christians began in the reign of Decius, and none were used with greater severity than Origen. He supported with incredible constancy the dreadful torments which the persecutors of the Christians invented against them; torments that were the more insupportable, as they were made to continue a long time, and as they took the greatest care to prevent his expiring in the midst of his tortures: but in the midst of the most excruciating torments, he discovered an heroic courage, and suffered nothing to escape him that was unworthy a disciple of Jesus Christ. He died at Tyre in 254, aged 69. He was the author of a great number of excellent works. The principal of those which have been handed down to us are, 1. A Treatise against Celsus, of which Spencer has given a good edition in Greek and Latin, with notes: this learned treatise has been translated into French by Elias Bouhereau, a protestant minister, born at Rochelle. 2. A great number of Homilies, with Commentaries on the Holy Scriptures. 3. *Philocalia*, and several other

(A) He is the first Christian (whose notions on this subject have come down to us) who believed in the restitution of all things. This is his sixth distinguishing tenet; to which is added this singular notion, that as Christ had been crucified in this world to save mankind, he is to be crucified in the next to save the devils. The other obnoxious tenets of Origen are these five: viz. 1. That in the Trinity the Father is greater than the Son, and the Son than the Holy Ghost. 2. The pre-existence of souls, which Origen considered as sent into mortal bodies for the punishment of sins committed in a former state of being. 3. That the soul of Christ was united to the word before the incarnation. 4. That the sun, moon, and stars, &c. were animated and endowed with rational souls. 5. That after the resurrection, all bodies will be of a round figure. It is probable that the mystic theology of the modern Quakers and other such sects is derived from Origen. See *Mosheim. Eccl. Hist.* vol. 1st.

Origen.

other treatises. 4. Fragments of his Hexaples, collected by Father Montfaucon, in two volumes folio. Of all Origen's books, the loss of the Hexaples is most to be regretted. This work was thus named from its containing six columns; in the first of which was the Hebrew text of the Bible; in the second, the same text in Greek characters; in the third, the Greek version of the Septuagint; in the fourth, that of Aquila; in the fifth, that of Symmachus; and in the sixth Theodosian's Greek version. This admirable work gave the first hint for our Polyglot Bibles. 5. The book of Principles; of which we have only an incorrect Latin version. In all his writings he discovers a surprising degree of modesty, candour, and humility; a noble and sublime genius, profound learning, and vast erudition. His manners were extremely pure, and he had a warm zeal for spreading the truths and morals of the Gospel.

Much has been written both for and against this celebrated father, both by his contemporaries and others: he has indeed suffered great abuse, which he did not deserve, and which we shall not retail; contenting ourselves with the following account of his character by Dupin, and some remarks on it by Dr Jortin. "Origen (says Dupin) had very quick parts, a very strong and enlarged imagination; but he relied too much on the vivacity of his genius, and often lost himself, out of too great earnestness to fathom and subtilise every thing. He had a very happy invention, and a more happy delivery of what he invented: but he had not that exactness in his inventions, nor that gracefulness of delivery as might be wished. He carried on his works with so great ease, that he is said to have dictated to seven or eight persons at a time; and he was so ready in expressing himself, that he made the greatest part of his homilies extempore: upon which account his style was not very correct or coherent. He had a vast memory, but often trusted too much to it. He was a person of most profound learning: he particularly sudied Plato's philosophy, and was indeed too much addicted to it for a Christian. He understood likewise the doctrines of other philosophers. He applied himself mightily to the study of human learning. He was neither ignorant of history nor mythology; and he had as great a knowledge in all the profane sciences, as those who studied nothing else. But he particularly excelled in the knowledge of the Holy Scriptures, which he learned all by heart; and that he might neglect nothing for attaining a right understanding of the letter thereof, he carefully examined all the versions of the Bible, and compared them all together with the Hebrew text, subjoining a literal commentary upon the most difficult places. He was not very well skilled in the Hebrew; yet he knew enough of it to understand it, and to observe the difference of the text and the translations. Nevertheless, he did not adhere to the literal explication of the Bible, but thought it necessary, for the sake of gaining it credit with the heathens, who despised its plainness and simplicity, and of rendering it more useful to the world, to give mystical and allegorical interpretations of every thing in it."

Bibl. Aut. Eccles. tom. i.

Dr Jortin tells us, "That Origen was very learned and ingenious, and indefatigably industrious. His whole life from his early years was spent in examining, teaching, and explaining the Scriptures; to which he joined the study of philosophy and of all polite literature. He was humble, modest, and patient, under great injuries and cruel treatment, which he received from Christians and Pagans: for though he ever had a considerable number of friends and admirers, on account of his amiable qualities and useful accomplishments, he was persecuted and calumniated by men, who had neither his learning nor his virtue, degraded from the order of presbyters, driven from his home, and excommunicated by one Demetrius bishop of Alexandria, who envied him, says Eusebius, for the reputation which he had gained. His inquisitive genius, and his mixing philosophy with Christianity, led him perhaps into some learned singularities and ingenious reveries; but he was by temper far from dogmatizing in such points, from fomenting schisms, and setting up himself for the head of a party. He lived in times when Christians were not so shackled with systems and determinations as they were afterwards, nor so much exposed to disingenuous and illiberal objections; and had more liberty to pursue their inquiries and to speak their mind.—He was ever extremely sober and exemplary, practising what he preached to others; and he lived and died poor, and destitute even of common conveniences."—The most complete edition of his works is that of Father Delarue, a Benedictine, in Greek and Latin. The celebrated Montfaucon likewise published, in 2 vols folio, some remains and fragments of his *Hexapla*.

Jortin's Remarks, vol. ii. p. 234, 238.

Origen || Original.

He ought not to be confounded with another ORIGEN, a Platonic philosopher, and the disciple and friend of Porphyry, who studied philosophy under Ammonius: perhaps this Origen was the founder of the ORIGENIANS.

ORIGENIANS (*Origeniani*), ancient heretics, who even surpassed the abominations of the Gnostics.

Epiphanus speaks of them as subsisting in his time; but their numbers, he says, were inconsiderable. He seems to fix their rise about the time of the great *Origen*; but does not say that they derived their name from him. On the contrary, he distinguishes them from the *Origenists*, whom he derives from *Origen Adamantius;* adding, indeed, that they first took their name from one *Origen;* by which he intimates, that it was not the great *Origen*. And St Augustine expressly asserts, that it was another. Their doctrines were shameful: they rejected marriage; they used several apocryphal books, as the acts of St Andrew, &c. and endeavoured to excuse their open crimes, by saying, that the Catholics did the same in private.

ORIGENISTS, in church-history, a Christian sect in the fourth century, so called from their drawing their opinions from the writings of Origen. The Origenists maintained, that the souls of men had a pre-existent state: that they were holy intelligences, and had sinned in heaven before the body was created: that Christ is only the Son of God by adoption; that he has been successively united with all the angelical natures, and has been a cherub, a seraph, and all the celestial virtues one after another; that, in future ages, he will be crucified for the salvation of the devils, as he has already been for that of men; and that their punishment, and that of the damned, will continue only for a certain limited time.

ORIGINAL, a first draught or design of any thing, which serves as a model to be imitated or copied.

Original Sin, the crime of eating the forbidden fruit, of which, it is said, all mankind are guilty at their conception, by the imputation of Adam's transgression; which is accounted for by supposing, that Adam, as he was to be the father, was also the federal head and representative, of the whole human race; and that, on his sinning, all that were to spring from him partook of his crimes. See Theology, &c.

ORIGUELA, a town of Valentia in Spain. It is seated between the mountains, on the banks of the river Segura, in a place fortified by nature, and in a fertile plain abounding in all things, especially corn. It contains 21,000 inhabitants, and has a university and a bishop's see. It is defended by an old castle; and is the capital of a government independent of Valentia, whose jurisdiction extends 30 miles in length and 15 in breadth. W. Long. 0. 56. N. Lat. 38. 22.

ORILLON, in *Fortification*, is a small rounding of earth, faced with a wall; raised on the shoulder of those bastions that have casemates, to cover the cannon in the retired flank, and prevent their being dismounted by the enemy. See Fortification.

ORIOLUS, or Oriole, a genus of birds belonging to the order of picæ. See Ornithology *Index*.

ORION, in fabulous history, was the son of Jupiter, Neptune, and Mercury. For as these gods were visiting the earth, they entered the house of Hyrieus, a native of Tanagra, in Bœotia, under the character of benighted travellers, on account of his being famed for hospitality to strangers. Hyrieus treated them in the best manner in his power; and even killed an ox, the only one he had, for their entertainment. At which the gods were so pleased, that they offered the old man whatever he would ask; who letting them know that he desired nothing so much as a son, they, to gratify his wish, caused the ox's hide to be brought before them, in which, having deposited their urine, they bade him keep it under ground for nine months. He then dug for the skin, and found it in a beautiful child, whom he called *Urion, ab urina*. The name was afterwards changed into Orion by the corruption of one letter, as Ovid observes: *Perdidit antiquam litera prima sonum*. Orion soon became conspicuous; and Diana took him among her attendants, and even became deeply enamoured of him. His gigantic stature, however, displeased Oenopion king of Chios, whose daughter Hero or Merope he requested in marriage. The king, not willing to deny him openly, promised to make him his son-in-law as soon as he delivered his island from wild beasts. This task, which Oenopion supposed to be impracticable, was soon performed by Orion, who eagerly demanded his reward. Oenopion, on pretence of complying, intoxicated his illustrious guest, and put out his eyes on the sea-shore, where he had laid himself down to sleep. Orion found himself blind when he awoke. He went, directed by the sound, to a neighbouring forge, where he placed one of the workmen on his back, and by his directions went to a place where the rising sun was seen with the greatest advantage. Here he turned his face towards the luminary; and, according to report, he immediately recovered his eye-sight, and hastened to punish the perfidious cruelty of Oenopion. Orion was reported to be an excellent workman in iron, and to have fabricated a subterraneous palace for Vulcan.

Aurora, whom Venus had inspired with love, carried him away into the island of Delos, that she might enjoy his company with greater security, but Diana, who was jealous of this, destroyed him with her arrows. Some say, that Orion had provoked Diana's resentment, by offering violence to Opis, one of her female attendants; or, as others say, because he had attempted the virtue of the goddess herself. According to Ovid, Orion died of the bite of a scorpion, which the earth produced to punish his vanity, in boasting that no animal on earth could conquer him. Some say that Orion was son of Neptune and Euryale, and that he had received from his father the privilege and power of walking over the sea without wetting his feet. Others assert, that he was a son of Terra, like the rest of the giants. He had married a nymph called *Sida*, before his connection with the family of Oenopion: but Sida was the cause of her own death, by boasting herself fairer than Juno. Diodorus says, that Orion was a celebrated hunter, superior to the rest of mankind, by his strength and uncommon stature. He built the port of Zancle, and fortified the coast of Sicily against the frequent inundations of the sea, by heaping a mound of earth called *Pelorum*, on which he built a temple to the gods of the sea. After death Orion was placed in heaven, where one of the constellations still bears his name. The constellation of Orion was placed near the feet of the bull. It was composed of 17 stars in the form of a man, holding a sword; for which reason the poets often speak of Orion's sword. As the constellation of Orion, which rises about the 9th day of March, and sets about the 21st of June, is generally supposed to be accompanied at its rising with great rains and storms, it has acquired the epithet of *aquosus*, given it by Virgil. Orion was buried in the island of Delos; and the monument which the people of Tanagra in Bœotia showed, as containing his remains, was nothing but a cenotaph. The daughters of Orion distinguished themselves as much as their father; and when the oracle had declared that Bœotia should not be delivered from a dreadful pestilence before two of Jupiter's children were immolated on the altars, they joyfully accepted the offer, and voluntarily sacrificed themselves for the good of their country. Their names were Menippe and Metioche. They had been carefully educated by Diana; and Venus and Minerva had made them very rich and valuable presents. The deities of hell were struck at the patriotism of these two females; and instantly two stars were observed to arise from the earth, which still smoked with their blood, and they were placed in the heavens in the form of a crown. According to Ovid, their bodies were burned by the Thebans, and from their ashes arose two persons, whom the gods soon after changed into constellations.

Orion, in *Astronomy*, one of the constellations of the southern hemisphere. The word is formed from the Greek *ουρειν*, "to make water;" the ancients supposing that it raised tempests at its rising and setting. The stars in the constellation Orion, in Ptolemy's catalogue are 37, in Tycho's 62, in the Britannic catalogue 80.

ORISTAGNI, an ancient town of the island of Sardinia, with an archbishop's see. It is pretty large and well fortified; but thinly inhabited, on account of the unhealthy air: it is seated on the western coast, in a bay of the same name, in E. Long. 8. 58. N. Lat. 39. 55.

ORIXA or ORISSA, a province of the Deccan in Hindostan, extending from the 16th to the 23d degree of north latitude, on the west side of the bay of Bengal. Its length from S. W. to N. E. is about 530 miles, its average breadth 90. The interior is wild, rugged, and uncultivated; but the coast is generally fertile and well inhabited. The Ooreas who live within the company's jurisdiction are a quiet and inoffensive people; but those who inhabit the interior are fierce and warlike. The population of the province is supposed to be four millions and a half, but is very unequally spread over the surface of the country. Three fourths of the territory are possessed by the British, the remainder by various petty native chiefs. The temple of Juggernaut is in this province.

ORIXA, a genus of plants belonging to the tetrandria class. See BOTANY *Index*.

ORKNEY ISLANDS, called *Orcades* by the ancients, certain islands on the north of Scotland (A), from which they are separated by a frith 20 miles in length and 10 in breadth.

As writing seems to have been unknown in the northern islands, during those periods which the antiquarian would call the most curious and important, the chief part of our information respecting the ancient state of the Orkneys must be derived from tradition and conjecture. Their mountainous situation, and natural jealousy of strangers, obstructed the progress both of knowledge and religion: for instead of receiving either fro their southern neighbours, we are certain that they derived their knowledge of Christianity from Norway, during the expeditions undertaken by that nation (in the end of the 10th or beginning of the 11th century) to make settlements in the Orkneys and on the coast of Caithness (B). The best (because it is in all

 probability

(A) The northern isles of Scotland have been often mentioned by ancient authors, and called by different names from those they now go by; so that it is sometimes difficult to know which of them are meant. The ancient name, however, of the islands which are the subject of this article, has never been disputed. The *Ebudæ*, it is agreed, are the modern Hebrides; and there is no doubt of the ancient Orcades being the same with the Orkneys. Of Thule, however, we are not so certain; and whether it means the Shetland i les, or Iceland, remains undetermined. Pythias, a Massilian, pretends to have visited these islands, and particularly Thule; but he does not mention the Orcades. The geographer Mela, who was contemporary with the emperor Claudius, is the next writer who describes the northern islands. Of the Orkneys he gives a remarkably just account, and says they were thirty in number, with narrow channels between them; but he is less accurate with respect to the rest. Pliny the Elder is the third who mentions the northern islands. He makes the number of the Orkneys to be forty, and of the Hebrides to be thirty. Solinus, the supposed contemporary with Agricola, is the next after Pliny. In his time, and according to his account, these islands had not a single inhabitant, and were overgrown with rushy grass. It seems on the whole to be pretty generally allowed, that Julius Agricola, who first sailed round Britain, discovered the Orcades, till then unknown, and subdued them. The Romans, never that we know, visited these islands again but once, which was probably after Honorius had defeated the Saxons in the seas of Orkney. Claudius was so far from reducing them (as is asserted by Jerome in his Chronicle), that Juvenal has these lines in Hadrian's time:

Arma quid ultra
Littora Juvernæ promovimus et modo captas
Orcades, et minima contentos nocte Britannos. SAT. II. 160.

In vain, O Rome, thou dost this conquest boast
Beyond the Orcades' short-nighted coast. DRYDEN.

Tacitus informs us, that before the completion of the first century, the Roman fleets sailed round Scotland, and landed in the Orcades to refresh.

(B) It has been asserted, that the Orkneys, as well as the isles of Shetland, were originally peopled from Norway, in the ninth, tenth, or eleventh century. Others again imagine, with as much probability, that the Picts were the original inhabitants, and call Orkney the ancient kingdom of the Picts. Certain singular houses, now overgrown with earth, are called *Picts houses;* and the Pentland frith (formerly *Pightland* or *Pictland*) is supposed to retain their name. Claudian's lines, cited by Mr Camden, prove, that the Picts, with some other German colony, particularly the Saxons, were at that time in possession of these isles; and so Ninnius expressly says. Many of the present inhabitants use the Norse language, which differs but little from the Teutonic or Pictish language, and was in general use to the last century; but except in Foula, where a few words are still known by the aged people, it is quite lost. The English tongue, with a Norwegian accent, is that of these islands; but the appearance of the people, in their manners and genius, evidently shows their northern origin. Ninnius. c. 5. puts their arrival at Orkney not less than 900 years after the coming of Brutus into Britain, which he says was in the time of Eli the Jewish high priest. The ancient surnames are of German original. Some date the first settlement of the Picts here A. M. 4867; when, emigrating from their native country, they planted a colony in Orkney, and thence crossing Pictland frith, and traversing Caithness, Ross, Murray, Mar, and Angus, settled in Fife and Lothian; thence called by our writers *Pictlandia*. Others think they did not settle here till the time of Reuther king of Scotland, when the Picts, joining with a party of the Scots, were repulsed, with the loss of their king Gethus, and many of the Picts and Scottish nobility, with great slaughter; but the invasions of the Britons, at the same time, constrained the Picts to fly to Orkney, where they chose for king Gothus their deceased sovereign's brother, probability the most authentic) account that we have of this early part of the history of the Orkneys, seems to be in Torfæus. See TORFÆUS. His history must, doubtless, have been compiled chiefly from tradition, which is far from being the surest mode of information. During the time of Gregory the Great, when by his policy the Picts were driven from other parts of Scotland, they came to the Orcades as an asylum; but it does not appear, and is far from being probable, that they received a favourable reception, for many of them migrated to Shetland, and from thence to the opposite coasts of Norway. A particular history of these islands, during those early ages, would afford little entertainment, because its authenticity is at least doubtful. These islands were at various times harassed and plundered by adventurers from Scandinavia; and the Norwegian princes frequently laid the inhabitants under tribute.

We have said that the Christian religion was transported to the Orkneys from Norway, and that this happened in the beginning of the 11th century. About which time Sigurdis possessed the entire dominion of those isles, and for many years exercised all the powers of a monarch in the north. At the same time Christianity had dawned on Scandinavia, and had become the established religion in the seat of government in Norway. Its doctrines interwove themselves with the policy of the nation; its principles, so nearly interesting to human happiness, made their farther publication an object of much moment to the adventurous princes, and gave a new law to their enterprises. While the power of these principles was acting with original force upon the minds of the people, and their zeal rendered them ambitious of any exploit, whereby they could diffuse their influence; Olaus prince of Norway equipped a squadron destined to carry the knowledge of the gospel to other shores. On this pious adventure he was accompanied not only by numbers of all ranks, whom, as usual, a love of enterprise invited; but by many persons of distinguished knowledge and abilities, men of sincere piety, who had become particularly well acquainted with the Christian doctrines, and entertained a deep sense of their infinite importance. These entered into the fleet, joyful in the prospect of spreading the truths which they revered through yet unenlightened countries; and the squadron soon appeared off the Orcades. Olaus got Sigurdis, on board of his fleet, with his son, and but a few attendants, and, as the heir of Harold, he claimed all the provinces over which Sigurdis reigned; and at the same time he ordered him to renounce and abjure the religion of his fathers, and to embrace Christianity. Delay was not permitted; Christianity was forced upon him and his subjects; and on the departure of Olaus, he carried the son of Sigurdis as an hostage for what he had engaged; which was to give honourable protection to all those holy men who might choose to reside in those parts for the purpose of instructing the people in the nature of the Christian doctrines; for many of the more intelligent and religious men who had come from Norway with Olaus, remained in the Orcades and in the north of Scotland, to fulfil their pious resolution of spreading the light of the gospel there. Olaus, with the rest of his followers, sailed on another expedition towards the frith of Moray. The death of Kindius his son, which happened soon after Olaus's return to Norway, released Sigurdis from his engagements with him; and he entered into one with Malcolm II. one of whose daughters he had in marriage, and by whom he had a son, Torphinus. Torphinus's bravery, magnificence, generosity, and hospitality, endeared him to the inhabitants; and he ruled without controul for many years, till Ronald, a grandson of Sigurdis, who had lived in Norway, and who was esteemed the rightful heir of the earldom of Orkney, made a successful descent upon it. Torphinus wished to give him battle; and in a sea-fight, with the assistance of some ships from Arninus, a man who had filled some of the first places in Norway, he totally defeated him. By courting the friendship of that court, his dominions remained quiet for the greater part of his life; the latter part of which was no less eminent for establishing salutary laws, and encouraging the arts of industry, than the former had been distinguished for military fame and success in the exploits of war. He lived to an advanced age, until after Malcolm III. had ascended the throne of Scotland. Torphinus had built a sumptuous church in Byrsa, where the first bishops of Orkney resided. In the decline of life he retired to that island, and, finishing his days with exemplary piety, was with much solemnity interred in the temple which he had raised. His country long lamented the loss of so celebrated a ruler, who had established security in it, through the influence of his laws, and had taught it to enjoy the arts and blessings of peace. He left two sons, Paul and Erland, who through the whole of their lives amicably shared both in the honours and administration of their father's extensive domain. During this period, the northern counties are said to have arrived at a very superior degree of cultivation and improvement, which became equally conspicuous in the richness of their lands, and in the mildness of their dispositions. Their sons, however, did not both inherit their father's virtues. Magnus, the son of Erland, was pious and

---

brother, till they were able to return to Lothian, and drive out the Britons. After this they flourished here, and were governed by kings of their own. There still remains a place called Cunningsga, the dwelling place of the minister of Sandwick, whose name and form bespeak it the residence of some of them. But no traces of their history remain, except the name of Belus, in ancient characters, on a stone in the church of Birsa, where still is to be seen one of the principal palaces. This government probably subsisted till the subversion of the Pictish kingdom in Scotland, A. D. 839, by Kenneth II. king of Scotland. On the whole, however, the time of the discovery and population of the Orkneys is certainly unknown. Probably it was very early; for we are told that they owe their name to the Greeks.

Orcades has memorant dictas à nomine Græco. CLAUDIAN.

and peaceable; a great promoter of religion, and anxious in patronizing the Roman missionaries, and in protecting the establishments of Christianity: but Hacon, the heir of Paul, was vehement, wild, and impatient of restraint. He saw how Magnus was revered, and envy drove him to revenge; for, by the most deliberate and deceitful villany, he got Magnus into his power, and murdered him without mercy. The latter part of his life was spent in penance, and in improving his dominions.

Magnus's singular piety, and the manner of his unfortunate death, were so well represented at the court of Rome, that he was canonized. Hacon left two sons, Paul the Silent, and Harold the Orator. Caithness came to Harold, and the Orkneys were governed by Paul.

Ronald, a descendant of St Magnus, an elegant and accomplished youth, appeared at the court of Norway, and was supported in a claim upon the Orkneys, as the heir of the canonized martyr. He sent messengers to Paul, and offered to share the government with him; but this proposal was refused, and the ambassadors were treated with great contempt. They, however, found persons of power disposed to second their master's views; who soon after their return set out, and vowed, if he succeeded, to build a magnificent church, and to dedicate it to St Magnus. All seemed satisfied with the enterprise; and, full of hope, the fleet set sail. Paul in the mean time put himself in a state of defence. By very artful manœuvres, however, Ronald obtained his purpose, and willingly shared his sovereignty with Harold, the legal heir of Paul. They lived amicably together; and on the assassination of Ronald, which was accomplished by a proud chieftain, who thought himself insulted, he was buried with great pomp. Harold now fully possessed the unrivalled sovereignty of the north, and lived long to enjoy it. We find that in 1196 he was able to bring 7000 men to the field, and a body of cavalry, against the army of William king of Scotland, but was immediately defeated. In the next year, the Caithnesians rebelled again, headed by one Roderick, and Torphinus, son to Harold. The king met and defeated them near Inverness. Roderick was slain; and William seizing on Harold in the extremity of Caithness, detained him till Torphinus surrendered himself as an hostage; but on some new treasons of the father, the king, according to the barbarity of the times, caused the eyes of the unhappy youth to be put out; and had him emasculated, of which he soon perished in prison. Harold died in the 73d year of his age; and with him ended, in its earls, the independent sovereignty of the north of Scotland. The Norwegians seem to have been in possession of these isles as late as 1266; for then Magnus IV. king of Norway, being worsted in war with the Scots, yielded them to Alexander III. king of Scotland by treaty, and Haquin king of Norway confirmed the possession of them to King Robert Bruce in the year 1312. Lastly, in 1464, Christian I. king of Norway and Denmark, when he gave his daughter in marriage to James III. king of Scotland, transferred all his right to them to his son-in-law and his successors; to make which more binding the Pope's confirmation was obtained. We are told by some, that Magnus sold them to Alexander for the sum of 4000 merks sterling, and a yearly acknowledgement of 100 merks.

They are about 30 in number; but many of them are uninhabited, the greater part being small, and producing only pasturage for cattle. The principal islands are denominated by the names of *Mainland*, *South Ronaldsha*, *Swinna*, *Flotta*, *Copinsha*, *Strupensha*, *Stronsa*, *Sanda*, *&c.* the terminations in *a*, or *ha*, being generally given in the Teutonic to such places as are surrounded by water. The currents and tides flowing between the islands are extremely rapid and dangerous. Near an island called *Swinna*, are two great whirlpools, called the *wells of Swinna*, which are counted dangerous by mariners, especially in a calm. When sailors find themselves sucked into the vortex, it is said they throw out a barrel, or some bulky substance, which smooths the water till it is sucked down and thrown up at a considerable distance, during which time the ship passes over in safety. But when there is a breeze of wind, these whirlpools may be crossed without any danger. The largest of these islands is called *Pomona*, in length 33, and in breadth 9 miles, containing 9 parish-churches, and 4 excellent harbours.

The air of these islands is moist, on account of the neighbourhood of the sea; and frost and snow do not continue long. In some places the soil is bare and mountainous, and in others sandy and barren; however, many of the islands produce large crops of barley and oats, but no wheat or other grain excepting what is inclosed in gardens. These, when duly cultivated, produce all kinds of kitchen herbs and roots, bringing even fruit-trees to maturity; but out of them, in the open country, there is scarce a tree or shrub to be seen, except juniper, wild myrtle, heath, and the cyur-hodon: yet this deficiency cannot be imputed to the poverty of the soil, or the nature of the climate: for the trunks of large oaks are frequently dug up in the marshes. This is likewise the case in the most barren parts of the Highlands of Scotland, where not a shrub is to be seen above the surface of the earth: nay, the inhabitants frequently find, deep in the earth, the roots of large trees, evidently exhibiting marks of the axe by which they were felled; so that these northern parts must have undergone some strange revolutions. The Orkneys produce great variety of herbs and berries, grass and corn, which last is exported as far as Edinburgh. In some of the islands, the natives have discovered mines of tin, lead, and silver, though none of them are wrought to any advantage; in others, we find abundance of marl, gray and red slate, quarries of freestone, and even of marble and alabaster. When the wind rages to any violence, the sea throws in plenty of timber, torn from other countries; and, not unfrequently, the people find large pieces of ambergrease. The fresh water in these islands is very pure and limpid; and though there are no large rivers in the Orkneys, the ground is well watered with lakes and pleasant rivulets, that not only serve to turn their mills, but also abound with trout of the most delicate flavour.

Besides the abundance of little horses, black cattle, sheep, swine, and rabbits, the inhabitants of the Orkneys rear all sorts of domestic animals and tame poultry. Their heaths and commons yield plenty of red deer, Orkney. deer, and all sorts of game, partridges, grouse, heath-cocks, plover, duck, teal, and widgeon: the sea-coasts teem with seals and otters; and are visited by whales, cod, ling, tusk, herrings, and all manner of fish: on the shore they find spermaceti, os sepiæ, and a great variety of shells and corallines, with a multitude of oysters, remarkably large muscles, crabs, and cockles. The rocks are covered with sea-fowl, wild geese, solan geese, barnacles, eagles, hawks, and kites. With respect to the barnacles, or, as the natives call them, the *cleck geese*, they are said to be found in shells sticking by the bills to trees, in several islands. Martin affirms he has seen them in this situation, but could not perceive them alive; and indeed the whole account of their generation and production, exhibited by the northern naturalist, is absurd and unphilosophical. The Orkney eagles are so strong, that according to the reports of the country, they have been known to carry away young children in their talons. Certain it is, they make such havock among the lambs, that he who kills an eagle is entitled by law to a hen from every house in the parish where it was killed. The king's falconer visits these islands every year, in order to fetch away the young hawks and falcons from their nests among the precipices: he enjoys a yearly salary of 20l. and may claim a hen or a dog from every house in the country, except those that are expressly exempted from this imposition.

The gentry of the Orkneys are civilized, polite, and hospitable; and live like those of Scotland, from whom they are chiefly descended. They live comfortably, are remarkably courteous to strangers, and drink a great quantity of wine, with which their cellars are generally well stored. Indeed the inhabitants of the Orkneys may be now justly deemed a Scotch colony. They speak the language, profess the religion, follow the fashions, and are subject to the laws, of that people. They are frugal, sagacious, circumspect, religious, and hospitable. The mariners are remarkably bold, active, dexterous, and hardy. Many surprising instances of longevity occur here, as well as in Shetland, of persons living to the age of 140. The Orkney women are generally handsome, and well shaped, and bring forth children at a very advanced age. In the Orkneys, some particular lands are held by a tenure called *Udal Right*, from Ulcrus, or Olaus, king of Norway, who farmed the lands, on condition of receiving one-third of the produce; and this right devolved in succession, without any charter granted by the sovereign. The inhabitants of Orkney, instead of measuring their corn, weigh it in pismores or pundlers. Their least denomination is a mark, consisting of 18 ounces, and 24 marks make a lispound, which is a Danish quantity. The poorer sort of people in the Orkneys appear veay meanly habited, with a piece of seal skin, instead of shoes; and living chiefly on salt fish, are subject to the scurvy. They are much addicted to superstitious rites; in particular, interpreting dreams and omens, and believing in the force of idle charms. The islands of Orkney, we have already observed, produce very bold, able, and hardy mariners. The common people, in general, are inured to fatigue, and remarkably adventurous, both in fishing during rough weather, and in climbing the rocks for the flesh, eggs, and down of sea-fowl. Formerly, while they were exposed to the invasions of the Norwegians, or western islanders, every village was obliged to equip a large boat well manned; and all the fencible men appeared in arms, when the alarm was given by the beacons lighted on the tops of the rocks and highest mountains. These beacons, known by the name of *ward-hills*, are still to be seen in every island. Their corn land they inclose with mud or stone walls, to preserve it from the ravages of their sheep, swine, and cattle, which wander about at random, without being attended by herdsmen: their ordinary manure, especially near the sea-coast, is sea-weed, which they carefully gather and divide into equal portions. Their sheep are marked on the ears and nose; but so wild, that when they have occasion to shear them in the month of May, they are obliged to hunt every individual, with dogs trained for that purpose. Their manner of catching sea-fowl is curious and particular. Under the rock where these fowls build they row their boat, provided with a large net, to the upper corners of which are fastened two ropes, lowered down from the top of the mountain by men placed in that station. These hoisting up the net, until it be spread opposite to the cliffs in which the fowls are sitting, the boatmen below make a noise with a rattle, by which the fowls being frightened, fly forwards into the bosom of the net, in which they are immediately enclosed and lowered down into the boat; others practise the method used in Iceland and Norway, and are lowered down by a single rope from the summit of the mountain; this is the constant way of robbing the hawk's nest. See *Bird-Catching*. In these islands some strange effects are produced by thunder and lightning. In the year 1680, the lightning entered a cow-house, in which 12 cows stood in a row, and killed every second beast as she stood, and left the rest untouched. The distempers that prevail mostly in the Orkneys are agues, consumptions, scurvy, and itch. The agues, which abound in the spring, the natives cure with a diet drink of bitters and antiscorbutics infused in ale: for phthisical complaints they use the plant arby, and the caryophyllus marinus boiled with sweet milk.

The isles of Orkney and Shetland compose one stewartry, and send one member to the imperial parliament. The right of superiority to the Orkneys was dismembered from the crown by the union parliament, and granted for a certain yearly consideration to the earl of Morton, by Queen Anne, who appointed him hereditary steward and justiciary. This nobleman possesses the power of creating certain judges, called *bailiffs*. There is one of these established in every island and parish, with power to superintend the manners of the inhabitants, to hold courts, and determine civil causes, according to the laws of Scotland, to the value of ten pounds Scots money, amounting to 16s. 8d.: but all contests of higher import are referred to the decision of the steward or his deputy, who resides at Kirkwall, which is the seat of justice. Subservient to the bailiffs are six or seven of the most reputable and intelligent inhabitants, who oversee the conduct of their fellows, acting as constables, and make report of all enormities to the bailiff; who causes the delinquent to be apprehended and punished; if the crime be within the extent of his judicial power; otherwise he transmits him to Kirkwall, where he is tried by the steward. The Protestant

testant religion prevails in the isles of Orkney, according to the rites and discipline of the kirk; these, and the isles of Shetland, constituting one presbytery, which assembles at Kirkwall. The country is divided into 18 parishes, containing 31 churches, and above 100 chapels.

The trade of the Orkneys is not very considerable, though it might be extended to great advantage. They supply with fresh provisions, for ready money, the ships and vessels that touch upon the coast in the course of northern voyages, or in their passage from the East Indies, when they go north about Ireland and Scotland, in time of war, to avoid the privateers of the enemy. They are also visited by those engaged in the herring-fishery, though there is not such a resort on this account to these islands as to the isles of Shetland. Nevertheless a good number of boats from the western parts of Scotland, as well as from Londonderry, Belfast, and other parts of Ireland, fish for herring as far north as the Leuze, and supply the Orkneys with tobacco, wine, brandy, and other spirituous liquors, cloths, and divers manufactures. These they change for fish, and oil extracted from porpoises, seals, and other sea animals. The people of Orkney export annually great numbers of black cattle, swine, and sheep; together with large quantities of corn, butter, tallow, salt, and stuffs made in the country, over and above the skins of seals, otters, lambs, and rabbits, down, feathers, writing-quills, hams, and wool; yet all these articles would, in point of profit, fall infinitely short of their herring fishery, were it prosecuted with industry, economy, and vigour.

The most valuable of their manufactures is kelp, and indeed the staple commodity was first introduced in 1722, by a Mr James Fea, of Whitehall, in Stronsay, since which period it has been gradually on the increase. From 1763 to 1778, there was manufactured, on an average, 1800 tons annually at four guineas per ton; from 1778 to 1792, the annual average produce was 3000 at 6l. per ton; from 1792 to 1794, above 4000 tons. Thus, from 1722 to 1794. a period of 72 years, the produce of the kelp was 291,976l. sterling, or more than the value of all the Orkney islands, even at the rate of 36 years purchase; the annual rent, exclusive of the kelp and fisheries, not exceeding 8000l. sterling.

As there are no merchants in the Orkneys at present who export fish on their own account, what herrings are taken they used to sell to the Dutch or Scotch dealers in and about Inverness. They generally fish for herring on the west side of the Orkneys; and are therefore more remote from markets than those who are employed in the same manner on the coast of Shetland. In the Orkney islands they see to read at midnight in June and July; and during four of the summer months they have frequent communications, both for business and curiosity, with each other, and with the continent: the rest of the year, however, they are almost inaccessible, through fogs, darkness, and storms. It is a certain fact, that a Scotch fisherman was imprisoned in May for publishing the account of the prince and princess of Orange being raised to the throne of England the preceding November; and he would probably have been hanged, had not the news been confirmed by the arrival of a ship.

We may reckon among the curiosity of the Orkneys, the *Phaseoli*, commonly known by the name of *Molucca beans*, and sometimes they are called *Orkney beans*. They are a sort of fruit found on the shore of the Orkney islands, being thrown on them by storms of westerly wind. They are of several distinct species, and are none of them the produce of those islands, nor of any places thereabout, but are probably of American origin, many of them being plainly natives of Jamaica, and other islands of the Indies.

They are found principally on those coasts which are most exposed to the waves of the great ocean, and are on these so plentiful, that they might be gathered in large quantities, if of any value; but the only use they are put to is the making of snuff-boxes out of them. Sir Robert Sibbald, and Mr Wallace, in their accounts of Scotland, have both named them *Molucca Beans*. Many strange fishes and curious shells are also frequently cast up by the ocean; of these last a vast variety are preserved for adorning the cabinets of modern naturalists. Sometimes exotic fowls are driven upon the Orkneys by tempestuous weather: fish, as large as whitings, have been thrown ashore to a considerable distance within the land. At Cantick-head, in the island Waes, and some other places, huge stones are often heaved up by the violence of the sea and wind, and cast over high rocks upon the land. A single Laplander has been seen more than once upon this coast, in his slender canoe, covered with skins, being driven hither by adverse winds and storms. The Orkneys are not altogether destitute of ancient monuments and curiosities of art. In Hoy we find an entire stone, 36 feet long, 18 in breadth, and 9 in thickness, lying between two hills, and known by the name of *dwarfie stone*. It is hollowed within by the tools of a mason, the marks of which are still apparent. The entrance is a square hole about two feet high, with a stone, by way of door, standing before it. Within we find a bed with a pillow cut out of the stone; at the other end is a couch of the same kind; and in the middle a hearth, above which there is a hole or vent for the exit of the smoke. This curiosity is found in the midst of a desolate heath, and is supposed to have been the residence of a hermit. In the very neighbourhood of this stone there is a very high and steep mountain, called the *ward-hill of Hoy*, near the summit of which, in the months of May, June, and July, something at noon-day is seen to shine and sparkle with remarkable lustre, supposed by the common people to be an enchanted carbuncle; many persons have clambered up the hill in quest of it, but found nothing. Perhaps this splendour is produced by the reflection of the sun on a small stream of water sliding over the face of a smooth rock. At Stennis, in Mainland, there is a causeway of stones over a loch or lake, at the south end of which we observe a circle of stones rising about 20 feet above the ground, each being six feet in breadth, and from one or two feet in thickness: between this circle and the causeway two stones of the same dimensions stand by themselves, and one of them is perforated in the middle. At the distance of half a mile from the other end of the causeway appears a larger circle of the same kind of stones, the diameter of which may amount to 110 paces; some of these stones are fallen; and to the east and west of the larger circle are two artificial green mounts. Both rounds are surrounded with a ditch; and one cannot view them without admiration, considering

considering the art that must have been used to bring such unwieldy masses together in this order. They were probably temples and places of sacrifice used in times of pagan superstition; and seem to bear a great affinity with the celebrated monument called *Stonehenge* on Salisbury Plain in England. In one of the mounts, at the north end of the causeway, the natives found nine *fibulæ*, or clasps of silver, formed into a circle, and resembling a horse-shoe. In many different places of the Orkneys we find rude obelisks or single stones of a great height, set up either as a memorial of battles, treaties, or the decease of remarkable personages. In Rousay, between two high mountains, there is a place which the natives distinguish by the appellation of the *camp of Jupiter Fring*: but the meaning of this name, handed down by tradition, is not yet known. At the west end of the Mainland, near Skeal, we find a surprising causeway, above a quarter of a mile in length, on the summit of high hills, composed of reddish stones of different magnitudes, impressed with various figures both on the under and upper surface. Some gentlemen in the neighbourhood have carried off the most beautiful of these stones, to be set in their chimneys by way of ornament, like the painted tiles of Holland. This country produces many sepulchres of different nations. In the plains or links of Skeal, the sand being blown away from the surface of the ground, several square catacombs appear, built of stones well cemented together, containing some parcels of black earth, and each secured by a large stone at the mouth. Sepulchres of the same kind are found at Rousum in Stronsa; which is likewise remarkable for a different kind of monument, consisting of one entire stone cylinder hollowed, with a bottom like that of a barrel, and a round stone to fill up the entrance; above, the stone was sharpened into an edge; within were found some burnt bones and red clay; and over it was placed a large flat stone for the preservation of the whole. These, in all probability, were Roman catacombs. In Westra divers Danish graves have been discovered: in one of these appeared the skeleton of a man, with a sword on one side and a Danish axe on the other. Some have been found buried with dogs, combs, knives, and other utensils. In many places of the country we find round hillocks or barrows, here known by the name of *brogh*, signifying, in the Teutonic language, burying place, supposed to have been the cemeteries of the ancient Saxons. In different parts of these islands we see the remains of great buildings, believed to have been fortresses erected by the Danes or Norwegians when they possessed the country. One of these, in the isle of Wyre, called the *castle of Coppi-row*, signifying a town of security, is surrounded by a fosse, and the first floor still remains above ground, a perfect square of stone wall, very thick, strongly built, and cemented with lime, the area within not exceeding ten feet in length. Of this Coppi-row the common people relate many idle fables. In the chapel of Clet, in the isle of Sanda, there is a grave 19 feet long, in which was found part of a man's back bone larger than that of a horse. Human bones of nearly the same size, have been dug up in Westra; and indeed this country is remarkable for producing men of a gigantic stature. Within the ancient fabric of Lady Kirk in South Ranalshaw, there is a stone four feet long and two feet broad, on which the prints of two feet are engraven, supposed to be the place where, in times of popery, penitents stood to do public penance. The cathedral of Kirkwall, the capital of the Orkneys, is a fine Gothic building, dedicated to St Magnus, but now converted into a parish church. Its roof is supported by 14 pillars on each side; and its steeple, in which is a good ring of bells, by four large pillars. The three gates of the church are chequered with red and white polished stones, embossed and elegantly flowered.

Campbell, in his Political Survey, suggests two improvements in the Orkneys: 1. The erecting an university; of which he recapitulates the probable advantages arising from their centrical situation: And, 2. Allowing the East India Company to erect a spacious magazine in one of these islands; where also a collector, and a sufficient number of king's officers, should reside, to receive the duties of such East India commodities as might be taken off by British subjects. These he proposes for the Orkneys in particular, and in addition to improvements proposed for the whole islands in general.

The following table exhibits a view of the population of the parishes of Orkney and Shetland, at two periods.

	Parishes.	Population in 1755.	Population in 1790—1798.
	ORKNEY.		
1	Cross, Burness, &c.	1250	1389
	Dearness and St Andrews	1650	1335
	Evie and Rendall	1798	1564
	Firth and Stenness	1108	1186
5	Harray and Birsay	2200	2013
	Holm	1185	702
	Hoy and Græmsay	520	410
	Kirkwall	1089	2550
	Ladykirk	750	803
10	Orphir	855	826
	Rousay and Eglishay	978	1072
	Shapinshay	642	730
	South Ronaldshay, &c.	1996	1954
	Stromness and Sandwick	2677	3012
15	Stronsay and Eday	1493	887
	Walls and Flota	1000	991
	Westray and Papa Westray	1290	1629
	Total, Orkney	23,381	23,053
	SHETLAND.		
	Bressay and Burray	1098	1225
	Delting	1221	1504
20	Dunrossness	2295	3327
	Fitlar and North Yell	1098	1346
	Lerwick	1193	1259
	Nesting	1196	1535
	Northmaving	1009	1786
25	Sandsting	911	1285
	South and Mid Yell	986	1422
	Tingwall	1412	1786
	Unst	1368	1988
29	Walls and Sandness	1450	1723
	Total, Shetland	15,210	20,186
	Orkney	23,381	23,053
	Total	38,591	43,239
			37,591
	Increase		4648

But

In 1801, according to the returns made to Parliament, the population of Orkney was 24,445, and that of Shetland was 22,379, and in 1811 the population of both was 46,153. For a fuller account of Orkney, see Barry's History of the Orkney Islands, 4to. 1805.

ORLE, ORLET, or *Orlo*, in *Architecture*, a fillet under the ovolo, or quarter round, of a capital. When it is at the top or bottom of a shaft, it is called *cincture*. Palladio uses the word orlo for the plenith of the basis of the columns.

ORLE, in *Heraldry*. See HERALDRY.

ORLEANOIS, a province of France, now forming the three departments of Loiret, Loire et Cher, Eure et Loire.

ORLEANS, the chief town of the department of Loiret, and formerly the capital of the government of Orleanois. It was anciently called *Genabum*, or *Cenabum;* and afterwards denominated *Aurelia*, *Aureliæ*, and *Aurelianum*, by the emperor Aurelian, who considerably enlarged it. In Julius Cæsar's time it was the capital of the Carnutes. It stands about 20 leagues south of Paris, on the northern bank of the Loire; across which Mr Wraxall says there is an elegant bridge of nine arches, the entrance by which is exceedingly noble and striking, the street which leads from it being composed of most elegant modern buildings. In general, however, excepting this street, it is very meanly built; the streets are narrow, and the inhabitants in general poor. It is surrounded with walls, and fortified with 40 towers. The streets almost all terminate at the quay for the convenience of trade. It is the seat of several courts of justice, and in 1800 contained 36,000 inhabitants. It is a bishop's see; and the cathedral is a most superb Gothic structure, and had the finest steeple in France till it was damaged in the time of the civil wars. There were 22 parishes in it, and a great number of churches. There are manufactures of cloths, serges, coverlets, printed calicoes, cotton thread, painted paper, refined sugar, &c. By the canal of the Loire it carries on a considerable trade in corn, wines, brandies, vinegar, timber, fire-wood, wools, &c. The canal begins about two miles above the city; is near 18 leagues in length; and terminates on the Loing, which falls into the Seine. The environs of Orleans, more especially in the province of Sologne, to the south of the Loire, are very agreeable. It is in general a level country, covered with corn and vines. To the north of the city is a forest, the largest in the whole kingdom. Before the revolution it belonged to the duke of Orleans: to whom the timber felled in it, one year with another, brought about 100,000 livres. Louis XIV. gave the dukedom of Orleans to his own brother Philip, who began and finished the canal; which, by the duties paid by vessels going up and down, brought in, one year with another, 150,000 livres. The bishop was suffragan to the archbishop of Paris, and had a revenue of 24,000 livres, out of which his tax to Rome was 2000 florins. A new bishop, it is said, on the first day of his entering, had the privilege of releasing all the prisoners in it, except those committed for treason. In the street leading from the bridge stands the celebrated monument where Charles VII. and Joan of Arc the Maid of Orleans, are represented on their knees before the body of our Saviour, who lies extended on the lap of the Virgin. It was erected by order of that monarch in 1458, to perpetuate his victories over the English, and their expulsion from his dominions. All the figures are in iron. The king appears bareheaded, and by him lies his helmet surmounted with a crown. Opposite to him is the Maid herself in the same attitude of grateful devotion to Heaven. It is a most precious and invaluable historical monument.

"In the Hotel de Ville (says Wraxall) is a portrait of the same immortal woman, which I studied long and attentively. Though it was not done till 1581, which was near 130 years after her decease, it is yet the oldest and best picture of her now existing. The painter seems undoubtedly to have drawn a flattering resemblance of her, and to have given his heroine imaginary charms. Her face, though long, is of exceeding beauty, heightened by an expression of intelligence and grandeur rarely united. Her hair falls loosely down her back, and she wears on her head a sort of bonnet enriched with pearls, and shaded with white plumes, tied under her chin with a string. About her neck is a little collar, and lower down, upon her bosom, a necklace composed of small links. Her dress, which is that of a woman, I find it difficult exactly to describe. It sits close to the body, and is cut or slashed at the arms and elbows. Round her waist is an embroidered girdle, and in her right hand she holds the sword with which she expelled the enemies of her sovereign and her country. I am not surprised at the animated and enthusiastic attachment which the French still cherish for her memory. The critical and desperate emergency in which she appeared; her sex, youth, and even the obscurity of her birth; the unparalleled success which crowned her enterprise; the cruel and detestable sentence by which she was put to death; the air of the marvellous spread over the whole narration, increased and strengthened by that veneration which time affixes to every great event—all these united causes conspired to place her above mortality. Rome and Athens would undoubtedly have ranked her among their tutelary deities, and have erected temples to her honour; nor can I help being amazed, that amidst the almost infinite number of modern saints who crowd and disgrace their churches, no altar has yet been dedicated to the Maid of Orleans." See FRANCE, N° 101.

The bridge was new built in the 18th century, and opened in 1760; and the French esteem it the finest in the world. E. Long. 1. 59. N. Lat. 47. 54.

ORLEANS, *New*, the capital of the state of Louisiana in North America. It is situated on the left side of the Mississippi river, 105 miles from its mouth. This place was founded by the French in 1720; and since it was ceded to the United States with the rest of Louisiana in 1803, its growth has been rapid beyond example. In 1817 it was estimated to contain 30,000 inhabitants, about one third only of whom speak English. It is the great depot of trade for all the countries watered by the Mississippi, Missouri, and Ohio, and must in progress of time become one of the first trading cities in the world. The exports in 1817 amounted to 9,024,812 dollars. The low situation of the town exposes it sometimes to inundation, though it is protected by an embankment; and the extensive marshes all round render it unhealthy. The streets are

are straight, wide, and run at right angles with another. The houses are generally of wood, and built low; but some of them are very handsome and splendidly furnished. The inhabitants are a mixture of all nations, but the French and Spaniards are the most numerous classes. The style of living is luxurious and expensive. About six miles below this town a battle was fought between the British and Americans, on the 8th January 1815, in which the former were defeated with great loss.

ORLEANS, *Peter Joseph*, a French Jesuit, and author of *Histoire des Revolutions d'Angleterre*, was born at Bourges in 1641. He taught belles lettres for some time in his society, but afterwards devoted himself to the writing of history. This pursuit he continued till his death, which happened in 1698. He wrote also a history of the Revolutions of Spain; a History of Two conquering Tartars, Chunchi and Cambi; the Life of Father Coton, &c. His History of the Revolutions in England, under the family of the Stuarts, from the year 1603 to 1690, was translated into English, and published at London 1711, in one vol. 8vo.: to which is prefixed an Introduction, by Laurence Echard, M. A. who says, that "the great varieties and wonderful changes in these reigns are here judiciously comprised in a moderate volume with no less perspicuity than strictness; and with a beautiful mixture of short characters, nice reflections, and noble sentences, which render the whole agreeable and instructive. But while the reader is entertained with so much skill and fineness, we ought to caution him with relation to the education and religion of the author; for though he has great marks of a generous candour, and a laudable deference to all superiors; yet he is to be considered, in all places, as one in favour with the French king, and not only a true papist, but a complete Jesuit."

ORLOPE, in the sea language, the uppermost space or deck in a great ship, reaching from the main to the mizen mast. In three deck ships, the second and lowest decks are sometimes called *orlopes*.

ORMOND, the northern division of the county of Tipperary, in the province of Munster in Ireland. For a long time it gave the title of *earl*, and afterwards of *marquis* and *duke*, to the noble family of Butler, descended from a sister of Thomas à Becket archbishop of Canterbury; till, at the accession of George I. the last duke was attainted of high treason, and died abroad. In that part of the country the family had great prerogatives and privileges granted by Edward III.

ORMSIDE, a small town of England, near Appleby, in Westmoreland. A great number of vessels of brass, some of which seemed to have been guilt, were discovered near the manor-house, by the water washing away the soil.

ORMSKIRK, in Lancashire, in England, is a handsome town, with a good inland trade, and a population of 3064 in 1811. By the late inland navigation it has an extensive communication with the rivers Mersey, Dee, Ribble, Ouse, Trent, &c. There is a bituminous earth about this place, from which oil of amber is extracted, that preserves raw flesh, and serves the poor people instead of candles. Not far from it is Latham House, which was gallantly defended in the civil wars by Charlotte countess of Derby, who held it to the last extremity against the parliament forces, till she was relieved by Prince Rupert. It was, however, ruined in a second siege; and sold by the family to Sir Thomas Bootle, who built a very magnificent house upon it.

ORMUS, a small island of Asia, at the bottom of the gulf of the same name, at the entrance of the gulf of Persia. It is about two leagues from the main land, and about six leagues in circuit. They catch excellent oysters about the island; and it yields plenty of fine white salt; also a kind of shining black sand, which is used for dusting writings, and is transported in considerable quantity to Europe. There is neither sweet water nor grass upon it, the soil being of a salt sulphureous nature. It was taken by the Portuguese in 1507, who fortified it; and it was afterwards frequented by a vast number of merchants, who were extremely rich. In 1622 the Persians, by the assistance of the English, conquered this place, and demolished the houses, which were 4000 in number, containing 40,000 inhabitants. Some time after, the Persians rebuilt the fort, and placed a garrison in it; but they could never bring it to be a place of trade as before: however, it is the key of the Persian gulf, as well on account of the importance of the place, as the commodiousness of the harbour. It is now almost deserted, for it produces nothing but salt, which sometimes is two inches deep upon the surface of the earth. E. Long. 56. 25. N. Lat. 27. 20.

ORNE, a department of France, including part of *ci devant* Normandy and Perche. The soil is low and moist, but being well adapted for pasture, great numbers of cattle and horses are raised. There are some considerable woods, and some productive mines of iron. The trade consists chiefly in grain, cyder, cattle, horses, hemp, and in serge, woollen cloths, lace, and linens, of which there are manufactures. The territorial extent of this department is 1,265,000 arpents, or 2400 square English miles. The population in 1800 was 397,931 persons. The contributions for the year 1802 amounted to 3,666,903 francs. Alençon is the chief town.

ORNITHIÆ, a name given by the ancients to certain winds, which usually blew in the spring, at the time when the birds of passage came over to them. Pliny says, that these winds blew from the west, and that by some the Etesian winds were called by this name. Others suppose that they blew from the north, or north-west.

ORNITHOGALLUM, STAR OF BETHLEHEM; a genus of plants belonging to the hexandria class; and in the natural method ranking under the 10th order, *Coronariæ*. See BOTANY *Index*.

ORNITHOLOGY.

INTRODUCTION.

1 Definition. THE term *Ornithology* is derived from the Greek ορνις, a bird, and λογος, *discourse*, and denotes that part of Zoology which treats of birds.

Birds are two-footed animals, covered with feathers, and furnished with wings. Like quadrupeds and the cetaceous tribe, they have warm blood, a heart with two ventricles, and two auricles, and lungs for the purpose of respiration; but they are distinguished from both by their feet, feathers, wings, and horny bill, as well as by the circumstance of their females being oviparous.

2 Ornithological writers. The elegant and beautiful colouring of many of the feathered race, the graceful ease of their flight, their various music, their tender solicitude for their offspring, their engaging instincts, their susceptibility of domestication, and their subservience to the sustenance of man, have, in all ages, contributed to interest the latter in the study of their history.

3 Aristotle and Pliny. Of the naturalists, however, whose writings have descended to us from antiquity, Aristotle and Pliny are the only two who appear to have entered into any details on a subject so inviting and important. Though the former composed no particular treatise on birds, he brings them under review in different parts of his History of Animals. In the third chapter of the eighth book, for example, he enumerates the different sorts of nourishment adapted to different species, and their various modes of feeding. The ninth book contains his very imperfect nomenclature, his remarks on the diversified modes of nidification, and some valuable observations on the family of eagles. His notion of the organization and habitudes of birds are interspersed in the body of the work, and introduced in the way of comparative reference to the structure and manners of other animals. Pliny's enumeration of the feathered species, is extended over most part of his tenth book, but is destitute of precise description, and encumbered with absurdity and fable.

Of the numerous ornithologists of more modern date, some have chiefly directed their labours to method and classification, others have been more solicitous to describe and delineate; some have treated of the whole class, others of particular portions of it; while, lastly, some have been contented to define and describe, and others have illustrated and enhanced their text by more or less accurate designs from living or prepared specimens. This combination of the pen and the pencil, which has so eminently contributed, in our day, to the acquisition and diffusion of knowledge, seems to have been unknown to the ancients.

Although the unavoidable limitation of our plan precludes a minute and critical report of the works to which we have just alluded, we shall briefly advert to a few of the most conspicuous. Among the first who excited, on the continent, a taste for the study of ornithology, and for a methodical distribution of that portion of science, we may mention Belon. Aware that nature is most successfully contemplated in her own works, he travelled from the laudable desire of collecting information, and communicated to the world the results of his enquiries. His History of Birds, a thin folio volume, divided into seven books, or parts, and illustrated by wooden cuts, was published at Paris, in 1555. His principle of classification being chiefly founded on the circumstances of habitation and food, and only occasionally on external forms and characters, is obviously very defective; his descriptions, though tolerably accurate, are, for the most part, too concise; and many of his plates are very inadequate representations of their originals. It must, at the same time, be allowed, that he frequently suggests judicious views of his subject; that he notes with ingenuity, the points of resemblance between the human skeleton and that of birds; that he has penned several passages which may still be perused with interest and instruction; that the *naïveté* of his manner is always pleasing, and that when we reflect on the period in which he flourished, he is entitled to no ordinary praise. 4 Belon.

5 Gesner. The celebrated Conrad Gesner, physician and professor at Zurich, and contemporary with Belon, has devoted the third volume of his History of Animals to the department of ornithology. It is an erudite, but ponderous tome, exhibiting alphabetical tables of the names of birds, in Hebrew, Chaldee, Arabic, Greek, Latin, and most of the spoken languages of Europe. His descriptions are compiled abridgements; but his references, at the close of each article, are very numerous; for if any author of his acquaintance happen to mention a bird, his name and the passage are duly commemorated. Gesner's arrangement differs in no respect from that of any common dictionary; and few of his engravings are executed with correctness. The curious reader will probably be gratified with the perusal of his account of the art of rearing birds for falconry, the diseases to which they are liable, and the remedies which the learned doctor prescribes.

6 Aldrovandus. The same topics are discussed by Aldrovandus, a physician of Bologna, who availing himself of the writings of the two preceding naturalists, added to their indigested stores, and compiled three folios, divided into 20 books, and illustrated by wooden plates. His catalogue, however, scarcely comprises any birds but such as are natives of Europe, and by no means all even of these. He too implicitly adopts the vague distinctions of Belon; and on various occasions, not only copies Aristotle with servility, but overlays his borrowed materials with a mass of dark commentary. The motley complexion of the whole production, in fact, betrays the desire of accumulation rather than the exercise of taste and judgement.

7 Johnston. Johnston, who published in 1657 a folio volume of 160 pages, did little else than greatly condense the heavy compilements of Gesner and Aldrovandus. He divides the whole class into land and water birds, and deduces his subordinate divisions from the nature of their aliments.

Introduction.

aliments. His descriptions are generally correct, but scanty; and even his figures, though traced with more character than those of his predecessors, bespeak a parsimony of engraving.

8 Willoughby.

The next writer of eminence in this department, who merits particular quotation, is Francis Willoughby, Esq. an Englishman gentleman, who laid the foundation of a more accurate arrangement. His work, which appeared in 1676, was revised and edited by his friend the celebrated Ray. It is divided into three books, of which the first is allotted to general views of the subject, and an explanation of the author's method. The first chapter treats of the form and external structure of birds, the second of their organization and internal structure. The sixth includes 24 queries, the answers to which, if founded on fact, would greatly contribute to the advancement of ornithology. Mr Willoughby formally recognizes the grand division of *terrestrial* and *aquatic*, comprising under the former those who live at a distance from water, and under the second, those which live on the margin or surface of that element. He then institutes his leading distinctions from the form of the bill and feet, and would doubtless have accomplished a more complete arrangement, had he uniformly adhered to the same principle; but in compliance with the prejudices of his time, he assumes the different kinds of food, the varieties of size, the nature of the flesh, and even moral qualities, as the grounds of subdivisions. At all events, however, he has the credit of having opened a career, which others have successfully pursued. His second and third books contain the description and history of the species, distributed according to the rules laid down in the first. To the exposition of each genus are prefixed two chapters of general observations; the first including the vague or fabulous accounts of the ancients, and the second such common properties as appertain to the genus. The author then proceeds to the specific details, stating the most important particulars with precision and neatness, and concluding with an account of peculiar habits.

9 Ray.

Ray, in his *Synopsis Avium*, follows, with a few exceptions, the method of his friend, referring at the same time to the tail feathers, and some parts of the internal conformation. The latter, we need scarcely remark, cannot with any propriety be adopted as generic or specific characters.

10 Barrere.

The new method of classing birds proposed by Monsieur Barrere in 1745, implies either a total ignorance or blameable neglect of the writings of Willoughby and Ray. As its only tendency was to confuse and perplex, we forbear noticing its details. Suffice it to remark, that it includes the peacock and man of war bird in the same family, and ranks the yellow hammer between the bustard and the ostrich. In his Essay on the Natural History of Guiana, the same author enumerates the birds in alphabetical order; but his catalogue has been more than doubled by subsequent travellers.

11 Klein.

Jacob Theodore Klein, member of several learned academies, published at Lubeck in 1750 a quarto volume, enttitled, *Historiæ Avium Prodromus, cum præfatione de ordine animalium in genere*. In this work he divides birds into families, orders, and tribes. His eight families are distinguished by the conformation of the feet, his orders by the form of the bill, and his tribes, sometimes by the form and proportions of the head, sometimes by accidental differences of the bill, and sometimes by the author's own fanciful ideas. From too great an anxiety to simplify, this naturalist is generally too brief, and adds to his obscurity by an affectation of learned phraseology.

12 Mœhring.

This last-mentioned quality likewise disfigures the scientific catalogue of Mœhring, physician to the prince of Anhalt, which appeared in 1752. His classes, orders, and genera, are founded on the formation of the feet and bill; and his descriptions of birds examined by himself, are usually accurate; but he is often misled by the errors of others, and the method which he proposes is complex and incommodious.

13 Linnæus.

In this summary of celebrated systematic ornithologists, we may assign to Linnæus the date of 1766, when he published the 12th edition of his *Systema Naturæ*. In so far as that astonishing body of arrangement respects the feathered tribes, it certainly manifests at once the extent and minuteness of the author's discriminating powers. As the same nomenclature and divisions are still the most familiar to British naturalists, we purpose to be chiefly regulated by them in the sequel, and consequently shall, for the present, wave any explanation of the Linnæan arrangement.

14 Salerne.

M. Salerne physician at Orleans, left behind him a MS. treatise on Ornithology, which was published by his friends in 1767. His method is that of Ray. The historical part is from the pen of Salerne himself; but the body of the text is a promiscuous and clumsy compilation. The typography is executed with neatness and elegance, and the plates, which are 31 in number, are engraved with uncommon skill; though the larger birds are for the most part represented on too small a scale.

15 Brisson.

M. Brisson of the Royal Academy of Sciences, published, in 1760, A System of Ornithology, in Latin and French, in six quarto volumes. He distributes birds into 26 orders, instituted from the form of the feet, bill, &c. 115 genera, which are determined by the peculiarities of the bill or mandibles, and about 1300 species. Each article is preceded by a numerous and accurate list of references and figures; many species, till then undescribed, are particularized; and the work is illustrated by upwards of 220 excellent engravings. The principal merit of Brisson's plan consists in the adoption of external and permanent characters, which enable the student to assign the name and station of a bird which he sees for the first time. The descriptions are equally accurate with those of Willoughby, and more copious. Though not exempt from errors and defects, this work still holds a respectable rank in the library of the ornithologist.

16 Buffon.

The Natural History of Birds, by the Comte de Buffon and his learned associates, is too generally known to require our analysis or criticism. Its great defect is want of scientific arrangement, a want which is scarcely redeemed even by the popular, luminous, and elegant style of the descriptions, combined with the highly finished execution of the coloured plates. With the exception, however, to which we have just alluded, we feel no hesitation in adopting the language of the English translator. "The history of birds possesses every quality that could recommend it to the public: it exhibits a clear and comprehensive view of the knowledge acquired in ornithology, scattered through a multiplicity of volumes, and

in

in various languages, it discusses and elucidates with critical accuracy, the numerous controverted points; it reduces the whole to simplicity, order, and elegance; and, by large additions of valuable matter, it greatly extends the bounds of the science."—"M. de Buffon was not to be deterred by the difficulty and extent of the undertaking. The correspondents of the king's cabinet continued to transmit numerous communications, and specimens from all parts of the world. Above eighty artists were, under the direction of the younger M. Daubenton, employed five years in the drawing, engraving, and colouring, of upwards of a thousand birds. But the commencement of the work which these were intended to illustrate was delayed two years, by reason of a severe and tedious indisposition, which during that space afflicted the excellent naturalist. And after he had recovered his health, he reflected that at his advanced period of life he could not reasonably expect to be able to accomplish the history of birds, and also that of minerals, in which he had already made some advances. He judged it expedient therefore to have recourse to the assistance of his friends; and he was peculiarly fortunate in the choice of the learned and eloquent M. Gueneau de Montbeillard, who cheerfully undertook the laborious task, and composed the greatest part of the two first volumes of the History of Birds, which appeared in 1771, under the name however of M. de Buffon. In his complexion of thought and mode of expression, M. de Montbeillard followed so closely his illustrious associate, that the public could not perceive any change. It was now proper to throw off the mask; and in the publication of the four subsequent volumes, each author prefixed his name to his own articles. The third volume was nearly printed when new assistance was received from the communications of James Bruce, Esq. of Kinnaird. That accomplished and adventurous traveller, in his return from Abyssinia, passed some days with M. de Buffon at Paris. The count was filled with admiration on seeing the numerous and elegant drawings which Mr Bruce had made of natural objects; and on several occasions he mentions the explorer of the source of the Nile in terms the most flattering and respectful. After the publication of the sixth volume in 1781, M. de Montbeillard was desirous of devoting the whole of his leisure in composing the History of Insects, which had become his favourite study. The three remaining volumes were therefore written by M. de Buffon himself; though he acknowledges that the Abbé Bexton had collected the nomenclature, formed most of the descriptions, and communicated several important hints. The work was completed in 1783; and as only a few copies of the illumined plates were on sale, and these extremely costly, a small set of engravings were made, to accommodate ordinary purchasers."

Sonnini's recent edition of Buffon's Natural History contains many valuable additions; and forms, perhaps, one of the most complete works of the kind that has yet appeared. In the department of ornithology, it presents us with descriptions and figures of every bird to which the editors could have access, either in the living or preserved state, or of which they could be favoured with drawings.

17 Mauduyt. Mauduyt's Dictionary of Ornithology, which makes part of the *Encyclopédie Méthodique*, deserves to be particularly quoted, on account of the preliminary discourses, the accuracy of the descriptions and references, and the correct execution of the plates. The whole forms an excellent collection of the most important particulars which lay within the author's reach; and we have occasionally availed ourselves of his labours in the compilement of the present article.

A series of splendid plates was executed at Florence, in illustration of Gerini's Ornithology; but they betray, in general, a disregard of nature, and are, in many instances, merely copied from imperfect drawings or inaccurate engravings. Gerini's nomenclature is likewise very faulty, and too frequently confounds species and varieties. 18 Gerini.

In 1773, the ingenious and indefatigable Mr Pennant published a small volume, entitled *Genera of Birds*. In his preface, he enters into a minute account of the external parts of birds, their feathers, flight, nidification, &c. In his selection of systematic arrangement, he gives the preference to that of Ray, whose plan appears to him to be so judicious, that it is scarcely possible to make any change in it for the better. At the same time, he admits, that latter discoveries had made a few improvements on his labours. "My candid friend, Linnæus," adds Mr Pennant, "will not take it amiss, that I in part, neglect his example; for I permit the *land-fowl* to follow one another, undivided by the *water-fowl* with pinnated feet, placing them between the *waders* or *cloven-footed* water-fowl, and the web-footed. The *ostrich*, and land-birds with wings useless for flight, I place as a distinct order. The *trumpeter* (*Psophia Linnæi*) and the *bustards*, I place at the end of the gallinaceous tribe. All are land-birds. The first *multiparous*, like the generality of the gallinaceous tribe; the last granivorous, swift runners, avoiders of wet places; and both have bills somewhat arched. It must be confessed, that both have legs naked above the knees, and the last, like the *waders*, lay but few eggs. They seem ambiguous birds, that have affinity with each order; and it is hoped, that each naturalist may be indulged the toleration of placing them as suits his own opinion." Mr Pennant's grand divisions, then, are into *land-birds* and *water-fowl*. The first he distributes into the six following orders. 1. *Rapacious*, 2. *Pies*, 3. *Gallinaceous*, 4. *Columbine*, 5. *Passerine*, and 6. *Struthious*. The second comprehends, 7. *Cloven-footed*, or *Waders*, 8. those with *Pinnated feet*, and 9. the *Web-footed*. 19 Pennant.

In 1781, Dr Latham commenced his *General Synopsis of Birds*, a work of much accurate detail, and extending to three double quarto volumes, with two of supplement. Admitting the primary division of Ray, he adheres, with a few exceptions, to the Linnæan genera, which, as well as the species, his opportunities of research enabled him to multiply to a very considerable amount. Each genus is illustrated by one coloured copperplate at least, usually of some rare species. Of these plates, however, the execution is sometimes coarse or meagre; and candour will not permit us to compliment the author on the purity or correctness of his style. His volumes, nevertheless, constitute a precious repository of descriptions and facts, and must always hold a distinguished place in the library of the ornithologist. Dr Latham is likewise the author of an *Index Ornithologicus*, which forms a convenient compend of his larger work, being comprised in two quarto volumes. 20 Latham.

About

Introduction.

21 Gérardin. About two years ago, Sebastian Gérardin de Mirecourt published an "Elementary View of Ornithology, or the Natural History of those Birds which usually occur in France," &c. This gentleman appears to have been born and bred in the department of the Vôges, in which he discharged the duties of professor of natural history, and which is known to contain a greater diversity of the feathered race than almost any province in Europe. His preliminary discourse explains the general topics of ornithology in language at once succinct and perspicuous. The five chapters of which it consists were submitted to the revision of the estimable Daudin, whose premature death his friends and science will long deplore. The arrangement of the work, which is limited to two octavo volumes, and a thin quarto volume of plates, has been chiefly regulated by that of Cuvier, in his Sketch of the Natural History of Animals; but M. Gérardin has ventured to introduce a few occasional alterations, which were suggested in the course of his teaching in the central school, and which he conceived would facilitate the progress of his pupils. His synonymy is that of Linnæus and Brisson; and his descriptions are generally minute, distinct, and accurate. On the whole, however, the reader is entitled to expect more copious information relative to the manners and habits of many of the species, than will be found in these results of thirty years application to the subject, combined with many favourable opportunities. We have also remarked a want of uniformity and precision in some of the author's statements. The engravings are chiefly valuable on account of the correctness of their outlines.

22 Hernandez. Of the numerous writers who have treated of the birds of particular countries, we may observe, that Hernandez, a Spanish physician, has described those of Mexico. His work consists of 229 chapters, each of which, generally, treats of a single species. As they are, however, designed only by their Mexican names, and described with too much brevity, their precise stations in the Linnæan arrangement are with difficulty ascertained.

23 Nieremberg. Similar objections apply to the work of Nieremberg, who has described the birds of the same country. From both we may infer, that the feathered tribes in Mexico are numerous, and diversified with the most brilliant colouring; and that the natives had made considerable progress in the study of their history.

24 Marcgrave. Brazil presents a still more rich and splendid field to the researches of the ornithologist; but Marcgrave, who professes to delineate its natural history, and allots his fifth book to the birds, is not less defective than the two writers whom we have just mentioned. His plates are not only wretchedly executed; but frequently do not correspond with the descriptions.

25 Sloane. Sir Hans Sloane, in his History of Jamaica, has represented 44 species of birds, in 18 plates, annexed to the second volume; but it is seldom that the reader can rely on the accuracy of his delineations.

29 Catesby. To Mr Catesby of the Royal Society, we are indebted for an excellent account of the birds of Carolina, Florida, and the Bahama islands, in two volumes imperial folio, in French and English. The first volume, and part of the appendix in the second, are devoted to the birds. The descriptions are concise and perspicuous, and accompanied with some interesting notices relative to the manners and habits of the species described. The plates, which are numerous, are generally faithful representations of the originals, and admirably well coloured. The method followed in these splendid volumes, approaches somewhat to that of Willoughby.

27 Schwenckfel. Schwenckfel a physician, who published in 1603 a natural history of Siberia, in two quarto volumes, includes the birds in his fourth book. His enumeration and description of the parts which belong to birds in common with other animals, and of the appropriate parts of the organization of the former, are neat and accurate. His differences, founded on habitation, food, &c. are less valuable. The introduction is followed by the enumeration of birds, in alphabetical order, according to their Latin names. The descriptions, though accurate, are, for the most part, too short; and though adequate to recall a bird already known, are not sufficient to convey a precise notion of those which are described for the first time. The historical portion is too much condensed; and with facts which are calculated to excite interest, the author often blends such as are superfluous, or improbable.

28 Brunnich. M. Brunnich published in 1764, an account of the birds of Denmark, and the neighbouring islands and provinces. In most instances he follows the Linnæan nomenclature, and sometimes the synonymy of Brisson. He chiefly dwells on the rare and non-descript species, but even then seldom enters sufficiently into detail, to enable the student to ascertain the species in question.

29 Sonnerat. M. Sonnerat, corresponding member of the Royal Academy of Sciences of Paris, published, in 1776, an account of his voyage to New Guinea, the Molucca and Philippine islands, the isle of France, and some other islands, in the Indian ocean; and in 1783, he favoured the world with a relation of his second voyage, to several parts of the East Indies and China. Though this zealous and learned naturalist was prevented by want of time, from forming very extensive collections, his descriptions and designs manifest both accuracy and taste. Besides correcting the errors of former travellers and voyagers, he has noticed a considerable number of birds for the first time, and most of them remarkable either for their singularity or beauty. His account of the wild cock and hen, the origin of our common domestic fowl, will be perused with peculiar interest.

30 Frisch. The splendid work of Frisch, a German naturalist, chiefly consists of coloured plates of the birds of Europe, arranged in 12 classes according to distinctions which are sometimes vague and incommodious. The figures are, for the most part, accurate and lively representations from nature, though in some instances, they are larger than the life. The author has bestowed particular attention on the different colourings of the two sexes of the same species.

31 Le Vaillant. M. le Vaillant, author of a voyage to the Cape of Good Hope, and of the natural history of the birds of Africa, is eminently distinguished by the ardour and acuteness with which he has prosecuted his ornithological researches, and has availed himself with laudable diligence of his rare opportunities of collecting accurate details relative to every species which he undertakes to illustrate. His natural history of the birds of paradise, rollers, promeropes, toucans, and barbets, is perhaps the most highly finished and sumptuous publication that has appeared in any of the departments of ornithology. The figures, about one hundred in number, are engraved by Pérée, from the drawings of Barraband, coloured by Langlois,

Introduction. Langlois, and retouched by the pencil of the original designer; while the elder Didot has executed the typography, in his best style, on vellum paper. Each figure is as large as life, and is usually drawn from a specimen in the highest state of preservation; and in many cases, an exact representation of the female bird has also been obtained. Though the pre-eminent merit of the work consists in the figures and descriptions, it is in a few instances agreeably diversified by traits of character, which the author remarked in the living bird, and by some interesting hints of a more general complexion, which his accurate and extensive observation enabled him to collect. We cannot, however, refrain from expressing a wish, that he had been more liberal of his synonyms and references, and that he had treated systematic writers with a little more respect. We should not forget, that methodical nomenclature, though the result of art, and liable to many errors, is entitled at least to subordinate regard, and as an unspeakable aid to the memory. Even if we should concede to our innovating author the propriety of those more fanciful arrangements to which he manifests a predilection, it would still admit of doubt, whether, on the whole, they would more accord with gradations unequivocally indicated by nature. Are we certain that, amid her countless productions, nature recognizes a single line of demarcation? or, that the study of ornithology would be essentially promoted by classing the sifilet with the jays, or every individual furnished with parade feathers among birds of paradise?

32 Desmarest. The natural history of tanagers, todies, and manakins by Anseline Gaëtan Desmarest, with coloured engravings, from drawings by Paulina de Courcelles, pupil of Barraband, is another of those recent and splendid productions of the Parisian press, which reflect so much honour on the zeal, industry, and taste of the French naturalists. The paper, type, and figures, all bespeak the excellence of the respective artists who have produced them, as well as the love of chaste and elegant embellishment which has presided over the undertaking. The ornamental style of the work, however, is not its sole passport to our favourable notice. The exposition of the three genera mentioned in the title, is a subject which calls for much critical research and laborious investigation. M. Desmarest, without presuming to extricate the whole nomenclature, lays down many important distinctions, and proceeds with circumspection, so far as his opportunities have enabled him to advance. "Before we enter," says he, "on the details of the species, it may be proper to mention, that we shall limit our descriptions to those which we have seen, and of which we have been enabled to exhibit figures. We shall, moreover, endeavour to analyse, and, if possible, to unravel the references of authors. Should success thus far attend us, we conceive that we shall have duly performed the part of zealous naturalists." Besides descriptions and plates of the male, the author has also, not unfrequently, represented the female, or young of the same species, or an individual as it appears in the moulting state. His pages will afford least entertainment to those, who delight to observe the instincts and economy of the feathered race; and who shrink from the minute adjustment of classification and synonymy. It ought, however, to be remembered that few authentic facts have been collected relative to the history of these foreign birds; and that though future travellers may increase the scanty stock of interesting notices, the exertions of the present author may not a little contribute to systematize and facilitate their observations.

The Natural History of Birds, by George Edwards, in four quarto volumes, without any reference to country or method, contains many excellent coloured designs and correct descriptions; and the same remark applies to his Gleanings of Natural History, the most considerable portion of which relates to birds. 33 Edwards.

Several of his countrymen have expounded or delineated the birds of our own island with more or less felicity of manner. The ornithological part of Pennant's British Zoology, Hayes's Natural History of British Birds, with their portraits accurately drawn, and beautifully coloured from nature; Lard's Natural History of British Birds, Lewin's Birds of Great Britain, with their eggs, in three volumes quarto, Walcott's Synopsis of British Birds, two volumes 4to, Bewick's History of British Birds, with figures engraved on wood, &c. &c. are all entitled to critical notice; but the limitation of our plan forbids us to dwell on them. We shall, therefore, close this portion of our introduction by pointing to a work which seems not yet to have procured its due share of the public favour; we mean the Ornithological Dictionary, or Alphabetical Synopsis of British Birds, by George Montagu, F. L. S. &c. in two small octavo volumes. We are acquainted with few publications of the kind that contain a larger quantity of accurate and important information within such a narrow compass. As a book of reference and consultation, it is well calculated to suit the occasions of ordinary readers, and even to convey instruction to the learned student. The synopsis and specific descriptions evince much diligence and accuracy; and various articles are enriched by the result of personal observation and extensive travel. Sufficiently aware of the fallible indications of plumage, the writer is more solicitous to reduce than to multiply distinctions; and in doubtful cases, has sometimes had recourse to the unequivocal test of dissection. A few of the articles, however, are dismissed with too much brevity, and the style is very deficient in polish and correctness. 34 British ornithologists. 35 Montagu.

If any of our readers are desirous of procuring a more complete catalogue of works published on ornithology prior to the year 1760, they will find it in Gronovius's *Bibliotheca regni animalis atque lapidei, ac recensio auctorum et librorum qui de regno animali et lapideo, methodicè, physicè*, &c. *tractant.*

The structure of the feathered tribes, and their habits of life, are wonderfully adapted to the various functions which they are destined to perform. The pointed beak, the long and pliant neck, the gently swelling shoulder, the expansive wings, the tapering tail, the light and bony feet, are all wisely calculated to assist and accelerate their motion through the yielding air. Every part of their frame is formed for lightness and buoyancy; their bodies are covered with a soft and delicate plumage, so disposed as to protect them from the intense cold of the atmosphere through which they pass; their wings are made of the lightest materials, and yet the force with which they strike the air is so great, as to impel their bodies forward with astonishing rapidity, while the tail serves the purpose of a rudder to direct them to the different objects of their pursuit. The internal structure of birds is no less wisely adapted to the 36 General observations on birds. 37 Suitable conformation.

same purposes; all the bones are light and thin, and all the muscles, except those which are appropriated to the movements of the wings, are extremely light and delicate. The lungs are placed close to the backbone and ribs. The air, entering into them by a communication from the windpipe, passes through, and is conveyed into a number of membranous cells which lie on the sides of the pericardium, and communicate with those of the sternum. In some birds, these cells are continued down the wings, and extended even to the pinions, thigh bones, and other parts of the body, which can be filled and distended with air at the pleasure of the animal. The feathers, too, and particularly those of the wings, contain a great quantity of air. The almost universal diffusion of this fluid in the bodies of birds is of infinite use to them, not only in their long and laborious flights, but likewise in preventing their respiration from being stopped or interrupted by the rapidity of their motion through a resisting medium. Were it possible for man to move with the swiftness of a swallow, the actual resistance of the air, as he is not provided with internal reservoirs similar to those of birds, would soon suffocate him.

38 Nutrition.

Birds, like quadrupeds, may be divided into granivorous and carnivorous. The former are furnished with larger intestines than those of the latter. Their food, which consists of grain of various sorts, is conveyed entire into the first stomach, or craw, where it undergoes a partial dilution by a liquor secreted from the glands, and spread over its surface. It is then received into another species of stomach, where it is farther diluted, after which it is transmitted into the gizzard, or true stomach, consisting of two very strong muscles, externally covered with a tendinous substance, and lined with a thick membrane of prodigious power and strength, in which organ the food is completely triturated, and prepared for the operation of the gastric juices. In order to ascertain the strength of these stomachs, Spallanzani had recourse to a great variety of ingenious experiments. Tin tubes, full of grain were forced into the stomachs of turkeys, and, after remaining 20 hours, were found to be broken, compressed, and distorted in the most irregular manner. In the space of 24 hours, the stomach of a cock broke off the angles of a piece of rough jagged glass, though, on examining the gizzard, no wound or laceration appeared. In a ball of lead, were fixed 12 strong needles, with the points projecting about a quarter of an inch from the surface. Thus armed, the ball was covered with a case of paper, and forced down the throat of a turkey. The bird retained it a day and a half without manifesting any symptoms of uneasiness, and the points of all the needles were broken off close to the surface of the ball, except two or three, of which the stumps projected a little. The same interesting observer relates, that he fixed 12 small and very sharp lancets, in a similar ball of lead, which was given in the same manner to a turkey cock, and left eight hours in the stomach, at the expiration of which the organ was opened; but nothing appeared except the naked ball, the lancets having been broken to pieces, and the stomach remaining sound and entire. Hence we may infer, that the stones so often found in the stomachs of many of the feathered tribes, may powerfully contribute to the comminution of grain and other hard substances which constitute their food.

Granivorous birds partake much of the nature and disposition of herbivorous quadrupeds, agreeing with them in the number of their stomachs, the comparative length and capacity of their intestines, the quality of their food, and the gentleness of their manners. Contented with the seeds of plants, with fruits, insects, and worms, their principal attention is directed to procuring food, hatching and rearing their offspring, and eluding the snares of men and the attacks of predaceous animals. As they are generally tractable and easily domesticated, man has selected for his own advantage those which are most prolific and profitable. Of these the hen, goose, turkey, and duck, are the most considerable, and form a valuable store of rich, wholesome, and nutritious food.

Carnivorous birds are provided with wings of great length, the muscles which move them being proportionally large and strong, so that they are enabled to keep long on the wing, in search of their prey. They are, besides, armed with strong hooked bills, and sharp and formidable claws. They have large heads, short necks, strong and brawny thighs, and a sight so acute and piercing, as to enable them to view their prey from the greatest heights in the air, and to dart down on it with incredible swiftness and undeviating aim. Their stomachs are smaller than those of the granivorous kinds, and their intestines are much shorter. The analogy between carnivorous birds and quadrupeds, is too obvious to escape the notice of even the superficial observer. Both of them are provided with weapons which indicate destruction and rapine, their manners are fierce and unsocial, and they seldom congregate, like the inoffensive granivorous tribes; but when not on the wing, retire to the tops of sequestered rocks, or to the depths of extensive forests, where they conceal themselves in sullen and gloomy solitude. Such of them as feed on carrion, have the sense of smelling so acute, that they can scent carcases at astonishing distances.

39 Flight and migration.

Without the means of conveying themselves with great swiftness from one place to another, birds could not easily subsist, the food which nature has provided for them being so irregularly distributed, that they are obliged to take long journeys to distant parts in order to procure the necessary supplies. Hence one cause of those migrations which are so peculiar to the feathered race. Besides the want of food, however, two other causes may be assigned, namely, the want of a proper temperature of air, and of a convenient situation for the important work of breeding and rearing their young. Such birds as migrate to great distances, are alone denominated *birds of passage*; but most species are more or less so, although they do not move to places remote from their former habitations. At particular periods of the year, most birds remove from one country to another, or from the more inland districts towards the shores, or *vice versa*. The seasons of these migrations are observed with the most astonishing order and punctuality; but the secrecy with which immense flocks take their departure, and the suddenness with which they reappear, are not easily explained. We are also apt to suppose, that, during long flights over immense tracts of water, the means of subsistence would inevitably fail, without reflecting on the superior velocity with which birds are carried forward in the air, and the ease with which they continue their exertions for a much longer

longer time than can be done by the strongest quadruped. Our swiftest horses are supposed to go at the rate of a mile in somewhat less than two minutes; and there is one instance on record of a horse that went at the rate of nearly a mile in one minute, but only for one second of time. In such cases an uncommon degree of exertion has been attended with its usual consequences, debility, and a total want of power to continue that exertion; but the motions of birds are not impeded by similar causes, and they not only glide through the air with a quickness superior to that of the swiftest quadrupeds, but can continue on the wing with equal speed for a considerable length of time. Now, if we can suppose a bird to go at the rate of only half a mile in a minute, for the space of 24 hours, it will, in that time, have gone over an extent of more than 700 miles; which is sufficient to account for almost the longest migration; and, if aided by a favourable current of air, there is reason to believe, that it will perform the same journey in a much shorter space of time.

The wings of birds are so constructed, that, in striking downwards, they expand very considerably, and, except that they are somewhat hollow on the under side, they form, in this act, almost two planes. The muscles that move the wings downwards are very large, and have been estimated, in some instances, at not less than the sixth part of the weight of the whole body. When a bird is on the ground, and intends to fly, it takes a leap, stretches its wings from the body, and strikes them downwards with great force. By this stroke, they are put into an oblique direction, partly upwards, and partly horizontally forwards. That part of the force which tends upwards is destroyed by the weight of the bird, while the horizontal impulse serves to carry it forwards. The stroke being completed, it moves its wings; and they, being contracted, and having their edges turned upwards, meet with very little resistance from the air. When they are sufficiently elevated, it makes a second stroke downwards, and the impulse of the air again moves it forward. These successive strokes act as so many leaps taken in the air. When the bird wants to turn to the right or left, it strikes strongly with the opposite wing, so as to impel the body to the proper side. If it wants to rise, it raises its tail, and if to fall, depresses it. When in a horizontal position, the tail keeps the body steady. A bird, by spreading its wings, can continue to move horizontally in the air for some time, without striking, because it has acquired a sufficient velocity; and the wings, being parallel to the horizon, meet with but small resistance. On alighting, it expands its wings and tail full against the air, that they may meet with all possible resistance. The centre of gravity in birds is somewhat behind the wings; and, to counterbalance it, most of them may be observed to thrust out their head and neck in flying. This is very apparent in the flight of ducks, geese, and several species of water-fowl, whose centre of gravity is farther backwards than in the land birds. In the heron, on the contrary, whose long head and neck, although folded up in flight, overbalance the rest of the body, the long legs are extended, in order to give the proper counterpoise, and to supply what is wanting in the shortness of the tail.

40

Lubrication of the feathers.

The feathers of birds would constantly imbibe the moisture of the atmosphere; and, during rain absorb so much wet, as would almost, if not wholly, impede their flight, had not the wise economy of nature obviated this by a most effectual expedient. They are furnished on the rump with two glands, in which a quantity of unctuous matter is constantly secreting. This is occasionally pressed out by means of the bill, and used for the lubrication of the feathers. The birds which share, as it were, the habitations of man, and live principally under cover, do not require so large a supply of this fluid, and, consequently, are not provided with such a large stock of it as those that rove abroad, and reside in the open element. Hence poultry, when wet, assume a ruffled and uncomfortable appearance.

41

Nictitating membrane.

As birds are continually passing among hedges and thickets, their eyes are protected from external injuries, as well as from too much light, when flying in opposition to the sun's rays, by a nictitating or winking membrane, which can at pleasure be drawn over the whole eye like a curtain. This covering is neither opaque, nor wholly pellucid, but somewhat transparent. By means of it the eagle is said to gaze at the sun.

42

Song.

It appears from observations, founded on numerous experiments, that the peculiar notes, or song, of the different species of birds, are altogether acquired, and are no more innate than language is in man. The attempt of a nestling to sing, may be compared with the imperfect endeavour of a child to talk. The first essay seems not to possess the slightest rudiments of the future song; but, as the bird grows older and stronger, it is not difficult to perceive its aim. While the scholar is thus endeavouring to form his song, when he is once sure of a passage, he commonly raises his tone, which he drops again when he is not equal to what he is attempting. A common sparrow, taken from the nest when very young, and placed near a linnet and goldfinch, though in a wild state it would only have chirped, adopted a song that was a mixture of these two. Three nestling linnets were educated, one under a skylark, another under a wood-lark, and a third under a tit-lark; and, instead of the song peculiar to their own species, they adhered entirely to that of their respective instructors. A linnet, taken from the nest, when but two or three days old, and brought up in the house of an apothecary at Kensington, from want of other sounds to imitate, almost articulated the words "pretty boy," as well as some other short sentences. These and other well-authenticated facts seem to prove, that birds have no innate notes, but that the language of those to whose care they are committed at birth, will be the language which they adopt in after life. It may, however, appear somewhat unaccountable why, in a wild state they adhere so steadily to the song of their own species only, when so many others are to be heard around them. This arises from the attention paid by the nestling bird to the instructions of its own parent only, generally disregarding the notes of all the rest. Persons, however, who have an accurate ear, and have studied the notes of different birds, can very often distinguish some that have a song mixed with those of another species; but these are in general so trifling as scarcely to be reckoned any thing more than mere varieties of provincial dialects.

34

Eggs.

All birds are oviparous, or produce eggs, from which, after the process of incubation, the young are extruded. These eggs differ in different species, in respect of number, figure and colour. They contain the rudiments

Introduction. rudiments of the future young, for the maturation of which a bubble of air is always placed at the large end, betwixt the shell and the inside skin. It is supposed, that, from the warmth communicated by the sitting bird to this confined air, its spring is increased beyond its natural tenor, and at the same time its parts are put into motion by the gentle rarefaction. Hence pressure and motion are communicated to the parts of the egg, and seem, in some unknown way, gradually to promote the growth of the young till the appointed time of exclusion. Housewives, when they suspect an egg is not good, put their tongue to the great end, to feel if it be warm. If that is not the case, it is considered a certain proof, that the air, having by degrees effected its escape, the egg is at length become putrid or addled.

44 Nests. The nests of birds are, in general, constructed with astonishing art, and with a degree of skill and neatness that often defies the efforts of the human hands. Both the male and female generally assist in this interesting concern. They each bring materials to the place, as sticks, moss, straws, &c. for the foundation and exterior; and hair, wool, or the down of animals or plants, to form a soft and commodious bed for their eggs, and for the tender bodies of their young when hatched. The outside of the nest usually bears so great a resemblance in colour to the surrounding foliage or branches, as not easily to be discovered even by persons who are in search of them.

45 Age. The term of life varies greatly in birds, and does not seem to bear the same proportion to the time of acquiring their growth as has been remarked with regard to quadrupeds. Most birds acquire their full dimensions in a few months, and are capable of propagation the first summer after they are hatched. In proportion to the size of their bodies, they possess more vitality, and live longer, than either man or quadrupeds. Notwithstanding the difficulties which arise in ascertaining the ages of birds, there are instances of great longevity in many of them, particularly geese, swans, ravens, and eagles, which have been known to attain the age of seventy, fourscore, or even a century. Pigeons usually live more than 20 years, and even linnets and other small birds have been kept in cages for nearly the same period.

46 Diseases. The diseases to which birds, in their natural state, are incident, are probably neither numerous nor formidable; at least we seldom meet with individuals of the feathered race which seem to labour under sickness or infirmity. In our northern latitudes they are indeed frequently subjected to the pressure of cold and hunger; but the debility and other symptoms attendant on these external accidents, hardly deserve to be noticed in a nosological point of view. Seclusion from the open air, and a total change of habits, induced by confinement and domestication, are usually accompanied by appropriate disorders, such as the pip, or swelling on the extremity of the tongue, a softening of the bill, a gradual decay of the feet, convulsions, and general pining. The moulting process, from which none of the species are exempted, may also be regarded, in some measure, as a diseased state of the animal. All birds moult, or cast their feathers once, and some twice, in the course of a year. This change takes place in autumn, or in the season which corresponds to it in different climates, and uniformly after the breeding season. Those which moult twice a year, also change their feathers in spring. Most of the young males, which bear originally the plumage of the mother, assume, at their first moulting, the colouring which they afterwards retain; but some species do not put on their characteristic garbs till the end of the second, or even of the third year. Among those which moult twice a-year, both males and females change their plumage; but the latter retain the same markings, while the former exhibit a more gaudy covering in the season which precedes their pairing, and a more sober one, often similar to that of the female, after the period of breeding. In most cases, the feathers fall off in gradual succession; but in some species nearly the whole plumage comes off at once, and is speedily replaced. This periodical affection is always attended with more or less languor and depression.

47 Anatomy. For the anatomy of birds, we beg leave to refer to the article *Comparative* ANATOMY; and shall close this introduction by a brief explanation of some of the most important technical terms in ornithology, employed by Pennant and Linnæus. 48 Technical terms.

Plate CCCXCII. fig. 1.

Fig. 1. *Cere* (*Cera*, Lin.),—the naked skin which covers the base of the bill in the hawk kind.

2. *Capistrum*,—a word used by Linnæus to express the short feathers on the forehead just above the bill. In some birds, these feathers fall forward over the nostrils: they quite cover those of the crow.

3. *Lore* (*Lorum*, Lin.),—the space between the bill and the eye, generally covered with feathers; but, in some birds, as in the black and white grebe, naked.

4. *Orbits* (*Orbita*, Lin.),—the skin that surrounds the eye, which is generally bare, particularly in the heron and parrot.

5. *Emarginated* (*Emarginatum*),—said of a bill which has a small notch near the end, as that of the butcher bird, thrush, &c.

6. *Vibrissæ pectinatæ*,—stiff hairs which grow on each side of the mouth, formed like a double comb, as in the goatsucker, flycatcher, &c.

7. *Alula spuria*, *Spurious* or *bastard wing*,—a small joint rising at the end of the middle part of the wing, or the *cubitus*, on which there are three or five feathers.

8. *Tectrices primæ*, *Lesser wing-coverts*,—the small feathers which lie in several rows on the bones of the wings. The under coverts are those that line the inside of the wings.

9. *Tectrices secundæ*, *Greater coverts*,—the feathers, which lie immediately over the quill-feathers and the secondaries.

10. *Primores*, *Quill-feathers* or *Primaries*,—the largest feathers of the wings, or those that rise from the first bone.

11. *Secundariæ*, *Secondary feathers* or *Secondaries*,—those that rise from the second bone.

12. *Tail-coverts* (*Uropygium*),—those which cover the base of the tail on the upper side.

13. *Vent-feathers* (*Crissum*),—those which lie from the vent to the tail underneath.

14. *Rectrices*, *Tail-feathers*.

15. *Scapulares*, or *Scapular feathers*,—those which take their rise from the shoulders, and cover the sides of the back.

16. *Nucha*.—the hind part of the head

17.

Introduction.

17. *Subulatum, Subulated* or *awl-shaped*,—applied to a bill that is straight and slender, in the form of an awl.

18. *Pes ambulatorius*,—all the toes divided to the bottom.

19. *Pes gressorius*,—the outer toe more or less united to the middle one, particularly conspicuous in the feet of the king's fisher.

20. *Pes scansorius*,—formed for climbing, like the foot of the woodpecker.

21. *Pes lobatus*,—finned, or lobed, like those of the grebes.

22. *Pes pinnatus*,—pinnated, or scolloped. The webs indented in the sides, as in coots and sandpipers.

23. *Pes tridactylus*, or *cursorius*,—wanting the back toe.

24. *Pes didactylus*,—composed of only two toes, as in the ostrich.

25. *Pes semi-palmatus, Semi-palmated*,—when the webs reach only half the length of the toes.

26. *Ungue postico sessili*,—when the hind claw adheres to the leg without any toe, as in the petrels.

27. *Digitis quatuor omnibus palmatis*,—all the four toes connected by webs, as in the corvorant.

Rostrum cultratum,—when the edges of the bill are very sharp, as in that of the crow.

28. *Unguiculatum*,—said of a bill furnished with a nail at the end, as those of ducks and goosanders.

29. *Lingua ciliata*,—a tongue edged with fine bristles, like that of the duck.

30. *Integra*,—plain, or even.

31. *Lumbriciformis*,—when the tongue is long, round, and slender, like a worm, as that of the woodpecker.

Pedes compedes,—when the legs are placed so far behind as to make the bird walk with difficulty, or as if in fetters, of which we have examples in the auks, grebes, and divers.

32. *Nares lineares*,—when the nostrils are very narrow, as in sea gulls.

33. *Emarginatæ*,—with a rim round the nostrils, as in the stare.

Iris, is that part which surrounds the pupil of the eye.

Mandibles, denote the upper and under parts of the bill.

Compressed,—vertically flattened at the sides.

Depressed,—horizontally flattened.

Caruncula,—a fleshy excrescence on the head.

Hypochondria,—the hinder sides of the breast and abdomen.

Ocellated,—with roundish concentric spots, of different colours.

Phalanges,—the articulations of the toes.

SYSTEMATIC EXPOSITION OF THE CLASS.

49 Orders.

ACCORDING to the Linnæan method, the class of *Aves*, or *Birds*, is distributed into six *Orders*, denominated *Accipitres, Picæ, Anseres, Grallæ, Gallinæ*, and *Passeres*.

50 Accipitres.

Order I. ACCIPITRES.

This natural order includes birds of prey, that have the bill somewhat hooked downwards, the upper mandible dilated near the point, or armed with a tooth, the nostrils wide, the feet short and strong, with four toes, three of which are placed forwards, and one behind; toes warty under the joints; claws hooked and sharp-pointed. They live on other animals alive or dead, and are themselves not eatable. They are monogamous, or live in pairs. The females are larger and more beautiful than the males, and generally lay about four eggs. This order includes *vultur, falco, strix*, and *lanius*.

51 Vulture.

Gen. 1. Vultur, *Vulture*.

52 Characters.

Bill straight, hooked at the point; head bare of feathers.

Birds of this genus are distinguished from eagles and hawks, by being gregarious, by the comparative heaviness of their flight, and by their living on carrion. The females, too, are hardly larger than the males. Unless pressed by hunger, they seldom attack living animals; they fly slowly, unless when very high in the air, and have an exquisite sense of smell. The tongue is large and fleshy; the legs and feet are strong, and mostly covered with scales; and the wings are lined, on the inside, with down.

53 Gryphus.

Condor, condur, or *cuntur*.—Very large, with a caruncle on the crown of the head, the whole of its length; the throat naked. Quills of the wings two feet and a half long, and an inch and a half thick; body black, back white; neck ruffed with long white feathers; throat red; head brown, and woolly; eyes black, irides chesnut; bill black, but tipt with white; feet black; claws straightish; tail small.—The female differs from the male, in having a tuft on the neck, in its brown colour, and in having no ruff. Brisson, however, has properly remarked, that the plumage of this species varies in colour, a circumstance which will, in some measure, account for the discordant descriptions of different authors. At the same time, we must regret, that the history of this enormous bird is so imperfectly known. Its extent of wing is variously stated, from nine to eighteen feet; and, while Fresier ascribes to it sufficient strength to carry off sheep, and boys of ten years old, Marco Paolo sturdily affirms, that it can lift an elephant from the ground high enough to kill it by the fall. Though very rare, Buffon suspects that it is not confined to South America, and that it does not essentially differ from the *roc* of the eastern nations, so famous in the Arabian tales; nor from the *laemmer geyer* of the German Alps. A preserved specimen in the Leverian Museum measured ten feet, from the tip of one wing to that of the other. It is described and figured in the second supplement to Latham's Synopsis. In Chili, the condors make their nests among the most inaccessible rocks, and lay two white eggs bigger than those of a turkey. They feed on dead carcases, and sometimes prey on sheep, goats, or even young calves, when they stray far from their dams, falling on them in flocks, plucking out their eyes, and tearing them in pieces. The country people

Accipitres. use every means to destroy such formidable invaders of their property, and seem to have succeeded in expelling them from the populous districts of both continents.

54 *Papa.* *King vulture*, or *king of the vultures*.—Caruncles on the nostrils; crown of the head and neck bare of feathers. The extreme length of the body does not exceed two feet three inches, and it is not thicker than the hen turkey. Its wings are short in proportion to the other vultures. The bill is thick and short, and begins its curvature only at the point; in some individuals it is entirely red, in others only red at the extremity, and black in the middle. In the cere, which is broad and orange-coloured, are placed the nostrils; and between them the skin projects like a loose jagged comb, falling indifferently on either side, according as the bird moves its head. Under the naked part of the neck is a collar, or ruff, composed of pretty long soft feathers of a deep ash colour, and so broad, that when the bird contracts itself, it can conceal the neck and part of the head like a cowl, whence some naturalists have given it the name of *monk*. The feathers on the breast, belly, thighs, legs, and under the surface of the tail, are white, slightly tinged with yellow; those of the rump and upper surface of the tail, are black in some individuals, and white in others. The other feathers of the tail are always black, and so are the great feathers of the wings, which are commonly edged with grey. The king of the vultures is a native of South America and the West Indies, and lives on carrion, rats, lizards, snakes, and excrements of all kinds, from which circumstance it has a most offensive odour.

55 *Aura.* *Carrion vulture*, or *turkey buzzard* (*carrion crow* of Jamaica).—Body gray brown; quill feathers black; bill white; the sides of the head warted; legs flesh-coloured. —Common in the W. Indies, and in N. and S. America. Somewhat larger than the black eagle. Is protected in America for its use in devouring dead carcases and serpents, which it does, along with dogs, in the greatest harmony. It will seize meat from the shambles, breathes a most fetid odour, and, when taken, vomits up an intolerably stinking matter. Roosts by night, in flocks, on the highest branches of trees. They are generally very tame in their wild state, probably owing to their being more caressed than molested by man.

56 *Leucocephalus.* *White, ash-coloured*, or *Angola vulture*.—Body snowy; quill and tail feathers black; collar white; head and lower part of the neck covered with white down; middle toe covered with 11 distinct scales; claws black. About the size of a female turkey. The female exceeds the male in size, and differs chiefly in being less tinged with reddish. The young have the whole of the naked parts about the head covered with a grayish down.—This species is usually seen in pairs, and not in large flocks, like many of the genus; or, if 10 or 12 alight on one carcase, they are accidentally allured by the smell, which acts on their delicate organs at inconceivable distances. They feed on all manner of carrion, and on lizards, snakes, frogs, and even excrements. They build among the rocks, and lay four eggs. In some parts of Africa they are very common, and in others more rare. The natives tame and respect them, as they contribute to rid their grounds of nuisances. They likewise occur in Norway and Sardinia. Mr Latham supposes that this species is the *vautour de Norvège* of Buffon; the *sacre d'Egypte* of the same author, perhaps the *Angola vulture* of Pennant, and the *rachamah* of Bruce. "When, however (adds this celebrated ornithologist), the division of the *vulture* genus into real species may take place, is not for us to determine; the variety among individuals, from different periods of life, as well as the different appearances of those in a state of confinement, to what the plumage has, when at large, cannot fail to create no small difficulty; added to that, very few travellers are naturalists in a sufficient degree to discriminate one part of nature from another; besides, the subjects in question being mostly extra European, we cannot wonder at being so long in the dark."

57 *Percnopterus.* Plate CCCXCIII. fig. 1. *Aquiline* or *Alpine vulture*.—The male of this species is almost wholly white; quill feathers black, with hoary edges, except the two outermost, which are wholly black. The female is all over brown, with the four outer quills black. In both the bill is black; cere yellow; nostrils constantly dripping moisture; feet naked. Inhabits Egypt, Palestine, Syria, and Persia. They fly in large troops, and are extremely useful in destroying mice, with which some countries, of which they are natives, are infested, such as Palestine. The same species, it is said, inhabits the Swiss Alps, where they are of an immense size. Some have been measured exceeding twelve feet from tip to tip of the wings.

58 Falco.

Gen. 2. Falco, *Falcon*.

Bill hooked, and furnished with a cere at the base; head covered with close-set feathers; tongue bifid.

59 Character. Though the birds of this genus are all carnivorous, they seldom feed on carrion, except when pressed by hunger, which they can endure for a long time. They have a very acute sight, and pounce down on their prey with astonishing swiftness and force. From their great strength, they are capable of carrying birds nearly as heavy as themselves, to a great distance, for provision to their young. Their middle toe is slightly connected with the outermost.

A. *Bill hooked only at the point, bearded at the base with extended bristles.*

60 *Serpentarius.* *Snake-eater*, or *secretary vulture*.—Body black; hind-head crested; tail feathers white at the tips, the two middle ones longest; legs very long. Bill black, cere white; orbits orange, and naked; irides pale cinereous; tail rounded; legs brownish; claws short, black, hooked, not very sharp; crest capable of being erected or depressed.—In seizing its prey, this bird makes use of its wings, with which it inflicts violent blows by means of a bony protuberance at the bend of the wing. It is also by its wings that it defends itself against the bites of venomous snakes, until the latter, tired with their efforts, or nearly bruised to death, are easily dispatched. This species likewise preys on turtles, lizards, and even grasshopers and other insects. When in a domesticated state scarcely any kind of food comes amiss to it; and, if young birds are presented to it, it will take them by the bill foremost, and swallow them whole. One of those which Le Vaillant killed, had 21 young turtles, 11 small lizards, and three snakes, in his stomach. Like other birds of prey, it is observed to bring up the undigested parts of its food, in the form of round pellets. In pairing time, two males will often be found engaged in a violent contest for a female. The secretary vulture is

Accipitres. is three feet high, remarkable for the length of its legs, and inhabits interior Africa and the Philippine islands. These birds make a flat nest, like that of the eagle, full three feet in diameter, lined with wool and feathers, in some high tuft of trees, and usually concealed from observation.

61 Harpeyia. *Crested* or *Oroonoko eagle*.—Head crested with long feathers; body beneath variegated; eyes with a nictitant membrane. Under the crop, white feathers, which, when the bird is irritated, fall to the ground. Erects the crest in the form of a coronet; is said to be able to cleave a man's skull at a stroke. Inhabits Mexico, Brazil, and other parts of South America, and is as large as a sheep.

62 Albicilla. *Cinereous* or *white-tailed eagle: erne* of the Scots.—Cere and feet yellow; tail feathers white, the middle ones tipt with black; head and neck pale cinereous; irides and bill pale yellow; nostrils, and the space between the eyes, bluish, with a few bristles; body and wings cinereous, mixed with brown; tail white; legs, below the knees, downy, glossy yellow; claws black. —Size of a turkey, feeds on birds and fish. Inhabits Europe, and frequently occurs in Scotland and the Orkney islands.

B. *Feet generally feathered, of a large size.*

63 Melanaetos. Plate CCCXCIII fig. 2. *Black eagle*.—Cere yellow; feet yellow, and somewhat downy; body rusty black, with yellow streaks; bill horn colour, verging on blue; irides chesnut; exterior part of the tail white, with blackish spots, tipt whitish; legs dirty white; toes yellow, claws black. Two feet ten inches long. Inhabits Europe and America.

64 Ossifragus. *Osprey* or *sea eagle*.—Cere and legs yellow; feet half covered with down; body of a rusty colour; inner vanes of the tail feathers white.—It is distinguished by the colour and figure of its nails, which are of a shining black, and form an entire semicircle; by its legs, which are naked below, and covered with small yellow scales; and by the beard of feathers which hangs from the chin, and which has occasioned its receiving the name of the *bearded eagle*. It measures from the end of the bill to the point of the nails, three feet and a half, and its wings expand to betwixt six and seven feet. It loves to haunt the sea shore, and often frequents inland tracts, near lakes, marshes, or rivers that are stocked with fish; but, though it preys on the finny tribe, it also attacks game, and, being large and strong, seizes and carries off geese and hares, and sometimes even lambs and kids. It catches fish even during the night, when the noise of its plunging into the water is heard at a great distance. In attempting to lay hold of overgrown fish, it is sometimes dragged under water, being unable to disengage its talons. It inhabits Europe and North America, and was found by Captain Cook, in Botany island. It is not uncommon in Scotland and Ireland. "From the astonishing height (says Mr Montagu), these and some other birds fly, we are led to believe they are capable of living in a much lighter air than other animals. From the top of some of the highest mountains in Scotland we have seen several soaring together at so great a distance as to appear scarcely larger than a swallow."[1] The female sea eagle seldom lays more than two eggs, and sometimes produces only a single young one.

65 Chrysaetos. *Golden eagle*.—Cere yellow; feet downy, and rusty-coloured; body dark brown, irregularly barred; tail black, and covered with ash-coloured bars. It greatly resembles the preceding, but is distinguished from it chiefly by its legs, which are yellow, short, strong, and covered with feathers to the feet. The general length of this species is about three feet and a half; the breadth eight feet; and it usually weighs about twelve pounds. It breeds in the most inaccessible rocks, and lays three or four white eggs. It inhabits Europe and Siberia, and is said to be not unfrequent in the mountainous parts of Scotland, Ireland and Wales, though it has been frequently confounded with the sea eagle. It feeds on lambs, kids, and all kinds of game, and has been known to carry off infants to its nest. It is remarkable for its longevity and abstinence from food; some having been kept in menageries for upwards of a century; and Pennant records an instance of one which lived twenty-one days without any sustenance whatever. It flies high, during serene weather, and descends nearer the earth in storms.

Ring-tailed, white-tailed, black, or *common eagle*.—Cere yellow; feet downy, and of a rusty brown colour; back brown; tail with a white transverse band. In the bill, cere, irides, and legs, it resembles the preceding, to which it is also nearly equal in size; but the plumage is rather darker, and the tail is white for two-thirds of its length. It inhabits Europe, Asia, and America; and is trained by the Tartars to hunt hares, antelopes, and foxes. In Scotland, it is very destructive to deer, which it will seize between the horns; and, by incessantly beating it with its wings, soon makes a prey of the harassed animal. It likewise makes great havock among the white hares and ptarmigans. It builds in high precipices and cliffs; and the nest of a pair has been observed in the same spot, in the Orkney islands, beyond the memory of man. Willoughby describes a nest of this species found in the Peak of Derbyshire, as composed of large sticks, lined with two layers of rushes, between which was one of heath. It contained one young, and an addle egg, and by them a lamb, a hare, and three heath pouts.—There is a variety, with a white tail, tipt with brown. 66 Fulvus.

White eagle.—Entirely white. Inhabits the Alps; of the size of the golden eagle. 67 Albus.

Fierce eagle.—Cere green; body brown above; back, belly, and tail coverts snowy, variegated with chesnut spots; tail feathers equal, brown, with four paler bands; bill leaden black; eyelids blue; irides yellow; head and neck ferruginous, mixed with whitish; quill feathers twenty-six, black above, white beneath, tipt with gray; tail feathers twelve, white beneath; claws sharp; upwards of two feet long; very rapacious; inhabits Russia; was found frequent near Astracan in the winter of 1769; will not touch dead animals. 68 Ferox.

Kite.—Cere yellow; tail forked; body brown; head whitish or grey; back and wing coverts dusky, edged with ferruginous, the under parts more or less ferruginous, streaked with dusky, and lightest in the breast; quill feathers dusky black, with bars more or less obscure; tail bright ferruginous; legs yellow; claws black. But there are several varieties. The female is somewhat larger than the male, measuring in length two feet four inches, and five feet six inches of outstretched wing. It is readily distinguished from its congeners by the remarkable forking of its tail, and by its smooth and even flight, which resembles a sailing or gliding through the air, 69 Milvus.

Accipitres. air, without any apparent motion of its wings. It frequently, however, soars very high, and, though beyond the reach of human vision, will distinctly perceive its prey, and dart down on it with irresistible force. Its attacks are confined to such animals as are found on the ground, such as young rabbits, hares, game of all kinds, poultry, and young birds incapable of flying. It will also destroy young lambs, and feed greedily on carrion; but in default of these, will readily devour mice, rats, worms, and even snakes.—The kite occurs as far north as Greenland, and as far south as Guinea and Senegal. It is common in England, where it continues the whole year; but from the more northerly latitudes, it retires to Egypt before winter, and is said to breed there, and returns in April to Europe, where it breeds a second time, contrary to the nature of rapacious birds in general. The nest is composed of sticks, and lined with wool, the inner bark of a tree, hair, and other soft materials, and is usually made in the fork of some large tree. The eggs are generally three, rarely four, somewhat larger than those of a hen, of a dirty white, with a few rusty spots at the larger end.

70 *Haliætos.* *Bald buzzard, osprey, fishing hawk*, &c.—Cere and feet blue; body brownish above, white below; head whitish; a brown bar descends from each eye by the sides of the neck to the wings; legs naked, short, strong; claws remarkably long, hooked, and black. Inhabits Europe, Siberia, and America, frequenting marshy places, and the neighbourhood of large rivers and lakes, pouncing on fish with great rapidity and dexterity, and carrying them off in its talons to a small distance to feed on them. It builds its nest on the ground among reeds, and lays three or four eggs of an elliptical form, rather less than those of a hen. Mr Montagu found the nest of this bird on the top of a chimney of a ruin in one of the islands of Loch Lomond. The usual length of the bald buzzard is two feet, and its extent of wing five. The species is now rarely met with in England, but may be frequently seen near the lake of Killarney in Ireland. There are several varieties, among which may be included those of Carolina and Cayenne. Some of the ancient writers, and even Linnæus, have very erroneously alleged, that the left foot of the bald buzzard is subpalmated.

C. *Legs naked, of a smaller size.*

71 *Buteo.* *Buzzard*, or *Puttock*.—Cere and feet yellow; body brown; belly pale, with brown spots. Scarcely any two individuals of this well-known species are precisely alike. The ordinary length of the body is twenty inches, and the extent of wing four feet and a half. The buzzard is one of our most common species of falcon. It is remarkable for its sluggish, inactive disposition, seldom remaining long on wing, except in the breeding season, when it ascends spirally to a great height. It makes its nest in the fork of a tree, of large sticks, and lines it with wool, hair and other substances, and sometimes takes possession of a deserted crow's nest, which it accommodates to its purposes. The eggs are two or three, rather larger than a hen's, of a dirty white, and, for the most part, with rust-coloured spots at the larger end. It feeds and tends its young with great assiduity; and Ray affirms, that, if the female be killed, the male takes charge of them, and patiently rears them till they are able to provide for themselves. This bird will continue for many hours perched on a tree or eminence, whence it darts on such birds, small quadrupeds, reptiles, or insects, as come within its reach.

Honey buzzard.—Cere black; feet half naked, and yellow; head ash-coloured; tail with cinereous bands, and tipt with white; of nearly the same size as the preceding, and, like it, subject to considerable varieties in its markings. Its nest in respect of form and materials, is similar to that of the buzzard, and it sometimes occupies that of other birds. Its eggs are of an ash-colour, with small brown spots. Mr White of Selborne found only one egg in the nest, smaller, and not so round as that of the buzzard. The name seems to have been given it from its feeding on the larvæ of wasps; but it is also fond of various other insects and of field mice, frogs, and lizards. It occurs in all the northern parts of Europe, and in the open tracts of Russia and Siberia, but is far from common in England. Buffon observes, that it is frequently caught in the winter, when it is fat and delicious eating. 72 *Apivorus.*

Moor buzzard, duck hawk, or *white-headed harpy*.—Cere green; body brownish; crown of the head, throat, axillæ, and feet, yellow. The colouring, however, is subject to considerable variety. Length twenty-one inches; weight twenty ounces. Preys on rabbits, young wild ducks, and other water fowl; and likewise feeds on fish, frogs, reptiles, and even insects; making its haunts in hedges and bushes near pools, marshes, and rivers. The nest is most frequently made on the ground, among short wood, furze, or fern, and sometimes though rarely, in the fork of a tree. It is composed of sticks and rushes, or coarse grass. The moor buzzard is not a bird of rapid flight, but pounces its prey on the ground, and is generally seen skimming over the surface; but, in the breeding season, the male will sometimes soar to a considerable height, and remain suspended on wing for a great length of time. Inhabits Europe. 73 *Æruginosus.*

Goshawk.—Cere black; feet yellow; body brown; tail feathers barred with pale bands, a white line over the eye; bill blue, black at the tip; irides yellow; head brown; body beneath white, waved with black; tail long, cinereous, and white at the tip; claws black. The wing, when closed, does not reach near the end of the tail; of an elegant slender shape, twenty-two inches long. Inhabits Europe, Tartary, and America; is rarely found in England, but is not uncommon in the more woody districts of Scotland, where it breeds, and is a great destroyer of game. It feeds on small birds and mice, and eagerly devours raw flesh. It tears birds to pieces before it eats them, but swallows the pieces entire, and frequently disgorges the hair and feathers, rolled up in small pellets. This species was formerly much prized in the sports of falconry, being used not only for partridge and pheasant, but also larger fowl, as geese and cranes, and sometimes for rabbits. 74 *Palumbarius.*

Gentil falcon.—Cere and feet yellow; body ash-coloured, with brown spots; tail with four blackish bands; somewhat larger than the preceding, though some ornithologists reckon it only a variety. It inhabits the Alps of Europe and North America. "In the days of falconry," observes the author of Elements of Natural History, "this species was in high esteem as a bold and spirited bird. It inhabits the north of Scotland. The king's falconer was anciently obliged to supply the court with hawks; and to this day the office is kept up in 75 *Gentilis.*

in Scotland; a nest of young birds being annually presented by the falconer to the barons of exchequer, who generally give them away in presents."

76 *Peregrinus.* *Peregrine falcon.*—Cere and feet yellow; body ash-coloured above with brownish bands, reddish white beneath, with blackish bands; tail spotted with white. Weighs between two and three pounds, is a bold and powerful bird, and inhabits Europe, and the north of Asia and America. It is not uncommon on most of our rocky coasts, usually frequenting such high cliffs as the guillemot and razorbill resort to for breeding. One that eloped from its master in the county of Forfar, on the 24th September 1772, with four heavy bells on its feet, was killed on the morning of the 26th of the same month, at Mostyn in Flintshire.

77 *Versicolor.* *Spotted falcon.*—Cere yellow; head and body above, white, with pale reddish spots, white beneath; breast a little spotted with ferruginous. Size of the buzzard. Inhabits England; but its history is little known.

78 *Griseus.* *Gray falcon.*—Cere and legs yellow; body dusky gray above, white with oblong black spots beneath; tail feathers long, the two middle ones uniform, the rest spotted. Bill blueish; irides red; head dusky brown before, white behind; sides and chin buff; quill-feathers spotted with white. Inhabits England; but is very rare, and by some esteemed only a variety.

79 *Candicans.* *Jer-falcon, gyr-falcon, Iceland falcon, white jer falcon*, &c.—Cere and feet of a greenish ash-colour; body white, spotted with brown. Bill blueish-ash, black at the tip; claws lead colour. Larger than the goshawk, and subject to variety, from age, sex, and climate, some in the northern latitudes being found quite white, others brown above, white beneath, spotted with brown, and the tail gray, with transverse brown lines. Inhabits Iceland and the north of Scotland, is a very bold bird, and in the days of falconry, was used for the larger species of game, as cranes and herons.

80 *Cachinnans.* *Laughing falcon.*—Cere and legs yellow; eyebrows white; body varied with brown and whitish; crown white, with a black ring. Back, wings, and rump brown; neck, chin, breast, belly, and under parts of the wings white; tail with yellow and black bands. Inhabits South America, and is said to *laugh*, when looked at.

81 *Lanarius.* *Lanner.*—Cere dull yellow; bill and feet blue; body marked with black longitudinal spots underneath. A white stripe over each eye; breast yellowish white, with brown spots; legs short; primary quill-feathers and tail dusky, with rusty oval spots: but there are two or three varieties. Rather less than the buzzard, has its name from tearing its prey into small pieces with its bill. The lanner is very bold, and was formerly used in falconry. It is found in many parts of Europe; inhabits Iceland and the Ferroe isles, Denmark, Sweden, and the Tartarian deserts. It is rare in England, but is said to breed in Ireland, and among the low trees and shrubs in the deserts about Astracan.

82 *Cyaneus.* *Hen-harrier.*—Cere white; legs tawny; body hoary blue; edges of the eye-lids yellow, with an arched line surrounding the throat; bill black; irides yellow; hind part of the head white, with pale brown spots; breast and belly white, the former streaked with dusky; two middle tail-feathers gray on both sides, the rest gray above, white beneath, and all streaked with dusky. These characters, however, are far from constant. This species, in its most perfect state, weighs about thirteen ounces, and is eighteen inches and a half in length. It feeds on birds, lizards, and other reptiles, and is particularly destructive to poultry. It flies low, skimming along the surface in quest of prey. The female nestles on the ground, and lays four eggs of a reddish colour, with a few white spots. Inhabits Europe and Africa. Wallis, in his Natural History of Northumberland, remarks, that it breeds annually on the Cheviot hills, and on the shady precipices under the Roman wall, near Craglake. Dr Latham and other eminent ornithologists have supposed that this and the following are male and female; but the repeated instances of hen-harriers of both sexes having been seen, leave it beyond all doubt that they constitute two distinct species.

83 *Pygargus.* *Ring-tail, ring-tail hawk, white-rumped bay falcon*, &c.—Cere and legs yellow; body cinereous; belly pale, with oblong rufous spots; orbits of the eyes white. Bill pale; irides yellow; tail longish, banded with dusky, and dotted with white, the male marked with transverse, and the female with longitudinal, spots beneath. Length 18 or 20 inches. Inhabits Europe, and the temperate parts of Siberia. Flies higher than the preceding, and sometimes perches on trees. Its eggs are white, much freckled with red.

84 *Tinnunculus.* *Kestril, kestral, stonegall*, &c.—Cere and legs yellow; back purplish-red, with black spots; breast with brown streaks; tail rounded. Crown of the head of a fine cinereous gray; greater quill-feathers black, very slightly tipped with whitish. Bill lead colour, irides dusky and large. The male weighs about seven ounces, and measures 13 inches in length. The female is considerably larger, and distinguished from the other sex by the head and tail being of the same colour as the back, which is not so bright a red brown as the male. Feeds principally on mice, in search of which it is frequently seen hovering in the air and stationary for a great length of time. Preys also on small birds and insects, and was formerly used for catching game. Inhabits Europe, Siberia, and the more temperate parts of North America. One of our most common birds of prey, especially among the rocks and cliffs of the coast, which favour its breeding. The nest is of sticks, and lined with wool and other soft materials; but it sometimes builds on trees, or is contented with the deserted nest of a magpie or crow. The eggs are usually four or five, of a dirty white, blotched with rust colour, of various shades.—It is a handsome bird, whose sight is acute, and whose flight is easy and graceful. It includes two or three varieties.

85 *Piscator.* *Fishing falcon.*—Legs brown; head ferruginous, with long feathers; body cinereous above, pale yellowish white beneath; tail pale brown above, blueish-ash beneath. Bill and irides yellow; margin of the upper feathers rusty brown, the under spotted in the middle with brown. Inhabits Senegal, where it is called *tanas*, preying chiefly on fish, which it takes out of the water, and retires to a convenient place to eat them piecemeal.

86 *Nisus.* *Sparrow hawk.*—Cere green; feet yellow; belly white, waved with grey; tail with black bands. The weight of the male of this species is about five ounces, that of the female nine: the former measures in length about 12 inches, the latter 15. The male is inclined to rust colour on the breast, the female to whitish. On the back of the head, in both sexes, is an obscure broken patch of white. The quill feathers are dusky, barred

Accipitres. red with black on the outer webs, and spotted with white at the base of the inner. The legs are long, slender, and yellow. In some the back is spotted with white, and others have the body entirely of that colour. The sparrow-hawk is very common in our wooded and inclosed districts, but is less frequent in the more champaign parts. The female sometimes builds her nest in hollow trees, high rocks, or lofty ruins, but more frequently takes possession of that which has been deserted by a crow, laying four or five eggs, of a dirty white or blueish tinge, blotched at one of the ends with rust colour. It is very widely diffused over the world, from Russia to the Cape of Good Hope. It is bold and spirited, making great destruction among pigeons, young poultry, and small birds of all kinds, which it will attack and carry off in the most daring manner; at the same time, that it is obedient and docile, and can be easily trained to hunt partridges, quails, larks, &c.

87 Subbuteo. *Hobby.*—Cere and feet yellow; back brown; neck white; belly pale, with oblong brown spots. Bill blue; orbits yellow; irides generally chesnut; lateral tail-feathers with blackish bars; primary quill-feathers with oval reddish spots; claws black. The male weighs about seven ounces, and the female nine, or more. Inhabits Europe and Siberia, breeds in Britain, but leaves us the latter end of October. It build in trees, and sometimes takes possession of a deserted crow's nest, laying three or four eggs, which are said to be white. Though small, it is inferior to none of the falcon tribe in courage, and will frequently pounce a partridge; but its favourite prey is the lark, which it terrifies to such a degree, that it sometimes flies to man for protection, and will allow a net to be thrown over it.

88 Æsalon. *Merlin.*—Cere and feet yellow: head rusty; body above, of a blueish ash, with spots and rusty streaks; beneath, yellowish-white, with oblong spots. Bill blueish; irides dusky; tail alternately streaked with dusky and reddish; claws black; eggs brown red. There are several varieties. The merlin is a small species of falcon, being scarcely larger than the blackbird, but is very rapid on wing, and was esteemed for its courage in hawking. It flies low, and is generally seen skimming along the side of a hedge, or over the surface of the ground, in pursuit of small birds. Inhabits Europe; visits the south of England in October, about the time the hobby retires, but has never been observed to breed farther south than Cumberland, where it has been found more than once, with four young ones, placed on the ground.

89 Minutus. *Minute falcon.*—Cere brown; legs yellow; body white beneath; tail-feathers brown, branded with black, About 11 inches long. Inhabits Malta; and occurs, though rarely, in England.

90 Pumilus. *Tiny falcon.*—Legs yellow; body brown-ash; beneath whitish, with blackish bars; crown whitish. Hardly six inches long. Inhabits Cayenne.

Gen. 3. STRIX, *Owl.*

91 STRIX.

92 Characters. Bill hooked; no cere; nostrils oblong, covered with bristly recumbent feathers; head, eyes, and ears large; tongue bifid.

These are nocturnal birds, with the organs of vision so constructed as to see in the dark. Their sense of hearing is very acute, by means of a particular membrane at the opening of the external ear. They can move the outermost toe either backwards or forwards. Accipitres. They feed on carrion, living small birds, hares, mice, field-mice, lizards, &c. When they venture abroad in day light, they are chaced, and insulted by smaller birds, especially by the crow. In their manner of life, round head, &c. they have some affinity to cats. During the winter, they live retired, fasting, or sleeping in towers and old walls.

A. *Eared.*

Great owl, great eared owl, great horned owl, &c.— 93 Bubo. Body of a reddish or tawney colour; irides yellow; head and body variegated with black, brown, ash, and rusty spots and lines; claws large, much hooked, and dusky. Liable to considerable varieties. Nearly the size of an eagle, and very strong, preying on hares, rabbits, moles, rats, mice, and sometimes bats and reptiles. It inhabits Europe, Calmuc Tartary, and South America, haunting mountainous rocks and caverns. Its nest is nearly three feet in diameter, and composed of sticks bound together by fibrous roots, and lined with leaves. It generally lays two eggs, somewhat larger than those of a hen, and variegated, like the bird itself. The young are very voracious, and are plentifully supplied with food by the parents. This bird is by no means common in Great Britain, though it has been occasionally shot both in England and Scotland. It endures day light better than most of the genus, flies low in the day, but sometimes soars very high during the night. 94

Virginian eagle owl.—Size of the common eagle owl; Virginiana. ear feathers large, rise above the base of the bill which Plate CCCXCIII. is black; irides golden yellow; upper part of the body fig. 4. brown, variegated with slender rufous and cinereous lines; under part pale-ash, transversely stripped with brown; throat white; lower part of the neck and sides of the breast orange brown, spotted with darker brown; quills and tail banded with brown; legs and half the toes covered with cinereous feathers; claws horn colour. Inhabits America, Kamtschaka, and Astracan. Is a little smaller than the great horned owl, and is supposed by some to be only a variety. 95

Ceylonese eagle owl.—Bill horn colour; irides yellow; Zeylonensis. upper part of the body pale reddish brown, under part Plate yellowish white; ears short, pointed; first quills and tail CCCXCIII. barred with black, white, and pale red; legs naked to fig. 3. the knees. Length 23 inches; weight two pounds and near 10 ounces. Native of Ceylon. 96

Long-eared or *horn owl.*—Ears with six feathers. Ears Otus. black and yellow; irides yellow; back and wing coverts dusky brown, gray, and yellowish-rusty; breast and belly pale yellow, with brown longitudinal lines; tail barred with ash-colour, and dusky; legs and feet feathered to the claws. About 14 inches long; but there is a variety that is much smaller, and another which is distinguished by the greater darkness of the body. Diffused over the four quarters of the globe, frequenting forests and wooded tracts, and manifesting a partiality to fir, box, or holly plantations, where it more readily conceals itself by day among the ever-green foliage. Its principal food is mice, and sometimes small birds taken at roost. It remains with us the whole year, and is frequently taken; yet little is known of its habits. 97

Short-eared owl, hawk owl, mouse hawk, &c.— Brachyotus. Ears short; body above brown, feathers-edged with yellow; beneath pale yellow, with longitudinal dusky streaks.

Accipitres. streaks; head small and hawk-like; bill dusky; irides yellow. Length 14 inches, stretch of wing three feet. Inhabits Europe, Siberia, and America, chiefly in mountainous or wooded countries, and feeds principally on field-mice. Visits England in the latter part of the year, and disappears in spring. It flies by day, and is sometimes observed in companies. It is supposed to breed in the Orkneys, and probably in Norway, making its nest of dry grass, on the ground, and laying three or four white eggs.

98 Scops. *Little horned owl*.—Ears of one feather each. Gray, rufous, brown or blackish, according to age; legs spotted with brown; toes and claws brown. Between seven and eight inches long. Inhabits Europe, and preys on field mice.

B. *Earless.*

99 Nyctea. *Snowy* or *great white owl*.—Body whitish, with a few brown lunated spots. Bill black, and almost hid in the feathers; irides yellow; legs covered with white feathers to the toes; claws black. This species is sometimes quite white, and sometimes varies with very numerous spots. About two feet long; flies abroad by day; preys on herons, hares, mice, and sometimes carrion, but is particularly fond of ptarmigans. Makes a howling noise. Inhabits the northern parts of Europe and America, particularly Sweden, Iceland, and Hudson's Bay, and sometimes, though rarely, Pennsylvania.

100 Nebulosa. *Gray* or *barred owl*.—Head, neck, breast, back, and wing coverts brown, spotted with white; belly and vent dirty white, streaked with brown; tail with brown and whitish bands, tipt with whitish. Weighs about three pounds, is two feet long, and four in extent of wing. Feeds on hares, mice, and cranes. Inhabits Hudson's Bay and New York, and rarely occurs in England.

101 Flammea. *White* or *common owl*.—Body pale yellow, with white spots, beneath whitish, with black spots. Bill white; irides dusky; tail feathers white within, with dusky lines on the outside; 14 inches long, and weighs about 11 ounces. This species is so well known, that we need not more minutely describe it. It inhabits Europe, America, and Northern Asia, and is by far the most common of British owls, being distinguished by various provincial appellations, as barn owl, gillihowlet, howlet, madge-howlet, church owl, hissing owl, screech owl, &c. It is partial to the habitations of man, and is rarely found in woods. Its ordinary haunts are barns, churches, old houses, and other uninhabited buildings, in which it continues during the day, but which it leaves in the evening, in quest of prey. Its flight is accompanied with loud and frightful cries, and its repose with a blowing noise, like the snoring of a man; when alarmed, it snaps its bill with great force. It makes scarcely any nest, but deposits five or six whitish eggs in the holes of walls. It feeds on mice, and small birds, which it swallows whole, and afterwards discharges the bones, feathers, and other indigestible parts at its mouth, in the form of small round cakes, which are called *castings*, and some bushels of which are sometimes found in the hollows of decayed trees, near farm-houses or villages, in barns, out-houses, &c. When a pair have young ones, they sally out alternately in quest of food for them, and generally return every five minutes, with a live mouse. Dr Latham mentions, that he received a specimen from Jamaica, which differed in no respect from our common owl.—The white owl is very susceptible of domestication, when taken young. Accipitres.

Tawney or *brown owl*, *common brown* or *ivy owl*, *black owl*, *howlet*, *wood owl*, &c.—Body ash-coloured, the third flag-feather the longest; plumage marked above with dusky spots and points; breast and belly yellowish, mixed with white; beneath with dusky streaks; irides dusky; tail with pale brown and black spots and lines. Fourteen inches long; stretch of wing two feet eight inches; weight of the female 19 ounces. Inhabits Europe and Tartary. This is another very common species. It resides chiefly in woods and plantations of fir; concealing itself in the thickest recesses; sometimes it settles on the ground, but if molested, takes shelter in a neighbouring tree. It is rarely seen on wing by day, except forced from its haunts, the light dazzling it to such a degree that boys hunt it down with sticks and stones. It breeds in the hollows of trees, and sometimes in barns, where it is protected by the farmer, as it is an excellent mouser. It lays two or three eggs of a roundish form, and dull white colour. It is the only species known to hoot, besides which, it makes a disagreeable screaming noise. It is a great enemy to young pigeons, leverets, young rats, &c. but chiefly subsists on mice.—"We have taken this bird," says Mr Montagu, "in its mature state, as well as young, and found no difficulty in either case of preserving them alive. They were never observed to drink; and indeed for many months together had no water offered them."—The *ulula* of Linnæus is now esteemed only a smaller variety of the *stridula*. 102 Stridula.

Little owl.—With white spots arranged in five rows on the flag-feathers; bill whitish brown; irides pale yellow; head, back, and wing coverts pale brown, with white spots; breast whitish, variegated with rusty. Scarcely larger than a blackbird, but varies considerably both in respect of size and markings. Inhabits Europe, North America, and the West Indies. Is very rare in England, though it has sometimes been found in Yorkshire, Flintshire, and the neighbourhood of London. It is said to frequent ruined edifices in France, and to build in chimneys, in Carniola: but it frequently nestles in the holes of rocks and walls, and lays five or six eggs, spotted with yellowish and white. It can fly by day, and give chase to swallows and other small birds on wing, but mice are its principal food. 103 Passerina.

White-fronted owl.—Body rusty brown, paler beneath; forehead white; quill feathers barred with black and white. Only five inches long. Native of North America. 104 Albifrons.

Gen. 4. Lanius, *Shrike*. 105 Lanius.

Bill nearly straight, with a dent on each mandible, near the end, naked at the base; tongue jagged at the point. 106 Characters.

The birds of this genus form a connecting link between the falcons and pies, and have been differently classed by different ornithologists. Though comparatively small, they are very courageous, will attack birds much larger than themselves, and are called *butcher birds*, because they frequently kill several, before they begin to feed. They fix on their victims with their talons, split the skull with their bill, and then feed on them at leisure.

Accipitres.

107 Collaris. *Collared shrike, canary biter*, or *fiscal*.—Tail wedged; body black, white beneath; first quill feathers white at the base; bill and head blackish; tail feathers, except the four middle ones, white at the tips. Very common at the Cape of Good Hope, also found in Senegal, and in the interior parts of Africa. Twelve inches long. Feeds on beetles, grashoppers, and other insects, which it not only catches with great dexterity; but when it cannot consume them all, will stick them on the pales of farm yards, till it has occasion for them. It also seizes on sparrows and canary birds, of which it devours only the brains.

108 Excubitor. *Cinereous shrike, great cinereous shrike, greater butcher bird, mattagess, night jar*, &c.—Tail somewhat cuneiform, white on the edges; back gray; wings black, with a white spot; bill black, with bristles at the base; upper parts of the plumage of a pale blue ash, the under parts white; legs black. The female differs chiefly in the under parts, which are of a dirty white, marked with numerous semicircular brown lines. There is a variety, with the body white, legs yellowish, and bill and claws blackish; and another with lesser wing coverts and reddish shoulders. Inhabits Europe and North America. Is rather a scarce bird in England, but is said to breed among some of our mountainous situations; coming in May, and departing in September. It makes a nest of heath and moss, lined with wool and gossamer, and lays six eggs, of a dull olive green, spotted with black at the larger end. According to Buffon, it is common in France, where it continues all the year; it kills rats, mice, and small birds, affixing its prey to a sharp thorn, and tearing it in pieces with its bill; it is also said to imitate the notes of some other birds, by way of decoying them to their destruction. Mr Pennant observes, that when kept in a cage, it sticks its food against the wires before it will eat it.

109 Collurio. *Red-backed shrike, lesser butcher-bird*, or *slusher*.—Tail somewhat wedged; back hoary; four innermost tail-feathers of one colour; bill of a leaden hue. Irides hazel; head and lower part of the back of a light gray, upper part of the back and wing-coverts of a bright rusty red; breast, belly, and sides, of a fine pale rose, or bloom colour; a black streak passes from the bill through the eyes; legs black. Length about seven inches; weight eight drams. The female weighs two drams more, and has all the upper parts of a ferruginous brown. The manners of this species are similar to those of the last. It kills small birds by piercing the skull with its bill, and insects by transfixing them on the thorn of the sloe-bush. It tears off the body of the chaffer, and leaves the elytra, wings, and head behind. It imitates the song of many of the sparrow tribe, and thus entices them within its reach. It chiefly haunts inclosed moist situations, makes its nest in some thick hedge, composing it very skilfully of moss and fibrous roots put together with wool and lined with hair, and lays five or six eggs of a bluish-white colour, with a circle of brown near the broad end. It inhabits Europe and Africa, visits Britain in May, and departs to some warmer climate in September. Among its varieties Gmelin includes *lanius rutilus* of Latham, or *woodchat*, which is very rare in this country.

110 Tyrannus. *Tyrant shrike*.—Body cinereous, white beneath; crown of the head black, with a longitudinal tawney streak. Eight inches long. There are several varieties, all natives of America and the West Indies, and all of a fierce and audacious disposition, fixing on the backs of other predaceous birds, and making a continual chattering noise, till they force them to retire.

Picæ.

ORDER II. PICÆ. 111 Picæ.

111 Characters. THE distinguishing marks of this order are, a bill somewhat compressed, more or less crooked, and always convex; toes divided, and adapted either for climbing (*scansorial*) or, for stepping, (*gressorial*). Some feed on insects, worms, and the flesh and offal of other animals, and some on the seeds and juices of plants. During the breeding season, they are monogamous, and make their nests on trees; and during incubation, the female is often fed by the male. There are a few genera, however, which do not exactly correspond with these characters.

Gen. 5. PSITTACUS, *Parrot*. 113 Psittacus.

114 Characters. Bill hooked; upper mandible moveable, and, for the most part, covered with a case; nostrils rounded, and placed in the base of the bill; tongue fleshy, obtuse, entire; feet scansorial.

This very numerous genus, which contains upwards of 140 species, is peculiar to the warmer regions of both worlds. The birds which belong to it, resemble the accipitres in the form of the bill, but in their manners coincide with the other genera of this order. They feed on the seeds and fruits of various plants; are very docile, and by means of their obtuse tongue, may be taught to imitate human speech. They climb easily, assisting themselves with their bill. They associate in pairs, and attain to a great age. Some species equal the domestic fowl in size, while others are no larger than a sparrow. In Europe, they sometimes lay eggs, but seldom sit on them. In their native climates, the male and female sit on them alternately.

A. *Tail long, and wedge-shaped.*

115 Macao. *Red and blue maccaw*.—Quill-feathers blue above, rufous beneath, scapulars varied with blue and green; cheek naked, wrinkled. Body scarlet; upper mandible white, lower black; temples white; wing-coverts generally yellow; tail long and red; feathers blue at the sides. Two feet seven inches in length, size of a capon. Inhabits Brasil, Guiana, and other regions of South America, affecting moist palm woods, and living on the fruit of the trees. When driven by hunger to feed on the manchineel apple, its flesh is poisonous, though the bird itself receives no injury. Makes its nest in decayed trees, enlarging the hole, if necessary, with its bill, and lining the inside with feathers. The female lays two eggs at a time, about the size of those of a pigeon, and spotted like those of a partridge. Breeds twice a year, the male and female sitting on the nest alternately, and reciprocally nursing and feeding the young birds. The latter are tamed with great ease, and may even be taught to speak, but the old birds are clamorous and unmanageable. Though the flesh is hard, black, and unsavoury, it makes good soup, and furnishes a great part of the food of the inhabitants of Cayenne, as well as other parts of South America. Like other parrots it is subject to fits when kept tame. The strength of its

Picæ. its bill is sufficient to break a peach-stone with great ease.

116 *Aracanga.* *Red and yellow maccaw.*—Pale scarlet; scapulars yellow, tipt with green; quill-feathers blue above, rufous beneath; cheeks naked and wrinkled. Size of the preceding. Inhabits Guiana, Brasil, and Jamaica.

117 *Tabuensis.* *Tabuan parrot.*—Head, neck, breast, and belly, purple; back and wing-coverts green; crown terminated by a lunular blue mark; first quill-feathers and greater part of the tail blue. Length, 19 inches. A beautiful species, found at Tonga Taboo, and the other Friendly isles in the South seas. The green variety, with the head, neck, breast, and belly, scarlet, occurs in New South Wales.

118 *Elegans.* *Beautiful parrot.*—Head, neck, and body, red beneath, brown above; interscapulars pale blue, mixed with red; tail greenish-brown, tipt with white. Varies, with the wings, tail, and body green above. From 12 to 15 inches long. Inhabits the Molucca islands.

119 *Pennantii.* *Pennantian parrot.*—Scarlet; fore part of the back black. waved with scarlet; sides and throat blue; quill-feathers each with a white spot. There is a variety with a pale band in the middle of each wing. The female has the upper parts of the neck and body greenish, top of the head red, and a patch of the same colour under each eye; chin and throat blue; lower part of the neck and breast, as also the rump and vent, red; middle of the belly dusky green; tail dark blue, fringed with chesnut; shoulders blue, and the rest of the wing the same, but darker. Fifteen inches long. Inhabits New South Wales.

120 *Gloriosus.* *Splendid parrot.*—Bright blood-red; back feathers edged with black; chin, wing, and tail blue. Sixteen inches long. Inhabits New Holland.

121 *Ornatus.* *Orange-billed parrot*, or *long parrakeet.*—Of a yellowish green colour; the hind part of the head, the throat, and breast red; crown of the head and ears blue, with ash-coloured orbits. Eight inches long. Inhabits India. Like other small species with long tails, is not easily taught to speak.

122 *Murinus.* *Gray-breasted parrakeet.*—Olive; face, chin, and breast mouse-colour, quill-feathers green. Bill and legs gray; tail five inches long. About the size of a thrush. Tame and gentle, and easily taught to articulate. Common at Monte Video.

123 *Cornutus.* *Horned parrot.*—Green; head scarlet, with two long feathers standing out like horns; collar and rump straw-colour; outer edge of the quill and tail feathers blue. Bill and legs black blue; temples orange; irides golden; wing-coverts at the tips and within dusky; tail black beneath. Length 11 inches, size of a small dove. Inhabits New Caledonia. Figured in Latham's Synopsis.

124 *Formosus* *Ground parrot, New Wales parrot*, or *black-spotted parrakeet of Van Diemen's Land.* Green; four middle tail feathers barred with green and black, the rest with black and yellow; bill and legs black; tail much wedged. This is a most elegant and beautiful species, about 12 inches long, inhabiting New South Wales, and other parts of New Holland, where it is known by the name of *goolingnang*. It is rarely seen, except on the ground, particularly in moist places. It is not known to perch on trees like other parrots, but rises from among the grass, and immediately alights in it again. The legs and toes are more slender than usual in this genus, and the claws more straight. Picæ.

Otaheite parrakeet.—Blue; feathers of the head long; chin and throat white; bill and legs red. Tongue fringed at the end; only five inches long; inhabits Otaheite, and feeds on the fruit of the banana. 125 *Taitianus.*

B. *Tails short, and even at the ends.*

Banksian cockatoo.—Splendid black; crest small; head and wing coverts dotted with buff; outer tail-feathers scarlet in the middle, barred and tipt with black. Nearly three feet long, but varies both in size and markings. Inhabits New Holland, and was brought to England by Sir Joseph Banks. Figured in Latham's first Supplement. 126 *Banksii.*

Great white cockatoo, or *yellow-crested cockatoo.*—White; crest folding, and yellow. Bill, cere, irides, legs and claws black; orbits naked and white; quill and lateral tail feathers, from the base to the middle, sulphureous on the inside; feathers of the neck loosely flowing; crest five inches long, and erectable. Length 18 inches; size of a domestic ordinary fowl. This, and several other species, frequently repeat the word *cockatoo.* Inhabits the Molucca islands. 127 *Cristatus.*

Ash-coloured or *hoary parrot.*—Bluish-gray; temples naked and white; tail scarlet. Bill black; cere white; irides yellowish white; legs cinereous; claws black. Subject to several varieties. About 20 inches long. Loquacious, and easily taught to speak. Inhabits Africa, and is sometimes called *jaco* from the sound which it commonly utters. 128 *Erythacus.*

Ceram or *purple parrot, Ceram lory*, &c.—Red; orbits ash-coloured; cheeks and wings green; hinder parts of the tail-feathers blue. There are three or four varieties. Size of a dove. Inhabits Ceram, and the other Molucca islands. 129 *Garrulus.*

Purple or *blue-cap lory.*—Red; cap violet; wings green; shoulders and cheeks blue; orbits brown. There is a variety with a blue cap, black orbits, and yellow collar. According to some writers, these are male and female. They inhabit the East Indies, and are remarkable for speaking distinctly, and quickly learning their lesson. They are in general scarce, and fetch a high price. 130 *Domicella.*

Violet cap, or *black-capped lory.*—Purple; cap violet; wings green; breast, cheeks, and tail blue; orbits pale flesh-colour. Upwards of 10 inches long; inhabits the Philippine isles, particularly Yolo. It is so familiar and playful, that it is much to be regretted that its duration of life proves so short in these colder regions. 131 *Lory.*

Yellow-winged parrot, or *yellow-headed creature.*—Green; front and orbits whitish; crown, cheeks, chin, throat, and remoter wing-coverts, yellow. Thirteen inches long. Inhabits South America. A friend of the count de Buffon had one of this species alive, which seemed much attached to its master, and yet of a very capricious temper, expecting a return for every demonstration of civility. In its wantonness, it would sometimes bite a little too hard, and laugh heartily, as if pleased with the act; but if chastised for the offence, it became the more refractory, and could be reclaimed only by gentle treatment. It took great delight in tearing every thing to pieces, was dull and silent if confined in 132 *Ochropterus.*

Picæ. in its cage; but when at large, chattered almost incessantly, and repeated every thing that was said to it. It was also, contrary to the disposition of many parrots, very fond of children. During the moulting season, it appeared dejected and uneasy for nearly three successive months. It was for the most part fed on hemp seed, nuts, fruits of all kinds, and bread soaked in wine, but preferred meat, if it could get it. It was observed, that if it fed on this last, it became dull and heavy, and soon lost its feathers. It was also remarked, that it kept its food for some time in its cheeks, whence it was gradually protruded by a sort of rumination.

133 *Passerinus.* *Passerine parrot*, or *blue and green parrakeet.*—Yellowish green, with a blue spot on the wings, which are blue below. Bill, cere, orbits, legs and claws, orange; primary wing-coverts blue. Inhabits Brasil and Guiana, and is the smallest of the genus, being only four inches in length, and of the size of the house sparrow.

134 *Cyanolyseos.* *Blue-collared parrot.*—Yellowish-green, collar blue, rump red. Larger than a pigeon. Inhabits Chili, where it is called *thecau*, and where it often does much injury to the corn, flying in great flocks. When the troop settles, one of them acts as sentinel on a tree, and gives the alarm if any person approaches, from which circumstance it is difficult to shoot them. This species breeds in the holes of rocks, laying two white eggs in the most inaccessible and craggy parts. From the tops of the cliff, the inhabitants let themselves down by ropes to take the eggs and young birds, which are reckoned delicate eating. If robbed of its young, this parrot will lay a second, and even a third, but rarely a fourth time. It is easily tamed, and learns to speak well.

135 *Melanocephalus.* *White-breasted parrot.*—Green, yellow beneath, cap black, breast white, orbits flesh colour. Length nine inches and a half. Inhabits Mexico, Guiana, and the Caraccas in South America. Frequents woods, and seldom approaches inhabited districts. Its call is a shrill whistle, which it often repeats in its flight, nor does it learn to talk. "These birds, says Dr Latham, fly in small numbers together, but are perpetually quarrelling with one another; and, if any one is taken, it refuses all food, till at last it is starved to death. Parrots of the most stubborn nature are often subdued by means of the smoke of tobacco; but this bird is only put into bad humour by the attempt. Whoever, therefore, would have these parrots must train them up young; and this would scarce be worth while, were it not for the sake of variety." Buffon has observed, that it is thicker and shorter-necked than most parrots, that its feathers are more stiffly set on, and that it is of a more dull and sluggish disposition.

136 *Senegalus.* *Senegal parrot.*—Green, yellow beneath, head cinereous, orbits black and naked. Bill cinereous, cere blackish, irides yellow, legs reddish ash. Size of a blackbird; length eight inches and a quarter. Plentiful in Senegal, where it flies in companies of five or six, and perches on the tops of the trees which are scattered in the sandy plains. Its cry is sharp and dissonant.

137 *Pullarius* *Ethiopian parrot*, or *red-headed Guinea parrakeet.*—Green; front red; tail tawney, with a black band, orbits cinereous. Size of a lark; length five inches and a half. Very common in Guinea, and also occurs in Ethiopia, the East Indies, and the island of Java.

Sapphire parrot, or *sapphire-crowned parrakeet.*—Green; rump and breast scarlet, crown (of the male) blue. It sometimes occurs with the head yellowish blue, 138 *Galgulus.* a transverse orange bar behind, and the front and under part of the throat and tail-coverts red. Five inches long. Inhabits the Philippine islands. Sleeps suspended by one foot, and is very fond of the fresh juice of the cocoa-nut tree. "If this is put in a cage (says Osbeck), it whistles very seldom, and commonly grows quite sullen; it hangs itself with its feet so, that the back is turned towards the earth, and seldom changes this situation: it is fed with boiled rice; in which manner in the year 1752, one was brought to Gottenburg.——We observed that their nests were remarkable for their exceeding fine texture; but we did not see the birds. If they had a different construction, the monkeys would be very mischievous to them; but now, before they can get to the opening, the lowest part, as the weakest, breaks in pieces, and the visitor falls to the ground, without any danger to the birds."

Gen. 6. Ramphastos, *Toucan.* 139 Ramphastos.

Bill large, hollow, convex, and serrated at the margins; 140 Characters. both mandibles incurvated at the tips; nostrils behind the base of the bill long and narrow; tongue feathered at the edges; feet mostly scansorial.

The birds of this genus seem to be limited to the tropical regions of South America, and are very impatient of cold. They feed on fruit, especially that of the palm trees. They are generally met with in small flocks of eight or ten, moving from place to place in quest of food, and advancing northward or southward as the fruits ripen, though they are not properly migratory. They make their nests in the hollows of trees abandoned by the woodpeckers, and not formed by themselves, the structure of their bill not allowing of the efforts necessary to make, or even enlarge a hole in the most tender wood, as it yields to the least pressure of the finger. They lay two eggs, and probably breed more than once in the year, as they are pretty numerous. If brought up young they are easily tamed, and become very familiar.

Green toucan.—Green, belly yellow, rump red. Upper mandible yellow, with red sides and a black line in 141 *Viridis.* the middle, the lower black; the base and space round the nostrils red, the teeth in both white, irides and orbits yellow, legs lead colour, claws black, tail wedged and inclining to ash beneath; head, chin, and throat in the male, black, in the female, bay, terminated by a black, narrow, transverse band. Fourteen inches long. Inhabits Cayenne. Its extraordinary large bill gives it a very singular appearance.

Pavonine toucan.—Green, feathers sprinkled with red 142 *Pavoninus.* spots. Bill variegated with yellow and black, legs and claws black. Seventeen inches long. Inhabits the sea-coasts of New Spain, and is said to feed on fish. This last circumstance, however, may admit of doubt. Most of the species will eat fish, and even flesh, in a state of confinement; but their frequent proximity to the water in their natural state, is probably occasioned by the situation of their favourite fruit.

Brasil toucan, or *Brasilian pie.*—Blackish, abdominal 143 *Piscivorus.* band and vent red, rump white. Twenty-one inches long.

Picæ. long. Inhabits South America. The propriety of its Linnæan designation is somewhat doubtful.

144 *Tucanus.* *Yellow-breasted toucan.*—Blackish; abdominal band, vent, and rump yellow. Nineteen inches long. Inhabits South America.

145 *Albus.* *White toucan.*—Entirely white. No other particulars are known of this species.

146 Momotus.

Gen. 7. Momotus, *Motmot.*

147 Characters. Bill strong, slightly curved, serrated at the edges; nostrils feathered, tongue feathered, tail wedged, feet gressorial.

148 *Brasiliensis.* Plate CCCXCV. fig 4. *Brasilian motmot*, or *Brasilian saw-billed roller.*—Green, front bluish-green, hind part of the head violet, crown black. Variegated with green, tawney, blue and cinereous. Body olive-green above, rusty beneath; head large, bill black, legs black, claws hooked. About a foot and a half in length, and nearly equal to a magpie in size. Inhabits Brasil, Cayenne, Mexico, and other parts of South America. It is a solitary bird, frequenting thick forests; chiefly seen on the ground, or on some low branch of a tree, taking short flights when disturbed, and pronouncing the word *houtou*. It makes a nest of dry grass and stalks on the ground, frequently in some hole deserted by an armadillo or other quadruped, and laying for the most part two eggs. It feeds on insects and raw flesh, the fragments of which it macerates in water. When taken, it strikes violently with its bill. Its voice is extremely harsh, weak, and tremulous.

149 Scythrops.

Gen. 8. Scythrops, *Channel-bill.*

150 Characters. Bill large, convex, cultrated, furrowed or channelled on the sides, with the tip bent; nostrils round, naked, placed at the base of the bill; tongue cartilaginous and bifid at the end; toes placed two before and two behind; tail consisting of ten feathers.

151 *Psittaceus.* *New Holland channel-bill, psittaceous* or *anomalous horn-bill.*—Bill pale brown, tipt with yellowish, convex, keeled; nostrils surrounded with a red wrinkled skin; orbits naked; head, neck, and under parts of the body pale bluish-gray; back, wings, and tail cinereous, the feathers mostly with dusky blackish tips; tail long, wedged, its feathers barred with black near the end, and tipt with white; legs short, scaly, and with the hooked claws black. Size nearly that of a crow, and the total length 27 inches. Inhabits New Holland, though not plentifully, and is seldom seen unless in the morning and evening, sometimes in small groups of eight or ten, but frequently in pairs, appearing about Port Jackson in October, and departing in January, but to what country is not known. Both on the wing, and when perched, they make a strange, loud, screaming noise, not unlike that of the common cock and hen when they perceive a hawk or other bird of prey hovering over them. They are supposed to feed principally on the seeds of the red gum and peppermint trees, which they swallow whole. The tail is sometimes displayed like a fan, which gives the bird a majestic appearance.

5

Picæ.

Gen. 9. Buceros, *Horn-bill.* 152 Buceros.

Bill convex, curved, sharp-edged, large, serrated at the margins, with a horny protuberance on the upper mandible near the base; nostrils behind the base of the bill; tongue short, sharp-pointed; feet gressorial. 153 Characters.

The birds of this genus are all inhabitants of the warmer regions of Asia and Africa, and seem to correspond to the toucans of the New World. According to Latham, the circumstance of their feeding on fish requires confirmation.

Philippine horn-bill.—Front bony, flat, and two-horned at the fore part. Varies with a vermilion bill, black belly, and the back and rump brown ash. Body black above, white beneath; quill feathers with a white spot; tail longish and black; legs greenish. Size of a common fowl; inhabits the Philippine islands, and has a cry like the grunting of a hog. It lives in the woods, and feeds on fruits, such as the Indian fig, pistachio, &c. which it swallows entire; and after digesting the pulp, brings up the stones whole, and still fit for vegetation. The Gentoos rank it among their gods. 154 *Bicornis.*

Abyssinian horn-bill.—Black; bony protuberance semicircular on the fore part; orbits, chin, and part of the throat naked, and irides brown. Greater quill feathers white. Total length, three feet ten inches; extent of wing, six feet. On the neck are several protuberances, as in the turkey cock, of a light blue colour, changing to red on various occasions. Occurs in Abyssinia, generally among the fields of *taff*, feeding on green beetles, which frequent that plant. It has a putrid smell, which has occasioned a supposition of its feeding on carrion. It has been seen with eighteen young ones, and usually runs on the ground; but when raised, flies both strong and far. It builds in large thick trees, and when it can, near churches; has a covered nest, like that of a magpie, but four times as large as an eagle's, placed firm on the trunk, at no great height from the ground, and the entry always on the east side. 155 *Abyssinicus.*

Indian horn-bill.—Protuberance flattened forwards, belly tawney, neck with a white collar. Two feet four inches long, rather bigger than a cock. Inhabits the Moluccas, and feeds chiefly on nutmegs, from which circumstance its flesh is very delicate, and has a fine aromatic flavour. In its native places, it is frequently tamed for the purposes of destroying rats and mice. 156 *Hydrocorax.*

Rhinoceros horn-bill, rhinoceros-bird, or *horned Indian raven.*—The horny process on the upper mandible recurved. Inhabits India. Three feet long, and nearly as big as a turkey. Feeds on flesh and carrion, and follows the hunters for the purpose of feeding on the entrails of the beasts which they kill. It is also said to feed on rats and mice, and after pressing them flat with its bill, to toss them up in the air, and swallow them whole, immediately on their descent. 157 *Rhinoceros.*

Panayan horn-bill.—Greenish black; under part of the body dusky red; the prominence of the upper mandible acute above and plane at the sides; bill very long, arched, dusky, having the sides marked transversely with orange-coloured furrows. Size of the raven. Native of the isle of Panay. 158 *Panayensis.* Plate CCCXCV. fig. 2.

Gen.

Picæ.

Gen. 10. Buphaga, *Beef-eater*.

159 Buphaga. 160 Characters. Bill straight, squarish; mandible gibbous, entire, more gibbous at the margins: feet gressorial.

161 Africana. *African beef-eater.*—Upper parts of the body gray-brown, under parts and rump yellowish; bill hardly an inch long, sometimes yellowish, tipt with red, sometimes black; tail wedged; legs and claws black. Eight inches and a half long. Inhabits Senegal, and other districts of Africa. Resembles the starling in its manners, appearing in small troops of a dozen or more. Alights on the backs of oxen, antelopes, and other quadrupeds, and by pressing the elevated part of the animal's hide, which contains the larva of the œstrus, forces it out, and regales on it. It is also said to feed on various kinds of insects. It has a sharp kind of cry, in no respect approaching to a song.

162 Crotophaga.

Gen. 11. Crotophaga, *Ani*.

163 Characters. Bill compressed, semi-oval, arched, carinated on the back; upper mandible angular at each edge; nostrils pervious, or going from one side of the bill to the other.

164 Ani. *Lesser ani.*—Blackish-violet; feet scansorial. Body black; tail long, and wedged; upper mandible incurved at the tip; nostrils oval; tongue fleshy, and entire; legs black. Length thirteen inches and a half; size of a blackbird; and sometimes known by the names of the *razor-billed blackbird*, or *great blackbird*. Inhabits South America and several of the West India islands. This species is gregarious to such a degree, that many females lay their eggs in the same nest, to make which they all unite in concert, and after depositing their eggs, sit on them close to each other, in order to hatch them, each striving to do the most for the general good. When the young are hatched, the parents exert themselves to feed the whole flock. It is still more remarkable, that as soon as the female has laid her eggs, she covers them with leaves, and repeats this operation as often as she is obliged to leave the nest for food. It generally breeds twice a-year; and the eggs are about the size of those of a pigeon, of a sea-green colour, and spotted at the ends. The lesser ani feeds on worms, insects, fruits, and grain, according to the season. The other species resemble this in appearance and manners, but vary somewhat in size and colouring.

165 Musophaga.

Gen. 12. Musophaga, *Plantain-eater*.

166 Characters. Bill strong, triangular, the upper mandible at the base elevated above the crown, both mandibles dentated on edges; nostrils in the middle of the bill; tongue entire and stout; toes placed three before and one behind.

167 Violacea. *Violet plantain-eater.*—Bill one inch and a half; the upper mandible nearly triangular, losing its attachment at the back part, and hanging over the crown; colour of the bill yellow, and reddish towards the end; irides brown; top of the head purple; neck, breast, body and wings violet; legs dusky-black, and very strong. This beautiful and rare bird is found on plains near the borders of rivers, in the province of Acra, in Guinea, and is said to live principally on the fruit of the plantain. Its total length is nineteen inches, of which the tail is six inches and one-third. It is described and figured in Latham's second supplement. Picæ.

Gen. 13. Glaucopis, *Wattle-bird*. 168 Glaucopis.

Bill incurvated, arched, the lower mandible shortest, with a caruncle below at the base; nostrils depressed, and half covered with a membrane nearly cartilaginous, cut at the point, and fringed; feet gressorial. 169 Characters.

Cinereous wattle-bird.—Body, bill, and legs black; caruncle first blue, then orange; irides blue, and very large; tail long and wedged; legs long; hind claws longer than the rest. Fifteen inches long; about the size of a jay. Inhabits New Zealand, where it is often seen walking on the ground, and sometimes, though more rarely, perching on treets. It feeds on various kinds of berries and insects, and even, according to some, on small birds. Its note approaches to whistling, and sometimes to a sort of murmuring that is not unpleasant. Its flesh is eatable, and by some esteemed savoury. 170 Cinerea.

Gen. 14. Corvus, *Crow*. 171 Corvus.

Bill strong, upper mandible a little convex, edges cultrated, and in most species, slightly notched near the tip; nostrils covered with bristles reflected over them; tongue divided at the end; toes, three forward, one backward, the middle one joined to the outer as far as the first joint. 172 Characters.

The greater number of this tribe are found in every climate. They are prolific, social, and clamorous; building on trees; laying six eggs; and living on grain, seeds, insects, &c. Some of them are apparently hurtful to agriculture; but their use in diminishing noxious vermin more than counterbalances the waste which they occasion.

Raven.—Black; back of a blueish-black; tail nearly rounded. Two feet two inches long. Varies with a few scattered white feathers, or is black and white, or entirely white. A well-known bird, a native of Europe, Asia, and America. Is hardy, cunning, voracious, and yet patient of hunger. Preys on young ducks and chickens, and even destroys young lambs and sickly sheep, by first picking out their eyes. Smells carrion at a great distance; gluts itself when an opportunity offers, retires to digest, and returns again to feed. Though easily domesticated, and taught to speak, it has a mischievous trick of purloining any thing glittering, and concealing it. "We have been assured (says Mr Montagu), by a gentleman of veracity, that his butler having missed a great many silver spoons and other articles, without being able to detect the thief for some time, at last observed a tame raven with one in his mouth, and watched him to his hiding place, where he found more than a dozen." The raven usually makes choice of the forks of the largest trees to build in; but many of them likewise breed on rocky coasts, and nestle in the most inaccessible parts of them. At this time they are very bold, and will not allow even the falcon to approach their nest with impunity. The male and female pair for life, and drive their young from their haunt, as soon as they are able to provide for themselves. The female lays five or six eggs of a blu- 173 Corax.

ish-green

Picæ. ish-green colour, blotched and spotted with brown and ash-colour, and somewhat larger than those of a crow.

174 Coronæ. *Carrion crow.*—Bluish-black; tail rounded; tail feathers acute. Varied with spottings of white, or entirely white; bill black, irides dusky, legs black. Distinguished from the rook by the bill, which is rather more convex towards the end, and by the reflected bristles at the base being always perfect. These marks, however, are obvious only in adults, and in young birds, the note is the only criterion, which in this is much more hoarse than that of the rook. This species weighs about nineteen ounces, and is eighteen inches long. It feeds on flesh, insects, and grain, but is particularly fond of carrion. It frequently attacks the eyes of dying animals, destroys weakly lambs, and when pressed with hunger, will even pursue birds on wing. It likewise makes havock among young game and poultry. It will frequently hide its food till hunger becomes more urgent. With the lesser species of hawks it wages constant war; nor will it suffer the kite, the buzzard, or the raven, to approach its nest with impunity. Carrion crows keep in pairs all the year, and seldom congregate but to regale on some carcase, or to roost in winter. They build in woods, on the branches of trees, making a nest of sticks, plastered with earth, and lined with some soft materials, as wool and hair. The eggs are four or five in number, of a greenish colour, spotted with dusky and ash.

175 Frugilegus. *Rook.*—Black; fore part of the head cinereous; tail somewhat rounded. Very like the preceding; but differs in its manners, being content with feeding on the insect tribe and grain. It is particularly fond of what is commonly called the *grub-worm*, which is the larva of the chaffer. The rook is gregarious at all seasons, resorting every spring to breed on the same trees, where their nests may be seen crowded one over another, on the upper branches. It lays four or five eggs, much like those of the crow. After their young have taken wing, they all forsake their nest-trees, but return to them again in October, to roost. On the approach of winter, they usually seek some more sheltered situation at night, but generally assemble first in the usual place, and then fly off together. Rookeries are sometimes the scene of violent contests between the old and new inhabitants An unfortunate couple of strangers will sometimes have their half-built nests torn in pieces, and be compelled to begin their work anew in some more undisturbed situation. "Of this (says Mr Bewick) we had a remarkable instance in Newcastle. In the year 1783, a pair of rooks, after an unsuccessful attempt to establish themselves in a rookery at no great distance from the exchange, were compelled to abandon the attempt. They took refuge on the spire of that building, and although constantly interrupted by other rooks, built their nest on the top of the vane, and brought forth their young, undisturbed by the noise of the populace below them; the nest and its inhabitants turning about with every change of the wind. They returned and built their nest every year on the same place till 1793, soon after which the spire was taken down." In England, rooks remain during the whole year; but both in France and Silesia they migrate. It is a singular circumstance, that the island of Jersey should be entirely without rooks; particularly when we know that they frequently fly over from Britain to France. The young birds, when skinned, and made into pyes, are much in request at some tables, but are nevertheless coarse eating.

176 Cornix. *Hooded crow*, or *royston crow.*—Ash-coloured; head, throat, wings, and tail black. Length twenty-one inches. Visits the south of England in October, and retires north to breed, in the beginning af April. In the Hebrides, and some parts of Scotland and Ireland, it is resident throughout the year. In open champaign districts, it feeds on grain, worms, and carrion; but it often resorts to the neighbourhood of the sea coast, where the various animal matters thrown up by the tide, afford a constant supply of food. It not only picks out the eyes of lambs and diseased sheep, but of horses, when entangled in bogs. The nest and eggs are similar to those of the common crow. It is not uncommon in many parts of Europe and Siberia.

177 Monedula. *Jackdaw.*—Brownish black; hind part of the head hoary; front, wings, and tail, black. Its varieties are, a white collar round the nack; white, with a yellowish bill; bright black, and eyes surrounded with white dots; black, with bill and legs red; wings white, bill somewhat curved; brownish, with white shoulders, &c. Weighs about nine ounces; length near thirteen inches. This very common bird frequents old towers, ruined buildings, and high cliffs, where it builds, as well as in holes of trees. The nest is made of sticks, and lined with wool and other soft materials; the eggs are five or six, and bluish, spotted with black. The jackdaw is gregarious, frequently flocks with rooks, and like the latter, feeds on grain and insects, is fond of cherries, and will devour carrion in severe weather. It is frequently seen to perch on the back of sheep, not only to rob that animal of its wool, as a lining to its nest, but also to pick out the ticks with which it is infested. Though easily made tame, and taught to speak, it is mischievous, and full of tricks.

178 Glandarius. *Jay.*—Wing-coverts blue, with white and black transverse lines; body variegated with purple and gray. This beautiful bird is very common in Great Britain, and in various parts of Europe and Siberia; frequenting wooded tracts, but not in flocks. It weighs seven ounces, and measures nearly thirteen inches in length. The nest, which is commonly built in high coppice wood, or hedges, and sometimes against the sides of a scrubby tree, is formed of sticks, lined with fibrous roots, and contains five or six eggs, of a light brown colour, not very unlike those of the partridge, but smaller, and obscurely marked with a darker shade of brown. The jay is a great devourer of fruit and grain, particularly acorns, peas, and cherries; will frequently plunder the nests of smaller birds of their eggs and young, and sometimes pounce on the old birds, on which it preys, as well as on mice. Its common notes are various, but harsh, and manifest a singular propensity to imitation and mimicry, counterfeiting the bleating of a lamb, the mewing of a cat, the cry of a kite or buzzard, the hooting of an owl, the neighing of a horse, &c. It has even been known to imitate very exactly the sound made by the action of a saw.

179 Cristatus. *Blue jay.*—Blue; collar black; wing-coverts with transverse black lines; crest blue; cheeks, chin, and belly, white; breast pale red; back pale purple; tail long, wedged, with black and blue lines, and tipt with white; legs black. Eleven inches long; inhabits North

Pica. North America; is gregarious; builds in marshy places; has a pleasant note; feeds on worms, serpents, chesnuts, &c. and is particularly destructive to the maize fields.

180 *Caryocatactes.* *Nut-cracker.*—Brown, dotted with white; wings and tail black; tail feathers black at the tip, the middle ones as if worn. Body with triangular white spots; vent white; crown and tail feathers without spots; feathers of the nostrils sometimes wanting; tongue bicuspidate. Length thirteen inches; size of a magpie. Inhabits Europe and Siberia, but is very rare in England. Its favourite food seems to be the kernels of nuts, which it hacks or splits with its bill.

181 *Pica.* *Magpie.*—Variegated black and white; tail wedged. Subject to considerable varieties. About eighteen inches long, and weighs between eight and nine ounces. Too well known to require particular description, being a common inhabitant of many parts of Europe, Asia, and America. Generally continues in pairs through the year; is mischievous and clamorous, and has a very indiscriminate appetite, rejecting hardly any species of animal food, or fruits, and devouring grain, when nothing else can be got. Is crafty and familiar; may be taught to pronounce words, and even short sentences, and will imitate any particular noise which it hears. Like other birds of its kind, is addicted to pilfering, and will hoard its provisions. The female builds her nest with great art, leaving a hole in the side for her admittance, and covering all the upper part with thorny branches, closely entangled, so as to secure her retreat from the rude attacks of other birds. The inside is furnished with a sort of mattress composed of wool, and other soft materials. She lays seven or eight eggs, of a pale green colour, spotted with black. During winter nights, magpies assemble in great numbers in some coppice or thicket, to roost, but separate again in the day.

182 *Mexicanus* *Mexican crow.*—Entirely bluish black. Bill, legs, and claws black. Size of the jackdaw. Inhabits New Spain, frequenting the neighbourhood of towns, and perpetually chattering with a strong and sounding voice.

183 *Pyrrhocorax.* *Alpine crow.*—Blackish; bill pale yellow, legs black. Size of the jackdaw; length fifteen inches. Inhabits the Alps and Pyrenees; has a sharp, disagreeable voice; lives on seeds and grain, and is injurious to corn fields. Its flesh is good eating.

184 *Graculus.* *Red-legged crow*, or *Cornish chough.*—Violet blackish; bill and legs red. Weighs about fourteen ounces; length nearly seventeen inches. Inhabits the Alps, Norway, England, Egypt, and Persia. In this island, it seems to be chiefly confined to Devonshire, Cornwall, and Wales. Mr Pennant observes, that it is also found in some parts of Scotland and the Hebrides. It is seldom seen at any great distance from the sea coast, where it breeds in the rocks and caverns, and not unfrequently in ruined towers. The nest is composed of sticks, and lined with a great quantity of wool and hair. The eggs are generally five, of a dull white, sprinkled with light brown and ash-coloured spots, mostly at the larger end. The note of the Cornish chough is somewhat like that of the jackdaw, but more shrill. Its food is grain and insects, though, in a state of confinement, it will greedily feed on flesh. It is easily tamed, but crafty, and will hide not only part of its food, but things of value. It is even alleged, that houses have been set on fire by its carrying off lighted sticks in its bill.

Gen. 15. Coracias, *Roller.*

Pica.

Bill sharp-edged, bent in at the point, base naked of feathers; tongue cartilaginous, and bifid; legs short; feet gressorial; toes three before, and one behind, divided to their origin. 185 Coracias. 186 Characters.

This genus is not confined to any particular region of the globe, as one or other of the different species may be met with in each of the four quarters of the world.

Common or *garrulous roller.*—Blue; back red; flag-feathers black.—The only species that has ever been met with in England, and that very rarely. Length twelve inches and a half; size of a jay. Vies with some of the parrots, in its shades of blue and green, mixed with white, heightened by the contrast of graver colours. It is wilder than the jay; frequents the thickest woods, and builds its nest chiefly on birch trees. It is plentiful in Germany, Sicily, and Malta, where they are sold in the markets and poulterers shops. It feeds on frogs, beetles, acorns, grain, and fruit, and in cases of necessity will even eat carrion. It is remarkable for making a chattering kind of noise. Its flesh tastes like that of a turtle. 187 Garrula.

Long-tailed roller.—Bill blackish, one inch and a half long; hind parts of the head green; upper parts of the back and scapulars fulvous glossed with green; lower part of the back, rump, and wing coverts, fine blue; upper tail coverts blue green; two middle feathers of the tail deep green, rest blue green; outer ones on each side twice the length of the others, and the projecting part deep blue; the shafts of all black; legs gray; claws blackish. Inhabits Angola. 188 Caudata. Plate CCCXCIV. fig. 1.

Docile or *tame roller.*—White, interspersed with reddish, bay beneath; legs yellow; tail feathers black, tipt with white; bill yellow; claws flesh-colour. Size of a jackdaw. Inhabits Persia; and has obtained its name from imitating the words and actions of those around it. 189 Docilis.

Noisy roller.—Black; patch on the wings; vent, base, and tip of the tail white. This species is very numerous at Norfolk island; and is very clamorous, especially at night. It is a very foolish bird; running after any person, and allowing itself to be knocked down with a stick. It is about nineteen inches long, and rather bigger than a jackdaw. 190 Strepera.

Gen. 16. Oriolus, *Oriole.* 191 Oriolus.

Bill conical, convex, very acute and straight; upper manible somewhat longer than the under, and slightly emarginated; tongue bifid and acute; feet gressorial. 192 Characters.

The birds of this genus are gregarious, noisy, numerous, voracious, and great devourers of corn. They chiefly inhabit America, and often build pendulous nests. The only European species, which also inhabits Asia and Africa, is the

Golden oriole, or *golden thrush.*—Pale yellow; lores and limbs black; outer tail feathers yellow on the hind part; bill and irides yellow; legs plumbeous. Nine inches and a half long. Inhabits Europe, Asia, and Africa; and is incident to several varieties. It is by no means uncommon in France, where it summers and breeds. Its nest is in the shape of a purse, fastened to the extreme divarications 193 Galbula.

divarications of the outmost twigs of tall trees, and composed of fibres of hemp, or straw, mixed with fine dry stalks of grass, and lined within with moss and lichens. The female lays four or five eggs of a dirty white, marked with small brown spots. She sits three weeks, and will not unfrequently suffer herself to be taken with the eggs and nest, and continue to sit on them in a cage, till she dies. The golden oriole is partial to grapes, figs, cherries, berries, and insects. It has a loud cry. Its flesh is reckoned good eating.

194 Picus. *Climbing oriole.*—Tawney; head, neck, and breast spotted with white; tail rounded; bill yellowish gray; legs blackish. Seven inches long. Inhabits Guiana, among trees, which it climbs like a pie, and picks out insects from under the bark.

195 Icterus. *Icteric oriole.*—Tawney; head, throat, back, quill and tail feathers, black; wings with a white spot; bill mostly black, with a brown base; irides yellowish; legs sometimes black and sometimes lead coloured, or gray white. Nine inches and a half long. Inhabits the warmer parts of America and the Carribee islands. Domesticated for the purpose of killing insects. In its wild state it is very agile and bold. It builds a large cylindrical nest, suspended to the end of a twig of a tree, with a view to defend its young from the attacks of snakes and other animals. Of these nests several may sometimes be seen near to one another, and not far from houses.

196 Phæniceus. *Red-winged oriole.*—Black; wing coverts tawney. Size of a starling; length from eight to nine inches. Occurs in Mexico, the Carolinas, Virginia, and as far as New York. Builds a thick pensile nest among reeds, or between the forks of trees, three or four feet from the ground, along with other birds, in the swamps, which are seldom accessible by man. In Louisiana these birds appear only in winter, and sometimes in such immense flocks, that three hundred or more are taken at one draught of the net. These nets are spread on some bare smooth path, at the side of a wood, with rice strewed to decoy the birds. To secure the multitudes that are caught, it is often necessary to knock most of them on the head upon the spot. Their common name in America is *maize-thief*, which they have acquired from the circumstance of their pecking a hole in the plant when green, and so destroying it.

197 Americanus. *Red-breasted oriole*, or *mocking-bird of Guiana.*—Black; chin, throat, breast, and upper corner of the wings red. Seven inches long, less than a blackbird. Inhabits Guiana and Cayenne; sings pleasantly, and imitates the notes of many other birds. The nest, which is built of hay, &c. is long, cylindrical, twelve or fifteen inches in circumference, and hangs from the high branches of the tallest trees.

198 Persicus. *Black and yellow oriole.*—Black; hind part of the back, spot on the wing-coverts, and base of the tail feathers, yellow. There are, however, several varieties. Bigger than a blackbird. Inhabits South America; forms a pendent nest, shaped like an alembic: four hundred of which may sometimes be seen together, hanging from the extreme branches of trees. The eggs are dirty white, with small pale brown spots.

199 Baltimorus. *Baltimore oriole*, or *Baltimore bird.*—Blackish; the under parts of the body, and band on the wings tawney; bill lead colour; greater wing coverts black, tipt with white; first quill feathers dirty white, edged with white; two middle tail feathers black, the rest black on the lower part, and orange above. These birds are found in many parts of America, the northern regions of which they occupy in summer, advancing even to Montreal in May, and returning southward in winter, which accounts for their appearance in Maryland and Virginia at that time. They make their nest of a soft downy matter, in the shape of a purse, tying it with threads to the extreme forks of the twigs of the tulip, plane, and hiccory trees. The country people call them *fire-birds*; and indeed, when in high plumage, their motions from branch to branch not unaptly resemble a flash of fire.

Weaver oriole.—Yellow; head brown, with a shade of golden; quill and tail feathers blackish, edged with orange. Inhabits near the Senegal; size of the golden oriole. "In the cage where these birds were kept (says Dr Latham), it was observed, that they entwined some of the stalks of the pimpernel, with which they were fed, in the wires; as this seemed to shew a disposition of making a nest, some rush-stalks were put into the cage; on which they presently made a nest large enough to hide one of them at least; but it was as often deranged as made, the work of one day being spoiled the next; serving to shew that the fabrication of the nest in a state of nature was the work of both male and female, and in all probability is finished by the last. They had a sharp but lively note. 200 Textor.

"A friend of mine described a bird to me, which he saw at the house of an acquaintance, which seemed to be this very bird. By accident having got a bit of sewing silk, it wove it among the wires of the cage, on which, more being put to it, it interlaced the whole very confusedly, so as to hinder most part of that side of the cage from being seen through. It was found to prefer green and yellow to any other coloured silk."

Banana oriole.—Tawney; head and breast chesnut; back, quill, and tail feathers, black. Seven inches long. Inhabits South America and the West India islands. Makes a nest of a curious construction, composed of fibres and leaves, exactly in the shape of the fourth part of a globe, sewed with great art under a leaf of a banana tree, in such a manner that the leaf forms one side of the nest. 201 Banana.

Hang-nest oriole, American hang-nest, Spanish nightingale, &c.—Frontlet and wreath black; crown, neck, back, and tail, reddish-brown; breast and belly tawney yellow. Inhabits the woods in Jamaica; sings sweetly; and builds a pendulous nest of stalks or thready moss, on the extreme branch of a high tree. 202 Nidipendulus.

Gen. 17. GRACULA, *Grakle*. 203 GRACULA.

Bill convex, sharp-edged, somewhat naked at the base; tongue entire, somewhat sharp, fleshy; feet formed for walking. 204 Characters.

All the species are extra-European; have a thick bill, compressed at the sides, with small nostrils at the base, and sharp hooked claws; the middle toe of the fore-feet connected at the base to the outer.

Minor, or *religious grakle.*—Violet black; spot on the wings white; hind-head with a yellow naked band. Size of a blackbird; length ten inches and a half. Inhabits 205 Religiosa.

Picæ. habits various parts of the East Indies; is very fond of cherries and grapes; and can be easily trained to whistle, sing, or speak.

206 Barita. *Boat-tailed grakle.*—Grayish; shoulders blue; quill feathers green on the outside. Size of a cuckoo, nearly thirteen inches long. The folding up of the tail feathers, instead of forming a plane surface at top, sinks into a hollow, like a deep gutter, which singularity is manifest only when the bird is flying, or perched, for when on the ground, it always carries its tail expanded. It inhabits Jamaica and North America, keeping company with the maize-thief and red-winged oriole. It feeds on maize, the fruit of the banana, &c. as well as on beetles and other insects.

207 Quiscala. *Purple grakle.*—Violet black; tail rounded. Upwards of thirteen inches long, though the female measures only eleven and a half. Inhabits Mexico, the warm parts of America, and Jamaica; sings sweetly; feeds on all kinds of grain, and makes great havock in the maize plantations. It lays five or six bluish eggs, with black stripes and spots.

208 Paradisea.

Gen. 18. Paradisea, *Bird of Paradise.*

209 Characters. Bill covered with a belt of downy feathers at the base; feathers of the sides very long; two of the tail feathers naked. Legs and feet very large and strong; three toes forward, one backward, the middle connected to the outer one as far as the first joint.

The birds of this genus, till lately, were very imperfectly known, and had given rise to various idle tales, such as their never alighting on the ground from their birth to their death; their living entirely on dew; their being produced without legs, &c. The circumstance which led to the last-mentioned error, was merely accidental; the legs and coarser parts of the wings having been pulled off in the course of preparing the birds for an ornamental article of dress. Though the birds of paradise occur in Japan, China, Persia, and various parts of India, they are believed to be properly natives of New Guinea, where they breed. The Dutch get them chiefly from Banda, where the story of their want of legs has been propagated, in order to enhance their value.

210 Apoda. *Great bird of Paradise.*—Feathers of the hypochondria longer than the body; the two intermediate tail feathers long and setaceous; the size of the body scarcely exceeds that of a thrush, though the plumage would indicate a bird as large as a pigeon; the length from the end of the bill to that of the tail is twelve inches and a half; the bill is greenish yellow, and an inch and a half long; the eyes are very small; the head, which is also small in proportion to the bird, as well as the throat and neck are covered with very short, dense, stiff feathers, of which those on the head and hind part of the neck are of a pale gold colour; the base of the bill is surrounded with black feathers, appearing like velvet, and changing in different lights to green; the fore part of the neck is golden green; the lower part of the neck behind the back, wings, and tail, are chesnut; the breast is of a deep chesnut, verging to purple; from under the wings proceeds a great quantity of feathers, with the webs so loose, as to appear like a herring-bone, some of them nearly eighteen inches long, some chesnut and purplish, others yellowish, and a few almost white; from the rump arise two feathers without webs, except for four inches next the base, and the same at the tips; the legs are stout and of a brown colour. These birds are found in the Molucca islands, and those surrounding New Guinea, particularly in Aroo, where they arrive with the westerly or dry monsoon, and whence they return to New Guinea, when the easterly or wet monsoon sets in. They are seen going and returning in flights of thirty or forty, conducted by a leader, which flies higher than the rest. During this flight they cry like starlings. By a sudden shifting of the wind, their long scapular feathers are sometimes so dishevelled as to preclude flying, when they fall to the ground, or are lost in the water. In the former case they cannot rise again into the air, without gaining an eminence, and are secured by the natives, and killed on the spot, as they cannot be preserved alive by art. They are likewise caught with bird-lime, or shot with blunt arrows, or intoxicated with the berries of *menispermum cocculus* put into the water which they are accustomed to drink. Their real food is not known with certainty. According to some, they feed on the red berries of the *waringa tree* (*ficus benjamina*), according to others, they are particularly fond of nutmegs; some assert that they live on large butterflies, and others, that they chase and devour small birds. It is only for ornament that they are coveted by such of the inhabitants of the east as are able to purchase them, the chiefs of the country wearing them constantly in their turbans. The grandees of Persia, Surat, and the East Indies, use them as aigrettes, and even adorn their horses with them. There is a lesser variety of this species, found in the Papua islands. 211

King's bird of Paradise, or *king's bird.*—Chesnut purple, whitish beneath; two middle tail-feathers filiform, feathered, and semilunar at the tips; breast bluish; cirri of the tail very long; feathers under the wings longer than the rest; tail short, truncate; from five to seven inches long, and about the size of a lark. It is said not to associate with any others of the bird of paradise, but shifts solitary from bush to bush in quest of red berries, and never gets on tall trees. It occurs in the islands of the Indian ocean, and returns to New Guinea in the rainy season, but is much more scarce than the preceding. Regia. 212

Magnificent bird of Paradise.—Chesnut brown above; chin green, with golden lunules; crown with a tuft of yellow feathers; first quill-feathers brown, secondary deep yellow; middle tail-feathers very long, with a very short fringe; legs and bill yellow, and the latter black at the tip and base. A singular and beautiful species, figured in Latham's Synopsis. Magnifica. 213

Gorget bird of Paradise.—Black, slight green beneath; hind head, nape, crown, and band on the middle of the belly fine green, a splendid gold-coloured crescent under the chin; tail feathers 12, unequal, the outer ones five inches long, and the two in the middle 22. Twenty-eight inches long. Figured in Latham's Synopsis. Nigra. 214

Superb bird of Paradise.—Crested; head, crown, and belly green; chin violet, silky; wings black; tail with a shade of green; bill black; legs brown; under the wings a tuft of loose, black, silky feathers, as long as the wings when folded. Eight inches and eight lines long. Native of the northern parts of New Guinea. Superba.

White

Picæ. *White bird of Paradise.*—Entirely white. Inhabits the Papuan islands, and is very rare.

215 Alba.

216 Trogon.

Gen. 19. Trogon, *Curucui.*

217 Characters. Bill shorter than the head, sharp-edged, hooked; mandibles serrated at the edge; feet scansorial; body long; nostrils covered with bristles; feet short, woolly; tail very long, consisting of 12 feathers.

The birds of this genus are all inhabitants of the tropical regions, and mostly inhabit South America. They live solitary, in the thickest recesses of moist woods, sitting and building on the lower branches of trees. They take but a short flight, and feed on insects and fruit. As they differ much in appearance, in different stages of life, a considerable degree of confusion has prevailed in the illustration of the species. They have the name of *curucui* from their note.

218 Curucui. *Red-bellied curucui.*—Of a greenish-gold colour, tawney beneath; throat black; lateral tail feathers, with white and black bars, the middle ones tipt with black. Somewhat less than a magpie; length 10 inches and a half. Inhabits Mexico, Brazil, and Peru. There are two or three varieties. At pairing time, only two or three are found together; and the male has a kind of melancholy note, by which their haunts are discovered. They begin to pair in April, and build in the hole of a rotten tree, laying three or four white eggs, about as big as those of a pigeon, on the bare rotten dust. During the incubation of the female, the male takes care to provide food for her, and to beguile the time by his song. The parents feed the young with small worms, caterpillars, and insects; and, when their nurslings are able to shift for themselves, they forsake them, and return to their solitary haunts, till nature prompts them to produce their second brood in August or September. Various attempts have been made, but without effect, to domesticate this species, as it obstinately refuses food, when in confinement.

219 Bucco.

Gen. 20. Bucco, *Barbet.*

220 Characters. Bill cultrated, compressed laterally; apex emarginated on both sides, and incurved, gape reaching below the eyes; nostrils covered with recumbent feathers; feet scansorial; bill strong, somewhat straight, almost covered with bristles; tail feathers usually ten.

The birds of this genus are all inhabitants of Africa, and the warmer parts of Asia and America, and are a dull and stupid race.

221 Tamatia. *Spotted-bellied barbet.*—Tawney brown, tawney white, spotted with black beneath; chin tawney; neck with a tawney lunule varied with black, a black spot behind the eyes; head very large; bill black; crown and front tawneyish; legs black. This bird occurs both at Cayenne and Brazil. It is clumsy, solitary, silent, and pensive, affecting only such places as are farthest from habitations, generally in the woods, where it chooses some low branch, well covered with twigs and foliage, on which it perches, with its large head resting between its shoulders for a long time together, allowing itself to be shot at several times before it makes its escape. It feeds on insects, particularly large beetles.

222 Elegans. *Beautiful barbet.*—Green; head and chin red, edged with blue; quill feathers brown, throat and breast yellow, the latter spotted with red; belly yellow, spotted with green; bill, legs, and claws cinereous, the latter tipt with yellow; a blue streak on each side of the mouth; tail wedged; quill feathers edged with green. Size of a sparrow, nearly six inches long. Inhabits the country of Maynas, on the borders of the Amazons, and is the most beautiful and active of the tribe. Picæ.

Gen. 21. Cuculus, *Cuckoo.* 223 Cuculus.

Bill smooth, weak, a little curved; nostrils bounded by a small rim; tongue arrowed, short, and pointed; feet scansorial. 224 Characters.

Of upwards of 50 species belonging to this genus, the first mentioned only is a native of Great Britain; and very few of the others are natives of Europe.

Common cuckoo.—Cinereous, whitish beneath, transversely streaked with brown; tail rounded, blackish, dotted with white; edges of the eyelids, opening of the mouth and palate saffron; when young, the whole body is brownish, the feathers edged with white; the upper part of the body is sometimes varied with reddish. It likewise occurs with wavings of gray; a double row of white dots on the middle tail feathers, and the bill, orbits, and legs of a sulphur colour. Size of the turtle dove; 14 inches long, and weighs about four ounces and a half. The female is rather less, and, in general, differs from the other sex, in the neck and breast being of a tawneyish brown, barred with dusky, and the wing-coverts marked with light ferruginous spots. Inhabits Europe, Asia, and Africa.—This well-known bird comes to us early in the spring, and almost invariably leaves us by the first of July, though the females may sometimes remain a little later, till they have deposited all their eggs. Such as are seen about the latter end of September or beginning of October, are the young of that year, or stragglers which have been wounded. The singular note of the male has given rise to the name of this bird, in most languages; the female is either silent, or makes only a chattering noise. Cuckoos build no nest, and what is more extraordinary, the female deposits her solitary egg in the nest of another bird, by which it is hatched. The nest which she selects for this purpose is usually that of the hedge sparrow, though sometimes also that of the water-wagtail, tit-lark, yellow hammer, green linnet, &c. Dr Jenner, in his valuable communication to the Royal Society, published in the second part of the 78th volume of their Transactions, observes, that while the hedge sparrow is laying her eggs, which generally takes up four or five days, the cuckoo contrives to deposit her egg among the rest, leaving the future care of it entirely to the hedge sparrow. This intrusion often occasions some discomposure, for the old hedge sparrow at intervals, while she is sitting, not only throws out some of her own eggs, but sometimes injures them in such a way, that they become addle; so that it frequently happens that not more than two or three of the parent bird's eggs are hatched with that of the cuckoo: and, what is very remarkable, it has never been observed, that the hedge sparrow has either thrown out or injured the egg of the cuckoo. When the hedge sparrow has sat her usual time, and has disengaged the young cuckoo and some of her own offspring from the shell, her own young ones, and any of her eggs that remain unhatched, are soon turned out; the young

225 Canorus.

Picæ. young cuckoo then remains in full possession of the nest, and is the sole object of the future care of its foster-parent. "The mode of accomplishing this (says the ingenious and interesting inquirer, in reporting his observations on a particular case), was curious; the little animal, with the assistance of its rump and wings, contrived to get the bird upon its back, and making a lodgement for its burden, by elevating its elbows, clambered backwards with it up the side of the nest till it reached the top, where, resting for a moment, it threw off its load with a jerk, and quite disengaged it from the nest. After remaining a short time in this situation, and feeling about with the extremities of its wings, as if to be convinced that the business was properly executed, it dropped into the nest again." Dr Jenner made several experiments in different nests, by repeatedly putting in an egg to the young cuckoo, which he always found to be disposed of in the same manner. But we are reluctantly compelled to withhold various other interesting details relative to this subject, and to refer our readers to the original communication. The young birds are observed to be helpless and foolish for a great length of time, but are capable of being tamed, and, when in confinement, will eat bread and milk, fruits, insects, eggs, and flesh, either cooked or raw; but, in a state of nature, they live chiefly on caterpillars and insects.

226 *Vetula.* *Long-billed rain cuckoo.*—Tail wedged; body brownish, testaceous beneath; eyelids red. Rather bigger than a blackbird. Inhabits woods and shrubberies in Jamaica, is easily tamed, flies short, sings before rain, and feeds on grains, insects, worms, small serpents, frogs, lizards, and small birds.

227 *Pluvialis.* *Rain cuckoo.*—Olive ash, rufous beneath; chin and throat white; outer tail-feathers edged with white. From 16 to 17 inches long, like the preceding. Inhabits Jamaica, and sings before rain. Both species are familiarly known by the names of *old man*, and *rain bird*.

228 *Ridibundus.* *Laughing cuckoo.*—Tawney; chin, throat, and breast cinereous; belly, thighs, and lower tail-coverts black; bill bluish black; irides white; tail half as long as the body. Sixteen inches long. Inhabits New Spain; has a voice like a man laughing, on which account it is dreaded by the Indians as ominous.

229 *Melanoleucos.* Plate CCCXCIV. fig. 4. *Coromandel crested cuckoo.*—Upper parts of the body black; under part white; a white spot on the edge of the wing; tail wedge-shaped and tipped with white; head crested; bill black; legs brown. Length eleven inches. Inhabits the coast of Coromandel.

230 *Pisanus.* *Pisan cuckoo.*—Tail wedged; body above varied with white and black, white beneath; head black and crested; chin and breast rufous. Rather larger than the common species, and has its name from having been once caught in Pisa.

231 *Indicator.* *Bee cuckoo, honey-guide, moroc,* &c.—Rusty gray, white beneath; eyelids naked, black; shoulders with a yellow spot; tail wedged, rusty; bill brown at the base, and surrounded with bristles, yellow at the tip; feathers of the thighs white, with a longitudinal black streak; quill-feathers brown above, gray brown beneath; first tail-feathers very narrow, rusty; the next sooty, the inner edge whitish; the rest brown at the tip on the inner web. Somewhat larger than the common sparrow. Native of the interior parts of Africa. This bird is very fond of honey and bee maggots; but being unable, by its own efforts, to procure them from the hollow of trees, it points out to man and to the animal called *ratel*, the nests of wild bees. The morning and the evening are its principal meal times; at least it is then that it shews the greatest inclination to come forth, and with a grating cry of *cherr, cherr, cherr*, to excite the attention of the ratel, as well as of the Hottentots and colonists. Somebody then generally repairs to the place whence the sound proceeds, when the bird, continually repeating its cry, flies on slowly and by degrees to the quarter where the bees have taken up their abode. The persons thus invited, follow accordingly, taking great care, at the same time, not to frighten their guide by any unusual noise; but rather to answer it now and then with a very soft and gentle whistle, by way of letting the bird know, that its call is attended to. When the bees nest is at some distance, the bird often makes long stages, or flights, waiting for its sporting companions between each flight, and calling to them again to come on; but it flies to shorter distances, and repeats its cry more frequently, and with greater earnestness, in proportion as they approach nearer the nest. When the bird has sometimes, in consequence of its impatience, got too far a-head of its companions, but particularly when, on account of the unevenness of the ground, they have not been able to keep pace with it, it will fly back to meet them, and, with redoubled cries, denoting still greater impatience, upbraid them, as it were, for being so tardy. When it arrives at the nest, whether the latter is built in the cleft of a rock, or in a hollow tree, or in some cavity of the earth, it hovers over the spot for a few seconds, then sits in silence, and for the most part concealed, in some neighbouring tree or bush, in expectation of the result, and with a view of receiving its share of the booty. Nor is it disappointed; the hunters, by way of acknowledgement, leaving it a considerable portion of that part of the comb in which the bees are hatching. Mr Barrow corroborates these details, and adds, that the moroc intimates to the inhabitants, with equal certainty, the dens of lions, tigers, hyænas, and other beasts of prey, and noxious animals. Le Vaillant mentions that the Hottentots are very partial to this bird on account of its services, and that once when he was on the point of shooting one, they intreated him to spare its life. Mr Bruce, by confounding this species with another peculiar to Abyssinia, has indulged in some very misplaced strictures on the accounts of Sparrman and Lobo.

Gen. 22. Yunx. 232 Yunx.

Bill smoothish, cylindrical, pointed, a little curved, weak; nostrils concave, naked; tongue very long, smooth, worm-shaped, armed at the point; tail feathers 10, flexible; feet scansorial. 233 Character.

This genus consists of only one species, and has, by most authors, been held distinct; for, though allied to some other genera, it perfectly coincides with none. The tongue and disposition of the toes correspond to those of the woodpecker; but the weakness of the bill distinguishes it from that family. It seems also to be nearly related to the cuckoo, did not its length of tongue form a marked distinction.

Wryneck.—Gray, varied with brown, and blackish; 234 *Torquilla.* belly reddish, with blackish spots; tail-feathers waved with

with black spots, streaks, and bars. Description, however, is very inadequate to convey an accurate idea of the elegant markings of this little bird. Its name seems to have been given it from the singular manner of turning its head over its shoulder and perpetually looking about, when the black list on the back of the neck gives it a twisted appearance. The weight of this beautiful bird is about ten drams, and its length seven inches. It inhabits Europe, Asia, and Africa, appearing in Britain about the same time with the cuckoo, and chiefly frequenting woods, or thickly inclosed countries, where trees or orchards abound. Its food principally consists of ants and other insects, of which it finds great abundance lodged in the bark and crevices of trees, and which it secures by a horny substance at the end of its long tongue. It likewise frequents ant hills, into which it darts its tongue and draws out its prey. It is never seen with any other society than that of its female, and as soon as the domestic union is dissolved, which is in September, they retire and migrate by themselves. It makes an artless nest of dry grass, on dusty rotten wood, in holes of trees, and lays nine or ten eggs, which are white aud transparent. If surprised in its nest, it stretches itself at full length; and erecting the feathers on the crown of its head, suddenly rises, making, at the same time, a short hissing noise, like that of a turkey cock. In the beginning of spring, it very frequently repeats a noise like that of the smaller species of hawks.

235 Picus.

Gen. 23. Picus, *Woodpecker*.

236 Characters. Bill angular, straight, wedged at the tip; nostrils covered with recumbent setaceous feathers; tongue round, worm-shaped, very long, bony, missile, daggered, beset at the point with reflexed bristles; tail feathers ten, hard, rigid, pointed; feet scansorial.

The birds of this genus climb trees, particularly those that are decaying or dead, in search of insects and their larvæ. The bone of their tongue terminates in two long slender cartilages, which proceed from below upwards, and from behind forwards, over the whole skull, under the skin, and are attached to the forehead near the base of the bill. By means of those elastic cartilages, the woodpeckers thrust out their filiform tongue to catch insects. The feet are formed for climbing, their tail is fitted for resistance and support, and their sharp-pointed and barbed tongue enables them to extract insects from their lurking places in trees. They are therefore unjustly persecuted and driven from plantations. They make their nests in hollows of trees. They have a membranous stomach, and want the cæcum.

237 *Martius.* *Great black woodpecker*.—Black, cap vermilion. In the female the hind head only is red; length 17 inches and a half. Size of a jackdaw; bill nearly two inches and a half long, of a dark ash colour, and whitish on the sides; irides pale yellow. Has all the habits of the green woodpecker, and is a great destroyer of bees. Makes its nest deep in some tree, which it has excavated for the purpose, and lays two or three white eggs; a circumstance which seems peculiar to most of the genus. Occurs in Europe, Siberia, and Chili; but rarely visits England.

238 *Erythrocephalus.* *Red-headed woodpecker*.—Head wholly red; wings and tail black; belly white. Eight inches and three quarters long, and weighs two or three ounces. This species inhabits Virginia, Carolina, Canada; &c.; but on the approach of winter, migrates more or less to the southward, according to the severity of the season, from which circumstance the North Americans foretel the rigour or clemency of the ensuing winter. The red-headed woodpeckers are very destructive to maize fields and orchards, and are fond of acorns. During the winter, they are very tame, and sometimes come into houses, as the redbreast with us. They are found chiefly in old trees; and the noise that they make with their bills may sometimes be heard at a mile's distance.

Gold-winged woodpecker.—Striated transversely with black and gray; chin and breast black; nape red; rump white. Chin of the female cinereous; length 11 inches; weight five ounces. Inhabits North America; is almost continually on the ground; feeds on worms and insects; and, in default of these, on berries and grass. When fat, is esteemed good eating. 239 *Auratus.*

Green woodpecker.—Green; crown of the head crimson; bill dusky, two inches long; inner circle of the irides reddish; outer white; temples blackish; quill feathers dusky, with whitish spots; tail blackish, obscurely barred with green, and tipt with white; legs greenish ash. Weighs about six ounces, and is thirteen inches long. Inhabits Europe, and is by no means uncommon in the wooded parts of England. It feeds on insects, and is particularly fond of bees. It is frequently seen climbing up a tree, or on the ground, in the neighbourhood of an ant hill. The hole which they make is as perfect a circle as if it had been described by a pair of compasses. It is curious to observe them try every part of a dead limb of a tree, till they have discovered the most sonorous, and then the strokes are reiterated with such velocity, that the head is scarcely perceived to move. The softer wood, such as the elm, ash, and asp, are, for the most part, attacked, for the purpose of nidification, and are perforated only where they exhibit symptoms of decay. The excavations are often deep, to give security to the eggs, which are generally four or five, and placed on the rotten wood without any nest. 240 *Viridis.*

Downy woodpecker.—Back longitudinally downy; outer tail feathers white, with four black spots. Weighs an ounce and a half, and measures only five inches and a half in length. Inhabits Carolina, Virginia, New Jersey, &c. and is a daring bird, and dangerous to orchards. As soon as it has pecked one hole in a tree, it makes another close to the first, in a horizontal direction, proceeding till it has made a circle of holes quite round the trunk, so that the tree frequently dries up and decays. 241 *Pubescens.*

Hairy woodpecker.—Back somewhat downy, in a longitudinal direction; outer tail feathers entirely white. From nine to twelve inches long. Like the former, is the pest of orchards. Inhabits North America, from Hudson's Bay to Carolina; and likewise occurs in the north of England. 242 *Villosus.*

Greater spotted woodpecker.—Variegated with black and white; hind head and vent red. Female, without red on the hind head. The weight of this species is about two ounces and three quarters, and the length nine inches. The bill is dusky, and an inch and a quarter long; the irides are reddish brown. Inhabits Europe, North America and Siberia. It is less frequent in England than the green species, to which it is nearly allied. 243 *Major.*

Picæ. allied in manners and habits, except that it rarely descends to the ground in search of food. Lays four or five white and glossy eggs on the decayed wood, without any formal preparation of a nest.

244 Medius. *Middle spotted woodpecker.*—Variegated with white and black; vent and cap red; cheeks white; three lateral tail feathers, tipt with white. Supposed by some to be only the young of the preceding species.

245 Minor. *Lesser spotted woodpecker.*—Variegated with white and black; crown red; vent testaceous or brick-coloured. There are two or three varieties. The weight of this small species is not quite five drams; and the length is about five inches and a half. Inhabits Europe and Asia, and has the habits of the *major*; but is of more rare occurrence.

246 Minutus. *Minute woodpecker.*—Chesnut gray; whitish, waved with brown beneath; crown red; hind head black, spotted with white. Only three inches and a half long, the least of its tribe. Inhabits Cayenne.

247 Cardinalis. Plate CCCXCIV. fig. 3. *Cardinal woodpecker.*—Black; under part of the body white, spotted with black; crown and back part of the head red; wings spotted with white; legs and bill blackish. Inhabits the isle of Luzonia.

248 SITTA.

Gen. 24. SITTA, *Nuthatch.*

249 Characters. Bill subulated, roundish, unbent, projecting straight forwards, and entire; the upper mandible somewhat longer than the under, compressed at the point; tongue notched, short, and horny at the apex; nostrils small, covered with bristles; feet gressorial.

The general manners of the whole of this genus are supposed to correspond with those of the ensuing species, which is the only one that is found in Britain.

250 Europæa. *European nuthatch.*—Cinereous, reddish beneath; tail feathers black, the four lateral ones beneath tipt with white. A black line through the eyes and ears; rump white, varied with rusty; the first tail feather with a white bar, two with a white spot, three or four tipt with white, five colour of the back. Inhabits Europe and Asia. Remains in England the whole year; but is local, and chiefly affects wooded and inclosed situations, selecting the deserted habitation of a woodpecker for its nest. The hole is first contracted by a plaster of clay, leaving only sufficient room for the bird to pass in and out. The nest is made of dead leaves, especially of those of the oak, which are heaped together without much order. The number of eggs is six or seven, and they are scarcely to be distinguished from those of the great titmouse, in size and markings. If the plaster at the entrance be destroyed when there are eggs in the nest, it is speedily replaced, to prevent the intrusion of the woodpecker and other birds of superior size which build in the same situation. No persecution will force this little bird from its habitation when sitting. It defends its nest to the last extremity, strikes the invader with its bill and wings, makes a hissing noise; and, after every effort of defence has been practised in vain, will suffer itself to be taken in the hand rather than desert its charge. The nuthatch is more expert in climbing than the woodpecker; for it runs in all directions up and down a tree. When employed in breaking a nut, its favourite position is with the head downwards. In the autumn it is no uncommon thing to find, in the crevices of the bark of an old tree, a great many broken nut shells, the work of this bird, which repeatedly Picæ. returns to the same spot for this purpose. When it has fixed the nut firm in a chink, it turns on all sides, to strike it with most advantage. This, with the common hazel-nut, is a work of some labour; but it breaks a filbert with ease. In default of nuts, this bird searches for insects and their larvæ among the moss on trees and old thatched buildings. It is commonly met with among orchards, and is sometimes seen, in the cyder season, picking the seeds from the refuse of the pressed apples. In spring it has a remarkably loud, shrill whistle, which ceases after incubation, and gives place, in autumn, to a double reiterated cry. It deserves to be remarked, that the singular jarring noise produced by some species of woodpeckers, by repeated strokes of the bill against the decayed limb of a tree, has been erroneously ascribed to the nuthatch. 251

Surinam nuthatch.—Reddish chesnut, dirty white beneath; middle of the back white; wings and tail black; Surinamensis. wing and tail coverts tipt, and secondary quill feathers edged, with white. Only three inches and a half long. Inhabits Surinam.

Gen. 25. TODUS, *Tody.* 252 TODUS.

Bill subulate, somewhat depressed, obtuse, straight, covered at the base with bristles; nostrils small, oval; feet gressorial. 253 Characters.

These mostly inhabit the warmer regions of America, and are nearly related to the family of fly-catchers; but are distinguished from them by having the middle and outer toe much connected, which, in the fly-catchers, are divided to the base. 254

Green tody.—Green; yellowish rosy beneath; breast Viridis. red; upper mandible brown, lower orange; irides chesnut; cheeks with a red spot; legs and claws gray. The male, according to Buffon, has the upper part of the body of a pale blue, the belly white, the breast and sides rose colour. This pretty species, which is about the size of a wren, and four inches long, occurs not only in the warmer parts of the American continent, but also in St Domingo, Jamaica, and other islands of the West Indies. The females are not uncommon in Jamaica. It is supposed to feed on soft insects, and is of a shy solitary disposition, frequenting the lonely parts of moist tracts of country, where it is observed to sit all of a heap, its head drawn in between its shoulders, and so stupid as almost to allow itself to be taken by the hand. 255

White-headed tody.—Black; subcrested head and Leucocephalus. chin white; bill blackish; the lower mandible white, tipt with blackish; wings short; tail even. Less than the redstart. Inhabits America. Figured in Latham's Synopsis. 256

Obscure tody.—Olive brown, yellowish-white be- Obscurus. neath; crown, quill, and tail feathers blackish. Size of the hedge sparrow. Inhabits North America, where it feeds on insects. Frequents the decayed parts of trees, and has all the actions of the fly-catcher. It has an agreeable note, two or three times repeated, but not what can be called a song. 257

King tody.—Blackish brown, reddish beneath; crest Regius. chesnut, spotted with white at the tip; chin and eyelids white; bill dusky brown; breast with transverse blackish lines; legs flesh colour. This singular and beautiful species

Picæ. species measures seven inches in length. Inhabits Cayenne, and is very rare.

258 Platyrhyncos. *Broad-billed tody.*—Yellowish-brown, yellow beneath; chin and spot on the crown white; wings and tail brown; bill very large and broad. Size of the nightingale. Figured by Latham.

259 Cristatus. Plate CCCXCV. fig. 3. *Crested tody.*—Crest scarlet; body brown, spotted with white; wing coverts spotted with white; feathers of the crest tipped with black. Native of Guinea.

260 Alcedo.

Gen. 26. Alcedo, *King's-fisher.*

261 Characters. Bill triangular, thick, straight, long, and acuminated; the tongue fleshy, very short, flat, and acute; feet, for the most part, gressorial.

The birds of this genus are dispersed over the whole globe; though it is supposed that only one species inhabits Europe. Most of them frequent rivers and the vicinity of waters, and live on fish, which they catch with singular art and dexterity. Sometimes they hover over the water, where a shoal of small fishes is seen playing near the surface; at other times, they wait with attention on some low branch, hanging over the water, for the approach of a single one, which is so unlucky as to swim that way. In either case they drop like a stone, or rather dart with rapidity on their prey. They seize the latter cross-ways in their bill, retire to a resting place to feed on it, devour it piecemeal, bones and all; and afterwards bring up the indigestible parts in pellets. The wings of most of this genus are very short; yet the birds fly rapidly, and with great strength. In their colours, blue of different shades predominates. Their nostrils are small, and generally covered.

262 Cristata. Plate CCCXCV. fig. 5. *Crested king's-fisher.*—Bill black; an inch and a half long; crown feathers long, forming a crest, of a greenish colour, and barred with black; a fine blue stripe on each side of the neck; upper part of the body bright blue; upper wing coverts violet, and each feather tipped with a bright blue spot; legs and claws reddish; length nearly five inches. Inhabits Amboyna and the Philippine islands.

263 Formosa. *Splendid king's-fisher.*—Tail short; body yellowish-green; shoulders, throat, and rump yellow; wings and crown of the head blue; bill yellowish-horn colour; head with a bright yellow stripe on each side; smaller wing coverts edged with yellow; legs reddish-brown. A beautiful species, which inhabits South America.

264 Ispida. *Common king's-fisher.*—Tail short; body blue above, orange-coloured beneath; lores red; bill black; crown and wing coverts green, with blue spots; tail of a beautiful blue; irides and legs red. In the female the bill is not so long as in the other sex. Frequents running streams and rivers, in the banks of which it generally takes possession of a rat's hole to deposit its eggs. This hole is ascending, and generally two or three feet in the bank; at the end is scooped a hollow, at the bottom of which is a quantity of small fish-bones, nearly half an inch thick, mixed with the earth, and which are probably the castings of the parent bird, as they are found even before they have eggs. On this disgorged matter the female lays to the number of seven eggs, which are perfectly white and transparent, and of a short oval form. Before the young are able to fly, the hole becomes extremely fetid by the fæces of the brood, which cannot be carried away by the parent birds, as is common with most of the smaller species. As the old birds have nothing in their bill, when they go in to feed their young, it has been inferred, that they eject from the stomach for that purpose. When the young are nearly full feathered, they are extremely voracious, and may be discovered by their constant chirping. This species is reckoned the most beautiful of all the British birds, weighs one ounce and a quarter, and measures seven inches in length. It inhabits Europe, Asia, and Africa. It was formerly believed, that if the body of this bird was suspended by a thread, some magnetic influence always turned its breast to the north. This, however, is as fabulous as the tradition, that its stuffed skin will preserve woollen cloth from the depredations of moths. There is a variety found in Senegal, about six inches and a half long, blue green varied with brown above, tawney beneath, and chin yellowish.

265 Alcyon. *Belted king's-fisher.*—Tail long, crested, bluish; belly white; breast ferruginous; a white spot before and behind the eyes; bill black; chin white; breast with a ferruginous band on the fore part; thighs rusty; shanks very short; legs brown; outer toe connected with the middle toe. Eleven inches long. Inhabits Carolina, and feeds on lizards and fish. It is subject to several permanent varieties, which occur in different parts of America.

266 Amazona. *Amazonian king's-fisher.*—Glossy green; under parts of the body and lunule on the neck white; sides variegated with green; tail spotted with white; bill and legs black. Thirteen inches long. Inhabits Cayenne.

267 Tuta. *Respected king's-fisher.*—Tail long; body olive above, white beneath; eyebrows white; collar greenish black. Bill black; lower mandible white. Legs black. Eight inches and a half long. Native of the Society islands, where it is held sacred by the inhabitants, as are the species denominated *venerata* and *sacra.*

268 Fusca. *Great brown king's fisher*—Crested, olive above, whitish and obscurely striated beneath; temples and hind head dirty white; tail rounded with rusty and steel-blue lines, and tipt with white. The female has no crest. Eighteen inches long. Inhabits New Guinea.

269 Cancrophaga. *Crab-eating king's fisher.*—Tail long; body blue-green, yellowish-tawney beneath; band through the eyes; wing coverts and tips of the quill-feathers black. Twelve inches long. Inhabits Senegal, and feeds on crabs.

270 Egyptia. *Egyptian king's-fisher.*—Brown, with rusty spots; whitish, with cinereous spots beneath. Size of the Royston crow. Inhabits Lower Egypt, about Cairo; builds in sycamore and date trees, and feeds on frogs, insects, and small fish, which last it meets with in the fields when they are flooded. Its cry approaches to that of the common crow.

271 Galbula.

Gen. 27. Galbula, *Jacamar.*

272 Characters. Bill straight, very long, quadrangular, pointed; nostrils oval, at the base of the bill; tongue short, sharp-pointed; thighs downy on the fore part; feet scansorial.

This is much allied to the preceding; but the toes are differently placed, namely, two before and two behind. The food of the jacamar is likewise different, as it feeds on insects alone; and, for that purpose, frequents moist woods.

Picæ. woods. Only four species have been described, and scarcely any information has hitherto been obtained relative to their economy and manners.

273 Grandis. *Great jacamar.*—Copper gold above, ferruginous beneath; head and limbs green gold; tail wedged, and longer than the body. Size of the green woodpecker. Native country unknown.

274 Paradisea. *Paradise jacamar.*—Two middle tail feathers very long; body golden green; throat and wings white beneath; bill and legs black; head violet brown; tail much wedged. Inhabits Cayenne and Surinam; is 11 inches and a half long; flies in pairs; is less solitary than its congeners, and feeds on insects.

275 Merops.

Gen. 28. Merops, *Bee-eater*.

276 Characters. Bill curved, quadrangular, compressed, carinated, pointed; nostrils small, at the base of the bill; tongue slender, the tip generally jagged; feet gressorial.

The birds of this genus, with a few exceptions, inhabit the old continent. Their general food is insects, and they are particularly fond of bees and wasps. They have no note beyond a whistle, and that far from agreeable. Like the king's-fisher, they breed in holes in the banks of rivers.

277 Apiaster. *Common bee-eater.*—Back ferruginous; belly and tail bluish-green; two of the tail feathers longer than the others; chin pale yellow; bill black; irides red; front blue green; crown, hind head, and neck, bay; a black streak from the bill to the hind head; tail wedged, the feathers edged inwardly with cinereous; legs chesnut; claws reddish black. A variety sometimes occurs with the bill convex and uncarinated, and the toes unconnected at the last joint. The common bee-eater measures 10 inches from bill to tail. It inhabits various parts of Europe, Asia, and Africa; and is very plentiful in the southern parts of Russia, particularly about the rivers Don and Wolga. In the third volume of the Linnean Transactions an account is given of one of this species having been shot, for the first time, in Britain, near Mattishal, in Norfolk, in July 1794. A flight of about 20 was seen in June; and the same flight, as was supposed, much diminished in number, was observed passing over the same spot in October following. They feed, on the wing, upon bees, gnats, flies, and other insects; or, in defect of these, upon seeds. Their nest is composed of moss, and the eggs, from five to seven, are perfectly white, and about the size of those of a stare. They are gregarious and migratory, quitting the colder latitudes, in great flocks, in autumn. When the sun shines on them, in their flight, they are a pleasing object, as they appear gilded. Kolben remarks, that they guide the Hottentots to the honey, which the bees lay up in the clefts of the rocks.

278 Viridis. *Indian bee-eater.*—Green; band on the breast black; chin and tail blue; two of the tail feathers longer than the others; bill and band across the eyes black; legs brown. There are several varieties. Eight inches and a half long. Inhabits India.

279 Superbus. *Superb bee-eater.*—Red; front, throat, and rump, blue; two middle tail feathers longer than the others. Nine inches long.

280 Carunculatus. *Wattled* or *New Holland bee-eater.*—Brown; belly yellow; wattles carunculated; tail wedged, tipt with white; bill black; nostrils pervious, and half covered with a membrane; crown blackish; a silvery stripe at the angle of the mouth; a long, orange, pendent caruncle behind the base of the lower mandible; legs brownish, the outer toe connected at the base to the middle one. Fourteen inches and a half long. Inhabits New Holland; is pretty numerous on the sea shores of that country; chatters incessantly; is very bold; feeds on insects, and sucks the honey from the different sorts of Banskia.

Horned or *knob-fronted bee-eater.*—Brown; head somewhat naked; under parts of the body and tips of the tail feathers whitish; a blunt short eminence, like the rudiment of a horn, on the fore head. Size of a missel thrush. This singular species also inhabits New Holland, and is well figured in White's Journal. 281 Corniculatus.

Red-winged bee-eater.—Under part of the body of an olive or dirty-white colour; throat yellow; wings and tail red, tipt with black; bill one inch long, black; legs black. Six inches long. Inhabits Senegal. 282 Erythropterus. Plate CCCXCV. fig. 1.

Gen. 29. Upupa, *Hoop*, or *Hoopoe*. 283 Upupa.

Bill arched, long, slender, convex, a little compressed, somewhat obtuse; nostrils small, at the base of the bill; tongue obtuse, entire, triangular, very short; feet gressorial. 284 Characters.

Of the species included under this genus, the first only is found in Britain. They feed on insects, haunt dunghills, and are, in general, uncleanly in their manners.

Common hoop.—Variegated with blackish and rufous white, beneath; crest pale orange, tipt with black; tail black, with a white band; bill and legs black; irides hazel; back and wings with black and white lines; neck reddish-brown; crest of a double row of feathers; tail feathers 10. The weight of this beautiful bird is about three ounces, and the length 12 inches. Inhabits Europe, Asia, and Africa; but only visits this country, occasionally, in autumn, and is very seldom known to breed with us. The female is said to have two or three broods in the year. Seldom makes a nest; but lays her eggs, which are generally four or five, bluish-white, and marked with pale brown spots, in the hollow of a tree, and sometimes in a hole of a wall, or even on the ground. Its food consists chiefly of insects of the beetle tribe. It is a solitary bird, two of them being seldom seen together. In Egypt, where they abound, they are seen only in small flocks. Its crest usually falls behind on its neck, except when it is surprised or irritated, and then it stands erect; the tail, too, being, in that case, usually erected, and spread like a fan. 285 Epops.

Grand hoop, or *grand promerops.*—Black; head, neck, and breast, glossy green; scapular and lateral tail feathers falcated; tail very long. "This most extraordinary and beautiful bird (observes Dr Latham), is near four feet in length, from the top of the bill to the end of the tail; the body is the size only of a middling pigeon, though much elongated in shape. The bill is three inches long, pretty much curved, and black; the head, hind part of the neck, and upper part of the belly, are of a shining green; the fore part of the neck, and lower part of the belly, without gloss; the scapular feathers are of a singular construction; the webs on one side of the shaft being exceeding short, and on the other of a great length; the shape of them falciform: they 286 Magna.

Picæ. they are of a purplish black colour, with the ends, for three quarters of an inch, of a most brilliant gilded glossy green, though some of them, in a different light, reflect a blue gloss; beneath each wing arises a thick tuft of feathers, eight inches and a half in length, and of a texture resembling the herring-bone ones in the *greater bird of Paradise;* and, besides these, on each side of the tail are five or six falciform feathers, with unequal webs, as the scapulars, though not half so much curved; the colour half dusky, half greenish brown; the last divided from the other colour, on each feather, in an oblique manner; the tail consists of 12 feathers, and is of an enormous length, the middle ones measuring no less than 28 inches; but each of the others shortens as it proceeds outwards, to the outer one of all, which is only five inches in length; the colour of all of them is blue black, with a polished steel gloss in some lights; the legs are black." Dr Latham has annexed a coloured figure. Little else is known of this remarkable species, except that it inhabits New Guinea.

287 Erythrorhynchos. *Red-billed hoop.*—Black green; belly black; tail wedged; six first quill and lateral tail feathers spotted with white; bill and legs red; feathers of the head and neck silky, and somewhat downy. Fifteen inches long. Inhabits Asia and Africa. Figured by Latham.

288 Certhia.

Gen. 30. Certhia, *Creeper.*

289 Characters. Bill arched, slender, somewhat triangular, pointed; tongue various, though generally pointed; feet formed for walking.

The birds of this genus are spread over the globe. They live chiefly on insects; their nostrils are small; their tail is composed of 12 feathers; their feet are large, with a large back toe; their claws are long and hooked. Most of them have an acute tongue; though in some it is flattened at the point, in others ciliated, in a few tubular. There are a considerable number of species, of which only one is a native of Britain.

290 Familiaris. *Common creeper.*—Gray; white beneath; quill feathers brown, ten of them with a white spot; head and neck brown, with black streaks; rump tawney; wing coverts varied brown and black; quill feathers dusky, tipt with white, edged and barred with tawney; breast and belly silvery; tail long, tawney, the feathers sloping off to a point. Weighs about two drams; length five inches. Inhabits Europe, Asia, and America. Runs with great facility on all sides of small branches of trees, in search of insects and their eggs, which constitute its food. Except the crested wren, it is the smallest of British birds; and though pretty common, is not seen without difficulty, from the ease with which on the appearance of any one, it escapes to the opposite side of the tree. Its nest is composed of dry grass and the inner bark of wood, loosely put together, and lined with small feathers; and it is usually constructed in some hole, or behind the bark of a decayed tree. The eggs are from six to eight, white, and minutely speckled with bright rust colour. During incubation, the female is fed by the other sex. The note of the common creeper is weak, monotonous, and deliberately uttered, but rarely heard in winter.—In North America, is found a variety of a considerably larger size.

291 Coccinea. *Hook-billed red creeper.*—Scarlet; wings and tail black; bill longer than the head, bent like a scimitar, legs and long claws blackish; tail feathers short, pointed; edges of the wings, and roots of the throat feathers, white. This beautiful species inhabits the Sandwich islands, and is much used by the natives in their feathered dresses. Picæ.

Mocking creeper.—Olive; crown inclining to violet; spot on the cheeks white; wings and subforked tail brown. Seven inches long. Inhabits New Zealand; has a very imitative voice, and sips the sweet moisture from the nectaries of flowers. 292 Sannio.

Cardinal creeper.—Black; head, neck, breast and line down the middle of the back, red; tail even. Size of the common species. Inhabits the island of Tanna, and sucks the nectaries of flowers. 293 Cardinalis.

Wall creeper, or *spider-catcher.*—Cinereous; wings with a tawney spot; bill subulate, sharp edged, longer than the head; neck whitish beneath; quill feathers black; wings with a rosy spot; tail feathers whitish; claws strong, particularly the hind one. The chin and throat of the female are white. Size of a sparrow, length six inches eight lines. Inhabits southern Europe and Asia. Is solitary; feeds on insects, and has the same manners as the common creeper, except that it haunts ruined edifices, old walls, arches, &c. and is particularly fond of spiders. According to Scopoli, it migrates singly towards the end of autumn. Its flight is vague and uncertain, and it climbs by leaps. Builds frequently in holes of walls. 294 Muraria.

Little brown and white creeper.—Brown; white beneath; eyebrows white; tail feathers brown, the outer ones white at the tip; a black streak from the bill to the eyes; quill feathers edged with a brassy hue. Three inches and a half long. Inhabits India. Feeds on flies, and is fond of honey. 295 Pusilla.

Blue creeper, or *certhia of Guiana.*—Blue; band across the eyes, chin, wings, and tail, black. Four inches long, and somewhat bigger than the common creeper. Makes its nest of dried stalks or grass, in the form of a retort, and open beneath, suspending it from the slender and extreme branches of trees, and thus securing it against the attacks of the monkey, snake, and lizard.—Varies, in having the bill and legs sometimes red. 296 Cærulea.

Collared creeper.—Glossy green; breast red, with a steel-blue bar on the fore-part. Four inches and a half long. Inhabits the Cape of Good Hope; feeds on insects and the nectar of flowers, and sings sweetly. 297 Chalybea.

Black and yellow creeper, *yellow-bellied creeper*, &c. —Black; pale yellow beneath; eyebrows whitish; outer tail feathers tipt with white. The markings, however, vary considerably. From four to five inches long. Inhabits the West Indies, and feeds principally on the juice of the sugar cane, which it draws out by insinuating its bill into any crevice or crack of the stalk. 298 Flaveola.

Braceletted creeper.—Green; wings, when folded, black above; beneath yellow; shoulders, bracelets on the thighs, and spots on the rump, sapphire blue; bill black; legs yellowish; body beneath whitish-green; vent yellowish; quill feathers black, inner edge yellow. Length five inches. Native of Surinam. 299 Armillata. Plate CCCXCIV. fig. 1.

Orange-backed creeper.—Bluish-gray; spot on the back, and under parts of the body yellow; bill and legs black; irides red. Three inches long. Inhabits China, and is remarkable for the sweetness of its song. 300 Cantillans.

Beautiful

Picæ.

301 *Pulchella* *Beautiful creeper.*—Two middle tail feathers very long; body glossy green; breast red; bill, legs, and tail feathers, blackish, the latter edged with gold; belly whitish; wings and greater coverts brown. Seven inches long. Inhabits Senegal.

302 *Famosa.* *Famous creeper.*—Two middle tail feathers very long; body glossy green; armpits yellow; lores black; bill, legs, claws, and tail black; a black line between the bill and eyes. Female green brown; yellowish beneath; breast green; two middle tail feathers shorter than in the male. Nine inches long. Inhabits the Cape of Good Hope.

303 *Lotenia.* *Loten's creeper.*—Blue; bar on the breast gold-red; lores black; bill subulate, black, twice as long as the head; tongue compressed at the tip; head, neck, back, rump, and upper tail coverts, sometimes blue, sometimes gold-green; breast, belly, and vent glossy black; in the female dirty white, spotted with black; wings black; lesser coverts violet; middle green; greater black; tail even. Upwards of five inches long. Inhabits Madagascar and Ceylon. Makes a cup-shaped nest, like that of a chaffinch, of the down of plants. The female generally lays five or six eggs. This species is sometimes chased by a very voracious spider, as large as itself, which seizes on the whole brood, and sucks the blood of the young birds.

304 Trochilus.

Gen. 31. Trochilus, *Humming bird.*

305 Characters. **Bill subulate, filiform, tubular at the tip, longer than the head; upper mandible sheathing the lower; tongue filiform, the two threads coalescing, and tubular; feet gressorial.**

The birds of this species are very small, and, with a very few exceptions, inhabit South America. Their bill and feet are weak, their nostrils minute, and their tongue is capable of being darted far out. They fly very rapidly, take their food on the wing, sucking the honey juice of flowers, and sometimes also swallowing insects, the fragments of which have been found in their stomachs. They are bold, pugnacious, and gregarious, and make a louder noise by the motion of their wings than by their voice. They construct an elegant hemispherical nest of the down of a species of thapsus, and suspend it from the branches of trees, where it is hid by the leaves, the female laying two white eggs of the size of peas, which are batched by the alternate incubation of the male and female. These minute birds are taken by aspersing them with water from a syphon, as the finest shot would blow them to pieces. They are said to hybernate. The brilliancy of their colouring greatly exceeds the powers of painting and description. The green, red, and blue of their diminutive plumage is like beaten gold, and reflects the most beautiful splendour in sunshine.

A. *Bill curved.*

306 *Paradiseus.* *Paradise humming bird.*—Red; wings blue; head crested; middle tail feathers very long; bill and legs black; wing coverts blue. Eight inches and a half long. Inhabits Mexico.

307 *Exilis.* *Little humming bird.*—Greenish-brown, with a scarlet gloss; wings and tail black; crest green at the base, tipt with gold; bill black. One inch and a half long. Inhabits Guiana.

Picæ.

Topaz humming bird.—Red; middle tail feathers very long; head brown; chin gold-green; rump green; bill, head, and neck black; breast rosy; back and wing coverts orange red; quill and middle tail feathers purple; the rest orange. Female almost entirely green gold. Six inches long. Inhabits Surinam. 308 *Pella.*

Mango humming bird.—Glossy green; tail nearly equal, and ferruginous; belly black, bill and legs black; a blue line dividing the colours of the back and belly; vent white; two middle tail feathers black. Four inches long. Inhabits Mexico, Brazil, and St Domingo. According to Albinus, it is also found in Jamaica, building its nest of cotton in the physic-nut-tree, and laying two white eggs as big as peas. There are several varieties. Under this species, Dr Latham relates the following interesting particulars. 309 *Mango.*

"We have before related a circumstance of the possibility of keeping humming birds alive for some time, by means of sugar and water; but this was in their own country and climate. In addition to this, we have been informed, on undoubted veracity, of the following fact: A young gentleman, a few days before he set sail from Jamaica to England, was fortunate enough to meet with a female humming bird, sitting on the nest and eggs; when, cutting off the twig, he brought all together on board the ship; the female became sufficiently tame, so as to suffer itself to be fed with honey, and during the passage hatched two young ones; however, the mother did not survive long, but the young were brought to England, and continued alive for some time in the possession of Lady Hammond. Sir H. Englefield, Baronet, and Colonel Sloane, both witnesses of the circumstance, informed me that these little creatures readily took honey from the lips of Lady Hammond, with their bills: one of them did not live long, but the other survived at least two months from the time of its arrival."

B. *Bill straight.*

Red-throated humming bird.—Green gold; tail feathers black, the three lateral ones ferruginous, tipt with white; chin flame colour; bill black; chin scarlet, with a beautiful gold gloss. The female brown above, whitish beneath; tail subequal, rusty at the base, and tipt with white. Three inches and one-fourth long. Inhabits America, as far north as Canada. This beautiful little creature flies so swiftly, that the eye is incapable of pursuing it, and the motion of its wings is so rapid as to be imperceptible to the nicest observer. It never feeds but on the wing, suspended over the flower from which it extracts its nourishment. Like the bee, having exhausted the honeyed juice of one flower, it wanders to the next, in search of new sweets. It is most partial to those flowers which have the deepest nectaries: and, in the countries which these birds inhabit, whoever sets plants of this description before his window, may depend on being visited by multitudes of them. It is very entertaining to see them swarming around the flowers, and trying every tube by thrusting in their bills. If they find that their companions have anticipated them, and robbed the flower of its honey, they will frequently, in a fit of rage, pluck it off, and throw it on the ground, or even tear it in pieces. Numbers will sometimes contend very fiercely for the possession of the same flower. During the conflict, they frequently pursue the fugitives into the apartments of those houses whose windows are left 310 *Colubris.*

Picæ.

left open, take a turn round the room as flies do with us, and then suddenly regain the open air. When feeding, they will allow persons to come within two yards of them; but, on a nearer approach, they dart off with wonderful swiftness. The red-throated humming bird most frequently builds on the middle of a branch of a tree, and the nest is so small, that it cannot be seen by a person who stands on the ground. It is quite round; the outside, for the most part, composed of the green moss common on old pales and trees, and the inside of the softest vegetable down which the birds can collect. Sometimes, however, they vary the texture, using flax, hemp, hairs, and other similar materials. They are sometimes, likewise, known to fix it on some low bush, on a stalk of the tobacco plant, or even on the side of a pod of ocra (*Hibiscus esculentus*, Lin.). The female lays two eggs, which are white, and equal in thickness at both ends. When these birds observe any one climbing the tree in which they have their nests, they attack him in the face, attempting to strike him in the eyes, and coming, going, and returning, with such swiftness, that one would scarcely credit it who had not seen it himself. This species, like the others of its genus, is seldom caught alive. A friend of Monsieur du Pratz had, however, this pleasure. He had observed one of them enter into the bell of a convolvulus; and, as it had quite buried itself to get at the bottom, he ran immediately to the spot, shut the flower, cut it from the stalk, and carried off the bird a prisoner. He could not, however, prevail on it to eat; and it died in the course of two or three days. Charlevoix informs us, that he had one of them in Canada, for about twenty-four hours. It suffered itself to be handled, and even counterfeited death, that it might escape; but it fell a real sacrifice to a slight frost during the night. "My friend Captain Davies informs me (says Dr Latham), that he kept these birds alive for four months by the following method:—He made an exact representation of some of the tubular flowers, with paper fastened round a tobacco pipe, and painted them of a proper colour. These were placed in the order of nature, in the cage in which the little creatures were confined: the bottoms of the tubes were filled with a mixture of brown sugar and water as often as emptied; and he had the pleasure of seeing them perform every action; for they soon grew familiar, and took their nourishment in the same manner as when ranging at large, though close under the eye."

311 *Moschitus.* *Ruby-necked humming bird.*—Green-gold; tail even and ferruginous, the two outer feathers tipt with brown; wings black; bill and legs blackish; crown, hind head, and neck ruby; body brown beneath. Female whitish gray beneath, with a gold spot on the breast and throat. Upwards of three inches long. Inhabits Guiana, Brazil, and Surinam. Reputed the most beautiful of the tribe.

312 *Mellivorus.* *White bellied humming bird.*—Tail feathers black, the lateral ones white; head blue; back green; belly white. Above four inches long. Inhabits Surinam. Edwards remarks, that the whole of the plumage, in the sun, seems as if mixed with threads of gold.

313 *Minimus.* *Least humming bird.*—Green; whitish beneath; lateral tail feathers white on the outer edge; bill and legs blackish; wings violet brown; tail feathers bluish-black, the primary totally gray; secondary gray from the middle to the tip. Female dirty greenish-brown, whitish beneath. Inhabits South America, and some of the West India islands. The least of all known birds; being hardly an inch and a quarter in length, and weighing from twenty to forty-five grains; thus being surpassed in weight and dimensions by more than one species of bee. The female is even less than the male.

Order III. ANSERES. 314 Anseres.

Bill somewhat obtuse, covered with a skin, gibbous at the base; mouth toothed; tongue fleshy; feet palmated, and formed for swimming. 315 Characters.

Most of the birds belonging to this order dwell much in the water. Their feet and legs are short, concealed under the feathers, and placed more behind than in other birds. Their toes are short, and generally compressed, so that they easily cleave the water, and by means of their membranes or webs, form, as it were, broad oars. Their plumage is thicker, closer, and better furnished with down than that of other birds. The gland which all birds have at the rump, and from which they express an oily matter to preserve their feathers moist, is most considerable in the anseres, and contributes to make their plumage impermeable to water. They feed on fish, aquatic animals, and plants. In general they are polygamous, and make their nests among reeds, or in moist places. The young are soon able to seek their own food; yet the mother leads and protects them for some time, and the male frequently kills them. For the most part they lay many eggs; and the flesh of many is eatable, though it frequently savours of oil, or of fish.

Gen. 32. Anas. 316 Anas.

Bill convex, obtuse, the edges divided into lamellated teeth; tongue fringed and obtuse; the three fore toes connected, the hind one solitary. 317 Characters.

This is a very numerous genus, and includes swans, geese, and ducks.

A. *Bill gibbous at the base.*

Wild swan, hooper, elk, whistling swan, &c.—Bill semicylindrical, and black; cere yellow; body white; eyelids naked, yellow; legs black; ribs eleven. This is obviously a distinct species from the common or mute swan, being of a smaller size, and having the windpipe differently constructed. It weighs from fifteen to twenty-five pounds, and measures nearly five feet in length. It inhabits Europe, Asia, and America, affecting chiefly the northern regions of the globe, and seldom appearing in England, except in hard winters. On the approach of spring, they quit their southern stations, and again retire northward to breed. A few indeed drop short, and perform that office by the way, halting in some of the Hebrides, Orkneys, Shetland, or some solitary island. But the great bodies of this species occur on the large rivers and lakes near Hudson's bay, and those of Kamtschatka, Lapland, and Iceland. They are said to return to the latter place in flocks of about a hundred at a time, in spring; and also to pour in on that island from the north, in nearly the same manner, on their way southward, toward the close of autumn, flying very high in the air, and in such a compact body, that the bill of one touches the tail of another. The young, which are 318 Cygnus.

are bred there, remain throughout the first year; and in August, when they lose their feathers, and are unable to fly, the natives kill them with clubs, shoot, and hunt them down with dogs, by which they are easily caught. The flesh is highly esteemed, as are the eggs, which are gathered in the spring. The Icelanders, Kamtschatkadales, and other inhabitants of the northern world, dress their skins with the down on them, sew them together, and convert them into various sorts of garments. The northern American Indians have recourse to the same expedient for clothing themselves, and sometimes weave the down as barbers do the cawls for wigs, and then manufacture it into ornamental dresses for the women of rank, while the larger feathers are formed into caps and plumes, to decorate the heads of their chieftains and warriors. They likewise gather the feathers and down in large quantities, and barter or sell them to the inhabitants of more civilized nations. Notwithstanding the fabulous accounts and poetical descriptions of the song of the dying swan, its voice is shrill, harsh, and piercing, not unlike the sound of a clarionet, when blown by a novice in music. It is asserted, however, by those who have heard the united and varied voices of a numerous assemblage of them, that they produce a more harmonious effect, particularly when softened by the murmur of the waters. At the setting in of frosty weather, wild swans are said to associate in prodigious multitudes, and, thus united, to use every effort to prevent the water from freezing; which they are enabled to accomplish for a considerable length of time, by constantly stirring and dashing it with their extended wings. The wild swan has been styled "the peaceful monarch of the lake," because, conscious of his superior strength, he fears no enemy, nor suffers any bird, however powerful, to molest him, at the same time that he preys on none of the feathered tribe. His vigorous wing shields him against the attacks even of the eagle, and his blows from it are so powerful, as to stun or kill the fiercest of his foes. His food consists of the grasses and weeds, and the seeds and roots of plants which grow on the margins of the water, and of the myriads of insects which skim over or float on its surface; occasionally, too, of the slimy inhabitants within its bosom. The female makes her nest of the withered leaves and stalks of reeds and rushes, and commonly lays six or seven thick shelled, white eggs. The incubation is said to last six weeks. Both male and female are very attentive to their young, and will suffer no enemy to approach them.

319 Olor. *Tame swan.*—Bill semicylindrical, black; cere black; body white. The plumage of this species is of the same snowy whiteness as that of the preceding, and the bird is covered next the body with the same kind of fine soft down; but it is of a larger size, and is furnished with a projecting, callous, black tubercle, or knob, at the base of the upper mandible. But the most remarkable distinction consists in the conformation of the windpipe, which, in the present species, enters at once into the lungs, so that the utmost noise the bird can utter, is a mere hiss: whereas, in the wild species, the windpipe first enters the chest a little way, is then reflected in the form of a trumpet; after which it enters a second time, when, dividing into two branches, it goes on to join the lungs. The manners and habits of both species in the wild state are very similar. The beauty, graceful motion, and majesty of this bird, when it is wafted along a piece of water, attract the admiration of every beholder: but, out of the liquid element, the elegance of its form in a great measure disappears. While the male and female are employed with the cares of the young brood, it is not safe to approach them; for they will fly on a stranger, and sometimes beat him to the ground by repeated blows. Notwithstanding, however, their great strength of wing, a slight blow on the head will dispatch them. Multitudes of this species are found in Russia and Siberia, as well as farther southward, in a wild state. They occur, without an owner, on the Trent, on the inlet of the sea near Abbotsbury in Dorsetshire, and on some other rivers and lakes, in different parts of the British isles. Those on the Thames have, for ages, been protected as royal property; and it is still reckoned felony to steal their eggs. In former times great numbers were reared for the table: but they are now reckoned by most a coarse kind of food. A fattened cygnet, however, is still accounted a great delicacy, and usually fetches upwards of a guinea in the poultry market. It is generally believed that the swan lives to a great age, though the term of three centuries, assigned to it by some authors, is certainly much exaggerated. The female nestles among the rough herbage near the water's edge, lays from six to eight large white eggs, and sits on them about as many weeks before they are hatched. The young do not acquire their full plumage till the second year. If kept out of the water, and confined to a court-yard, the swan soon becomes dirty, dull, and spiritless. Its usual food consists of fish and water plants.

320 Atrata. *Black swan.*—Black; wings edged with white; bill red; upper mandible blackish at the tip, a yellow spot near the lip; legs black; feet paler. Extent of wing four feet eight inches. Inhabits various parts of New Holland; but little is known respecting its manners.

321 Hyberborea. *Snow goose.*—Body snow-white; front yellowish; ten first quill feathers black; bill and legs red. Size of a goose; length two feet eight inches; extent of wing three feet and a half; weight between five and six pounds. Great numbers of this species occur about Hudson's bay; visit Severn river in May, and stay a fortnight, but go farther north to breed. They return to Severn Fort about the beginning of September, and stay till the middle of October, when they depart for the south, and are observed in immense flocks attended by their young. At this time many thousands are killed by the inhabitants, who pluck and eviscerate them, and put them into holes in the earth, where they are preserved quite sweet by frost, throughout the severe season. These birds seem also to occupy the west side of America and Kamtschatka. In the summer months they are plentiful on the arctic coast of Siberia; but never migrate beyond 130° of longitude. They are supposed to pass the winter in more moderate climes, as they have been seen flying over Silesia; probably on their passage to some other country, as it does not appear that they continue there. Those of America, in like manner, winter in Carolina. The Siberians decoy them by a person covered with a white skin, and crawling on all fours, whom they are stupid enough to mistake for their leader, and whom they follow, when driven by men in their rear, till he entangles them in nets, or leads them into a sort of pond prepared for the purpose.

322 Antarctica. *Antarctic goose.*—Snowy; bill black; legs yellow. The

Anseres. The female has the tail flesh-coloured, and the body brown, with transverse white lines. From twenty four to twenty-six inches long. Inhabits Falkland islands.

323 Leucoptera. *Bustard goose.*—White; two middle tail feathers, primary quill feathers, and greater wing coverts, black; nape, and upper part of the back, with numerous black lines; wings with a blunt spine at the flexure, and a dusky green spot; greater wing coverts tipt with white; secondary quill feathers half black, half white; legs black. This is the *sea-goose* of Clayton, and the *white-winged antarctic goose* of Brown. It measures from thirty-two to forty inches in length, stands pretty high on its legs, walks and flies with great ease, and has not that disagreeable cackling cry peculiar to the rest of its kind. It generally lays six eggs; and its flesh is reckoned wholesome, nourishing, and palatable. Inhabits the Falkland islands.

324 Cinerea. *Loggerhead goose*, or *racehorse duck.*—Cinereous; dusky beneath; vent white; wings and tail short and black; bill, irides, and tubercle on the wings and legs, yellow. Length thirty-two inches; weighs from twenty to thirty pounds. Observed on Falkland islands, Staaten Land, &c.; mostly in pairs, though sometimes in large flocks. From the shortness of their wings, they were unable to fly, but they used them in the water as oars, and swam so rapidly, that it was very difficult to shoot them when on that element. In order to catch them, the sailors would surround a flock with boats and drive them on shore, where, unable to raise themselves from the ground, they ran very fast; but soon growing tired, and squating down to rest, were easily overtaken and knocked on the head. Their flesh, however, was not much relished, being rank and fishy.

325 Tadorna. *Sheldrake*, or *burrow duck.*—Bill turning up at the point; forehead compressed; head greenish black; body white and variegated; bill and legs red; head and neck violet; collar white; back white; breast brown; belly white, with a black line; first quill feathers black, the next violet, inner ones ferruginous, the last white; tail white, tipt with black. The female has less vivid colours. This elegant species of duck weighs about two pounds and a half, and measures about two feet three inches. It inhabits Europe and Asia, and is not uncommon on many parts of our coasts, remaining all the year. The female makes choice of a rabbit burrow, wherein to deposit her eggs, which are numerous, amounting sometimes to sixteen, and which she covers with down from her own body. The nest is generally near the water, whither the female leads her young soon after they are hatched. This species is rarely met with remote from salt water; but if the eggs are taken and hatched under a hen, the young become tame, and may be kept in ponds. They very seldom breed when in a state of confinement. Their principal food consists of sea-weeds, small shell-fish, and marine insects. The flesh is rancid

326 Fusca. *Velvet duck.*—Blackish; lower eyelid and spot on the wings, white; bill yellow, black in the middle, gibbous at the base; legs red. Female without the gibbosity on the bill, and body blackish. From 20 to 22 inches long. Inhabits Europe and South America. It is sometimes, though not often, seen on our coasts in winter. Frequents Hudson's bay, where it breeds in summer; and is not uncommon in Russia and Siberia. Lives on fuci and shell-fish. The female makes its nest of grass, and lays from four to 10 white eggs. The catching of this species is a favourite diversion of the Tungusi, who dwell on the river Ochota, and who chase great numbers of these birds, during the moulting season, into shallow water, and then knock them down with clubs. They take many of them alive, and, thrusting a needle through their eyes, carry fifty or more on a string. It is alleged that the birds, thus treated, will live for two or even three days. Anseres.

Scoter, or *black diver.*—Body quite black; bill gibbous at the base; head and neck sprinkled with purple; tail somewhat wedged. Female of a browner hue, and without the protuberance at the base of the bill. Length 22 inches; feeds on grass and shell-fish, and tastes rancid. These birds inhabit Europe and North America, and mostly reside at sea, distant from the shore. With us they are seen only in the winter season, when they are plentiful on some parts of the coast of France. They are great divers, and abound in most of the northern regions of the world. They want the horny nail at the end of the bill, which is common to the rest of the genus. As they taste strongly of fish, they are allowed by the Romish church to be eaten in Lent. 327 Nigra.

White fronted or *laughing goose.*—Brown; white, spotted with black beneath; front and rump white; bill and legs flame colour. Breast cinereous; tail dusky, edged with white. Two feet four inches long. Inhabits Europe, Asia, and America. and visits the fenny parts of England, in small flocks in winter. During severe weather it is killed on the coast as well as on rivers, and not uncommonly brought to market and sold for the common wild goose. It leaves us in the earliest spring, none being seen after the middle of March. 328 Albifrons.

B. *Bill equal at the base.*

Scaup duck.—Black; shoulders waved with ash colour; belly and spot on the wings white; bill broad, bluish ash; irides yellow; head and neck greenish black; back and wing coverts waved with black, and cinereous; legs and primary quill-feathers dusky; secondary white, tipt with black; tail coverts, and vent, black. Female brown; bill black, surrounded with a circle of white feathers; neck rusty; belly, and bar on the wings, white; legs black. From 18 to 20 inches long; feeds on shell-fish, and inhabits Europe, northern Asia, and America. It is found in Iceland, Lapland, Sweden, Norway, Russia, and Siberia, and as high as Hudson's bay in America. In England, it appears in the winter season, in small flocks, and is frequently observed in fresh waters. In October it begins to emigrate southward in flocks. It also frequently lives in holes under ground. 329 Marila.

Gray lag goose, or *wild goose.*—Bill semicylindrical; body cinereous above, paler beneath; neck striated; bill flesh-coloured and tipt with white; rump and vent white; legs flesh-coloured; claws black, wants the wing spot. Weighs eight or nine pounds, and is about 33 inches long. Varies much in colour by domestication, in which state it is our common tame goose. Inhabits in flocks the northern parts of Europe, Asia, and America; resides the whole year in the Lincolnshire fens, where it breeds, laying eight or nine eggs which are hatched in 28 or 30 days. Frequents lakes and rivers, and lives to a great age. The domestic goose is well known. It is bred in great multitudes in the fens of Lincolnshire, both on account of its flesh and feathers. The geese are there attended by a person called 330 Anser.

a

Anseres. a *gozzard*, who drives them to feed and water. They are plucked five times a year, once for quills and feathers, and four times for feathers only. If the season prove cold, many of them die by this cruel operation. Tame geese have been known to live for 80 years. They generally retain the white rump and vent feathers of their original stock. They feed on water insects, worms, and plants; and by means of two rows of strong sharp teeth within their bills, they crop the herbage in meadows, and do much injury to young corn.

331 *Ruficollis.* *Red-breasted goose.*—Black; white beneath; bill small, conical; neck rufous; spot between the bill and eyes white. Length 21 inches; weight about three pounds. Inhabits Russia and the northern parts of Siberia, but is very rarely found in England. In winter it migrates towards Persia. It is a beautiful species, and its flesh is in high request.

332 *Segetum.* *Bean goose.*—Cinereous; dirty white beneath; bill compressed at the base; tail-coverts white; legs saffron; bill reddish in the middle, black at the base and tip; head and neck inclined to ferruginous; quill-feathers edged with black; tail with white; claws white. Measures from two feet and a half to three feet in length, and weighs from five to seven pounds. Inhabits Hudson's bay and the Hebrides, particularly the isle of Lewis, where it remains all summer and breeds These birds migrate to England in autumn, and leave it again in May, lighting, on their passage, on corn fields, and feeding on the green wheat. In their migration they fly at a great height, sometimes in a straight line, and sometimes in the form of a wedge, cackling as they advance. This species is often killed, and sold for the common wild goose, with which it has been long confounded.

333 *Borealis.* *Garland duck.*—Bill narrow; head green; breast and belly white. Inhabits the fens of Iceland, but is very rare.

334 *Erythropus.* *Bernacle goose.*—Ash-coloured; front white; body waved with black and white above; neck black; belly white; bill short, black, with a flesh-coloured spot on each side, a black spot between the bill and eye; tail white beneath; legs blackish. Twenty-five inches long. Inhabits the north of Europe and Hudson's bay, and appears in large flocks on the north-west coasts of Britain during winter. They are then very wild and shy; but, on being taken, become quite familiar in a few days. In February they quit our shores, and retire as far as Lapland, Greenland, and even Spitzbergen, to breed. In the darker ages this species was seriously believed to be produced from the *lepas anatifera*, a shell which is often found adhering by a pedicle to logs of wood that have lain long in the sea, from which circumstance it obtained the name of *tree-goose* and *clakis*.

335 *Bernicla.* *Brent* or *brand goose.*—Brown; head, neck, and breast, black; collar white; bill, wings, tail and legs, black; broad spot on each side of the neck; tail-coverts and vent white; belly and shoulders cinereous; flanks streaked with white; considerably smaller than the preceding. Inhabits Europe, Asia, and North America. These birds appear on our coasts, particularly in the west of England, during winter, and in Shetland are called *horra geese*. But they are most plentiful in Ireland, where they are taken in nets placed across the rivers, especially in those which empty themselves into the northern parts of the Irish channel. Sometimes they appear in vast flocks on the coast of Picardy, destroying all the corn near the sea. They migrate northward in summer, and return south in autumn, flying high in wedge-shaped flocks. They feed on *polyganum viviparum*, *empetrum nigrum*, and other plants, but chiefly on aquatic plants and marine vermes. They are easily tamed, and reckoned good for the table.

336 *Mollissima.* Plate CCCXCVI. fig. 1. *Eider*, *edder*, or *Cuthbert duck.*—Bill cylindrical; cere wrinkled, and bifid on the hind part; bills, legs, front, ocular band, breast, lower part of the back and belly black; middle of the head, upper part of the back, shoulders, and wing coverts white; a green blotch beneath the hind head. The female almost wholly obscurely ferruginous, with black lines; tail and primary quill-feathers dusky. The young are not mature in plumage till the third, or perhaps the fourth year. This species is nearly double the size of the common duck, and about 22 inches long. It inhabits the high latitudes of Europe, Asia, and America, and feeds chiefly on testaceous animals. It is rarely, if ever, seen in the south of England, but breeds in the north of Scotland, particularly on the Western isles, as also on the Farn islands, on the coast of Northumberland, in June and July. The nest is made on the ground, composed of marine plants, and lined with down of exquisite fineness, which the female plucks from her own body. The eggs are usually five, and of a greenish colour. In Iceland the eider ducks generally build their nests on small islands not far from the shore, and sometimes even near the dwellings of the natives, who treat them with so much attention and kindness as to render them nearly tame. Two females will sometimes lay their eggs in the same nest, in which case they always agree remarkably well. As long as the female is sitting, the male continues on watch near the shore, but as soon as the young are hatched, he leaves them. The mother, however, remains with them a considerable time afterwards; and it is curious to observe her attention in leading them out of the nest almost as soon as they creep from the eggs. Having conducted them to the water's edge, she takes them on her back and swims a few yards with them, when she dives, and leaves them on the surface to take care of themselves. They are seldom afterwards seen on land. When the natives come to the nest, they carefully remove the female, and take away the superfluous down and eggs. They then replace the mother, and she begins to lay afresh, covering the eggs with new down; and when she can afford no more, the male comes to her assistance, and covers the eggs with his down, which is white. When the young ones leave the nest, which is about an hour after they are hatched, it is once more plundered. The best down, and most eggs, are got during the first three weeks of their laying; and it has generally been observed that they lay the greatest number of eggs in rainy weather. One female, during the time of laying, usually yields half a pound of down, which, however, is reduced one half after it is cleaned. When pure, it is sold in Lapland at the rate of two rixdollars a pound. It is extremely soft and warm, and so light and elastic, that a couple of handfuls, squeezed together, are sufficient to fill a covering like a feather bed, which is used in those cold countries instead of a common quilt or blanket. The Iceland company at Copenhagen, generally export every year

Anseres. year from 1500 to 2000 pounds weight of down, cleaned and uncleaned, exclusive of what is privately exported by foreigners. The Greenlanders kill these birds with darts, pursuing them in their little boats, watching their course by the air-bubbles when they dive, and always striking at them when they rise wearied to the surface. Their flesh is valued as food, and their skins are made into warm and comfortable under garments.

337 *Moscata.* *Muscovy duck.*—Face naked, with red caruncles; legs and orbits naked, and with the bill red; tip of the bill and space round the nostrils black; crown black; temples, chin, and throat white, varied with black; breast and lower part of the belly brown, mixed with white; back and rump brown, with a green gold gloss; upper part of the belly white; three first quill feathers white, the rest brown; tail feathers twenty, the outer white, the rest green gold. Two feet long: native of Brazil, and is domesticated in Europe. Has its name, not as vulgarily alleged, from the country of Muscovy, but from the circumstances of its smelling of *musk*, which arises from the liquor secreted in the gland of the rump. Like other domesticated fowls they are subject to great varieties. They are a thriving and prolific species, and not only associate, but sometimes breed with the common duck. Their flesh is much esteemed. Mr Pennant says they are met with wild about Lake Baikal in Asia; Ray, that they are natives of Louisiana; Marcgrave, that they reside in Brazil; and Buffon, that they occur in the overflowed savannas of Guiana, where they feed in the day time on the wild rice, and return in the evening to the sea. He adds, that they nestle on the trunks of rotten trees, and that after the young are hatched, the mother takes them, one after another, by the bill, and throws them into the water. Great numbers of the young brood are said to be destroyed by the alligators.

338 *Clypeata.* *Shoveler.*—Extremity of the bill dilated, rounded, with an incurved nail; bill black; irides yellow; head and neck violet green; breast white, and lunulated; back, wings, and wedged tail brown; belly chesnut; vent white; first and second wing coverts pale blue, greater brown, tipt with white, the rest edged with white; legs tawney. The female has a considerable resemblance to the common duck, but both sexes are very apt to vary in their colourings. This species inhabits Europe, Asia, and North America, but is by no means common in Britain. A few remain in France during the breeding season, making a nest of rushes, in which they lay 10 or 12 rufous-coloured eggs.

339 *Rubens.* *Red-breasted shoveler.*—Brown; chin and breast chesnut; wings tipt with gray, wing-spot purple, edged with white; tail short, white; bill broad, brownish yellow; head large; eyes small; irides yellow; legs small, slender and bay. Size of a tame duck. Sometimes found in the fens of Lincolnshire, but is rare, and little known.

340 *Mersa.* *Ural duck.*—Waved with cinereous and yellowish, and spotted with brown; brown, speckled with gray beneath; throat brown-yellow, waved with black; tail long, black, wedged. Rather bigger than the common teal. Is not unfrequent in the greater lakes of the Ural mountains, and the rivers Oby and Irtisch. Is not seen on the ground, being, from the situation of its legs, unable to walk; but it swims well and quickly, with the tail immersed in the water as far as the rump, and serving as a rudder, contrary to the common method of a duck's swimming. The nest is formed of reeds.

341 *Strepera.* *Gadwall*, or *gray.*—Wing-spot rufous, black, and white; bill flat, black; legs tawney; rump black; back brown, waved with paler; breast and belly gray, varied with white. Nineteen inches long. Inhabits Europe and Northern Asia. Visits Britain in winter, but not in great numbers. Supposed to breed in Sweden, and probably in Russia and Siberia. It is said to be a great diver, and to feed chiefly by night, concealing itself among the reeds and rushes during the day. It makes a noise not unlike that of the mallard, but louder. Its flesh is savoury.

342 *Clangula.* *Golden eye.*—Black and white; head turned; violet; a large white spot at each corner of the mouth; bill black; irides golden; lower part of the neck, breast, and belly, white; back and rump black; legs red. The markings of the female are, head red brown; neck gray; breast and belly white; wing coverts varied with dusky and cinereous; middle quill-feathers white; the rest and tail black; legs dusky. About 19 inches in length. Inhabits Europe, Asia, and North America.

Birds of this species do not assemble in large flocks, nor are they numerous on the British shores or on the lakes in the interior. They are late in taking their departure northward in the spring, and in their flight they make the air whistle with the vigorous quick strokes of their wings. They are excellent divers, and seldom set foot on shore; on which, it is said, they walk with great apparent difficulty, and, except in the breeding season, only repair to it for the purpose of taking their repose. They build in the hollows of trees, and prey on shell-fish, mice, fish, and frogs.

The *anas glaucion*, or *mosillon*, seems to be only a variety of the golden eye in one stage of its plumage, before it arrives at maturity.

343 *Glocitans.* *Bimaculated* or *clucking duck.*—Subcrested; brown, waved with black; head green; a ferruginous spot before and behind the eyes; breast with black spots; wing-spot green, edged with white. Length 20 inches; occurs along the Lena, and about Lake Baikal, and has been taken in a decoy in England. Has a singular note, somewhat like clucking.

344 *Penelope.* *Wigeon, whewer*, or *whim.*—Tail pointed; vent feathers black; head bay; front white; back waved with black and white; bill plumbeous, with a black nail; head and upper part of the neck red, with blackish spots; breast claret; body above waved with cinereous and blackish; wing-spot blue green; black before and behind; wing-coverts varied brown and white; belly white; legs lead colour. Female waved with brown; breast paler. Twenty inches long. Inhabits Europe, Asia, and Africa. Visits England in autumn, when great numbers are taken in decoys, being esteemed an excellent food. It likewise frequents our rivers and salt-water inlets in small flocks. Its is remarkable for uttering a whistling or piping noise, which is frequently heard as it flies during the night. It lives on frogs, worms, insects, and water plants, and is sometimes domesticated. There is a variety with a silvery wing-spot, and the throat waved with ash-colour.

345 *Acuta.* *Pin tail duck.*—Tail pointed, long, black beneath; hind head with a white line on each side; back waved with cinereous; bill black, bluish at the sides; head ferruginous; throat white, a little spotted; body white beneath;

Anseres. neath; wings brown; wing spot violet, ferruginous on the fore part, black and white on the hind part; tail brown, edged with white, two middle feathers longer. Female less; wing-spot straw-coloured, and edged with white. Inhabits Europe, Asia, and America. These birds are seldom numerous in England, but flocks of them are sometimes abundantly spread along the isles and shores of Scotland and Ireland, and on the interior lakes of both these countries. This species measures twenty-eight inches in length, and is esteemed excellent eating.

346 *Ferruginea.* *Ferruginous duck.*—Reddish-brown; bill dilated and rounded at the base; feet pale blue. Weight 20 ounces. Inhabits Denmark and Sweden, but very rarely occurs in this country.

347 *Glacialis.* *Long-tailed duck.*—Tail pointed, long; body black, white beneath; bill black, orange in the middle; head on the fore part and sides reddish-gray; hind-part, breast, and belly, white; scapulars long and white; sides of the neck with a black spot; lower part of the breast, back, wings, and tail, chocolate; four middle tail-feathers black, two middle ones longer, the rest white; legs dusky-red, or blackish. The female has the tail shorter and wedged; the body varied with blackish, rufous, and gray; the back black; collar and lower part of the belly white, Of the size of a wigeon. Inhabits Europe, Asia, and America, frequenting both the interior lakes and the sea shores of these quarters of the world. The birds of this species do not, in the winter, like many of the other tribes, entirely quit their northern haunts, but considerable numbers remain there, enduring the rigours of the season, and enjoying, in summer, the perpetual day of an unsetting sun. Numerous flocks, however, spread themselves southward in the winter, from Greenland and Hudson's bay, as far as New York in America, and from Iceland and Spitzbergen over Lapland, the Russian dominions, Sweden, Norway, and the northern parts of the British isles in Europe. The flocks which visit the Orkney isles appear in October, and continue there till April. About sunset they are seen in large companies going to and returning from the bays, in which they frequently pass the night, making such a noise, as in frosty weather may be heard some miles. They are rather scarce in England, to which they resort only in very hard winters, and even then in small straggling parties. They fly swiftly, but seldom to a great distance, making a loud and singular cry. They are expert divers, and supposed to live chiefly on shell-fish. The female makes her nest among the grass near the water, and, like the eider duck, lines it with the fine down of her own body. According to Latham, she lays five eggs, which are of a bluish white colour, and about the size of those of a pullet.

348 *Ferina.* *Pochard*, or *red-headed wigeon.*—Waved with ash-colour; head brown; pectoral band; vent and rump black; bill broad, blue, tipt with black; irides tawney; head and neck bay; breast and upper part of the back black; scapulars and inner wing-coverts undulated with black and white; belly whitish, with dusky lines at the sides; legs plumbeous. Female darker; head pale reddish-brown; wing-coverts and belly cinereous. Nineteen inches long; weight 28 ounces. Inhabits Europe, Asia and America. This species is frequently caught in the decoys in England, though it is not known to breed there. In some counties it is called *poker*, *dunbird*, or *great-headed wigeon*. It is of a plump round shape, Anseres. walks with a waddling and ungraceful step, but flies rapidly, and in flocks of from 20 to 40, commonly in a compact body. It is much in request for the table, but is not easily domesticated. The male has a labyrinth, or enlargement of the trachea, near the junction with the lungs, a singular conformation peculiar to the male of several species of the duck tribe, but the use of which is still unknown. In winter the pochard migrates southward, as far, it is said, as Egypt.

Garganey.—Wing-spot green; a white line above the eyes; bill lead colour; crown dusky, with oblong streaks; cheeks and neck purple, with white streaks; breast light brown, with semicircular black bars; belly white, lower part and vent speckled; first quill-feathers cinereous, outer webs of the middle ones green; scapulars long, narrow, striped with white, ash colour and black; tail dusky; legs lead-colour. Female, with an obscure white mark over the eye; plumage brownish-ash; wings without the green spot. Length 17 inches. Inhabits Europe and Asia. By some called *pied wigeon*, or *summer teal*. Frequents only the fresh waters, feeding on seeds and aquatic plants. Is not common in Britain, and is said to be impatient of cold. 349 *Querquedula.*

Teal.—Wing-spot green; a white line above and beneath the eyes; bill black; irides hazel; head and neck bright bay; a broad green band behind the eyes to the nape, and terminating beneath in a white line; body whitish, with transverse blackish lines above; fore part of the neck and breast with round black spots; wing-spot green, edged beneath with white, obliquely black above; vent black in the middle. The female is distinguished by the head and neck varied with whitish and brown, and the vent totally white. There are two permanent varieties, of which the first is the wing-spot varying in colour; the body brown-ash above, rufous-white beneath, and black spots on the belly. The second has the cheek, chin, and under parts of the body white-rufous, and the wing-spot without black. Weight about 12 ounces; length 14 inches and a half. The smallest of the duck tribe, and in high request at the table. Inhabits Europe and Asia; visits us in winter, and frequents our fresh waters in small flocks. Many are caught in the decoys, and a few breed in Wolmer Forest, in the morasses about Carlisle, &c. The female makes a large nest composed of soft dried grasses lined with feathers, and cunningly concealed in a hole among the roots of reeds and bulrushes, near the edge of the water. The eggs are of the size of those of a pigeon, from six to ten in number, and of a dull white colour marked with small brownish spots. The male has a bony labyrinth in the lower part of the windpipe. 350 *Crecca.*

Mallard, or *wild duck.*—Cinereous; middle tail feathers (of the male) recurved; bill straight; collar white; bill greenish-yellow; head and neck glossy-green; scapulars white, with waved brown lines; back brown; vent black-green; breast chesnut; belly gray; wing-spot violet-green, edged above with a black and white line; two middle tail feathers dark-green, and recurved. Female reddish-brown, spotted with black. Very subject to vary, especially by domestication, when it is our common tame duck. About 23 inches long. Weight about two pounds and a half. Inhabits Europe, Asia, and America; is very common in marshy places in many 351 *Boschas.*

Anseres. ny parts of this kingdom, but no where occurs in greater plenty than in Lincolnshire, where prodigious numbers are annually taken in the decoys. In only ten decoys in the neighbourhood of Wainfleet, as many as 31,200 have been taken in one season. There is a prohibition, by act of parliament, against taking them between the first of June and the first of October. They do not always build their nest close to the water, but often at a good distance from it, in which case the female will take the young in her beak, or between her legs, to the water. They have sometimes been known to lay their eggs in a high tree, in the deserted nest of a magpie or crow; and an instance has likewise been recorded of one found at Etchingham in Sussex, sitting on nine eggs in an oak, at the height of 25 feet from the ground, the eggs being supported by some small twigs laid crossways. Like many of the tribe, the mallards, in vast numbers quit the north at the end of autumn, and migrating southward, arrive in the beginning of winter in large flocks, and spread themselves over the lakes and marshy wastes of the British isles. They pair in the spring, when the greater number of them again retire northward to breed, but many straggling pairs stay with us; and they, as well as preceding colonists, remain to rear their young, which become natives, and remain with us throughout the year. The common domestic variety of this species assumes very different markings; but the male, even in its tame state, retains the curling of the feathers at the tail. Habits of domestication, however, have deprived the tame duck of that sprightly look and shape which distinguish the mallard, and have substituted a more dull and less elegant form and appearance in their stead. It is also deserving of remark, that ducks pair, and are monogamous in the wild state, but become polygamous when tame. The Chinese make great use of ducks, but prefer the tame to the wild. We are told that most of them in that country are hatched by artificial heat. The eggs being laid in boxes of sand, are placed on a brick hearth, to which is communicated a proper degree of heat during the time required for hatching. The ducklings are fed with cray-fish and crabs, boiled and cut small, and afterwards mixed with boiled rice; and in about a fortnight they are able to shift for themselves. The proprietors then provide them with an old *step-mother*, who leads them where they are to find provender; being first put on board a boat, which is destined for their habitation, and from which the whole flock, amounting often to 300 or 400, go out to feed, and return at command. This method is commonly practised during the nine warmest months of the year, and especially during rice harvest, when the masters of the duck boats row up and down according to the opportunity of procuring food, which is found in plenty at the tide of ebb, as the rice plantations are overflowed at high water. It is curious to observe how these birds obey their masters; for some thousands belonging to different boats will feed at large on the same spot, and on a signal given will follow their leader to their respective boats without a single stranger being found among them. No fewer than 40,000 such boats are supposed to ply on the Tigris. When confined to dry situations, ducks degenerate in strength, beauty, and flavour. They feed on various animal and vegetable substances, for which they unceasingly search with their curiously constructed bills, sifting and separating every alimentary particle from the mud. When older, they also devour worms, spawn, water-insects, and sometimes frogs and small fishes, together with the various seeds of bog and water plants. Anseres.

Black-billed whistling duck.—Brown; head somewhat crested; belly spotted with white and black. Smaller than the preceding. Inhabits Guiana and Jamaica; winters in Carolina, and builds and sits on trees. 352 *Arborea.*

Red-crested duck.—Black; head and upper part of the neck testaceous; crown reddish, that of the male crested; wings beneath, and at the edges white; tail brown. Female brown, and wants the crest. Inhabits the Caspian sea, and the lakes of the Tartarian deserts; is sometimes also found in Italy and Barbary. 353 *Rufina.*

Tufted duck.—Crest pendent; body black; belly and wing-spot white; bill broad, livid, tipt with black; irides golden; head greenish; shoulders blackish-brown, with pale straw-coloured dots; legs dusky-blue. Female brownish, wants the crest. Sixteen inches long. Inhabits Europe and Northern Asia. There are several varieties. It is not uncommon with us in winter, and is frequently seen in our fresh waters as late as near the end of March. It is often brought to market, and sold for wigeon. It lives not only in fresh water, but in the sea; dives well, and feeds on small fishes, crabs and shellfish, and likewise on the seeds of aquatic plants, particularly those of the common rush. 354 *Fuligula.*

Gen. 33. Mergus. 355 Mergus.

Bill toothed, slender, cylindrical, hooked at the point; nostrils small, oval, in the middle of the bill; feet four-toed, outer toe longest. 356 Characters.

The birds of this genus live on fish, and are very destructive in ponds.

Crested merganser.—Crest globular, white on each side; body brown above, white beneath; bill and legs black; irides golden; crest larger than the head, edged with black. Female brown; crest less and ferruginous. Length seventeen inches and a half; weight nearly 23 ounces. An elegant species, which inhabits North America, appearing at Hudson's bay about the end of May, and building, close to the lakes, a nest composed of grass, lined with feathers from its own breast. 357 *Cucullatus.*

Goosander.—A longitudinal crest, somewhat erect; the breast white, without spots; the tail feathers ash-coloured; shaft black; bill, legs, and irides red; greater quill-feathers black; lesser white. Weight about four pounds; length two feet four inches. Inhabits Europe, Asia, and America. Sometimes visits our rivers and lakes in severe winters, but retires to the more northern latitudes to breed. It has been known to build on trees, but more frequently among rocks or stones, and lays 14 eggs, which, with the bird itself, are eagerly devoured by the weasel. It swims with only the head above the surface of the water; dives deep; remains a long time below, and rises at a considerable distance. Its flesh is rancid and scarcely eatable. In quest of fish, it dives with great celerity, and holds its slippery prey with great security by means of its toothed bill, so admirably adapted to the purpose. 358 *Merganser.*

Dun diver, or *sparkling fowl.*—Crested; cinereous; head and upper parts of the neck bay; chin, middle quill feathers, and belly white; bill and irides red; belly sometimes flesh colour. Weighs about 38 ounces; measures 359 *Castor.*

Anseres. measures 25 inches in length. Inhabits the same countries with the preceding, and by some naturalists is reckoned the female; but the labyrinth, or enlargement at the bottom of the windpipe, seems to prove it to be a male, and consequently a distinct species.

360 Serrator. Plate cccxcvi. fig. 2. *Red-breasted merganser.*—Crest pendent; breast reddish and variegated; collar white; tail-feathers brown, varied with cinereous; under part of the bill and legs red; feathers of the sides of the breast large, white, edged with black, covering the fore part of the folded wings. Female with scarcely any crest; head and beginning of the neck rufous. Twenty-one inches long. Inhabits the northern parts of Europe, Asia, and America. Breeds in Greenland, Hudson's bay, Newfoundland, Siberia, the north of Scotland, &c. Makes its nest of withered grass, and down torn from its own breast, on dry land, and lays from eight to 13 white eggs, equal in size to those of a duck.

361 Albellus. *Smew*, or *white nern.*—Crest pendent; hind head black; body white; back and temples black; wings variegated; bill and legs black; wing-spot white; nape, oval spot from the bill surrounding the eyes, back, and two arched lines on each side, near the beginning of the wings, black. Female has the head smooth and gray; band across the eyes black, and under the eyes a white spot; body blackish brown above; white beneath; upper part of the head bay; chin white. From 15 to 17 inches long. Inhabits Europe and America. Breeds in the Arctic regions, and is driven to the south only by severe weather.

362 Minutus. *Minute smew*, or *lough diver.*—Brown ash; under parts of the body and chin white; head and upper part of the neck ferruginous; wing-spot white before and behind. Very much resembles the female of the preceding, but wants the black oval eye-spot. About 14 inches and a half long. Is rarely met with in the south of England, and only in winter when the weather is severe. It dives with great ease in pursuit of fish, and remains long under water.

363 Alca.

Gen. 34. Alca, *Auk.*

364 Characters. Bill toothless, short, compressed, convex, often transversely furrowed: lower mandible gibbous near the base; nostrils linear; legs (in most cases) three-toed.

The birds of this genus are mostly inhabitants of the Arctic seas; are accounted stupid, breed in holes, which they themselves often dig, and in the caverns and fissures of rock, where they rest during the night. In respect of colour, they are generally uniform, being black above, and white beneath. They are shaped like a duck, with their feet placed behind the centre of gravity; their bills are large, having the surfaces crossed with furrows, and ending in an acute point. They lay but one egg, which is very large, considering the size of the bird.

365 Arctica. *Puffin.*—Bill compressed, two-edged with two grooves; orbits and temples white; upper eyelid daggered or furnished with a pointed callus; body black; cheeks, breast, and belly white; bill red, with a black base; legs red. Weighs between 12 and 13 ounces; length upwards of 12 inches. Inhabits the northern seas of Europe, Asia, and America, in vast flocks. Appears on many parts of our rocky coast about the middle of April, and begins to breed about the middle of May. On the Dover cliffs, and other such places, they deposit their single egg in the holes and crevices: in other places they burrow like rabbits, if the soil is light, but more frequently take possession of rabbit burrows, and lay their egg some feet under ground. On St Margaret's island, off St David's, the fishermen put their hands into the holes, and the puffins seize them so obstinately, that they allow themselves to be drawn out. In other places they are caught with ferrets, and the young are taken and pickled. About the latter end of August they retire from our coasts, and have all migrated by the beginning of September. Their principal food is small fish, particularly sprats, with which they feed their young.

Great auk, or *penguin.*—Bill compressed, edged; an oval spot on each side before the eyes. Bill black, with eight or ten grooves; wings short and imperfect; secondary quill feathers tipt with white; legs black. Three feet long. Inhabits Europe and America; occurs in the most northern parts of Britain, and breeds in the isle of St Kilda, appearing about the beginning of May, and retiring about the middle of June. The shortness of its wings renders them useless for flight, but of singular service in diving under water, where they act as fins, and thus enable it to pursue its prey with great velocity. It lays an egg six inches long, white and marked with purple spots, close to the sea mark, being incapable of flying, and almost of walking. 366 Impennis.

Razorbill.—Bill with four grooves, and a white line on each side as far as the eyes. Bill black; the largest groove white; body black above, the under parts, from the middle of the throat, white; secondary quill feathers tipt with white; legs black. In the young bird the bill has but one groove, and, in the still younger, there is no line from the bill to the eyes. Eighteen inches long. Inhabits Europe and North America. The birds of this species associate with the guillemots, and also breed in the same places. About the beginning of May they take possession of the highest impending rocks, for the purpose of incubation, and on the ledges of these rocks they assemble in great numbers, sitting closely together, and often in a series of rows one above another. There they deposit their single large egg on the bare rock, and notwithstanding the multitudes of them which are thus mixed together, yet no confusion takes place; for each bird knows her own egg, and hatches it in that situation. The razorbill is provincially called *auk*, *murre*, *falk*, *marrot*, and *scout*. 367 Torda.

Dusky auk.—Size of the missel thrush; the length 11 inches. Upper mandible of the bill bent at the point; colour yellow brown; the ridge white; irides white, and surrounded with a black circle; forehead covered with downy feathers, which are reflexed, half one way, and half the other: behind the eyes a stripe of white; head and neck black; upper parts of the body black; legs livid; webs black. Inhabits Japan and Kamtschatka. Is sometimes seen at a great distance from land, when it is solitary, but on land is gregarious. 368 Tetracula. Plate cccxcvii. fig. 1.

Perroquet auk.—Bill compressed, with a single groove in each mandible; a white spot on the upper eyelid, between and under the eyes. Inhabits the sea between Japan and Kamtschatka, and often intimates approaching land to mariners. 369 Psittacula.

Tufted auk.—Entirely black; bill with three transverse grooves, 1¼ inch in length, scarlet; sides of the head, 370 Cirrata. Plate cccxcvii. fig. 1.

Anseres. head, space round the eyes, and the angle of the throat, white; a yellow tuft of feathers rises from the upper eyebrow, and stretches to the neck; legs brownish orange; claws black; length 19 inches; female less; the tufts smaller, and the bill crossed only with two grooves. Inhabits Kamtschatka and the neighbouring islands.

371 *Alce.* *Little auk, little black and white diver, Greenland dove, sea turtle*, &c.—Bill without furrows and conical; the whole abdomen and tips of the flag feathers white; feet black. There is a variety that is totally white, and another with a rufous breast. Nine inches long. Inhabits Europe and America, particularly Spitzbergen, Greenland, and Newfoundland, where they are called *ice birds;* but they are rare visitants of the British isles.

372 *Pygmæa.* *Pigmy auk.*—Bill carinated, depressed at the base; body black above, cinereous beneath. Seven inches long. Inhabits the islands between Asia and America.

373 APTENODYTES.

Gen. 35. Aptenodytes, *Penguin.*

374 Characters. Bill straight, a little compressed and sharp-edged; upper mandible longitudinally and obliquely grooved, the lower truncated at the tip; tongue with reflected prickles; wings fin-shaped, without quill feathers; feet placed behind, four-toed, and palmated.

The birds of this genus resemble those of the preceding in colour, food, habit, and apparent stupidity, as also in the situation of their feet, in their erect walk, in their nests, and in their eggs. They differ from them, however, in this, that they are all inhabitants of the South seas, from the equator to the Antarctic circle. They are quite incapable of flying, the feathers on their wings being so short as to resemble scales. They are fortified against cold by an abundance of fat; they swim very swiftly; on land they sit erect, in a singular manner and in vast multitudes, and they cackle like geese, only in a hoarser tone. Their nostrils are linear, and hidden in a furrow of the bill; their wings are covered with a strong dilated membrane, and their tail-feathers very rigid.

375 *Chrysocome.* *Crested penguin.*—Bill reddish brown; legs reddish; frontal crest black, erect, auricular, sulphur colour, and shed on each side; body bluish black, white beneath; wings white beneath. Female with a yellowish stripe on the eyebrow. Twenty-three inches long. Inhabits the Falkland islands, and the southern parts of New Holland. Called *hopping penguin* and *jumping jack*, from its action of leaping quite out of the water, for three or four feet at least, on meeting with the least obstacle. Though more lively than its congeners, it is so foolish as to allow itself to be knocked on the head with a stick, or even to be taken by the hand. When irritated, it erects its crest in a beautiful manner. These birds make their nests among those of the pelican tribe, with which they live in tolerable harmony, and seldom lay more than one egg, which is white, and larger than that of a duck.

376 *Patachonica.* *Patagonian penguin.*—Bill and legs black; ears with a golden spot; lower mandible tawney at the base; irides hazel; head and hind part of the neck brown; back dark blue; breast, belly, and vent white. Four feet three inches long. Inhabits Falkland islands and New Guinea. M. Bougainville caught one, which soon became so tame as to follow and know the person who had the care of it; at first it fed on flesh, fish, and bread, but after some time, grew lean, pined and died. This species is not only the largest, but the fattest of its genus; and its flesh, though not very unpalatable, is black. Anseres.

377 *Demersa.* *Cape penguin.*—Bill and legs black; eyebrows and pectoral band white. Size of a large duck; length 21 inches. Inhabits the Atlantic and Antarctic seas, chiefly round the Cape of Good Hope. Lays two white eggs, which are reckoned delicious eating. Like all of the genus, swims and dives well, but hops and flutters in a strange awkward manner on land, and if hurried stumbles perpetually, or makes use of its wings instead of legs, till it can recover its upright posture, crying at the same time like a goose, but with a hoarser voice. There are two or three varieties.

378 *Minor.* *Little penguin.*—Bill black; legs white. Fifteen inches long. Inhabits New Zealand. Digs deep holes in the earth, in which it lays its eggs.

379 PROCELLARIA.

Gen. 36. Procellaria, *Petrel.*

380 Characters. Bill toothless, a little compressed, hooked at the point; mandibles equal; nostrils cylindrical, tubular, truncated, lying on the base of the bill; feet palmated, hind claw sessile, and without a toe.

The birds of this genus all frequent the deep, where they endure the greatest storms, being hardly ever seen on shore, except at breeding time. They are, however, capable of walking, and their legs are bare of feathers a little above the knee. They feed on the fat of dead whales and fish, and have the faculty of spouting oil from their nostrils.

381 *Pacifica.* *Pacific petrel.*—Black, dusky beneath; legs spotted with black; bill plumbeous and much hooked; nostrils elevated, oval, distinct, obliquely placed; legs pale. Twenty-two inches long. Inhabits, in vast flocks, the islands of the Pacific ocean. These flocks disappear at once, dipping under water altogether, and then rise as suddenly.

382 *Urinatrix.* *Diving petrel.*—Blackish brown; white beneath; bill and chin black; legs blue green, without the spur behind. Eight inches and a half long. Inhabits New Zealand in numerous flocks, and dives remarkably well, often rising at considerable distances, with surprising agility. They croak like frogs, and sometimes make a noise like the cackling of a hen.

383 *Pelagica.* Plate CCCXCVII. fig. 3. *Stormy petrel, stormfinch, Mother Cary's chicken*, &c. —Black, with a white rump. This species is about the size of a swallow, and in its general appearance and flight, not unlike that bird. Length about six inches. The stormy petrel is rarely seen on our shores, except in some of the northern islands, where it breeds in the holes of rocks, or under loose stones, in the months of June and July. At all other seasons it keeps far out at sea. Multitudes of them are seen all over the vast Atlantic ocean, especially before stormy weather. They often skim with incredible velocity along the hollows of the waves, and sometimes on the summits, braving the utmost fury of the tempest. As they appear to run on the surface of the sea, they have their name from an allusion to *Peter's* walking on the water. The inhabitants of the Faroe isles draw a wick through the body of this bird, which is so fat as to burn when lighted, and serve the purpose of a candle.—There is a variety with the

Anseres

the body black; head and sides bluish; scrag green, and wing coverts and rump spotted with green. Both sorts are excellent divers, feed on small fishes, are mute during the day, and clamorous in the night.

384 Nivea. *Snowy petrel.*—Snow white; shafts of the feathers and bill black; legs dusky blue. One foot long. Inhabits the colder parts of the Southern sea, especially in the neighbourhood of ice, the masses of which they often haunt in considerable flocks.

385 Glacialis. *Fulmar petrel*, or *fulmar.*—Whitish; back hoary; bill and legs yellowish; nostrils composed of two tubes, lodged in one sheath. About the size of the common gull, and 17 inches long. Inhabits the Northern and Southern seas; breeds in Greenland, Spitzbergen, St Kilda, &c. laying one large white egg. It is a bold and stupid bird, and very fat, living on fish, dead whales, and other carcases and filth, in quest of which it often follows ships for a great way. Its flesh, though rancid, is eaten raw, dried or boiled, by the Kurile islanders, the Greenlanders and St Kildians, and the oil when expressed is used both for food and lamps. The young are in season about the beginning of August, when the inhabitants of St Kilda endeavour to surprise them in their nests, to prevent them from spouting out their oil, which they do by way of defence. This oil is there valued as a catholicon; and every young bird yields nearly an English pint of it, which is carefully preserved. When the thermometer is above 52 degrees, it is very pure, but at a lower temperature becomes turbid.

386 Gigantea. *Giant petrel, osprey petrel*, or *breakbones.*—Brownish, spotted with white; white beneath; shoulders, wings, and tail brown; bill and legs yellow; a naked, wrinkled, yellow membrane at the angles of the mouth. Bigger than a goose; length 40 inches; expansion of the wings seven feet. Common in the high southern latitudes, and sometimes found, though more rare, in the Northern seas. Is often seen sailing with the wings expanded, close to the surface of the water, but without appearing to move them. At Christmas harbour, Kerguelen's land, &c. they were so tame, that they suffered themselves to be knocked on the head with a stick, by our sailors, on the beach. Though their chief food is fish, they also feed on the carcases of seals and birds. Many of the sailors confound them with the *albatross*, though such of them as are better informed, call them *Mother Cary's geese*. They are reckoned to be very good food. An individual of this species is figured in Latham's Synopsis.

387 Gelida. *Glacial petrel.*—Bluish-ash; back blackish; chin, throat, and breast, white; bill yellow; legs blue. Nineteen inches long. Inhabits the icy seas.

388 Capensis. *Pintado*, or *pintado petrel.*—Variegated with white and brown, and sometimes with yellowish and brown; bill and legs black; temples white and black. Size of the kittiwake; length 14 inches. This is the *pintado bird* of Dampier, the *white and black spotted peteril* of Edwards, and the *Cape pigeon* of our sailors. It is seldom seen much to the north of 30 degrees, and is most frequent about the Cape of Good Hope, and the neighbouring regions. It flies in very numerous flocks, which almost sweep the surface of the water. Our voyagers have traced them to New Zealand, Falkland islands, and various regions of the southern hemisphere. The sailors often catch them with some tarred string, or a bit of lard on a fishing rod. Sometimes they appear in such immense numbers, that 700 have been taken in one night. They feed on fish, but more frequently on the carcases of whales, &c.

Shearwater petrel, or *shearwater.*—Black above; white beneath; legs rufous; bill yellow, tipt with black; hind head whitish-ash; spurious wings spotted with black; first quill and tail feathers brown without and white within. Weight 17 ounces; is 15 inches long, and nearly the size of a pigeon. Inhabits the Southern and Arctic seas. Breeds in the isle of Man, and in the Orkneys, in the former of which it is called *manks puffin*, and in the latter *lyre*. It takes possession of a rabbit burrow or other hole, and lays one white egg, blunt at each end, which is hatched in August. Though the flesh is rank and fishy, it is much relished by some. Great numbers are killed and barrelled with salt. These the inhabitants boil, and eat with potatoes. There is a variety that is cinereous above, white beneath, and with a clear white tail. 389 Puffinus.

Gen. 37. Diomedea, *Albatross*. 390 Diomedea.

Bill straight, upper mandible hooked at the point, lower truncated; nostrils oval, wide, prominent, lateral; tongue very small; toes three, all placed forwards. 391 Characters.

Only four species are known to belong to this genus.

Wandering Albatross, or *man of war bird.*—White; back and wings with white lines; bill pale yellow; legs flesh colour; quill feathers black; tail rounded, and lead coloured; bill grooved, dirty yellow; nostrils remote from the base, and rising out of the furrow; tail feathers fourteen; thighs naked. From three feet and a half to four feet long; bigger than a swan; weighs from twelve to twenty-eight pounds: and extends its wings from ten to thirteen feet. Inhabits most seas, but chiefly occurs within the tropics. It is frequent about the Cape of Good Hope, and towards the end of July appears in great numbers in Kamtschatka, and the seas which separate that part of Asia from America. It is very voracious, feeding on the salmon, which are found in shoals in the mouths of rivers, on the flying-fish, when forced out of the water by the coryphœna, and on other fishes, which it devours whole, and in such quantities, as to be prevented by their weight from rising, though in general it soars very high. It likewise preys on mollusca, and is itself attacked by the sea-eagles, and the larus cataractes. On the shore of South America, it builds about the end of September, a nest of earth on the ground, from one to three feet high, and lays a number of eggs, which are four inches and a half long, and eatable, though the white of them does not coagulate with heat. Its voice resembles the braying of an ass, and its flesh is dry and hard. 392 Exulans. Plate CCCXCVI. fig. 5.

Chocolate albatross.—Bill whitish; body deep chesnut-brown; belly pale; face and wings whitish beneath. Three feet long. Inhabits the Pacific ocean. 393 Spadicea.

Yellow-nosed albatross.—White; bill black; keel of the upper mandible and base of the lower yellow; body above black-blue, white beneath. Three feet long. Occurs in the Southern hemisphere, from 30° to 60°, all round the pole. Flies five or six feet above the water. 394 Chlororhynchos.

Sooty albatross.—Brown; head, bill, tail, quill feathers and claws sooty-brown; area of the eyes white. Three feet long. Inhabits the Southern ocean within the antarctic 395 Fuliginosa.

Anseres. arctic circle. Called *quaker* by the sailors, on account of its brown plumage.

396 Pelecanus.

Gen. 38. Pelecanus, *Pelican*.

397 Characters. Bill straight, bent at the point, and furnished with a nail: the nostrils form an almost obliterated slit; face somewhat naked; legs balancing the body equally; the four toes connected by a membrane.

The pelicans are gregarious, fond of fish, and in general remarkable for their extreme voracity. For the most part they keep out at sea, but some of them are likewise found in the interior parts of continents. They have all a long bill, in a lateral furrow of which lie the nostrils. Several of the tribe are rendered useful to mankind by being taught to fish.

A. *Bill without teeth.*

398 Onocrotalus. *White or common pelican*.—White; gullet pouched; bill from fifteen to sixteen inches long, red; upper mandible depressed and broad, the lower forked; bag at the throat flaccid, membranaceous, capable of great distension; irides hazel; gape of the mouth wide; head naked at the sides, covered with a flesh-coloured skin; hind-head somewhat crested; body faintly tinged with flesh colour; spurious wings and first quill feathers black; legs lead colour. Larger than a swan, and about five feet long. Inhabits Asia, Africa, and South America. In fishing, this bird does not immediately swallow its prey, but fills its bag, and returns to the shore to devour at leisure the fruits of its industry. As it quickly digests its food, it has generally to fish more than once in the course of the day. At night it retires a little way on the shore to rest, with its head resting against its breast. In this attitude it remains almost motionless, till hunger calls it to break off its repose. It then flies from its resting-place, and raising itself thirty or forty feet above the surface of the sea, turns its head, with one eye downwards, and continues to fly in that posture till it sees a fish sufficiently near the surface, when it darts down with astonishing swiftness, seizes it with unerring certainty, and stores it up in its pouch. It then rises again, and continues the same manœuvres, till it has procured a competent stock. Clavigero informs us, that some of the Americans, to procure a supply of fish without any trouble, cruelly break the wing of a live pelican, and after tying the bird to a tree, conceal themselves near the place. The screams of the wounded and confined bird attract others of its kind, which eject for it a portion of provisions from their pouches. As soon as the men observe this, they rush to the spot, and after leaving a small quantity for the bird, carry off the remainder. The female feeds her young with fish macerated for some time in her bag. The pelican is susceptible of domestication, and may even be trained to fish for its master. Faber mentions an individual of this species which was kept in the court of the duke of Bavaria above forty years, and which seemed to be fond of the company of mankind, and of vocal and instrumental music. When a number of pelicans and corvorants are together, they are said to practise a singular method of taking fish. They spread into a large circle, at some distance from land; the pelicans flapping on the surface of the water with their extensive wings, and the corvorants diving beneath, till the fish contained within the circle, are driven before them towards the land; and as the circle contracts by the birds drawing closer together, the fish at last are brought into a small compass, when their pursuers find no difficulty in filling their bellies. In this exercise they are often attended by various species of gulls, which likewise obtain a share of the spoil. The pelican generally builds in marshy and uncultivated places, particularly in islands and lakes, making its nest, which is deep, and a foot and a half in diameter, of carices, and lining it with grass of a softer texture. It lays two or more white eggs, which, when persecuted, it sometimes hides in the water. When it builds in dry and desert places, it brings water to its young in its bag. It walks slowly, flies in flocks, and lives in society with other birds.

Rose-coloured pelican.—Rosy; gullet pouched; bill and legs black; area of the eyes naked; pouch yellow. Size of a goose. Inhabits Manilla. 399 Roseus.

Frigate pelican, or *frigate bird*.—Tail forked; body and orbits black; bill red; belly of the female white. Three feet long; extent of the wings fourteen feet. Inhabits within the tropics. This is the frigate bird of Dampier and other navigators. From its great expanse of wing, it is capable of flying very smoothly, and so high as to be scarcely visible, remaining much in the air, and remote from land. It feeds on fishes, particularly flying fish, on which it darts with the greatest velocity. It not unfrequently likewise preys on other piscivorous animals. It builds in trees or on rocks, and lays one or two eggs of a flesh colour, and spotted with red. 400 Aquilus.

Lesser frigate pelican.—Tail forked; body ferruginous; bill and orbits red. Resembles the last, but less. 401 Minor.

Corvorant.—Tail rounded; body black; head somewhat crested; bill blackish; the base of the lower mandible covered with a yellowish skin, extending under the chin, and forming a pouch; irides green; chin white, surrounded with a yellowish arch; tail long and lax, consisting of fourteen feathers; thighs with a white spot, dotted with black; legs black. Three feet long; size of a goose, but more slender, and weighs about seven pounds. Inhabits Europe, Asia, and America. Common on many of our sea-coasts, building its nest on the highest parts of cliffs that hang over the sea, and laying three or more pale green eggs, about the size of those of a goose. In winter these birds disperse along the shores, and visit the fresh waters, where they commit great depredations among the fish. They are remarkably voracious, and have a very quick digestion. Though naturally extremely shy and wary, they are stupid and easily taken when glutted with food. Their smell, when alive, is more rank and offensive than that of any other bird, and their flesh is so disgusting, that even the Greenlanders will hardly taste it. It is not uncommon to see twenty of these birds together, on the rocks of the sea coast, with extended wings, drying themselves in the wind. In this attitude they sometimes remain for nearly an hour, without once closing their wings; and as soon as the latter are sufficiently dry to enable the feathers to imbibe the oil, they press this liquor from the receptacle on their rumps, and dress the feathers with it. It is only in one particular state that the oily matter can be spread on them, namely, when they are somewhat damp; and the instinct of the birds teaches them the proper moment. Corvorants were formerly 402 Carbo.

sometimes

Anseres. sometimes trained in this country, as they still are in China, for the purpose of catching fish for the table. With this view they were kept with great care in the house, and when taken out for fishing, they had a leathern thong tied round their neck, to prevent them from swallowing their prey.

403 Graculus. *Shag.*—Tail rounded; body black, brown beneath; tail feathers twelve; head and neck black, with a green gloss; back and wing-coverts purple black, glossy at the edges; middle of the belly dusky; legs black. Weighs about four pounds. Length twenty-nine inches. The female weighs about three pounds and a quarter; and is only twenty-seven inches long. Inhabits the northern seas of Europe. Swims with its head erect, and the body under water. On perceiving the flash of a gun, dives instantaneously, and rises at a considerable distance. Has the manners and habit of the preceding, and devours a prodigious quantity of fish. Near the Cape of Good Hope a variety occurs with a yellow chin, and wedged tail. Another, which frequents the coasts of Cayenne and the Carribbee islands, is blackish above, brown beneath; and has the feathers above edged with black.

404 Pygmaeus. *Dwarf shag.*—Tail wedged; feathers twelve; body black, with a few scattered white spots. Female brown, without spots. Size of the garganey. Inhabits the Caspian sea.

405 Cristatus. *Crested shag.*—Shining green, dusky beneath; bill and legs dusky; head crested. From two to three feet long. Inhabits the northern seas of Europe, occurs on our own coasts, and both in appearance and manners, resembles the *graculus*.

B. *Bill serrated.*

406 Thagus. *Saw-billed pelican.*—Brown; tail rounded; gullet pouched, and covered with short cinereous feathers; bill one foot long; each mandible hooked; pouch very large; legs black. Size of a turkey; extent of wings nine feet. Inhabits Chili.

407 Bassanus. *Gannet, or soland goose.*—Tail wedged; body white; bill and quill feathers black; face blue; irides yellowish; tail feathers twelve; eyes surrounded with a naked skin of fine blue; legs black, and greenish on the fore part. Three feet long. Weighs seven pounds; and inhabits Europe and America. This species of pelican haunts the Bass island in the frith of Edinburgh, Ailsa, on the coast of Ayrshire, the island of St Kilda, and hardly any where else in Europe. It arrives at these spots in March, and continues till September. As it must let itself fall before it takes wing, it requires a steep and precipitous breeding station. It makes a rude nest of sticks, grass, sea-plants, &c. and lays one egg. While the female is occupied with incubation, the male brings her food, which consists almost entirely of herrings and sprats. In the bag under their bill they are able to fetch four or five herrings at a time, and a great number of sprats, which the young bird extracts from the mouth of the old one, with its bill, as with pincers. The young begin to be taken in August, and by some are relished as an exquisite morsel; but the old ones are tough and rancid. The fowler who seizes the young, is let down by a rope from the top of a cliff, and is sometimes stationed on the slippery projection of a rock, with the perpendicular precipice of four hundred feet or more beneath him. The young are of a dark gray colour, and continue so for a year or more, when they gradually become white, except the tips of their wings, which are always black. In September and October the old birds leave their breeding places, and migrate southward, following, as is alleged, the shoals of herrings. In December they are often seen off Lisbon plunging for sardines; but after that period it is not well known what becomes of them till March. They are common on the coasts of Norway and Iceland, and are said to be met with in great numbers about New Holland and New Zealand. They also breed on the coast of Newfoundland, and migrate southward along the American shores as far as South Carolina. Of this species there are two varieties. The first is brown, spotted with white, and white beneath, with naked and blackish. The second is brown, with triangular white spots, whitish, and spotted with brown beneath; the bill, wings, tail, and legs brown.

Lesser gannet.—Tail wedged; body whitish; all the quill feathers black; face red. Two feet and a half long. Inhabits the Chinese, Indian, and American seas. 408 Piscator.

Booby.—Tail wedged: body whitish; primary quill feathers tipt with blackish; face red; bill gray, brownish at the base; irides pale ash; chin bald, yellowish; body white beneath; tail brownish at the tip; legs yellowish. Has its name from being so foolish as to alight on one's hand, if held out to it, when tired. Builds in places bare of trees, making its nest on the ground. Its flesh is black and rancid. 409 Sula.

Fishing corvorant.—Tail rounded; body brown, whitish, and spotted with brown beneath; throat white; bill yellow; irides blue. Inhabits China, where it is tamed for the purpose of catching fish. 410 Sinensis.

Lesser booby.—Black, white beneath; face downy. Eighteen inches long. Inhabits Cayenne. 411 Parvus.

Gen. 39. PLOTUS, *Darter.* 412 Plotus.

Bill straight, pointed, toothed; nostrils an oblong slit near the base; face and chin naked; legs short; all the toes connected. 413 Character.

The birds of this genus have a small head, and long slender neck. They inhabit the southern and warmer latitudes, and live chiefly on fish, which they take by darting the head forwards, while the neck is contracted like the body of a serpent.

White-bellied darter.—Head smooth; belly white. Inhabits Brazil. Two feet ten inches long. Builds on trees, and is scarcely ever seen on the ground. When at rest, it sits with the neck drawn in between the shoulders. The flesh is oily and rancid. 414 Anhinga.

Black-bellied darter.—Head smooth; belly black. About three feet long. Inhabits Ceylon, Java, &c. There are several varieties. 415 Melanogaster. Plate CCCXCVI. fig. 4.

Surinam darter.—Head crested; belly white. Thirteen inches long. Inhabits Surinam. Is domesticated, and feeds on fish and insects, especially flies, which it catches with great dexterity. 416 Surinamensis.

Gen. 40. PHAETON, *Tropic Bird.* 417 Phaeton.

Bill sharp-edged, straight, pointed, the gape extending beyond the bill; nostrils oblong; hind-toe turned forwards. 418 Character.

The

Anseres. The species of this genus inhabit the South sea, especially between the tropics. Their bill is compressed and bent a little downwards; the lower mandible angulated. The feet have four toes, which are palmated. The tail is cuneiform, and distinguished by the great length of the two intermediate feathers.

419 *Æthereus.* Plate CCCXCVI. fig. 3. *Common tropic bird.*—White; back, rump, and lesser wing-coverts streaked with white; two middle tail feathers black at the base; bill red. Two feet ten inches long; size of a wigeon. Flies very high, and at a great distance from land; feeds on young sharks, dolphins, and albicores. On land, where it is rarely seen except in the breeding season, it sits on trees, and builds on the ground, in woods. It is well known to navigators, to whom it generally announces their approach to the tropic, though this indication is by no means infallible, as the bird sometimes wanders to the latitude of $47\frac{1}{2}°$. It is subject to varieties. Its flesh is indifferent.

420 *Melanorhynchos.* *Black-billed tropic bird.*—Streaked black and white, white beneath; bill black; quill feathers tipt with white; tail feathers with black. Nineteen inches and a half long. Inhabits Palmerston and Turtle islands.

421 *Phœnicurus.* *Red-tailed tropic bird.*—Rosy flesh colour; bill and two middle tail-feathers red. Two feet ten inches long, of which the two middle tail feathers measure one foot nine inches. Builds in hollows in the ground, under trees, and lays two yellowish-white eggs, with rufous spots. Inhabits the Mauritius.

422 Colymbus.

Gen. 41. Colymbus.

423 Characters. Bill toothless, subulate, straight, and pointed; throat toothed; nostrils linear, at the base of the bill; feet placed far behind.

The birds of this family walk on land with awkwardness and difficulty, but swim and dive with great dexterity. The guillemots chiefly inhabit the sea; have a slender tongue, of the size of the bill. The latter is compressed, and covered with short feathers at the base; the upper mandible a little bent; flesh tough, and, like the eggs, nauseous. The divers frequent also the northern lakes, have a strong bill, less pointed, cylindrical, the edge of the mandible turned in, and the upper longer than the under; the nostrils divided in the middle by a membrane; the tongue long, sharp, serrated at the base on each side; legs slender, a black band between the thighs; tail feathers twenty. These birds are monogamous, fly with difficulty, and frequent fresh water in the breeding season. The grebes have no tail, a strong bill, lores naked, tongue a little cleft at the tip, body depressed, thickly covered with short shining plumage, wings short, and legs compressed. They are frequently found about the fresh waters of southern Europe.

424 Guillemot.

A. Feet three-toed. Guillemot.

425 *Lacteolus.* *White guillemot.*—Snowy; bill and legs brownish and flesh-coloured. Size of the garganey. Inhabits the Netherlands.

426 *Grylle.* *Black guillemot, spotted guillemot, Greenland dove, sea turtle,* &c.—Body black; wing-coverts white. But these general markings are incident to great variety. The more special characteristics are; bill black; inside of the mouth and legs red; upper wing-coverts in the middle, and lower part of the belly, white. Weighs fourteen ounces, and measures nearly the same number of inches in length. Inhabits Europe and America. Frequents the Faroe islands, the Bass, St Kilda, &c. visiting these places in March, making its nest far under ground, and laying one egg of a dirty white, blotched with pale rust colour. Except at breeding time, it keeps always at sea, lives on fish, flies low, and generally in pairs. It cannot, without much difficulty, rise from the ground. In the Orkney islands, it is called *tyste.* The Greenlanders eat its flesh, and use its skin for clothing, and its legs as a bait to their fishing lines.

Lesser guillemot.—Black, with a narrow stripe across the wings, cheeks and under parts white. Weight eighteen or nineteen ounces; length about sixteen inches. Inhabits the northern seas of Europe, and in winter frequents the frith of Forth in vast flocks; where it feeds on sprats, and is called *marrot* or *morrot.* Many doubts have been entertained with regard to this bird, Dr Latham and other ornithologists having considered it as the young of the succeeding species. It is to be observed, however, that besides the difference in size and plumage, this bird is rarely met with in the south till the month of November, whence it has been called the *winter guillemot,* whereas the other species always leaves us before September, and does not again appear till the ensuing spring; and that its young, when they depart, are exactly like the old ones. 427 *Minor.*

Foolish guillemot, or *scout.*—Body black; breast and belly snowy; secondary quill feathers tipt with white; bill black; inside of the mouth yellow; legs and tail blackish. Seventeen inches long. Inhabits the northern seas of Europe, Asia, and America. This species is likewise called *marrot* in Scotland, and *lavie* in St Kilda. In that island it appears about the beginning of February, and is hailed by the inhabitants as the harbinger of plenty. A St Kilda man descends in the night, by the help of a rope, to the ledge of a precipice, where he fixes himself, and tying round him a piece of white linen, awaits the arrival of the bird, which, mistaking the cloth for a piece of the rock, alights on it, and is immediately dispatched. In this way 400 are sometimes taken in one night, and at dawn the fowler is drawn up. The foolish guillemot lays but one egg, which is very large, unprotected by any nest, and has such a slender hold of the rock, that when the birds are surprised, and fly off suddenly, many of them tumble down into the sea. These birds seldom quit their eggs unless disturbed, but are fed with sprats and other small fish by the male. In places where they are seldom molested, it is with difficulty they are put to flight, and may sometimes be taken with the hand; others flutter into the water, appearing not to have much use of their wings. 428 *Troile.*

B. Four-toed, and palmated. Diver. 429 Diver.

Red-throated diver or *loon.*—A ferruginous shield-like spot beneath the neck; body brown, with minute white spots above, white beneath; bill black; head and chin cinereous, spotted with brown; neck with small white and brown lines above; legs dusky. Weighs about three pounds. Length near two feet and a half. Inhabits the north of Europe, Asia, and America, and is seldom seen far southward, except in very severe winters. In the breeding season it frequents the lakes, making a nest among the reeds and flags, and lays two eggs of an ash colour, marked with a few black spots. In Iceland it 430 *Septentrionalis.*

Anseres. it is said to make its nest of moss and grass, lined with down, among the grass of the shores contiguous to the waters. It breeds in the north of Scotland, but is seldom observed in the south of England. It lives on marine vermes, crabs, and the smaller fishes, with which it is sometimes taken in nets. It swims and flies swiftly; and when it screams in its flight is said to presage a storm.

431 Arcticus. *Black-throated diver.*—Head hoary; neck violet black beneath, with an interrupted white band; bill black; body black above, white beneath; sides of the neck white, spotted with black; shoulders and wing-coverts with white spots, the former square, the latter round; quill feathers dusky. Two feet long. Inhabits the northern parts of Europe, Asia, and America, frequenting both the sea and lakes. Before rain, it is restless and clamorous; occurs in Scotland, but is not common in England.

432 Stellatus. *Speckled diver* or *loon.*—White beneath; hind-head and quill feathers dusky; throat pale ash; back, flanks, rump, and tail, spotted with white; bill horn colour; legs brown. The weight of this species is about four pounds, and the length 27 inches. It inhabits the north of Europe and America, and is among the most common of the diver tribe found in this country, being frequently seen in winter, in our bays and inlets, and sometimes in fresh-water rivers and lakes. From its attending the sprats in the Thames, it is called *sprat loon* by the fishermen. In the northern regions it lays two eggs, the size of those of a goose, dusky, and with a few black spots, in the grass, on the borders of lakes.

433 Glacialis. *Northern diver*, or *greatest speckled diver.*—Head and neck purplish black; chin and upper part of the neck with a white interrupted band; upper part of the body, bill, legs, and tail black; back with square white spots disposed in rows; wing-coverts with white dots. The largest of the genus; sometimes weighing fifteen or sixteen pounds, and measuring nearly three feet and a half in length. Inhabits the north seas, and breeds in the fresh waters, in Iceland, Greenland, &c. Frequents the seas about the Orkneys, all the year round, without breeding there. The skin, which is tough, and well covered with soft down, is dressed in some parts of Russia, &c. and used as clothing.

434 Immer. *Immer, imber*, or *ember goose*, or *diver.*—Body blackish and waved with white above, white beneath; feathers of the back, wings, and tail edged with white. Two feet long. Inhabits the Arctic ocean, and also, it is said, the lake of Constance, where it is called *fluder*. Unless in severe winters, it is rare in England, but is more common on the Scottish and Orkney coasts. It makes its nest on the water, among reeds and flags. It feeds on fish, after which it dives with great celerity, and is sometimes taken under water by a baited hook.

435 Grebe.

C. *Feet four-toed, lobed. Grebe.*

436 Cristatus. *Crested grebe, gray* or *ash-coloured loon, &c.*—Head rufous; collar black; secondary quill feathers white; bill flesh-coloured, brown at the tip; lores and irides red; body brown above, white beneath; head tumid, and varies in colour by age. During the first year, this bird has a smooth head, and a white spot on the wings; and during the second, a long downy tuft on each side of the throat. This is the largest of the grebes, weighing about two pounds and a half, and measuring twenty-one inches in length. It occurs in almost every lake in the northern parts of Europe, as far as Iceland, and southward to the Mediterranean, and is also found in various parts of America and Siberia. It is common in the fens and lakes in various parts of England, where it breeds. The female makes her nest of various kinds of dried fibres, stalks and leaves of water plants, as of the nymphæa, potamogeton, hottonia, &c. and the roots of menyanthes trifoliata, and conceals it among the flags and reeds which grow in the water, and where it is erroneously said to float. The young are fed on small eels. In some countries, ladies muffs and other ornamental articles of dress are made of the skin of the belly of this species, which has a fine down of a dazzling whiteness. It requires five skins to make a muff, which sells at four or five guineas. The tippet grebe is the female or young of this species.

Eared grebe, or *dobchick.*—Blackish-brown above, white beneath; head black; ears crested, and ferruginous; bill and legs black; irides and lores red; primary quill feathers dusky, secondary white. There is a smaller variety with a double crest, and the neck spotted with chesnut. This species is about twelve inches long, and inhabits the northern lakes of Europe and Siberia. It is also met with in southern climates, but is not numerous in England. According to Pennant, it breeds in the fens near Spalding in Lincolnshire, and the female makes a nest not unlike that of the preceding, laying four or five small white eggs. 437 Auritus. Plate CCCCVIII. fig. 4.

Horned grebe.—Head glossy-green; a yellow tufted band through the eyes; neck and breast tawney. Size of the preceding. Inhabits North America. 438 Cornutus.

Little grebe, or *small dipper.*—Of a reddish brown above, white, with spots beneath; head smooth; feathers of the body edged with reddish; lower part of the belly gray; upper wing-coverts, and first and last quill feathers blackish, rest of the quill feathers white; bill blackish; base of the lower mandible reddish; legs blackish green. Inhabits Europe, North America, the Philippine isles, and the Delta in Egypt. The least of the grebe tribe, weighing only between six and seven ounces, and measuring from the tip of the bill to the rump, ten inches. It seldom quits the water, and is a remarkable diver, feeding on fish, insects, and aquatic plants; constructing a large nest, a foot thick, of grass and the stalks of aquatic plants, in the midst of the waters which pervade it, and laying five or six whitish eggs, which it covers when it leaves the nest. In several parts of this country it is called *didapper*. 439 Minor.

Red-necked grebe.—Subcrested, brown; chin, cheeks, and region of the ears cinereous; under part of the neck and breast rusty-red; belly, and secondary quill feathers white; bill black, the sides tawney at the base; irides tawney; legs dusky. Seventeen inches long; and weighs nearly nineteen ounces. Inhabits Europe, but is very rare in Britain. 440 Rubricollis.

Dusky grebe, or *black and white dobchick.*—Head smooth; body dark brown above; front, under parts of the body, and tips of the secondary quill feathers, white. Eleven inches long. Inhabits Europe and America. Breeds in the fens of Lincolnshire, and is found, in the winter, in our inlets on the coast, particularly in Devonshire, where it is by no means uncommon. 441 Obscurus.

Black-chin grebe.—Head smooth; body blackish; chin black; throat ferruginous; belly cinereous, mixed with 442 Hebridicus.

Anseres. with silvery. Somewhat larger than the little grebe. Inhabits Tiree, one of the Hebrides.

443 Larus.
Gen. 42. Larus, *Gull*.

444 Characters. Bill straight, sharp edged, a little hooked at the tip, and without teeth; lower mandible gibbous below the point; nostrils linear, broadest on the fore part, and placed in the middle of the bill.

The birds of this genus have a light smooth body; long wings; a strong bill; the tongue somewhat cleft; the feet short; bare of feathers above the knee; with a small back toe. They inhabit the north; feed chiefly on fishes, and even on those that are dead. When harassed, they throw up or discharge their food. As the young are sometimes spotted to their third year, the extrication of this species is attended with doubt and difficulty.

A. *Nostrils without a cere.*

445 *Tridactylus.* *Tarrock*, or *kittiwake*.—Whitish; the back grayish; tips of the tail feathers, except the outermost, black; three toes. In maturer age, the characters are; back whitish hoary; quill feathers white; hind toe unarmed. Ornithologists, in fact, seem now to be agreed, that *L. tridactylus* and *L. rissa*, are only varieties of the same species. A third variety occurs, distinguished by an oblique black band on the wings, and white chin. About the size of a pigeon; about fourteen inches long. Inhabits Europe, Asia, and America. Breeds on the cliffs about Flamborough-head, the Bass, isle of May, the rocks near Slains Castle, &c.; lays two eggs; feeds on fishes, and seeks its food in company of seals and whales. It swims and flies rapidly, and is often clamorous. Its flesh is much relished by the Greenlanders, who also make clothing of its skin. One that was kept and tamed, knew its master's voice at a distance, and answered him with its hoarse piping note. It had a voracious appetite, and though plentifully fed on bread, would rob the poultry of their share.

446 *Minutus.* *Little gull*.—Snowy; head and beginning of the neck black; back and wings russet; bill brown red; legs scarlet. Size of a thrush. Inhabits Russia and Siberia.

447 *Canus.* *Common gull*.—White; back hoary; primary quill feathers black at the ends, the fourth and fifth with a black spot at the tip, the outer one black without; bill yellow; irides hazel; legs greenish white. A variety is met with that has the head spotted with brown; neck brown above, and tail feathers white, with a black band. This is generally supposed to be the younger bird. Inhabits Europe and America. Seventeen inches long; of the size of a pigeon; and is seen in numerous flocks, continually screaming. Lives on fishes, vermes, and the larvæ of insects; builds among rocks and stones, and is a foolish bird. The most common and numerous of all the British gulls, breeding on rocky cliffs, and laying two eggs, nearly the size of those of a common hen, of an olive brown colour, marked with dark-reddish blotches. At the mouths of the larger rivers they are seen in numbers, picking up the animal substances which are cast on shore, or come floating down with the ebbing tide. For this kind of food they watch with a quick eye, and it is curious to observe how such as are near the breakers will mount up the surface of the water, and run splashing towards the summit of the wave to catch the object of their pursuit. At particular seasons, this species also resorts to the inland parts of the country, to feed on worms, &c. Some persons who live near the sea, commonly eat this, as well as various other kinds of gulls, which they describe as being good food, when they have undergone a certain sweetening process before cooking; such as burying them in fresh mould for a day, or washing them in vinegar. This species breeds on the ledges of rocks, close to the sea shore, sometimes not far above the water. This bird is frequently seen in winter, at a considerable distance from the coast. It flocks with rooks in severe weather, and will follow the plough for the sake of the larvæ of the chaffer. 448

Marinus. *Black-backed gull*, or *great black and white gull*.—White; back black; bill yellow; lower mandible with a red spot near the tip and black in the middle; irides yellow; lower part of the back white; quill feathers black, tipt with white; legs flesh-coloured. The markings, however, vary considerably with the age of the bird. The weight of this species is four pounds and three quarters; and the length near thirty inches. It inhabits Europe and America. Though not very plentiful on our coasts, it is occasionally seen in small flocks of eight or ten, sometimes in pairs, but never associating with the other gulls. It cackles like a goose, lives chiefly on fish, but also infests the eider duck, and even lambs. It has been known to tear and devour the largest fish on the hooks, when left dry by the ebbing tide. It breeds on the steep holmes, and Lundy island, in the Bristol channel, makes a nest in the clefts of the highest rocks, and lays three eggs of a blackish gray colour, with dark purple spots, and eatable. Its skin is used for clothing by the Eskimaux and Greenlanders; and the young not only affords a fine down, but an article of food. 449

Herring gull.—White; back brown; legs yellow; *Fuscus.* bill yellow; irides straw-coloured; five first quill feathers black above. Weight about thirty-three ounces. Length twenty-three inches. Inhabits Europe, Asia, and North America, proceeding southward in winter as far as the Black and Caspian seas, Jamaica, and the islands on the shore of South Carolina. It lives on fish, especially herrings, which it seizes with great boldness, and the shoals of which it accompanies in flocks. It is sometimes observed to trample the soft sand, by moving its feet alternately in the same place, for the purpose, it is supposed, of forcing up sand eels, or some hidden prey. This species is very common on the British shores; makes its nest of dry grass on the projecting ledges of the rocks, and lays three eggs of a dull whitish colour, spotted with black. Fishermen describe it as the constant, bold, and intruding attendant on their nets, from which they find it difficult to drive it away. 450

Black-headed gull.—Whitish; head blackish; bill *Atricilla.* red; legs black. Eighteen inches long. Inhabits Europe and America. Flies about the shores in flocks, with a continual clamour; and builds in pine trees. 451

Laughing or *black-headed gull*.—Whitish; head blackish; bill and legs pale red. Eyelids red; irides hazel; *Ridibundus.* head and chin dusky brown; and in the full grown bird black; first ten quill-feathers white-edged, and tipt with black, the rest cinereous, tipt with white; claws black. This species has its name from its singular cry, which resembles a horse laugh. It is fifteen inches long; inhabits Europe, America, and the Bahama islands; and breeds in the pools and fens of England, making its nest on the ground, with rushes, dried grass, &c. and laying three greenish brown eggs, spotted with tawney.

Anseres. tawney. "In former times (says Mr Bewick), these birds were looked upon as valuable property by the owners of some of the fens and marshes in this kingdom, who every autumn caused the little islets or hafts in those wastes, to be cleared of the reeds and rushes, in order properly to prepare the spots for the reception of the old birds in the spring, to which places at that season they regularly returned in great flocks to breed. The young ones were then highly esteemed as excellent eating; and on that account were caught in great numbers before they were able to fly. Six or seven men, equipped for this business, waded through the pools, and with long staves drove them to the land, against nets placed upon the shores of these hafts, where they were easily caught by the hand, and put into pens ready prepared for their reception. The gentry assembled from all parts to see the sport."——"These were the *sea-gulles* of which we read as being so plentifully provided at the great feasts of the ancient nobility and bishops of this realm. Although the flesh of these birds is not now esteemed a dainty, and they are seldom sought after as an article of food, yet in the breeding season, where accommodation and protection are afforded them, they still regularly resort to the same old haunts, which have been occupied by their kind for a long time past."

B. *Nostrils covered with a cere.*

452 *Parasiticus.* *Arctic gull.*—Two middle tail feathers very long; bill and legs dusky; body black above; temples, front, and under parts of the body white; breast with a dusky band. Female brown beneath; twenty-one inches long. Inhabits Europe, Asia, and America. Breeds in the Hebrides and Orkneys, among the heath, making its nest of grass and moss, in some marshy place, and laying two eggs, the size of those of a hen, ash-coloured and spotted with black. It is very rapacious, and pursues the lesser gulls, not for their dung, as some have asserted, but to make them disgorge what they have lately eaten, which it dexterously catches and devours before it reaches the water. It is to be remarked, that all this tribe are voracious, and if chased by a hawk, or other bird that creates alarm, readily disgorge, in order to lighten themselves, and thus escape by flight. It is no uncommon thing to see them bring up a large quantity of half digested food, when slightly wounded by shot; and tamed gulls will do the same, if driven by a dog. It may also be observed, that gulls float highly on the surface of the water by reason of the quantity of feathers in proportion to their weight, and seem to be incapable of diving. If they should be wounded ever so slightly, and fall into the water, they never attempt to dive like other aquatic birds.

453 *Crepidatus.* *Black-toed gull.*—Varied with dirty white and brown, paler beneath; two middle tail feathers a little longer; bill black; breast and belly white, with numerous dusky and yellowish lines; flanks and vent transversely black and white; wing-coverts and tail black, edged with white or brownish; legs bluish; toes and connecting membrane black. Weight about eleven ounces; length fifteen or sixteen inches. Inhabits Europe and America, but is not common on the British shores. Its habits nearly coincide with those of the preceding species. Its excrement is said to be red, from the circumstance of its feeding on the *helix janthina*.

454 *Catarractes.* *Skua gull.*—Grayish; quill and tail feathers white at the base; tail nearly equal; bill dusky, much hooked, upper mandible covered half way with a black cere; body brown above, rusty-ash beneath; legs blackish, rough, warty; claws hooked, black; hind-toe short, with a sharp-hooked claw; two feet long. Inhabits Europe and America. These fierce birds are met with by navigators in the high latitudes of both hemispheres, where they are much more common than in the warm or temperate parts of the globe. They are often mentioned in Captain Cook's Voyages, and, from their being numerous about Falkland islands, the seamen call them *Port Egmont hens*. They are also common in Norway, Iceland, the Shetland and Faroe isles, &c. They prey not only on fish, but also on the lesser sorts of water fowl, and are so courageous in defence of their own young, that they attack either man or beast, that dares to disturb their nest. They make their nests among the dry grass, and, when the young are reared, they disperse themselves commonly in pairs over the ocean. In the island of Foula, in Shetland, the skua gull is called *bonxie*, and is a privileged bird, there being a fine of 10l. Scotch for destroying its eggs, because it keeps off the eagle during the whole breeding season.

Gen. 43. STERNA, *Tern.* 455 Sterna.

Bill subulate, somewhat straight, pointed, a little compressed, without teeth; nostrils linear; tongue pointed; wings very long; tail generally forked. 456 Characters.

The birds of this genus are mostly inhabitants of the ocean, and feed on fishes. They are seldom afraid of man.

Sooty tern.—Black above; upper parts of the body, cheeks, front and shafts of the quill and tail feathers white; sixteen inches long. Inhabits the Atlantic and Antarctic seas. 457 Fuliginosa.

Noddy.—Body black; front whitish; eye-brows black; bill and legs black; hind-head cinereous; fifteen inches long; found chiefly within the tropics; is clamorous, seldom goes far from shore, and always rests there during the night. It builds on the rocks, and its eggs are reckoned excellent food. 458 Stolida.

Sandwich tern.—White; back and wings hoary; cap black; front with white spots; quill feathers blackish, with a white shaft; bill black, yellowish at the tip; legs black; wings longer than the tail; egg olive-brown, with purplish and crowded spots; eighteen inches long. Inhabits the Kentish coast, generally appearing about Romney, in the middle of April, and departing in the beginning of September. It is not uncommon about Sandwich, where it was first particularly noticed by Mr Boys. The circumstance of its breeding in England has not been perfectly ascertained. The *hævia* of some authors, or the *Kamtschatkan tern* of Pennant, appears to be only a variety, which is black, with paler colours above; white beneath; and bill and legs black. 459 Cantiaca.

Common or *greater tern.*—Two outer tail feathers half black, and half white; bill and legs crimson; the former tipt with black; crown and area of the eyes black; rest of the head, neck, tail, and body, white beneath; back and wings cinereous; outer tail feathers black on the outer edge. There is a variety with black legs, and the outer tail feathers entirely white. The weight of this species is about four ounces and a quarter; and 460 Hirundo.

Anseres. and its length fourteen inches. Inhabits Europe, Asia, and America. It frequents our flat, sandy, or shingly shores, and lays three or four eggs, of the size of a pigeon's, of an olivacious brown, and spotted and blotched with dusky, among stones, without making any nest. It is noisy and restless, constantly on wing, in search of insects and small fish; in pursuit of which it darts into the water with great force, seizes its prey, and instantly returns; for, though web-footed, it is not observed to swim or dive. It is commonly known by the name of the *sea-swallow*, and, in some parts, by that of the *gull teaser*, from its persecuting the smaller gulls, and obliging them to disgorge. In New England it is called *mackarel gull*, and at Hudson's bay it is known by the name of *black-head*. The young birds are mottled with brown and white, and are, most probably, the *brown tern* described by Ray and other ornithologists.

461 Alba. *White tern.*—White; bill and legs black; length between two and three inches. Inhabits the Cape of Good Hope.

462 Nigra. *Black-headed tern.*—Body hoary; head and bill black; legs red; size of the preceding. Inhabits Europe.

463 Minuta. Plate CCCXCVII. fig. 5. *Lesser tern.*—Body white; back hoary; front and eye-brows white; bill yellow, tipt with black; irides brown; cap black; a black band through the eyes; legs yellow; eight inches and a half long. Inhabits Europe and America. It has the habits of the common species, but is far less numerous. It lays two eggs, of a very pale brown, spotted all over with cinereous and dusky, and placed in a small depression among the shingle, without any nest.

464 Fissipes. *Black tern.*—Body black; back ash-coloured; belly white; feet red; bill black; male with a white spot on the chin; wings and tail cinereous; vent and lower tail coverts white; length ten inches. Inhabits Europe and America, and has all the actions and manners of the other species, but seems to prefer fresh-water insects and fish to marine. It feeds on the verge of pools, in swampy places, and often remote from the sea. In the fenny parts of Lincolnshire and Cambridgeshire it is called *car-swallow*. Though very plentiful about the reedy pools of the Romney marshes, it keeps to the edges of the stagnant water, and is rarely seen on the adjoining sea shore, till after the breeding season, and even then not very commonly. It lays three or four eggs about the size of those of a magpie, of an olive brown colour, blotched and spotted with brown and black.

465 Rynchops.

Gen. 44. Rynchops, *Skimmer*.

466 Characters. Bill straight; upper mandible shorter than the under, the latter truncated at the apex; tail forked and shorter than the wings; nostrils linear, and the back toe small.

467 Nigra. *Black skimmer*, or *cut-water*.—Blackish; white beneath; bill red at the base; the lower mandible grooved; front and chin white; wings with a transverse white band; two middle tail feathers black, the next edged with white; legs red; twenty inches long. Inhabits Asia and America. This bird is ever on the wing, sweeping the surface of the water, dipping in its bill, or at least the under mandible, to scoop out the smaller fishes on which it feeds. In stormy weather it frequents the shores, and is contented with oysters and other shell-fish.

Grallæ.

Order IV. GRALLÆ.

468 Grallæ.

Bill subcylindrical, and somewhat obtuse; tongue entire and fleshy; legs naked above the knees; the feet are commonly furnished with four toes, of which three stand forwards, and one backwards, sometimes wholly unconnected, and at other times half connected by a web. Some species, too, have only three toes; their legs are long, that they may seek their food in marshy and swampy places, for which reason they have also a long neck, and, for the most part, a long bill. Their bodies are oval, and somewhat compressed, and their tail is generally short. They build chiefly on the ground and in marshy places, and feed principally on fishes and water insects. They are all more or less migratory, and such as inhabit the more northern countries of Europe, universally leave them at the approach of winter. 469 Characters.

Gen. 45. Phænicopteros, *Flamingo*. 470 Phænicopteros.

Bill bare, toothed and bent as if broken; nostrils linear; the feet four-toed and palmated, the membranes semicircular on the fore part; hind toe not connected. 471 Characters.

The birds of this genus combine the anseres with the grallæ. They have the neck and legs long; the bill strong and thick, the upper mandible carinated above, and denticulated at the margin, the under one compressed and transversely sulcated; the nostrils above covered with a thin membrane, and communicating with each other; the back-toe very small, and the web which connects the fore-toes reaching to the nails.

Red flamingo.—Flag feather black. This singular bird is scarcely so big as a goose, but has the neck and legs in a greater disproportion to the body than any other bird; the length from the end of the bill to that of the tail being four feet and two or three inches; but to the end of the claws, sometimes more than six feet; the bill is four inches and a quarter long, and of a structure different from that of any other bird, the upper mandible being very thin and flat, and somewhat moveable, the under thick, and both bending downwards from the middle; the end, as far as the curvature, is black, and the rest reddish-yellow; a flesh coloured cere extends round the base of the bill to the eye; the neck is slender and of an immoderate length; the tongue, which is large and fleshy, fills the cavity of the bill, has a sharp cartilaginous tip, and is furnished with twelve or more hooked papillæ on each side, which bend backwards. The bird, when in full plumage, which it does not acquire till the third year, is of a most beautiful deep scarlet, except the quills, which are black. The flamingo affects the warmer latitudes; and, in the old continent, is not often met with beyond the 40th degree north or south. It is met with every where on the African coast and adjacent isles to the Cape of Good Hope, and sometimes on the coast of Spain and Italy, and even on those of France that lie on the Mediterranean, having been found at Marseilles and for some way up the Rhone. It is seen also on the Persian side of the Caspian sea, and from thence along the western coast as far as the Wolga. They breed in the Cape de Verd isles, particularly in that of Sal, constructing a nest 472 Ruber. Plate CCCXCVIII. fig. 1.

 of

of mud in the shape of a hillock, with a cavity at top, in which the female generally lays two white eggs, of the size of those of a goose, but more elongated. The hillock is of a sufficient height to admit the bird's sitting on it conveniently, or rather standing, as the legs are placed one on each side at full length. Sometimes the female will deposit her eggs on the projecting part of a low rock, if otherwise adapted to the above-mentioned attitude. The young are not able to fly till they are grown, but they can previously run with amazing swiftness. In this immature state, they are sometimes caught and easily tamed. In five or six days, they became familiar, and even eat out of the hand, and drink a great quantity of sea water. It is, however, difficult to rear them, as they are very liable to pine from want of their natural subsistence, which chiefly consists of small fish and water insects. These they take by plunging the bill and part of the head into the water, and from time to time trampling the bottom with their feet, to disturb the mud, and raise up their prey. In feeding they are said to twist the neck in such a manner, that the upper part of their bill is applied to the ground. Except in the breeding season, flamingos are generally observed in great flocks, and at a distance appear like a regiment of soldiers, being often ranged alongside of one another on the borders of rivers. When the Europeans first visited America, they found these birds on the shores tame and gentle, and no way distrustful of mankind. We learn from Catesby, that when the fowler had killed one, the rest of the flock, instead of attempting to fly, only regarded the fall of their companion in a kind of fixed astonishment; so that the whole flock were sometimes killed in detail, without one of them attempting to make its escape. They are now, however, extremely shy, and one of their number acts as sentinel, while the rest are feeding. The moment that this guard perceives the least danger, he gives a loud scream, like the sound of a trumpet, and instantly all are on the wing, and fill the air with their screams. The flamingo, when at rest, stands on one leg, the other being drawn up to the body, with the head placed under the wing on that side of the body on which it stands. Its flesh is esteemed tolerable eating, and that of the young has been compared to partridge. Pliny, Martial, and other writers of antiquity, have celebrated the tongue as a morsel of exquisite relish.

473 *Chilensis.* *Chili flamingo.*—Quill feathers white; bill covered with a reddish skin; head subcrested; measures five feet from the bill to the claws. Inhabits Chili; frequents only fresh waters, and is extremely shy.

474 PLATALEA.

Gen. 46. PLATALEA, *Spoonbill.*

475 Characters. Bill long and thin, the tip dilated, orbicular and flat; nostrils small at the base of the bill; tongue short and pointed; feet four-toed and semipalmated.

476 *Leucorodia.* *White spoonbill.*—Body white; chin black; hind head somewhat crested. Bill black, brown or spotted; tongue heart-shaped; irides gray; lores, orbits, and naked dilatable chin, black; quill feathers sometimes tipt with black; legs black. This species admits of two varieties, of which the first has the wings varied with black and white, and the legs yellowish; and the second has the body all white, and the legs flesh coloured. The white or common spoonbill weighs about three pounds and a half, and measures two feet eight inches in length. It inhabits from the Feroe isles to the Cape of Good Hope; but rarely occurs in England. It lives on grass, carices, the roots of reeds, serpents, frogs, muscles, and other shell-fish, but especially on fishes, which it often seizes from other birds. It makes its nest in high trees, near to the sea, and lays three or four white eggs, sprinkled with a few pale red spots. The flesh, especially of the young bird, tastes like that of goose.

Roseate spoonbill.—Body rose-coloured; tail coverts scarlet; bill cinereous white, with a furrow parallel with the edges; face and chin naked and whitish; legs gray. This species also frequently appears of a blood red hue; the neck white; collar black; and tail feathers scarlet. Two feet three inches long. Inhabits South America and Jamaica. Figured in Latham's Synopsis. 477 *Ajaja.*

Dwarf spoonbill.—Body brown above; white beneath. Size of a sparrow. Inhabits Guiana and Surinam. 478 *Pygmæa.*

Gen. 47. PALAMEDEA, *Screamer.* 479 PALAMEDEA.

Bill conical, the upper mandible hooked; nostrils oval; feet four-toed, cleft, a very small membrane connecting the toes at the root. 480 Characters.

Horned screamer.—Wings with two spines at the curvature, front horned; bill and legs black; irides golden; body blackish above, white beneath; wings reddish beneath; spine strong, sharp, horny, triangular, yellow; horn on the front recurved, round, whitish, three inches long; hind toe straight. Three feet four inches long. Inhabits the fenny parts of South America; making a large nest of mud, in the shape of an oven, on the ground, and laying two eggs the size of those of a goose. It is remarked, that they are always met with in pairs, and if one dies, the other mourns to death for the loss. On hearing the least noise, or seeing any one, even at a distance, they rise from the ground and make a loud screaming noise. They feed principally on herbs, seeds, and reptiles The flesh of the old bird is tough and ill tasted; but that of the young, though very dark, is frequently eaten by the natives. 481 *Cornuta.*

Crested screamer.—Wings unarmed; front crested. Size of a heron. Inhabits Brazil. 482 *Cristata.*

Gen. 48. MYCTERIA, *Jabiru.* 483 MYCTERIA.

Bill a little bending upwards and sharp-pointed; upper mandible triangular; front bald; nostrils linear; tongue small or wanting; four-toed and cleft. 484 Characters.

American jabiru.—White; quill and tail feathers purplish-black; bill long, stout and black; head and neck bald, two-thirds of the neck blackish, the rest red; hind head cinereous; legs long, stout and blackish. Nearly six feet long. Inhabits the savannas of South America; is migratory and gregarious, makes its nest in large trees, lays two eggs, and tends the young till they can descend to the ground. The colour of the young birds is gray; the second year it changes to rose colour, and the third to pure white. They are very wild and voracious, and destroy great quantities of fish. The flesh of the young birds is said to be good eating, but that of the old is hard and oily. 485 *Americana.*

Indian jabiru.—White; band over the eyes, lower part of the back, quill and tail feathers, black; bill blackish; 486 *Asiatica.*

Grallæ. blackish; upper mandible gibbous at the base; lower tumid beneath; legs flesh-coloured. Inhabits India, and feeds on shell-fish.

487 *Novæ Hollandiæ.* *New Holland jabiru.*—Body purplish-green above, under parts, neck and shoulders white; head purplish, spotted with white; neck feathered; irides yellow; first quill feathers white; tail black and white. Full six feet long; is supposed to live chiefly on fish. Inhabits New Holland. Figured in Latham's Supplement.

488 CANCROMA.

Gen. 49. CANCROMA, *Boatbill.*

489 Characters. Bill gibbous, and shaped like an inverted boat; nostrils small, and placed in a furrow; tongue small; toes divided.

490 *Cochlearia.* *Crested boatbill.*—Crested; cinereous; belly rufous; crown and lunule on the neck black; bill brown; lores naked and blackish; crest long, pendulous and pointed; legs yellowish-brown; toes connected at the base. The body is sometimes spotted with brown. Twenty-two inches long. Inhabits South America; perches on trees which overhang the water, and darts down on the fish as they swim underneath. It likewise feeds on crabs.

491 SCOPUS.

Gen. 50. SCOPUS, *Umbre.*

492 Characters. Bill thick, compressed, long and straight; nostrils linear and oblique; feet with four unconnected toes.

493 *Umbretta.* Plate CCCXCVIII. fig. 4. *Tufted umbre.*—With a crest; bill brown, with a longitudinal furrow on each side, in which are placed the nostrils: lower mandible narrower towards the end, and a little truncated; crest thick, tufted and lax; body brown; tail obscurely barred; legs longish and brown. Female not crested. Twenty inches long. Inhabits Africa.

494 ARDEA.

Gen. 51. ARDEA.

495 Characters. Bill straight, pointed, long, somewhat compressed, with a furrow from the nostrils towards the tip; nostrils linear; tongue sharp; feet four-toed, cleft; toes connected at the base.

The birds of this numerous genus have long feet and necks, and live on amphibious animals and fishes.

A. *Crested, and bill scarcely longer than the head.*

496 *Pavonia.* *Crowned heron*, or *crown bird.*—Crest bristly and erect; temples with two naked wattles; bill brownish; irides gray; crown covered with short silky feathers; crest circular, yellowish, tipt with black; temples and wattles red; body bluish ash; wing-coverts white, the greater ones reddish, those next the body blackish; tail and greater quill feathers black, the secondary bay; legs dusky. The female is black, where the male is bluish-ash, has no wattles on the throat, and the long feathers on the breast less conspicuous. This beautiful species, the *balearic crane* of Ray, and the *crowned African crane* of Edwards, is two feet nine inches long; and inhabits Africa, particularly the coast of Guinea, as far as the Cape de Verd islands. At the latter it is said to be very tame, and so familiar as to come into the court-yards to feed with the poultry. It is supposed to feed chiefly on worms and vegetables, often sleeps on one leg, runs very fast, and not only flies well, but continues on wing for a long time together. The flesh is said to be very tough.

497 *Virgo.* *Demoiselle heron, demoiselle of Numidia*, or *Numidian crane.*—A tuft of long, white, pendant feathers behind each eye; bill yellowish; the base greenish, tip red; irides red; head and tips of the primary quill feathers black; feathers of the breast long and pendulous; crest over the eyes turned back, and pendulous; body bluish-ash; crown cinereous; head, neck, throat, breast and legs black. The wind-pipe does not, as in the generality of birds, go straight forwards into the lungs, but first enters a cavity in the keel of the breast bone, for about three inches, when it returns, after making a bend forwards, and then passes into the chest. This elegant species is about the size of the common crane; and three feet three inches long. It is found in many parts of Africa and Asia, but most plentifully about *Bildulgerid*, the ancient Numidia, and Tripoli. It also occurs at Aleppo, and in the southern plain, about the Black and Caspian seas, and not unfrequently beyond Lake Baikal, about the rivers Selenga and Argun, but never ventures to the northward. It affects marshes and rivers, subsisting chiefly on fish. In the Crimea it builds its nest in open plains, generally in the vicinity of the salt lakes. The young birds are brought to market by the Tartars, and are so susceptible of domestication, that they even afterwards breed in the farm-yards. From the gentleness of its manners and the elegance of its form, it is often kept in menageries. In confinement, it often assumes strange and uncouth attitudes, and seems occasionally to imitate dancing; and Keysler mentions one in the gallery at Florence, which had been taught to dance to a certain tune, when played or sung to it.

B. *Cranes; head bald.* 498 *Cranes.*

Common crane.—Hind head naked and papillous; cap and quill-feathers black; body cinereous; innermost tail feathers jagged; bill greenish-black; front covered with black down; hind head red, with a few scattered hairs, and a cinereous area beneath; temples and upper neck white; legs black. There is a variety with the body white; and the lower part of the neck and quill feathers black; bill greenish black; front covered with black down; hind head red, with a few scattered hairs, and a cinereous area beneath; temples and upper neck white; legs black. Weighs near 10 pounds; length five feet. Inhabits Europe and Asia, and annually migrates in flocks to the southern parts of Asia and Africa, in autumn. The course of their flight is discovered by the loud noise which they make; for they soar to such a height as to be scarcely visible to the naked eye. Like the wild geese, they form themselves into different figures, describing a wedge, a triangle, or a circle. It is said that formerly they visited the fens and marshes of England, in great numbers; but they seem now, in a great measure, to have forsaken our island. They are seen in France in the spring and autumn; but generally only as passengers. They make their nests in marshes, and lay two bluish eggs. They feed on reptiles of all kinds, and on several sorts of vegetables, particularly green corn; among which, if a flock alights, it makes great havock. Like other large birds, the crane has much difficulty in commencing its flight. 499 *Grus.*

Siberian crane.—White; temples and front naked, red, wrinkled; ten first quill feathers shining black; bill and legs red. Stands four feet and a half high. Inhabits the marshy flats of Siberia, and feeds on reptiles, worms, and small fish. 500 *Gigantea.*

C. *Storks;*

C. *Storks; orbits naked.*

501 Storks. 502 Ciconia. *White stork.*—White; orbits and quill feathers black; bill, legs and skin red; greater wing coverts black. Inhabits Europe, Asia, and Africa. Is about the size of a turkey; and measures three feet three inches in length. Feeds on fish and reptiles, and in several countries is protected for its use in destroying serpents. Vast numbers annually resort to some parts of Holland, and even as far north as Russia, to breed, but rarely visit England. They observe great exactness in the time of their autumnal departure from Europe to more favoured climes. They pass a second summer in Egypt, and the marshes of Barbary; pairing in the former country, and rearing a second brood. Before each of their migrations, they rendezvous in amazing numbers, and are for a while much in motion among themselves, till, after making several short excursions, as if to try their wings, they all on a sudden take flight with great silence, and with such speed, as in a moment to be out of sight. At Bagdad, hundreds of their nests are to be seen about the houses, walls, and trees; and at Persepolis, the remains of the pillars serve them to build on, every pillar having a nest on it. Shaw mentions flights of them leaving Egypt, and passing over Mount Carmel, each half a mile in breadth. The good-natured Hollanders provide boxes for them to build their nests in, on the tops of their houses, and resent any injury done to the birds as an offence committed against themselves. The stork is of a mild and affectionate disposition; and though it has a grave air, yet, when roused by example, is not averse from gaiety. "I saw", says Dr Hermann, "in a garden where children were playing at hide and seek, a tame stork join the party, run its turn when touched, and distinguish the child whose turn it was to pursue the rest, so well, as, along with the others, to be on its guard."—To this bird the ancients ascribed many of the moral virtues, as temperance, vigilance, conjugal fidelity, and filial and parental piety.

503 Nigra. *Black stork.*—Brown; breast and belly white. Two feet nine inches long. Inhabits Europe and Asia. Feeds on fish and reptiles; is timid, and retires into thick woods and inaccessible fens.

504 Herons. D. *Herons; middle claw inwardly serrated.*

505 Dubia. *Gigantic heron.*—Glaucous above; dirty white beneath; bill a little triangular. This is a large species, measuring from tip to tip of the wings, nearly 15 feet. The bill is of an enormous size, and 16 inches round at the base. The head and neck are naked, except a few straggling curled hairs. The feathers of the back and wings are of a bluish ash colour, and very stout; those of the breast long. The craw hangs down the fore part of the neck, like a pouch, thinly covered with down. The belly is covered with a dirty white down, and the upper part of the back and shoulders surrounded with the same. The legs and about half of the thighs are naked, and the naked parts are full three feet in length. The gigantic heron inhabits Bengal, and is sometimes found on the coast of Guinea. It arrives in the interior parts of Bengal before the period of the rains, and retires as soon as the dry season commences. Though its aspect is far from inviting, it is one of the most useful birds of these countries, in clearing them of snakes and noxious reptiles and insects. They sometimes feed on fish; and one of them will generally devour as much as would serve four men. On opening the body of an individual of this species, a land tortoise, 10 inches long, and a large black cat, were found entire within it, the former in the pouch and the latter in its stomach. Being, undaunted at the sight of mankind, they are soon rendered familiar; and when fish or other food is thrown to them they catch it very nimbly, and immediately swallow it entire. A young bird of this kind, about five feet in height, was brought up tame, and presented to the chief of the Bananas, where Mr Smeathman lived. It regularly attended the hall at dinner time, placing itself behind its master's chair, frequently before any of the guests entered. The servants were obliged to watch it carefully, and to defend the provisions by beating it off with sticks: yet notwithstanding every precaution, it would frequently snatch off something from the table, and one day purloined a whole boiled fowl, which it swallowed in an instant. It used to fly about the island, and roost very high among the silk cotton trees; from this station, at the distance of two or three miles, it could see when the dinner was carried across the court; when darting down, it would arrive early enough to enter with some of those who carried in the dishes. When sitting, it was observed always to rest itself on the whole length of the hind part of the leg. Sometimes it would stand in the room for half an hour after dinner, turning its head alternately as if listening to the conversation. These birds are found in companies, and when seen at a distance, near the mouths of rivers, advancing towards an observer, it is said that they may be easily mistaken for canoes on the surface of a smooth sea, and when on the sand banks, for men and women picking up shell-fish on the beach.—From their immense gape, they have obtained the name of *large throats*, and from their swallowing bones, that of *bone eaters* or *bone takers*. 506

Night heron.—Crest on the hind head white, horizontal, of three feathers; back black; belly yellowish. Nycticorax. The female has the head smooth and brown; belly brownish and white beneath; and the first quill feathers with a white spot at the tip. About 20 inches long. Inhabits Europe, Asia, and America. Only one instance occurs of its having been met with in England. It is pretty common in Russia, particularly on the Don, where it builds in trees, and is also met with at Astracan during summer. It is said to lay three or four white eggs, and sometimes to build among the rocks. It has a very uncouth and rough voice, like that of a person straining to vomit. 507

Crested purple heron.—Hind head black; crest pendent, and composed of two long feathers; body olive above, purplish beneath. Two feet 10 inches long. Inhabits Asia. 508 Purpurea.

African heron.—Crested; body cinereous; neck, breast and belly, ferruginous; chin white; neck with three black lines; bill and legs yellow; crest of three long feathers; feathers of the breast and rump mixed with ferruginous; a broad black line from the nape to the back, and another on each of the sides. About three feet long; and smaller than the common heron. Inhabits Asia and Africa, and has been twice found in England. 509 Caspica.

Common heron.—Hind head with a pendent crest; Major. body ash coloured; line on the neck beneath and pectoral bar black. The female has the hind head smooth and black; back bluish and whitish beneath; and the breast

Grallæ

breast with oblong black spots. Bill dusky; base yellowish beneath; area of the eyes naked and greenish; irides yellow; temples black; front, crown, and neck, white above; spurious wings and greater quill feathers black; scapulars and feathers of the throat long, lax, and narrow; body white beneath; legs dirty green. The weight of this species is about three pounds and a half; and the length about three feet four inches. Inhabits almost every where in fenny places, and is common in England. It is a great destroyer both of sea and fresh water fish, being enabled, by the great length of its legs, to wade into some depth of water, where it stands motionless, till some of the finny tribe approach, when it darts its bill into them in an instant. Its digestion being as quick as its appetite is voracious, it commits great devastation in ponds and shallow waters. It will likewise eat frogs and vegetables. They are frequently observed to feed by moon light, when the fish come into the shoaler waters. In the breeding season, herons are gregarious, and make their nests very near one another. Pennant mentions having seen eighty nests on one tree, and Mr Montagu once saw a heronry on a small island in a lake, in the north of Scotland, on which there was but a single scrubby oak, which not being sufficient to contain all the nests, many were placed on the ground. The nest is large and flat, made of sticks lined with wool and other soft materials. The eggs are four or five in number, of a greenish-blue, and about the size of those of a duck. Heronries were much prized in the days of falconry, and some are yet to be seen in several parts of the kingdom. In flying, this species hides its head between its shoulders, and its legs hang down. When it flies very high it presages a storm. If taken young, these birds may be tamed: but when the old birds are captured, they soon pine away, refusing every kind of nourishment. The body is very small and always lean, and the skin is scarcely thicker than membrane used by the gold beaters. Linnæus had made the two sexes distinct species, and others were long of the same opinion: but later observations have corrected the mistake.

510 *Garzetta.* *Egret*, or *little egret*.—Hind head crested; body white; bill black; lores and legs greenish; irides yellowish; crest consisting of some short, and two long feathers; face naked and green; claws black. Nearly a foot long, and weighs one pound. Inhabits marshy places, in temperate regions, in the four quarters of the world. If we may judge from the bill of fare of the famous feast given by the archbishop Nevil, these birds were formerly plentiful in England; for no fewer than 1000 were in that list. It is, however, now become a very rare bird in this kingdom. Its plumes were formerly used to decorate the helmets of warriors, but are now applied to ornament the head dresses of European ladies, and the turbans of the Persians and Turks. Its habits are analogous to those of the common heron.

511 *Egretta.* Plate CCCXCVIII. fig. 3. *Great egret*.—Somewhat crested, white; legs black; feathers of the back and breast lax, narrow and very long. About two feet long. Inhabits South America. Is shy and solitary, lying hid among the tall reeds, and feeding by night.

512 *Herodias.* *Great heron*.—Hind head crested; body brown; thighs rufous; breast with oblong black spots. Above five feet long. Inhabits the lakes and rivers of Virginia, and feeds on lizards, frogs, and fish.

513 *Cærulea.* *Blue heron*.—Hind head crested; body blue; bill and lores blue; legs green. In the female, the head and neck are dusky purple; the chin and middle of the throat white, and the back lead colour. There is a subcrested variety blue green, with the chin and throat white. Another is varied with brown, yellow, and cinereous; steel black above; white beneath; and wings and tail greenish. From 16 to 18 inches long. Inhabits America. Found in Carolina in spring, and in Jamaica, and other islands of the West Indies, in winter. It has also been met with at Otaheite, and other islands of the South seas, where it is much respected.

514 *Comata.* *Squacco heron*.—Ferruginous; white beneath; hind head with a long white pendent crest, edged with black. About 15 inches long. Inhabits Europe and Asia. A white variety, with a smooth head, the upper part, crown, breast and back reddish, and which inhabits Coromandel. Has been once shot in England.

515 *Stellaris.* *Bittern*; in provincial English, *bittour*, *bumpy coss*, *butter bump*, and *miredrum*.—Head smoothish; body testaceous above, with transverse spots; paler beneath, with oblong brown spots. About two feet and a half long. Inhabits Europe, Asia, and America, affecting the more temperate regions in winter, and migrating northwards in summer. Though not a plentiful species in Britain, it is occasionally found in the breeding season, in the less frequented reedy marshes, and swampy moors, well clothed with rushes, where it forms a nest on some stump, by collecting sedges or other coarse plants together. It lays four or five eggs of a light olive green colour, inclining to cinereous. At this season the male makes a singular bellowing noise, vulgarly supposed to be produced by the bird putting his bill into a reed. It is with difficulty roused from its lurking place, flies heavily, and frequently lights again at a small distance, so that it becomes an easy prey to the sportsman. About sunset, it sometimes soars to a great height in the air, with a spiral ascent, making at the same time a loud and singular noise. Its flesh is accounted a delicacy.

516 *Botaurus.* *Greater bittern*—Head smoothish, black; body cinereous brown above; rufous beneath; lores and naked orbits yellow; throat white, streaked with black and reddish. Three feet nine inches long. Inhabits Italy.

517 *Alba.* *Great white heron*.—Head smooth; body white; bill tawney; legs black; bill six inches long; irides yellowish; lores green. Three feet six inches long. Inhabits Europe, Asia, and America. Is rare in England.

518 *Carunculata.* *Wattled heron*.—Back, wings, legs and crown black-blue; smooth head and neck white; body black beneath; bill and chin caranculated. Five feet long. Inhabits Africa.

519 *Exilis.* *Minute bittern*.—Smooth head and upper part of the body reddish-bay; white beneath; sides of the neck rufous; wings and tail black. Twelve inches and a half long. Inhabits Jamaica.

520 *Minuta.* *Little bittern*.—(Male). Head smooth; body brown; reddish beneath; tail feathers greenish black; lores yellowish. (Female). Body brown; edges of the feathers reddish; reddish beneath; crown, back, wings and tail black; bill yellow green; naked part of the face yellow; irides saffron; legs green brown. This beautiful species is scarcely larger than a fieldfare, and about 15 inches long, from the tip of the bill to the end of the tail. The female lays four or five white eggs, of the size of those of the blackbird, and which are placed on a

Grallæ. a few dried flags on the ground. Inhabits Europe and Asia, but is rare in England.

E. *Bill gaping in the middle.*

521 *Pondiceriana.* *Pondicherry heron.*—Gray-ash; quill feathers long and black; middle claw not serrated; bill yellow, thick at the base, pointed at the tip, and a little bent in, gaping in the middle; space between the bill and eyes feathered; legs yellow. Fourteen inches and a half long. Inhabits India.

522 *Coromandeliana.* *Coromandel heron.*—White; back, wings and tail black; upper mandible serrated from the middle to the tip; bill yellow, thick at the base, and pointed at the tip; legs reddish-yellow; upper part of the head with black lines; lores and chin naked and black; irides red; toes connected at the base. Inhabits Coromandel, and feeds on fish and reptiles.

523 *Scolopacea.* *Scolopaceous heron.*—Brown; throat and breast streaked with white; chin and legs white; wings and tail copper-colour. Twenty-five inches long. Inhabits Cayenne.

524 TANTALUS. Gen. 52. TANTALUS, *Ibis.*

525 Characters. Bill long, subulated, roundish, somewhat arched; face naked; tongue short and broad; jugular pouch naked; nostrils oval; feet four-toed and palmated at the base.

526 *Loculator.* *Wood ibis.*—Face bluish; bill reddish; legs, quill and tail feathers black; body white; bill nine inches long, yellowish-brown; irides reddish. The male has the head and neck naked, wrinkled and black-blue; and the female has the neck gray and downy. Three feet long. Inhabits New Holland and the warmer parts of America. Is stupid and slow in flight, sitting on trees, and feeding on herbs, seeds, fruits, fish, and reptiles. The flesh is good. Of this species there are two varieties, the first having the head and neck white, blended with yellow, the body black, and belly cinereous; and the second distinguished by white wing-coverts, with a black blotch in the middle.

527 *Igneus.* *Glossy ibis.*—Head and neck black; legs green; body varied with glossy-blue, blackish, green and claret; dark rufous beneath; quill and tail feathers green-gold; bill green. Thirteen inches and a half long. Inhabits Russia, and was once shot in Cornwall.

528 *Niger.* *Black ibis.*—Face, bill, and legs reds; body black. From 30 to 40 inches long. Inhabits Egypt.

529 *Ibis.* *Egyptian ibis.*—Face red; bill pale yellow; quill feathers black; body reddish-white. This is a large bird, somewhat exceeding the stork, and measures from 30 to 40 inches in length. The bill is seven inches long, the colour yellow, growing reddish towards the tip, slightly curved, and ending in a blunt point. The fore part of the head, all round as far as the eyes, is naked and reddish. The skin under the throat, is also bare and dilatable; the plumage reddish white, most inclining to red on the back and wings; quills and tail black; the legs long; and the thighs bare for three parts of their length. Hasselquist adds that the irides are whitish, and the end of the bill and the legs black; and that it is found in Lower Egypt, in great plenty, in places just freed from the inundations of the Nile. It lives on frogs and insects, and is seen in gardens morning and evening, and sometimes so abundantly, that whole palm trees are covered with them. When at rest they sit quite erect, their tail touching their legs. The same author believes it to be the ibis of the ancients; first, because it is common in, and peculiar to Egypt; secondly, as it eats serpents; and, thirdly, because the urns which contain the remains of embalmed birds, found in the sepulchres along with the mummies, seem to contain birds of this size. Its figure represented Egypt, in the hieroglyphic writing of its inhabitants. In that country it is still called *Pharaoh's bird*, and builds in the palm trees.

530 *Rubra.* *Scarlet ibis.*—Face, bill and legs red; body scarlet; wings tipt with black. Twenty-one inches long. Inhabits South America. Sits on trees, but lays its greenish eggs on the ground. The young are at first black, then gray, whitish just before they fly, and afterwards grow gradually red.

531 *Alba.* Plate CCCXCVIII. fig. 1. *White ibis.*—This species is 22 inches long, and about the size of the whimbrel; the face, bill and feet reddish; body white; tips of the wings green; the male and female nearly alike. Native of Brazil, but towards the end of summer migrates to the north, and is found in great numbers in the marshy lands of Carolina, feeding on fish and aquatic insects. Here they remain for about six weeks: the fat and flesh of the white ibis are said to be of a saffron colour, but though not much esteemed, is sometimes eaten.

532 CORRIRA. Gen. 53. CORRIRA, *Courier.*

533 Characters. Bill short, straight, toothless; thighs longer than the body; feet four-toed, palmated; hind toe unconnected.

534 *Italica.* *Italian courier.*—Ferruginous above; white beneath; two middle tail feathers white, tipt with black; bill pale yellow, black at the end, with a large gap; irides a double circle of bay and white. Less than the curlew. Inhabits Italy, and runs swiftly.

535 SCOLOPAX. Gen. 54. SCOLOPAX.

536 Characters. Bill roundish, obtuse, and longer than the head; nostrils linear; face covered with feathers; feet four-toed; hind toe consisting of many joints.

The birds of this and of the succeeding genus are with difficulty ascertained, being subject to differ in appearance from sex and age, and their colours shading into one another. The markings of their feet, however, are pretty constant, and therefore afford one of the best criteria.

537 *Pygmea.* *Pigmy curlew.*—Arched bill, and legs black; body varied with ferruginous, brown, and white; white beneath; rump white; quill and outer tail feathers edged with white. Size of a lark. Inhabits Europe, and is very rare in England.

538 *Arquata.* *Common curlew.*—Bill arched, blackish; legs bluish; wings blackish, with snowy spots; lower mandible reddish at the base; body above, and breast, streaked with dusky brown; chin, rump, belly, and vent, white; quill feathers black, spotted with white within; legs bluish; toes flat and broad. This species is subject to vary considerably in size, weighing from 20 to upwards of 30 ounces; the length of the largest being about 25 inches. Inhabits the moist and fenny places of Europe, Asia, and Africa. A rufous and black variety, with a smaller body, and longer bill, occurs in America. The curlew

Grallæ. curlew is common on most of our coasts, in winter, when it is gregarious, and feeds on small crabs, and other marine insects and worms. In the spring it retires inland, and commonly to the more northern parts of the kingdom, to breed, resorting to the most retired situations on the heath-covered mountains, or in extensive and unfrequented marshes. It makes no nest; but deposits among the heath, rushes, or long grass, four eggs, of a pale olive colour, marked with brownish spots. The young make use of their legs as soon as they are hatched, but cannot fly for a considerable time. The flesh of this species is eatable, but is best in summer, when the bird feeds on frogs, worms, and water insects. In winter it is rank and fishy.

539 *Phaeopus.* *Whimbrel.*—Bill arched, and black; legs bluish; back with rhomboid brown spots; rump white; lower mandible reddish at the base; body above, and breast brownish, with dusky brown streaks; chin, rump, belly, and vent, white; tail brown, with dusky bars; quill feathers black, spotted with white on the inside. About half the size of the preceding; but agreeing with it in appearance and habits. It is also more scarce in this country.

540 *Nigra.* *Black snipe.*—Bill and legs red; body black. Inhabits the islands between Northern Asia and America.

541 *Nutans.* *Nodding snipe.*—Bill black; legs greenish; body cinereous; crown and upper part of the back dusky red, and streaked; the lower white, spotted with black. Size of the common snipe. Inhabits Labrador, and is constantly nodding the head.

542 *Rusticola.* *Woodcock.*—Bill straight, reddish at the base; legs cinereous; thighs covered; head, with a black band on each side; upper mandible longer, reddish at the base; front cinereous; lower eyelid white; crown, neck above, back, and wing-coverts, ferruginous, mixed with black and gray; chin pale ash; threat yellowish, with small dusky spots; body whitish beneath, with dusky lines; quill feathers dusky, with triangular rufous spots; tail rounded, cinereous at the tip; legs brownish. Length 15 inches; weight from 12 to 15 ounces. This well-known species is subject to great variety, and inhabits the northern countries of Europe, Asia, and Africa, migrating in winter to the more temperate regions. In Britain it seldom appears in numbers till about the middle of November; but some occasionally appear as early as the latter end of September, or beginning of October. They generally come to us with northerly or easterly winds, when the more northern countries become frozen; and if the frost in those parts where they breed is suddenly severe, large flights are sometimes met with on our coasts, where they remain for a day, to recruit their strength, and then disperse. In England they are not so plentiful as formerly, when the art of shooting flying was less practised. A great many, however, are yet to be found in the more uncultivated parts of Devonshire, Cornwall, and Wales, as well as in the north of Scotland; but they are nowhere so abundant as in the large tracts of woods in Ireland. In severe weather, they accumulate, from the moors and inland counties, to the woods in the west of England. It is one of the few winter birds that occasionally breed with us. It builds a nest of a few fibres, or dry leaves, on the ground, generally at the root of a tree, and lays four eggs, somewhat larger than those of a pigeon, of a yellowish white, spotted and blotched with rufous brown and ash colour. Its usual food is insects and worms, for which it bores with its bill into moist places, feeding principally at night, when its call resembles that of the snipe. In some countries the woodcock remains the whole year, only moving in the breeding season, from the plains to the mountains. In this country, it usually prepares for its departure about the middle of March, when flocks come down to the sea coast, and, if the wind is favourable, are soon out of sight; but if it be contrary, they linger till it change.

Little woodcock.—Bill straight; legs brownish; front cinereous; hind head black, with four transverse yellowish lines; chin white; body above black, waved with slight tawney; yellow beneath. Eleven inches and a half long. Inhabits America. Its flesh is reckoned exquisite. 543 *Minor.*

Great snipe.—Legs and crown black, the latter with a pale divided line down the middle, a pale streak above and beneath the eyes; body varied above, white beneath; bill like that of the woodcock; lower feathers of the body, except the middle of the belly, edged with black; quill feathers dusky; tail feathers reddish, and, except the two middle ones, with black lines. Weighs about eight ounces; length 16 inches. Inhabits Siberia, and very rarely England. 544 *Major.*

Common snipe.—Bill straight, tuberculated; legs brown; body varied with blackish and tawney, white beneath; front with four brown lines; crown, bill, ocular band, and wings, black; chin pale rusty; tail-feathers black at the base; rump variegated. The weight of this species is about four ounces, and the length nearly 12 inches. It is met with in marshy situations, in almost every part of the world, and is very plentiful in our own island. In very wet times it resorts to the hills; but more generally frequents the marshes of the plains, where it can penetrate the earth with its bill, in quest of worms. Some few remain with us the whole year, and breed in the more extensive marshes and mountainous bogs. The nest is made of the materials around it, as coarse grass or heath, and placed on a dry spot, near a splash or swampy place, the eggs, like that of the lapwing, being much pointed, and invariably placed with their smaller ends inwards. In the breeding season the snipe changes its note entirely. The male will keep on the wing for an hour together, mounting like a lark, uttering a shrill piping noise, and then descend with great velocity, making a bleating sound, like that of an old goat, which is alternately repeated round the spot possessed by the female, especially while she is sitting on her nest. The young ones run off soon after they are freed from the shell; but they are attended by the parent birds, until their bills have acquired a sufficient firmness to enable them to provide for themselves. When undisturbed in its retreats, the snipe walks leisurely, with its head erect, and keeps moving the tail at short intervals. But it is rarely observed in this state of tranquillity, being extremely watchful, and perceiving the sportsman, or his dog, at a great distance, and either concealing itself among the variegated withered herbage, so similar in appearance to its own plumage, that it is almost impossible to discover it, or, as happens more frequently, springing and taking flight beyond the reach of the gun. When first disturbed it utters a kind of feeble whistle, and generally flies against the wind, turning nimbly in a zig-zag direction, and 545 *Gallinago.*

Grallæ. and sometimes soaring almost out of sight. From its vigilance and manner of flying, it is very difficult to shoot; but some sportsmen can draw it within range of their fowling-piece, by imitating its cries, and others are contented to catch it in the night by springes. The snipe is much esteemed as a delicious and well flavoured dish; and though it is very fat, it rarely disagrees even with the weakest stomach.

546 *Guallinula.* *Jack-snipe, judcock*, or *gid.*—Bill straight, tuberculated; body variegated; legs greenish; lores brown; rump varied with violet; bill black; body variegated with testaceous, black, violet, and glossy green; head with pale yellow and black lines, reaching from the bill to the hind head; breast spotted; belly and vent white. Eight inches and a half long. Inhabits Europe, Asia, and America. Is found in the same places with the preceding, but is more solitary and rare. It will lie among rushes, or other thick covert, till in danger of being trampled on, and, when roused, seldom flies far. It comes to us later than the common snipe, and is never known to remain in this country during the breeding season. It is as much esteemed as the snipe, and is cooked in the same manner.

547 *Glottis.* *Greenshank.*—Bill straight, the lower base red; body beneath snowy; legs greenish; bill black; the lower mandible bending a little upwards; eyebrows and lower part of the back white; head, neck, and back, pale cinereous; shafts of the feathers spotted with brown; quill feathers dusky, spotted with white on the inside; tail white, with dusky lines; legs very long. Weight about six ounces: length 14 inches. Inhabits Europe, Asia, and America. Is sometimes seen, in small flocks, on our coasts, in winter; as also in the marshes and fens contiguous to the sea. Some few are supposed to remain with us all the summer, and to breed in our fens. The greater part, however, retire northward to breed, and are found in Sweden, Russia, and Siberia. Their flesh, like all the rest of this genus, is well flavoured, and reckoned good eating.

548 *Calidris.* *Redshank*, or *pool-snipe.*—Bill straight, red; legs scarlet; secondary quill feathers white; bill black towards the tip; irides reddish hazel; head and neck cinereous above; back and shoulders greenish-brown; wing-coverts cinereous, mixed with dusky and brown, and spotted with whitish; secondary quill feathers, except the two inner ones, white towards the tip; primary dusky, the four or five inner ones tipt with white; line over the eyes white; a dusky spot between the bill and eyes; short dusky streaks on the chin and throat; under part of the body and rump white, with small dusky spots; each of the tail feathers with 12 or 13 transverse black lines. Weighs about five ounces, and is 12 inches long. Inhabits Europe and America. Is not uncommon in some parts of England, residing the greater part of the year in the fen countries, where it breeds and rears its young. It lays four eggs, which are whitish, tinged with olive, and marked with irregular spots of black, chiefly on the thicker end. When disturbed it flies round its nest, making a noise like a lapwing. It is not so common on the sea shores as several of its congeners, and is of a solitary disposition, being mostly seen alone, or only in pairs.

549 *Totanus.* *Spotted snipe, red-legged godwit*, or *spotted redshank.*—Blackish, with white spots; white beneath; lines on the breast and bands on the lateral tail feathers blackish; legs red. Size of the greenshank. Inhabits Europe, frequenting the banks of rivers, and feeding on the smaller shell-fish and other vermes. Seldom visits Britain.

Lesser godwit, judrake snipe, or *stone plover.*—Bill inclining a little upwards at the point, red at the base; body gray brown, varied with rufous; white beneath; quill feathers white at the base, the four first without spots; tail white at the base; irides whitish; cheeks reddish; back brown; quill feathers blackish; feathers round the bill reddish white. Seventeen inches long, and weighs nine ounces. Inhabits the north of Europe, and is gregarious; but seldom occurs in Britain. 550 *Limosa.*

Red godwit, or *red-breasted godwit.*—Bill a little recurved, yellowish; legs black; body reddish-rusty beneath; bill blackish at the tip; head, neck, breast and body, ferruginous above, and, except the neck, streaked with black; lower part of the back and rump rufous white; greater quill feathers black without, the base white within; secondary and tail feathers half black and half white. Weight about 12 ounces; length 18 inches. There is a variety with the head and neck cinereous, and the chin and belly white. Inhabits Europe and America, and is gregarious, but rarely seen with us. 551 *Lapponica.*

Common or *gray godwit.*—Bill straight, reddish yellow; legs greenish; head and neck reddish; three of the quill feathers black, with a white base; a broad white streak from the bill to the eye; body reddish-brown above; feathers with a dusky spot in the middle. Subject to very considerable variety both in size and plumage. In general, it weighs from seven to twelve ounces, and measures from 15 to 16 inches. It inhabits Europe, Asia, and Africa; continues with us the whole year, and resorts to the fens in spring for breeding. In the winter it is found on our shores, particularly at the mouths of large rivers and inlets, where the mud and sand become bare at low water, and where it feeds on insects. It is much esteemed by epicures as a great delicacy, and sells very high. It is caught in nets, to which it is allured by a *stale*, or stuffed bird, in the same manner, and at the same season, as the ruffs and reeves. 552 *Ægocephala.*

Godwit.—Brown, edged with whitish; neck whitish, with small brown spots; chin and belly white; quill feathers with black bands; bill a little turned up, brown, with a purple base; tail feathers white; the two middle ones wholly, the rest barred with brown on the outer side. Sixteen inches long. Inhabits Europe. Regarded by some ornithologists as only a variety of the *ægocephala.* 553 *Leucophæa.*

Cinereous godwit.—Legs long, cinereous; head, neck, and back varied with cinereous and white; chin and breast white, spotted with ash; bill thicker than in the greenshank; tail with cinereous lines. Size of the greenshank. Inhabits Licolnshire; but is very rare, and seems to be imperfectly known. 554 *Canescens.*

Cambridge godwit.—Legs orange; bill red; body brown ash above, white beneath; wing-coverts and tail feathers barred with black; lesser wing-coverts brown, edged with white and barred with black; quill feathers blackish, white within; the secondary barred with white. Larger than the redshank. Was shot near Cambridge, and first described by Pennant. 555 *Cantabrigiensis.*

Grallæ.

Gen. 55. Tringa, *Sandpiper*.

556 Tringa. Bill roundish, as long as the head; nostrils small, linear; tongue slender; feet four-toed; hind toe of

557 Characters. one joint, and raised from the ground.

The birds of this genus frequent the plains and shores, and hardly touch the ground with their back toe.

558 Pugnax. *Ruff* and *reeve*.—Bill and legs rufous; three lateral tail feathers without spots; face with flesh-coloured granulations; bill sometimes black or yellowish; irides hazel; back of the neck with a large tuft of feathers, which fall off in moulting season. Female pale brown; back spotted with black; tail brown; the middle feathers spotted with black; breast and belly white. The ruffs, or males, are so very variable in their markings, that two are seldom found alike. Buffon mentions that Klein compared above 100 ruffs together, and found only two that were similar. About one foot long. Inhabits Europe and Siberia. The male does not acquire the ornament of his neck till the second season, and, before that time, is not easily distinguished from the female, except by being larger. After moulting, at the end of June, he loses his ruff and the red tubercles of his face; and from that time, till the spring of the year, he again, in plumage, looks like his mate. These birds leave our island in the winter, and are then supposed to associate with other congenerous species. In the spring, as soon as they arrive again in England, and take up their abode in the fens where they were bred, each of the males (of which there appears to be a much greater number than of females) immediately fixes on a particular dry or grassy spot in the marsh, about which he runs round and round, until it is trodden bare, wishing, apparently, to invite the female to take joint possession, and become an inmate. As soon as a single female arrives, and is heard or observed by the males, her feeble cry seems to rouse them all to war; for they instantly begin to fight; and their combats are described as being both desperate and of long continuance, the female, at the end of the battle, remaining the prize of the victor. It is at the time of these battles, that they are caught in the greatest numbers in the nets of the fowlers. They are also at other times caught by day nets, and are drawn together by means of a stuffed reeve, which is placed in some suitable spot for that purpose. The ruff is much prized as a delicious dish, and is sought after with great eagerness by the fowlers who live by catching them and other fen birds, for the markets of the metropolis, &c. Before they are offered for sale, they are commonly put up to feed, for about a fortnight, on boiled wheat, and bread and milk, mixed with hemp-seed, to which sugar is sometimes added; in consequence of which mode of treatment they soon get very fat. In the beginning of May the female makes her nest in a dry tuft of grass, in the fens, and lays four white eggs, marked with rusty spots.

559 Vanellus. *Lapwing, pewit, bastard plover*, &c.—Legs red; crest pendent; breast black; bill black; irides hazel; crown shining black; crest on the hind head four inches long; cheeks and sides of the neck white; a black line beneath each eye; throat black; hind part of the neck mixed with white, ash-colour, and red; back and scapulars glossy green; some of the feathers with ferruginous tips; lesser wing-coverts shining black, blue, and green; greater quill feathers black, the four first with a white spot at the end; lesser black on the upper half, white on the lower; belly white; vent and tail coverts orange; outer tail feathers white; the rest on the lower half black, tipt with dirty white; upper white. Weighs between seven and eight ounces. Is found in most parts of Europe, as far north as Iceland; and in the winter is met with in Persia and Egypt. The chief food of the lapwings is worms; and sometimes they may be seen in flocks nearly covering the low marshy grounds in search of these, which they draw with great dexterity from their holes. When the bird meets with one of those rolls of earth that are thrown out by the perforations of the worm, it first gently removes the mould from the mouth of the hole, then strikes the ground at the side with its foot, and steadily and attentively waits the issue; while the reptile, alarmed by the shock, emerges from its retreat, and is instantly seized. In the evening, the lapwings pursue a different plan, running along the grass, and feeling under their feet the worms, which now come forth, invited by the coolness of the air. Thus they obtain a plentiful meal, and afterwards wash their bill and feet in the small pools or rivulets. They remain in this country the whole year. The female lays four olive-coloured eggs, spotted with black, on the dry ground, near some marsh, on a little bed of dry grass which she prepares. She sits about three weeks, and the young are able to run within two or three days after they are hatched. The parent exhibits the greatest attachment to them, and has recourse to very amusing artifices to allure boys and dogs from approaching them. In place of waiting the arrival of the enemies at the nest, she boldly pushes out to meet them. When as near as she dare venture, she rises from the ground with a loud screaming voice, as if just flushed from hatching, though, probably, at the same time, not within 100 yards of her nest. She then flies with great clamour and apparent anxiety, whining and screaming round the invaders, striking at them with her wings, and sometimes fluttering as if she was wounded. To complete the deception, she becomes still more clamarous as she retires from the nest. If very near, she appears altogether unconcerned; and her cries cease in proportion as her fears are increased. When approached by dogs, she flies heavily, at a little distance before them as if maimed, still clamorous and bold, but never offering to move towards the quarter where her young are stationed. The dogs pursue, in expectation every moment of seizing the parent, and by this means actually lose the young; for the cunning bird, having thus drawn them off to a proper distance, exerts her powers, and leaves her astonished pursuers to gaze at the rapidity of her flight. These birds, when tamed, clear gardens of worms and snails. Their flesh and eggs are both reckoned delicacies for the table. In winter they join in large flocks, but are then very shy. 560

Gambet, gambet sandpiper, or *red-legged horseman*.— Gambetta. Bill and legs red; body variegated with pale yellow, and cinereous; white beneath; bill tipt with black; irides yellowish green; wing-coverts and scapulars cinereous, and edged with yellow; first quill and tail feathers dusky, the latter edged with yellow. About the size of the greenshank. Inhabits the northern parts of Europe and America, but seldom occurs in France or England.

Welsh

Grallæ.

561 *Nigricans.* *Welsh sandpiper.*—Blackish-ash; chin and middle of the belly white; base of the bill and legs red. Eight inches and a half long. Inhabits Glamorganshire and Caermarthenshire.

562 *Interpres.* *Turnstone, Hebridal sandpiper,* or *sea-dotterel.*—Legs red; body black, varied with white, and ferruginous; breast and belly white; bill black, a little turned up at the tip; cheeks and neck black above; tail black in the middle, and white at the ends. Female more dusky; head varied with brown and whitish; neck blackish above. Though these are the usual characteristics, the species is very subject to varieties. About the size of a throstle; length nine inches and a half, and weight rather more than four ounces. Inhabits the sea coasts of Europe and America. Though not known to breed with us, it visits some of our shores in August, and departs in spring. The name has been given it from its manner of turning up the stones in search of worms and marine insects. It makes a slight nest on the dry ground or sand, and lays four olive-coloured eggs, spotted with black. This species is not uncommon in the north of Scotland.

563 *Striata.* *Striated sandpiper.*—Base of the bill and legs yellow; tail feathers white, barred with brown; most of the quill feathers white. Nearly 11 inches long. Inhabits Europe and North America. Feeds on shell-fish and mollusca, which it searches for at the ebb of the tides, and on insects which it catches, hanging over the water like a swallow.

564 *Macularia.* *Spotted sandpiper.*—Base of the bill and legs flesh colour; all the body spotted; eye-brows and double band on the wings white; bill dusky; body above greenish-brown, white, with dusky spots beneath; two middle tail feathers greenish-brown, the rest white, with dusky lines. Female without spots beneath. About the size of a thrush, and eight inches long. Inhabits Europe and North America; is migratory, and is sometimes, though rarely, found in Britain.

565 *Cinerea.* *Ash-coloured sandpiper.*—Cinereous above, white beneath; legs dusky green; head spotted with black; neck with dusky streaks; back and wing-coverts with concentric black semicircles, varied with cinereous and white; tail coverts black and white; tail cinereous, edged with white; breast spotted with black; membrane surrounding the toes narrow and toothed. Length about 10 inches; weight from four ounces and a quarter to five and three quarters. This species, like most of the tribe, is subject to considerable variety. It inhabits Europe and America; visits some parts of our coasts, in large flocks, in winter, and departs about the latter end of March or beginning of April.

566 *Fusca.* *Brown sandpiper.*—Pale brown, spotted with black above, white beneath; fore part of the neck streaked with black; tail cinereous; wing-coverts edged with whitish; bill and legs black. Size of a jack-snipe. Inhabits England, but is very scarce.

567 *Lincolniensis.* *Black sandpiper.*—White, varied with gray and brown spots above, with oblong brown and black spots beneath; two middle tail feathers all black. Size of a thrush. Inhabits England, chiefly in Lincolnshire.

568 *Lobata.* *Gray phalarope,* or *great coot-footed tringa.*—Bill subulate, and bent in at the tip; feet pinnate; breast waved with white; bill black; front white; crown dusky; neck pale ash above; back, rump, and shoulders dove-colour, with dusky spots; wing-coverts and quill feathers brown; breast and belly white; tail dusky, edged with cinereous; legs black; membrane round the toes indented. Size of the common purre; weight one ounce. Inhabits Europe, Asia, and America. Congregates about the borders of the Caspian sea, and is not common in Britain. In stormy weather, it swims in numbers on lakes; but in fine weather, is solitary among the fens.

569 *Hyperborea.* *Red phalarope,* or *cock coot-footed tringa.*—Bill subulated, bent in at the tip; feet pinnate; breast cinereous; sides of the neck ferruginous; bill black; band through the eyes blackish; bar on the wings white; rump with blackish bands. The female is gray above, rufous beneath, with the eyebrows and base of the tail reddish, and the rump white; bill yellowish; band above the eyes reddish; bar on the wings white, and the rump spotted with blackish. Eight inches long. Inhabits northern Europe and America; but is rarely met with in our own country. These birds go in pairs, and catch insects in the water with their bill. They do not dive, and are but bad swimmers. The female makes her nest on dry ground, and lays four eggs.

570 *Alpina.* *Alpine sandpiper,* or *dunlin.*—Brown testaceous; breast blackish; tail feathers whitish-ash; legs brownish; belly white; two middle tail-feathers a little longer. Weighs from nine to eleven drams; length of the largest eight inches. Inhabits Europe, Asia, and America, and is not uncommon on our own coasts during great part of the year. The female lays four eggs, of a dirty white, blotched with brown round the thicker end, and marked with a few small spots of the same colour on the smaller end.

571 *Ochropus.* *Green* or *wood sandpiper.*—Bill dotted at the tip; legs greenish; back brown green; belly and outer tail feathers white; bill greenish; crown and hind head dusky ash; rump variegated; eyebrows white. Inhabits Europe, North America, and Siberia. This elegant species weighs about three ounces and a quarter; length full 10 inches. It is by no means plentiful in Britain, and, except in pairing time, lives solitary. It is never seen near the sea; but frequents rivers, lakes, and other fresh waters. It runs on the shores, or skims the surface of the water. It utters a cry as it rises, and sometimes dives when pursued by the buzzard. It feeds on the fry of small fishes and worms. Though its flesh tastes somewhat of musk, it is considered as a great delicacy. It comes to us about the middle of September, and leaves us as late as the end of April, when it departs northward to breed.

572 *Littorea.* *Shore sandpiper.*—Smooth bill, and legs cinereous; quill feathers brown, the shaft of the first snowy. Near 11 inches long. Inhabits Europe; and is ranked by some ornithologists among British birds.

573 *Grenovicensis.* *Greenwich sandpiper.*—Body varied above; neck cinereous beneath; belly, vent, and sides of the rump white; bill black; legs greenish; crown brown, streaked with black; neck ash-coloured beneath; back and wing-coverts brown ferruginous, edged with whitish; hind part of the back, rump, and lesser wing-coverts cinereous; tail cinereous, the feathers waved towards the tip, which is pale rusty. Size of the preceding, but very rare. The circumstance of one having been shot near Greenwich, has given rise to the trivial name.

574 *Maritima.* *Sea* or *selninger sandpiper.*—Varied above with gray and black, white beneath; legs yellow; middle of the back

Grallæ. back violet; throat and tail dusky; four outer tail feathers very short, and edged with white. Size of a stare. Inhabits Norway and Iceland. A small flock of this species, consisting of 10 or 12, was once observed, some years ago, near Bexhill, on the 8th of December.

575 *Hypoleucos.* *Common sandpiper*.—Bill smooth; legs livid; body cinereous, with black stripes, white beneath; bill brown; irides hazel; head brown, with black streaks; eyebrows white; neck cinereous above; back and wings greenish-brown, with numerous, narrow, dusky lines; quill feathers brown, and, except the first, with a white spot within; tail rounded, and glossy-green brown. Weight about two ounces; length seven inches and a half. Inhabits Europe and America. Visits this country in the spring, chiefly frequenting our lakes and rivers, on the borders of which it makes a nest composed of moss and dried leaves, and most commonly placed in a hole in the bank. It lays four or five eggs of a dirty white, marked with dusky and cinereous spots, mostly at the larger end. When disturbed, it makes a piping noise as it flies; and, when running on the ground, the tail is constantly in motion. In autumn it is liable to be much infested with the *hippobosca hirundinis*.

576 *Canutus.* *Knot*.—Bill smooth; legs ash-coloured; primary quill feathers serrated; outermost tail feather white, without spots; bill dusky ash; irides hazel; lores dusky; eyebrows and band on the wings white; body cinereous above, white beneath; lower wing-coverts tipt with white; chin and breast with minute spots; belly and vent with dusky lines; rump with brown semicircles. Nine inches long, and weighs four ounces and a half. Inhabits Europe and America. In Lincolnshire, and the other fenny districts of England, it is caught, in great numbers, by nets, into which it is decoyed by carved wooden figures to represent itself. It is also fattened for sale, and esteemed by many equal to the ruff in the delicacy of its flavour. The season for taking it is from August to November, after which the frost compels it to disappear. This bird is said to have been a favourite dish with Canute king of England; and Camden remarks that its name is derived from his.

577 *Cinclus.* *Stint*, *purre*, or *sanderling*.—Bill and legs black; lores white; body and rump gray and brown; head and neck pale cinereous above, with brown streaks; back and wing-coverts brownish-ash, the greater tipt with white; throat white, mixed with brown; breast and belly white; two middle tail feathers more dusky, the rest edged with white: the legs are sometimes brown. The country people frequently call it *ox-bird*, *ox-eye*, *least snipe*, *sea-lark*, or *wagtail*. It is nearly eight inches in length, and weighs about an ounce and three quarters. Inhabits Europe, Asia, and America. During winter it is found on all our coasts, appearing in vast flocks, and especially affecting the flat sandy shores and inlets. They leave us in April, though it is suspected that some remain with us all the year. These birds run nimbly near the edges of the flowing and retiring waves, and are almost perpetually wagging their tails, while they are, at the same time, busily employed in picking up their food, which consists chiefly of small worms and insects. On taking flight, they give a kind of scream, and skim along the surface of the water with great rapidity, as well as with great regularity, not flying directly forward, but performing their evolutions in large semicircles, alternately approaching the shore and the sea in their sweep, the curvature of their course being indicated by the flocks appearing suddenly and alternately in a dark or in a snowy white colour, as their backs or their bellies are turned to or from the spectator.

Little sandpiper.—Bill and legs brown; body reddish 578 *Pusilla.* beneath; outer tail feathers with a white shaft; rump variegated; bill tipt with black; greater wing-coverts and quill feathers brown, tipt with white; tail dusky; breast and belly white. About the size of a hedge-sparrow, and between five and six inches long. Inhabits Northern Europe and Nootka Sound; and has been once or twice killed in England.

Gray sandpiper.—Bill black; legs greenish; body 579 *Squatarola.* gray, white beneath; head, back, and wing-coverts, edged with greenish-ash; cheeks and chin with oblong dusky spots, and with the belly and rump white; tail barred with black and white. Weight about 7 ounces; length 12 inches. Inhabits Europe and America. Is not plentiful on our shores, seldom more than six or seven being seen in a flock, and all of them retiring northward to breed. In Siberia and Carolina, it is said to be found in large flocks.

Red or *Aberdeen sandpiper*.—Bill and legs brown; 580 *Islandica.* body ferruginous beneath; secondary quill feathers edged with white; body thickly sprinkled with black, and ferruginous above; wing-coverts white on the outer edge; rump and vent whitish, the former waved with black, the latter with a few black streaks; quill feathers black, with white shafts; tail feathers cinereous, with white shafts. From eight to ten inches long. Inhabits the north of Europe and America. Sometimes appears in great flocks on the coasts of Essex and the north of Scotland. In summer it frequents the neighbourhood of the Caspian sea, and also the river Don. It is perpetually running up and down on the sandy banks, picking up insects and small worms, on which it feeds.

Gen. 56. CHARADRIUS, *Plover*. 581 CHARADRIUS.

Bill roundish, obtuse, straight; nostrils linear; feet formed for running, three-toed. 582 Characters.

The birds of this genus frequent the mouths of rivers, and the neighbourhood of torrents, and seem to enjoy rainy weather. From this last circumstance is derived their French name *pluvier*, and the English *plover*.

Ring plover, *ring dotterel*, or *sea lark*.—Breast black; 583 *Hiaticula.* front blackish, with a white band; crown brown; legs yellow; upper half of the bill orange, lower black; irides hazel; body gray-brown above, white beneath; eggs bluish-white, with small round purplish spots. Of this species there is also a gray variety, with the collar and belly white; and another gray-ash, with the front and collar white, and the lower half of the tail black, tipt with rusty; the former inhabiting Spain, and the latter America. The more common sort is a native of both Europe and America, and is a well known visitant of our shores in summer; usually arriving in spring, and migrating in autumn, or at least retiring to the more inland parts of the country. It weighs about two ounces, and is between seven and eight inches long. It pairs early in May, and makes no nest, but lays four eggs in a small cavity in the sand, just above high-water mark. They are of a cinereous brown, marked all over with small black and ash-coloured spots. It is to be remarked

Grallæ. ed, that these and other birds which lay invariably only four eggs on the ground, place them so as to occupy the least possible space, that is, with the small ends touching each other as a centre. The ringed plover is greatly attached to its young, and will practise various deceptions to save them from men and dogs; sometimes fluttering along the ground as if crippled, and sometimes seeming to tumble head over heels repeatedly, till it has enticed its enemy to a distance from its young, and then it flies off.

584 *Vociferus.* *Noisy plover.*—Bands on the breast, neck, front, and cheeks white; tail pale yellow, with a black bar; legs yellow. Between nine and ten inches long. Inhabits America. Is very restless and clamorous.

585 *Morinellus.* *Dotterel.*—Breast ferruginous; band over the eyes, and line on the breast white; legs black; bill black, depressed in the middle; front mixed with dusky and gray; hind head black, temples and chin white; upper part of the neck, back and wings, gray-brown; line across the breast white; middle of the belly black, reddish-white below; greater quill feathers brown, and some of them edged with white; tail olive brown, with a dusky band near the end, and tipt with white. The female is distinguished by a dusky band over the eyes, and brown crown. The crown of this species is sometimes varied with white, gray-brown, and yellowish; the body beneath yellowish, mixed with white; the two middle tail feathers brown, and the lateral ones white. Weight between four and five ounces; length nearly 10 inches. Inhabits Europe, and makes this island a resting station in its migratory flights to and from its breeding place. It is seen on some of our downs, heaths, and moors, from April to the beginning of June; returns again in September, and remains till November. On the Wiltshire downs, it resorts to the new sown corn or fallow-ground, for the sake of worms and beetles, its principal food. In the autumn it flies in flocks of five, six, or more. It is a stupid bird, and easily shot, but much esteemed for the delicacy of its flesh.

586 *Himantopus.* *Long-legged plover*, or *long shanks.*—White; back and wings black; bill black, longer than the head; legs red, and very long; bill black, slender, tapering to a sharp point, the upper mandible a little longer than, and bent over, the lower; irides red; neck dusky spots above. There is a variety with white and black wings, and the tail feathers white. This extraordinary species is certainly the longest legged bird, in proportion to its bulk, hitherto known; the length from the apex of the bill to the end of the tail being thirteen inches, and from that to the end of the toes, five inches more. It is rare in Britain, and in many parts of Europe, so that its manners are very imperfectly known. According to Latham, it is common in Egypt, being found there in the marshes in October. Its food is said to consist principally of flies. It is likewise plentiful about the salt lakes, and often seen on the shores of the Caspian sea, as well as by the rivers which empty themselves into it, and in the southern deserts of Independent Tartary. It is also often met with in the warmer parts of America, and sometimes in Jamaica.

587 *Pileatus.* Plate CCCXCIX. fig. 2. *Hooded plover.*—Bill and feet red; face naked, having a yellowish carunculated membrane; head and part of the neck black; hind head furnished with a few short pointed feathers hanging like a crest; beneath white; body above rufous gray; under part white. Ten and a half inches long. Native of Senegal. Grallæ.

Gen. 57. Recurvirostra, *Avocet.* 588 Recurvirostra.

Bill depressed, subulated, recurved, pointed, flexible at the tip; feet palmated, four-toed, hind toe not connected, very short, and placed high up; nostrils narrow, pervious; tongue short. 589 Characters.

Of this singular genus there are only three species, of which the first inhabits Europe. 590 *Avocetta.*

Scooping avocet.—In provincial English, *butter-slip*, *scooper*, *yelper*, *picarini*, *crooked bill*, *cobler's awl*, &c. Variegated with white and black; bill three inches and a half long; irides hazel; crown black, a white spot behind and beneath the eyes; rest of the head, neck, back, exterior part of the wings, lesser quill feathers, tail, and under part of the body white; inner scapulars, and greater quill feathers without and at the tips black; legs bluish, and very long membrane connecting the toes indented. Resides in the temperate parts of Europe; weighing thirteen ounces, and measuring, from the tip of the bill to the end of the tail, eighteen inches. It breeds in the fens of Lincolnshire, and on Romney Marsh, in Kent. The female lays two white eggs, tinged with green, and marked with large black spots. In winter these birds assemble in small flocks of six or seven, and frequent the shores, particularly the mouths of large rivers in search of worms and marine insects, which they scoop out of the mud or sand. They seem to be particularly fond of the *cancer pulex*, or *locusta*. By means of their long legs, they run over shores that are covered five or six inches with water. In their movements they are lively, alert, volatile, and difficult to catch. When the female is frightened off her nest, she counterfeits lameness; and, when a flock is disturbed, they fly with their necks stretched out, and their legs extended behind, over the head of the spectator, making a shrill noise, and uttering a yelping cry of *twit, twit*, all the time.

American avocet.—Head and neck reddish; back black, white beneath. Fourteen inches long. Inhabits North America and New Holland. 591 *Americana.* Plate CCCXCIX. fig. 1.

White avocet.—White; lower wing coverts brownish; bill orange; legs brown. Fourteen inches and a half long. Inhabits Hudson's bay. 592 *Alba.*

Gen. 58. Hæmatopus. 593 Hæmatopus.

Bill compressed, the tip an equal wedge; nostrils linear; tongue a third part as long as the bill; feet formed for running, three toed, cleft. 594 Characters.

Sea pie, or *pied oyster-catcher.*—Bill, eyelids, and legs red, the former sometimes tipt with black; irides scarlet; body sometimes totally black; frequently the head, neck, and body above black; white beneath; a small white spot under the eyes; breast with a white semicircular band; middle wing coverts at the tips, and greater, entirely white; quill feathers spotted with white on the inside; tail from the middle to the base white, lower half black; claws black. Weight seventeen ounces, length sixteen inches. Inhabits almost every sea shore, but seems never to quit the coast. Congregates in small flocks in winter, and chiefly subsists on marine insects 595 *Ostralegus.* Plate CCCXCIX. fig. 3.

Grallæ. sects and shell-fish, especially on oysters, which it seizes with great adroitness. It makes no nest, but deposits its eggs on the bare ground, above high water mark. The eggs are generally four, of an olivaceous brown, blotched with black, and somewhat larger than those of the lapwing. The male is very watchful at the time of incubation, and on the least alarm, flies off with a loud scream, and the female instantly runs from her eggs to some distance, and then takes wing. It is a shy bird, but becomes bolder when the young are hatched. The latter are capable of running as soon as they quit the eggs, and are led by their parents to their proper food. The young are easily tamed.

596 Glareola.

Gen. 59. Glareola, *Pratincole*.

597 Characters. Bill strong, short, straight, and hooked at the tip; nostrils at the base of the bill, linear and oblique; gap of the mouth large; feet four-toed, toes long, slender, connected at the base by a membrane; tail forked, consisting of twelve feathers.

598 *Austriaca.* *Austrian pratincole.*—Gray brown above; collar black; chin and throat white, breast and belly reddish-gray. Very subject to vary in its plumage. Inhabits the heaths of southern Europe. About nine inches long. Feeds on worms and aquatic insects; is very restless and clamorous, and lays about seven eggs.

599 *Senegalensis.* *Senegal pratincole.*—Bills, legs, and whole body brown. Nine inches and a half long. Inhabits near the Senegal, and also Siberia.

600 *Novia.* *Spotted pratincole.*—Brown, spotted with white; lower part of the belly and vent reddish-white, with black spots; bill and legs black. Size of the *austriaca*. Inhabits Germany.

601 Fulica.

Gen. 60. Fulica.

602 Characters. Bill convex; upper mandible arched over the lower at the edge; lower gibbous near the tip; nostrils oblong; front bald; feet four-toed and sub-pinnated.

Birds of this tribe frequent waters, and feed on worms, insects, and small fish. They have a compressed body; the bill thick, and bent in towards the tip; the upper mandible reaching far up the forehead, and the wings and tail short. They are divided into *gallinules* or *water hens*, and *coots*. The former have the feet cleft; the upper mandible membranaceous at the base, and the wings concave; while the latter have the toes surrounded by a scalloped membrane; the mandibles equal; nostrils oval, narrow and short.

603 Gallinule.

A. *Feet cleft.* *Gallinule.*

604 *Chloropus.* *Common gallinule*, or *moor hen*.—Front tawney; bracelets red; body blackish; bill red, with a greenish tip; irides red; body sooty above, mixed with olive; cinereous beneath; outer edge of the wings and lower tail-coverts white; legs greenish; toes flat and broadish. Weighs from 14 to 16 ounces; length 14 inches. Inhabits Europe and America, and is a very common species, being found in most sedgy and slow rivers, or streams of water, and frequently in ponds abounding in weeds, where it can lie concealed. It feeds principally on insects, seeds, and vegetable productions of various sorts, in quest of which it frequently quits the water. It runs fast, and is equally expert in swimming and diving, but flies heavily, and with its legs hanging down. As it runs or swims, it is continually flirting up the tail, when the white underneath is very conspicuous. The nest is made of flags or rushes, and placed near the surface of the water, on some branch of a tree or bush, and sometimes on the stump of an old willow. The eggs are commonly five or six, but sometimes nine or ten, of a light yellowish brown, marked with rust-coloured spots. The young are hatched in about three weeks, and instantly take the water. This species breeds twice or thrice in the course of a season. Its flesh is reckoned delicious.

605 *Porphyrio.* *Purple gallinule.*—Front red; bracelets many; body green; violet beneath. Fifteen inches long. Common in most temperate and warm countries. Is docile and easily tamed. Stands on one leg, and lifts the food to its mouth with the other. Feeds on fish, roots, fruits, and seeds.

606 Coot.

B. *Feet pinnated.* *Coot.*

607 *Atra.* Plate CCCXCIX. fig. 4. *Common*, *black*, or *bald coot*.—Front flesh-coloured; bracelets greenish-yellow, body blackish; bill yellowish-white; front, except in pairing time, white; legs yellowish green; outer edge of the wings white. There are several varieties. Length 18 inches; weight from 20 to 30 ounces. Inhabits Europe, Asia, and America. It occurs in Great Britain at all seasons of the year, and is not supposed to migrate to other countries, but changes its stations, and to remove from the pools, where the young have been reared to the larger lakes, where flocks assemble in the winter. The female commonly builds her nest of a great quantity of coarse dried weeds, well matted together, and lined within with softer and finer grasses, in a bush of rushes surrounded by the water. She lays from 12 to 15 eggs at a time, and commonly hatches twice in a season. Her eggs are about the size of those of a pullet, and of a pale brownish-white colour, sprinkled with numerous small dark spots, which, at the thicker end, seem as if they had run into each other, and formed bigger blotches. As soon as the young quit the shell, they plunge into the water, dive, and swim about with great ease, but they still gather about the mother, and take shelter under her wings, and do not entirely leave her for some time. They are first covered with a sooty-coloured down, and are of a shapeless appearance; and, while in this state, before they have learned by experience to shun their enemies, they are often sacrificed to the rapacity of the pike, the kite, moor-buzzard, &c. A female of this species built her nest in Sir William Middleton's lake at Belsay, in Northumberland, among the rushes, which were afterwards loosened by the wind, so that the nest was driven about, and floated on the surface of the water; notwithstanding which, she continued to sit as usual, and brought out her young on her moveable habitation. The common coot swims and dives with great ease, but is a bad traveller, and may be said not to walk, but to splash and waddle between one pool and another, with a laboured, ill balanced, and awkward gait. During the day it usually skulks among the rushes or other water plants, rarely venturing abroad, except in the dusk, or at night, in quest of herbage, seeds, insects, and fishes. The sportsman and his dog can seldom force it to spring from its retreat, as it will rather bury itself in the mud than take wing, or,

if it be very closely pursued, and compelled to rise, it gets up with much flustering and apparent difficulty.

608 *Aterrima.* *Greater coot.*—Front white; bracelets red; body blackish. Has much the appearance and manners of the last, but is larger and blacker. It is found both in England and Scotland. The French eat it on meagre days.

609 *Cristata.* *Crested coot.*—Blue black; naked front and crown red; caruncle red, bifid, erect; bracelets red, green, and yellow; bill whitish, with a red base; legs dusky. Eighteen inches long. Inhabits China and Madagascar.

610 VAGINALIS.

Gen. 61. VAGINALIS, *Sheath-bill.*

611 Characters. Bill strong, thick, conical, convex, and compressed; upper mandible covered above with a moveable horny sheath; nostrils small, placed before the sheath; tongue round above, flattened beneath, and pointed at the tip; face naked and papillous; wings with an obtuse excrescence under the flexure; legs strong; four-toed; naked a little above the knees; toes rough beneath; claws grooved.

612 *Alba.* *White sheath-bill.*—Bill black at the base; sheath a horny yellow or black plate, nearly covering the nostrils; face naked; and in the adult bird, beset with white, or pale orange warts; a brown or blackish wart above the eyes, larger than the rest; feathers white; excrescences on the wings blackish; legs two inches long, and generally reddish. The only species of the genus; about the size of a pigeon. From 15 to 18 inches long; inhabits New Zealand and the South seas, and feeds on shell-fish and carcases.

631 PARRA.

Gen. 62. PARRA, *Jacana.*

614 Characters. Bill tapering, somewhat obtuse; nostrils oval, in the middle of the bill; front covered with lobated caruncles; wings spinous.

615 *Chilensis.* *Chilese jacana.*—Claws moderate; legs brown; hind head subcrested. Inhabits Chili. Size of a jay, but has longer legs; feeds on worms and insects; is noisy, and defends itself by the spurs on the wings. Builds in the grass, and lays four tawney eggs, speckled with black.

616 *Jacana.* *Chesnut jacana.*—Hind claws very long; legs greenish. Ten inches long; inhabits watery places in South America, and utters, almost unceasingly, a shrill disagreeable cry.

617 *Chavaria.* *Faithful jacana.*—Toes long; legs tawney; hind head crested; bill dirty white; upper mandible like that of the dunghill cock; a red membrane on both sides at the base of the bill, extending to the temples, in the middle of which are the eyes; irides brown; hind head with about 12 blackish feathers; three inches long, forming a pendent crest; rest of the neck covered with thick black down; body brown; wings and tail blackish; wing-spurs two or three, and half an inch long; belly light black; thighs half bare; toes so long as to entangle each other in walking. About the size of a cock, and stands a foot and a half from the ground. Inhabits the rivers and inundated places near Carthagena in America; feeds on herbs; has a clear and loud voice, a slow gait, and easy flight. The natives keep one of these birds tame to wander with the poultry, and defend them against birds of prey, which it does by means of the spurs on its wings. It never deserts the charge committed to its care, and brings them home at night. It will readily suffer itself to be handled by grown up persons, but not by children.

Gen. 63. RALLUS, *Rail.* 618 RALLUS.

Bill thickish at the base; attenuated on the back towards the tip; compressed; a little incurved and pointed; tongue rough at the tip; body compressed; tail short; feet four-toed and cleft. 619 Characters.

The birds of this genus have the bill a little inflected; small nostrils; tongue rough; and the tail very short.

Land rail, crake, corn-crake, daker-hen, &c.—Wings reddish-rusty; bill and legs brown-ash; irides hazel; feathers of the body reddish-brown; the upper ones black in the middle; chin very pale; belly whitish-yellow. About nine inches and a half long. Inhabits the sedgy parts of Europe and Asia. From its appearing at the same time with the quail, and frequenting the same places, it is sometimes called *king of the quails*. Its well known cry is first heard as soon as the grass becomes long enough to shelter it, and continues till the grass is cut; but the bird is seldom seen, as it skulks in the thickest parts of the herbage, and runs so nimbly through it, winding and doubling in every direction, that it is difficult to come near it. When hard pushed by the dog, it sometimes stops short and squats down, by which means its too eager pursuer overshoots the spot, and loses the trace. It seldom springs but when driven to extremity, and generally flies with its legs hanging down, but never to a great distance. As soon as it alights, it runs off, and before the fowler has reached the spot, the bird is at a considerable distance. It is a migrative species, appearing with us about the latter end of April, and departing in October. On its first appearance, and till the female begins to sit, the male is frequently heard to make a singular kind of noise, much resembling that of a comb when the finger is drawn along the teeth of it, and which has been used as a decoy. When they first arrive, they are very lean, but before their departure, become excessively fat, and are much sought after for the delicacy of their flesh. 620 *Crex.*

Water rail, brook ouzel, bilcock, velvet runner, &c.—Wings gray, spotted with brown; flanks spotted with white; bill orange beneath; bill black, reddish at the base; irides red; feathers of the upper part of the body olive-brown, and black in the middle; the lower ones cinereous; those of the lower part of the belly and vent edged with rufous; quill feathers dusky; lower tail coverts white; tail feathers short, black; the two middle ones at the tip, the rest edged with ferruginous; legs dusky red. Length about 12 inches; weight four ounces. Inhabits watery places in Europe and Asia. Though not very plentiful, it is sometimes found in various parts of Great Britain, in low situations, about water courses and rivulets, where it seeks shelter among sedge-rushes, and reeds, and is seldom put to flight, depending chiefly on its legs for safety. When roused, it flies only a small distance, and that in a heavy and awkward manner, with its legs hanging down. It runs nimbly, and frequently flirts up its tail. The nest is made 621 *Aquaticus.*

Grallæ. made of sedge and coarse grass among the thickest aquatic plants, or in willow beds. The female lays six or more eggs, rather larger than those of a blackbird, very smooth, and of a pure white. This bird continues with us all the year, and by many is erroneously believed to be the land rail metamorphosed in the autumn, without knowing perhaps that the latter leaves this country at that season, and that the difference of the bills alone constitutes an essential distinction.

622 Porzana. *Spotted gallinule*, or *spotted water-hen*.—Two middle tail feathers edged with white; bill and legs pale olive; bill greenish-yellow; irides hazel; head brown, spotted with black; line over the eyes pale gray; neck above, and flanks brown-ash, with small white spots; back and wing-coverts olive, with black stripes, and near the edges of the feathers with white spots; the greater with white stripes and lines; cheeks, chin, and throat, pale gray, with brown spots; breast brown, with white spots; belly varied with cinereous and white; vent ochre-yellow. The weight of this elegant species is about four ounces; length nine inches. Inhabits Europe and North America; is migrative and scarce in England, and seems to have the manners and habits of the preceding.

623 Niger. *Black rail*.—Black; bill red at the base, brown at the tip; legs brown or red. Nine inches long. Inhabits Africa.

624 Pusillus. *Dwarf rail*.—Stripped with ferruginous and black; body black beneath, with narrow white bands; throat and breast bluish. Size of a lark. Inhabits near the salt lakes of Dunria.

625 Psophia.

Gen. 64. Psophia, *Trumpeter*.

626 Characters. Bill cylindrical, conical, convex, somewhat pointed; the upper mandible longest; nostrils oval and pervious; tongue cartilaginous, flat, and fringed at the tip; feet four-toed and cleft.

627 Crepitans. *Gold-breasted trumpeter*.—Black; back gray; breast glossy-green; orbits naked, red; bill yellowish-green; legs strong, tall, brownish ash or green; the back toe a round protuberance beneath, at a little distance from the ground; tail very short; feathers of the head downy; of the lower part of the neck squamiform; of the shoulders ferruginous, lax, pendulous, and silky; scapulars long and hanging. The *agami* of voyagers and others. Nearly 22 inches long, and about the size of the common domestic fowl. Inhabits South America, particularly the interior of Guiana, in considerable troops. In its native haunts is not distrustful of man, and is susceptible of domestication in an eminent degree, acquiring many of the social habitudes of the dog. It emits from the lungs a harsh and uncommon noise, not unlike that of a child's trumpet. It stands on one leg, and sleeps with its neck drawn in between the shoulders.

628 Undulata. *Undulated* or *African trumpeter*.—Crest of the hind head short, whitish; that of the breast long, black, and pendent. Size of a goose. Inhabits Africa.

629 Gallinæ.

Order V. GALLINÆ.

630 Characters. Bill convex; the upper mandible arched and dilated at the edge over the lower; nostrils half-covered with a convex cartilaginous membrane; tail feathers more than 12; feet cleft, but connected at the innermost joint; claws broad; toes scabrous below, and formed for scratching up the ground. In most species the males have spurs on the legs. They live chiefly on the seeds of plants, but likewise eat insects, grubs, and worms, which are macerated in their crop. They are polygamous, and build rude nests, for the most part, on the bare ground, the female laying many eggs at a time. They collect their young about them by a particular cry when they feed them, and lead and protect them till they moult. They are easily tamed, and are useful on account of their flesh, their eggs, and their feathers. Gallinæ.

Gen. 65. Otis, *Bustard*. 631 Otis.

Bill somewhat convex; nostrils oval and pervious; tongue bifid, pointed; feet formed for running; three-toed; tall; naked above the thighs. 632 Characters.

Great bustard.—Wave spotted, with black and rufous; whitish beneath; head (of the male) and each side of the throat crested; head and neck cinereous; quill feathers black; tail with rufous and black lines, and from 18 to 20 feathers; pouch beginning under the tongue, and reaching to the breast; long, capacious, and fit to hold near seven quarts of water; legs dusky. The male weighs from 20 to 30 pounds, and the female about 10 or 12; length about four feet. Inhabits the open plains of Europe, Asia, and Africa. It is the largest of British birds, and is now almost extinct in our island. It makes no nest, but the female lays her eggs in some hole in the ground, in a dry corn field. The eggs are two in number, as big as those of a goose, and of a pale olive-brown, marked with spots of a deeper colour. If during her absence from the nest, any one handles, or even breathes on the eggs, she immediately abandons them. Bustards feed on green corn, the tops of turnips, and various other vegetables, as well as on worms; and they have also been known to eat frogs, mice, and young birds of the smaller kind, which they swallow whole. They are remarkably shy and timid, carefully avoiding mankind, and being easily driven away in whole herds by the smallest dog. They are slow in taking wing, but run with great rapidity; and the young are even sometimes coursed and taken by greyhounds. Though not properly migratory, they leave their usual haunts in very severe winters, when the downs are covered for any length of time with snow, and repair to the more inclosed and sheltered situations in small flocks, and even stray to a great distance. In the Crimea they are seen in large flights, especially during winter, when the wings and crop feathers are sometimes so encumbered with ice, that the bird is unable, in the snow, to take the run previous to flying, in consequence of which many are caught by the hand, or by means of dogs, and brought to market alive. The flesh, particularly of the young, when kept a little time, is excellent. 633 Tarda.

Arabian bustard.—Ears with erect crests. Size of the preceding. Inhabits Asia and Africa. 634 Arabs.

Little bustard, or *field duck*.—Head and throat smooth; bill gray-brown; crown black, with rufous bands; temples and chin reddish white, with small dark spots; neck (of the male) black, with a white collar; body above varied with black, rufous, and white; beneath 635 Tetrax.

Gallinæ.

and outer edge of the wings white. About the size of a pheasant; length 17 inches. Inhabits Southern Europe and Asia. A few instances are on record of its having been found in England. In France, it is frequently served at table as a delicacy, though the flesh be blackish. In June it lays from three to five eggs, of a glossy green, and the young are able to fly in August.

636 *Afra.* Plate CCCC. fig. 1.

White-eared bustard.—Black; back cinereous; ears white; in the male the bill and legs are yellow; the crown is cinereous, and the wings are marked with a large white blotch, the neck behind, and thighs above the knees, have a white collar; the tail feathers 14; the female is cinereous, and the thighs and belly black. Length 22 inches. Native of the Cape of Good Hope.

637 *Houbara.*

Ruffed bustard.—Yellowish, spotted with brown; feathers of the neck long, whitish, with black shafts; quill feathers black, with a white spot in the middle. Size of a capon. Inhabits Africa and Arabia.

638 *Oedicnemus.*

Thick-kneed bustard, stone curlew, or *Norfolk plover.*—Gray; two first quill feathers black, white in the middle; bill sharp pointed; legs cinereous; bill black; legs greenish-yellow; lower eyelid naked, pale yellow; a yellow line above and beneath the eyes; a brown line from the bill, under the eyes to the ears; knees thick, as if swollen; belly and thighs white. Weighs about 17 ounces; length 18 inches. Inhabits Europe, Asia, and Africa. With us it is a migrative species, making its first appearance the latter end of April, or beginning of May, when the male is heard to make a very loud shrill noise, particularly in the dusk of the evening. It chiefly frequents large corn fields, heaths, or warrens, in open hilly situations; makes no nest, but lays two light-brown coloured eggs, blotched and streaked with dusky, on the ground. Its food chiefly consists of insects and worms, and sometimes also of mice, frogs, and toads. In the autumn, these birds assemble in small flocks preparatory to their departure, and are seldom seen after the beginning of October. When flying, they stretch out their feet straight behind, like the heron. The young are hardly to be distinguished from the stones in which they generally harbour.

639 STRUTHIO.

Gen. 66. STRUTHIO.

640 Characters.

Bill subconical; nostrils oval; wings short, unfit for flight; feet formed for running.

641 *Camelus.* Plate CCCC. fig. 2.

Black ostrich.—Feet with two toes; head small; bill horn-colour; irides hazel; eyelids fringed, head and greater part of the neck bald, flesh-coloured, with a few scattered hairs; feathers of the body lax, black, and decomposite; the webs on each side equal; quill and tail feathers snowy, waved, and long, with a sprinkling of black on the edge or tip; chest callous; wing spurs two, one at the end of the wing, and one on the spurious wing; thighs and flanks naked; feet strong, gray-brown; toes connected at the base, the outer very short, and unarmed. The ostrich stands so very high as to measure from seven to nine feet, from the top of the head to the ground; from the back, however, it is seldom more than three or four feet, the rest of its height being made up by its extremely long neck. In the sandy and burning deserts of Africa and Asia, the black ostriches are seen in such large flocks, as sometimes to have been mistaken for distant cavalry. Their strong jointed legs, and cloven hoofs, if we may use the expression, are well adapted both for speed and defence. Their wings and all their feathers are insufficient to raise them from the ground. Their voise is a kind of hollow mournful lowing; and they graze on the plain with the quacha and the zebra. In the interior parts of southern Africa they frequently make great havock in the corn fields, destroying the ears of wheat so effectually, that in a large tract of land, it often happens that nothing but the bare straw is left behind. In running, they have a proud and haughty look, and even when closely pursued, never appear to be in great haste, especially when the wind is with them, and they can easily accelerate their progress by flapping their wings, so as to outstrip the swiftest horse. But if the weather be hot and calm, or if the birds have by any accident lost a wing, the difficulty of outrunning them is not so great. The ostrich is one of the few polygamous birds found in a state of nature, one male being generally seen with two or three, and frequently with five females. It has been commonly believed that the female, after depositing her eggs in the sand, and covering them up, allows them to be hatched by the heat of the climate, and leaves the young to shift for themselves. Recent travellers have, however, assured us, that no bird whatever has a stronger affection for her offspring, and that none watches her eggs with greater assiduity. It is true, that during the intense heat of the day, when incubation is less necessary, she sometimes forsakes them, but she always carefully broods over them by night. Kolben affirms that this species sit on their eggs like other birds, and that the males and females take this office by turns, as he had frequent opportunities of observing. Nor is it more true, that they forsake their young as soon as excluded from the shell. On the contrary, the old ones are very assiduous in supplying them with grass and water, are careful to defend them from harm, and will even themselves encounter every danger in their defence. All the females which are attached to one male, deposit their eggs in the same place, to the number of ten or twelve each, about the size of a child's head. These they hatch all together, the male also taking his turn of sitting on them. Thus from sixty to seventy eggs have sometimes been found in one nest, and Linnæus erroneously assigned them to one female. The term of incubation is six weeks. The nest appears to be merely a hole in the ground, formed by the birds trampling the earth for some time with their feet. If the eggs are touched by any person in the absence of the parents, they immediately discover it by the scent, at their return, and not only desist from laying any more in the same place, but trample to pieces with their feet all those that have been left. On this account the Africans are very careful in taking part of the eggs away not to touch any of them with their hands, but always fetch them out of the nest with a long stick. Within the eggs are frequently discovered a number of small oval-shaped pebbles, of the size of a marrowfat pea, of a pale yellow colour, and exceedingly hard. These eggs are reckoned a great delicacy, and are prepared in various ways. From their large size, one of them is sufficient to serve two or three persons at a meal. The ostrich itself is chiefly valuable for its plumage; and the Arabs have reduced the chase of it to a kind of science. They hunt it,

Gallinæ.

it, we are told, on horseback, and begin their pursuit at a gentle gallop; for should they, at the outset, use the least rashness, the matchless speed of the game would immediately carry it out of their sight, and in a very short time, beyond their reach. But when they proceed gradually, it makes no particular effort to escape. As it does not go in a direct line, but runs first on one side, and then on the other, its pursuers save much ground by rushing directly onward. In a few days at most, the strength of the animal is exhausted, and it then either turns on the hunters, and fights with the fury of despair, or hides its head, and tamely receives its fate. Frequently, also, the natives conceal themselves in ostrich skins, and thus are enabled to approach near enough to surprise them. Some persons breed up these birds in flocks, for they are tamed with very little trouble, and may be rendered very useful in a domestic state. Besides the valuable feathers which they cast, the eggs which they lay, their skins, which are used by the Arabians as a substitute for leather, and their flesh, which many esteem excellent food, they are sometimes made to serve in place of horses. It is pleasant to observe with what dexterity they play and frisk about in a tame state, particularly in the heat of the day, when they will strut along the sunny side of a house, with great majesty, perpetually fanning themselves with their expanded wings, and seeming, at every turn, to admire and be enamoured of their own shadows. They are very tractable and familiar towards persons who are acquainted with them, but are often fierce towards strangers, whom they frequently attempt to push down by running furiously on them, and when they succeed thus far, they not only peck at their fallen foe with their bill, but strike at him violently with their feet. While thus engaged, they sometimes make a fierce hissing noise, and have their throat inflated, and mouth open; and at other times, make a kind of cackling noise. During the night they often utter a doleful or hideous cry, somewhat resembling the distant roaring of a lion, or the hoarse tone of a bear or an ox, as if they were in great agony. They will swallow with the utmost voracity rags, leather, wood, iron, or stone, indiscriminately. "I saw one at Oran (says Dr Shaw), that swallowed, without any seeming uneasiness or inconvenience, several leaden bullets, as they were thrown upon the floor, scorching hot from the mould." Mr Adanson mentions two ostriches which afforded him a sight of a very extraordinary nature. They were so tame, that two little blacks mounted both together on the back of the largest. No sooner did he feel their weight, than he began to run as fast as possible, and carried them several times round the village, as it was impossible to stop him otherwise than by obstructing the passage. To try their strength, he directed a full-grown negro to mount the smallest, and two others the largest. This burthen did not seem at all disproportioned to their strength. At first they went at a pretty sharp trott, but when they became heated a little, they expanded their wings, as if to catch the wind, and moved with such fleetness that they scarcely seemed to touch the ground. "Most people (observes M. Adanson) have, one time or other, seen a partridge run, and consequently must know that there is no man whatever able to keep up with it: and it is easy to imagine, that if this bird had a longer step, its speed would be considerably augmented. The ostrich moves like the partridge, with this advantage; and I am satisfied that those I am speaking of would have distanced the fleetest race horses that were ever bred in England. It is true, they would not hold out so long as a horse, but they would undoubtedly be able to go over the space in less time. I have frequently beheld this sight, which is capable of giving one an idea of the prodigious strength of an ostrich, and of showing what use it might be of, had we but the method of breaking and managing it as we do a horse."

Emeu, or *cassowary*.—Feet three-toed; helmet and dewlaps naked; bill and legs black; gape very large; irides topaz; eyelids fringed; nostrils nearly at the tip of the bill; eyes large; helmet horny, reaching from the base of the bill to the middle of the crown, three inches high, the fore part blackish, the hind part yellow; temples and neck bald, wrinkled, and reddish, with a blue or purple tinge, and covered with a few scattered hairs; two pendant caruncles, partly red and partly blue, on each side of the neck; chest on which it rests callous; feathers brownish-black, lax, generally two from one shaft; no tail; wings consisting of about five naked dusky shafts; claws straight. Five feet and a half long. Inhabits within the torrid zone in Asia; is a fierce and bold bird; kicks with its feet like a horse, grunts like a hog, feeds on vegetables, which it swallows whole; lays greenish eggs, more oblong than those of the black ostrich; runs very swiftly, and is incapable of flying. 642 *Casuarius.*

New Holland cassowary.—Feet three-toed, crown flat; shanks serrated behind. Seven feet two inches long. Inhabits New Holland. 643 *Novæ Hollandiæ.*

American ostrich.—Feet three-toed, and a round callus behind. Nearly the height of a man. Inhabits South America; feeds on fruits, flesh, and flies, defends itself with its feet, and calls its young by a kind of hiss. 644 *Rhea.*

Gen. 67. DIDUS, *Dodo*. 645 DIDUS.

Bill narrowed in the middle, with two transverse wrinkles; each mandible bent in at the tip; nostrils oblique, near the edge of the middle of the bill; face naked beyond the eyes; legs short and thick; feet cleft; wings unfit for flight; no tail. 646 Characters.

Hooded dodo.—Black, waved with whitish; head hooded; feet four-toed; bill strong, large, bluish, with a red spot; the upper mandible yellowish at the tip, the lower bulging near the tip; gape very large; irides whitish; plumage soft; belly whitish; head large, black, as if covered with a cap; feathers of the rump curled, inclining to yellow; legs yellowish; claws wanting. This uncouth species is rather bigger than a swan, and nearly three feet in length. It inhabits the islands of Mauritius and Bourbon in the Indian ocean. According to Helbert, it seldom weighs less than 50 pounds; has a slow pace; the body round and fat: and the stomach so strong as to digest stones. It is, however, so seldom met with that its true history is little known. 647 *Ineptus.*

Solitary dodo.—Varied with gray and brown; feet four-toed; eyes black; spurious wings, terminating in a round protuberance. The female with a white protuberance, resembling a teat, on each side of the breast. Size of a turkey. Inhabits the island of Rodrigue, where it is not uncommon, though seldom more than 648 *Solitarius.*

Gallinæ. two are found together. It makes its nest in by-places, of leaves of the palm, a foot and a half in thickness, and lays one egg, bigger than that of a goose. The male sits in his turn, and does not suffer any bird to approach within two hundred yards of the spot when the hen is sitting. The incubation lasts seven weeks. Some months elapse before the young can shift for itself. The old ones in the mean time treat it with affection and tenderness, and are faithful to each other afterwards, though they may occasionally mix with others of their kind. The young bird, though timid, is stupid enough to allow a person to approach it; but when grown up, it is more shy, and will not be tamed. They are chased in the winter season, viz. from March to September, being then fat, and the young birds are much esteemed for the table.

649 Pavo.

Gen. 68. Pavo, *Peacock*.

650 Characters. Bill convex and strong; head with a crest of feathers turning forwards; nostrils large; rump feathers long, broad, expansile, and covered with eye-like spots.

651 *Christatus.* *Crested peacock.*—Head with a compressed crest; spurs solitary. It is impossible to describe the beauties of this well-known species in adequate terms. Its matchless plumage, as Buffon observes, seems to combine all that delights the eye in the soft and delicate tints of the finest flowers, all that dazzles it in the sparking lustre of the gems, and all that astonishes it in the grand display of the rainbow. Its head is adorned with a tuft, consisting of 24 feathers, whose slender shafts are furnished with webs only at the ends, painted with the most exquisite green, mixed with gold. The head, throat, neck, and breast, are of a deep blue, glossed with green and gold; the back of the same, tinged with bronze; the scapulars and lesser wing-coverts are of a reddish cream-colour, variegated with black; the middle coverts deep blue, glossed with green and gold; the greater coverts and spurious wing are of a reddish-brown, as are also the quills, some of which are variegated with black and green; the belly and vent are black, with a greenish line. But the distinguishing character of this bird is its train, which rises just above the tail, and when erected, forms a fan of the most resplendent hues. The two middle feathers are sometimes four feet and a half long, the others gradually diminishing on each side. The shafts, which are white, are furnished from their origin nearly to the end with parted filaments of varying colours, ending in a flat valve, which is decorated with what is called the *eye*. This is a brilliant spot, enamelled with the most enchanting colours, yellow, gilded with various shades, green, running into blue and bright violet, varying according to its different positions, the whole receiving additional lustre from the centre, which is a fine velvet black. When pleased or delighted, and in sight of his females, the peacock erects his tail, and displays all the majesty of his beauty, and he frequently turns slowly round, as if to catch the sunbeams in every direction, accompanied with a hollow murmuring voice. His cry at other times is very disagreeable, and often repeated. The peahen is somewhat less than the cock, and though furnished both with a train and crest, is destitute of those dazzling beauties which distinguish the male. She lays five or six eggs of a whitish colour, in some secret spot, where she can conceal them from the male, who is apt to break them; and she sits from 25 to 30 days, according to the temperature of the climate and the warmth of the season. Peacocks were originally brought from the distant provinces of India, and thence have been diffused over every part of the world. They are sometimes found in a wild state in many parts of Asia and Africa. The largest and finest are said to be met with in the neighbourhood of the Ganges, and on the fertile plains of India, where they grow to a great size. In colder climates, they require care in rearing; and do not acquire their full plumage till their third year. In former times they were considered as a delicacy, and made a part of the luxurious entertainment of the Roman voluptuaries. The females of this species, like the pheasant, have been known to assume the appearance of the male, by a total change of colour, which is said to take place, after they have done laying. A white variety of peacock occurs not unfrequently, in which the eyes of the train are barely visible, and may be traced by a different undulation of shade on the pure white of the tail. 652

Bicalcaratus. *Iris peacock.*—Brown; head subcrested; spurs two; bill blackish; the upper mandible, from the nostrils to the tip, red; irides yellow; crown black; face naked; temples white: neck shining brown, with black lines; upper part of the back, shoulders, and wing-coverts brown, with yellowish stripes; the feathers near the tip with a large purple gold spot; lower part of the back and rump spotted with white; body brown beneath, with transverse black streaks; quill feathers dusky; legs brown. Larger than a pheasant. Inhabits China.

Gen. 69. Meleagris, *Turkey*. 653 Meleagris.

Bill conical, and incurved; head covered with spongy caruncles; chin with a longitudinal membranaceous caruncle; tail broad, and expansile; legs spurred.

American or *common turkey*.—Front and chin carunculated; breast of the male tufted. Female without a spur. Upwards of three feet and a half long. Inhabits America; and is very generally domesticated. In a wild state it lives in woods, and feeds on nuts, acorns, and insects. It roosts on the highest trees; is very irascible, and impatient of any thing red. The cock struts with an inflated breast, expanded tail, red face, and relaxed frontal caruncle, making a singular inward noise, which when it is uttered shakes the whole body. The eggs are numerous and white, with reddish or yellow spots. The females lay them in spring, generally in some retired or obscure place; for the cock, enraged at the loss of his mate while she is employed in hatching, is otherwise apt to break them. They sit on their eggs with so much perseverance, that if not taken away, they will almost perish with hunger before they will entirely leave the nest. In a wild state, turkeys are gregarious, and associate in flocks, sometimes of about five hundred. They are very swift runners, but fly awkwardly; and about the month of March they become so fat, that they cannot fly beyond three or four hundred yards, and are then easily run down by a horseman. The hunting of these birds forms one of the principal diversions of the Canadians. When the latter have discovered the retreats of the turkey, which in general are near fields of nettles, or where there is plenty of any kind of grain, they send a well-trained dog in the midst of the flock. 654 Gallipavo.

The

The birds no sooner perceive their enemy than they run off at full speed, and with such swiftness that they leave the dog far behind; he, however, follows, and as they cannot go at this rate for any length of time, at last forces them to take shelter in a tree, where they sit, spent and fatigued, till the hunters come up, and with long poles, knock them down one after another. Turkey cocks, among themselves, are very fierce and pugnacious, and yet, against other animals, are usually weak and cowardly. The disposition of the female is in general much more mild and gentle than that of the male; and when leading out her young family to collect their food, though so large and apparently so powerful a bird, she gives them very little protection against any rapacious animal that comes in her way, but rather warns them to shift for themselves. It deserves to be remarked, that though this species is reared with some difficulty, yet in its wild state it is found in great plenty in the forests of Canada, that are covered with snow for more than three-fourths of the year. It is easily hurt by hunger or rain. They are bred in great numbers in Norfolk, Suffolk, and some other counties, from whence they are driven to the London markets in flocks of several hundreds. The drivers manage them with great facility, by means of a bit of red rag tied to the end of a long stick, which, from the antipathy that these birds bear to that colour, effectually answers the purposes of a scourge. We need scarcely notice, that the flesh of the turkey is reckoned a delicate food. The Indians make an elegant clothing of the feathers, by twisting the inner webs into a strong double string with hemp, or the inner bark of the mulberry-tree, and working it like matting, so that the whole appears rich and glossy, and as fine as silk shag. The natives of Louisiana make fans of the tail; and of four tails joined together the French used formerly to form a parasol.

655 *Satyra.* *Horned turkey.*—Head with two horns: body red, with eye like spots; bill brown; nostrils, front, and area of the eyes covered with black hair-like feathers; crown red; horns callous, blue, bent back; caruncle of the chin dilatable, blue, varied with rufous; legs whitish, spurred; tail feathers twenty. The female has the head covered with feathers, without horns or gular caruncle; feathers of the head and upper part of the neck black-blue, long, and decumbent; rest of the body, as in the male, red with eye-like spots; spurs more obtuse. Rather less than the preceding. Inhabits India.

656 PENELOPE.

Gen. 70. Penelope.

657 Characters. Bill naked at the base; head covered with feathers; chin naked; tail with twelve feathers; legs without spurs.

658 *Cristata.* *Guan.*—Head with an erect crest; temples violet. Two feet six inches long. Inhabits Brazil and Guiana, where it is frequently tamed, its flesh being reckoned very delicate. It frequently utters a sound like the word *jacu.*

659 *Cumanensis.* *Jacu* or *yacou.*—Blackish; crest and first quill feathers white. Size of a hen turkey. Inhabits Cayenne and Guiana. It erects its crest, expands its tail, and cries in a mournful tone, like a young turkey. It builds on the ground, is easily tamed, and is often domesticated.

660 *Marail.* *Marail turkey.*—Greenish-black; naked orbits; and legs red; throat somewhat naked, speckled with white. Size of a common fowl, and not dissimilar in shape. Though not much known to naturalists, it is common in the woods of Guiana, at a distance from the sea. It is generally seen in small flocks, excepting at breeding-time, when it is only met with in pairs, and then frequently on the ground, or on low shrubs, at other times on high trees, on which it roosts during the night. The female makes her nest on some low bushy tree, as near the trunk as possible, and lays three or four eggs. When the young have been hatched for ten or twelve days, they descend with the mother, which scratches on the ground like a hen, and broods them, till they can shift for themselves. They breed twice a year. The young birds are easily tamed, and seldom forsake the places where they have been brought up. Their cry is not unharmonious, unless they be irritated or wounded, when it is harsh and loud. Their flesh is much esteemed.

661 CRAX.

Gen. 71. Crax, *Curassow.*

662 Characters. **Bill strong and thick; the base of each mandible covered with a cere; nostrils in the middle of the cere; feathers covering the head, turned spirally forward; tail large, straight, and expansile.**

663 *Alector.* Plate CCCC. fig. 4. *Crested curassow.*—(Male). Cere yellow; body black; belly white; bill black or horny; cere reaching from the middle of the bill behind the eyes; crest erect, black, and three inches long; tail black and roundish, eleven inches long, feathers fourteen; spurs none. (Female). Red; head bluish; crest white, tipt with black; bill cinereous; irides red; legs brown. Subject to much variety. Three feet long. Inhabits the mountainous woods of South America. Lives on fruits, roosts on trees, and is often domesticated on account of its white and delicate flesh. They are frequently kept tame in our menageries, and readily mix with other poultry, feeding on bread and grain, but they are unable to bear the dampness of the grass of our meadows, which renders their toes subject to rot off. Dr Latham mentions an instance in which the whole of one foot was gone, and but part of one toe left on the other, before the creature died.

664 *Globicera.* *Globose curassow*, or *curassow bird.*—Yellow; gibbosity of the nostrils globular; body blackish-blue, lower part of the belly white; bill yellow, tipt with cinereous; gibbosity yellow, and very hard; irides red; orbits white; crest black, tipt with white; legs pale rusty. (Female). Bill and legs cinereous; head and crown black; crest black, with a white band; some of the feathers of the neck tipt with white; throat, breast, back, and wings brown; upper part of the belly white, and some of the feathers tipt with black; vent yellowish brown; tail black, with four transverse white bands. Size of the preceding. Inhabits Guiana.

665 PHASIANUS.

Gen 72. Phasianus, *Pheasant.*

Bill short and strong; cheeks covered with a smooth naked skin; legs generally with spurs.

666 Characters. The females produce many young ones at a brood, and take care of them for some time, leading them abroad, and pointing out food for them. The young are at first clad with a thick soft down. The nests of the whole tribe are formed on the ground.

667 Gallus. *Common cock*, or *wild cock*.—Comb on the crown, and two wattles on the chin compressed; ears naked; tail compressed and erected; feathers of the neck linear, long, and membranaceous at the tips; body, when wild, less than the common cock; comb large, indented, shining-red; temples and line from the crest to the eyes naked and flesh-coloured, a clay-coloured spot of the shape of a man's nail, and covered with short feathers, behind the eyes; feathers of the rest of the head and neck long, narrow, gray at the base, black in the middle, and tipt with white; feathers of the upper part of the body grayish, with a white and a black streak; breast reddish; greater wing-coverts reddish-chesnut, with transverse black and white streaks; tail coverts glossy violet; middle tail feathers long and falcated; spurs large and curved. The female without comb and wattles; head and neck gray; cheeks and chin whitish; body more dusky, and varied with brown gray and rufous; and wants the spurs. Inhabits India in a wild state, is every where domesticated, and subject to innumerable varieties in size and colour. His beautiful plumage and undaunted spirit, as well as his great utility, have rendered him a favourite in all countries into which he has been introduced. The cock is very attentive to his females, hardly ever losing sight of them. He leads, defends, and cherishes them, collects them together when they straggle, and seems to eat unwillingly till he sees them feeding around him. Whenever a strange cock appears within his domain, he immediately attacks the intruder, and, if possible, drives him away. The patience and perseverance of the hen in the hatching, are truly extraordinary, but are too familiar to most of our readers to require to be detailed. Though by nature timid, and apt to fly from the meanest assailant, yet, when marching at the head of her brood, she is fearless of danger, and will fly in the face of the fiercest animal that offers to annoy her. As the chickens reared by the hen bear no proportion to the number of eggs which she produces, many artificial schemes of rearing have been attempted. Chickens have long been hatched in Egypt by means of artificial heat. This is now chiefly practised by the inhabitants of a village called Berme, and by those who live at a little distance from it. Towards the beginning of autumn, these persons spread themselves all over the country, and each of them is ready to undertake the management of an oven. These ovens are of different sizes, each capable of containing from forty to eighty thousand eggs; and the number of ovens in different parts is about three hundred and eighty-six. They are usually kept in exercise for about six months; and as each brood takes up twenty-one days in hatching, it is easy in every one of them to produce eight different broods of chickens in the year. The ovens consist only of a low arched apartment of clay. Two rows of shelves are formed; and the eggs are placed on them in such a manner as not to touch each other. They are slightly moved five or six times in the course of twenty-four hours. All possible care is taken to diffuse the heat equally throughout, and there is but one aperture, just large enough to admit a man stooping. During the first eight days, the heat is rendered great, but during the last eight it is gradually diminished, till at length, when the young brood are ready to come forth, it is reduced almost to the state of the natural atmosphere. Every keeper of an oven obliges himself to deliver to his employer only two thirds of as many chickens as there have been eggs entrusted to him; and he is a gainer by this bargain, as it always happens, except from some unlucky accident, that many more than that proportion of the eggs are productive. In this way it has been calculated that the Egyptian ovens give life annually to near a hundred millions of chickens. This useful and advantageous mode of hatching eggs was introduced into France by the ingenious and indefatigable Monsieur de Reaumur, who, by a number of experiments, reduced the art to certain principles, and applied it to the production of all kinds of domestic fowls. The young brood are generally hatched a whole day before they taste food, and then a few crumbs of bread are given for a day or two, after which time they begin to pick up grain and insects for themselves. In order to save the trouble of attending them, capons are taught to watch them in the same manner as hens. M. de Reaumur informs us, that he has seen above two hundred chickens at once, all led about and defended by only three or four capons. It is asserted that even cocks may be taught to perform this office, which they will continue to do all their lives afterwards. Among the endless varieties of this species, the English game cock stands unrivalled by those of any other nation for its invincible courage, and on that account is made use of as the instrument of the inhuman sport of cock-fighting. The Athenians allotted one day in the year to this barbarous pastime; and the Romans are said to have learned it from them, and to have introduced it into this island. Henry VIII. was so fond of the sport, that he caused a commodious house to be erected for that purpose, which, though now applied to a very different use, still retains the name of the *cock-pit*. The Chinese, the Sumatrians, and others in the eastern parts of the world, are so addicted to this savage diversion, that, in the paroxysms of their frenzy, they will sometimes risk not only the whole of their property, but their wives and children, on the issue of a battle. The cock, it is well known, is a watchful bird, and crows clapping his wings. The hen will lay eggs the whole year, provided she has plenty of food and cold water, gravel, and a warm place. After laying she has a peculiar note of triumph and exultation. Her heat is increased while hatching, but if put into cold water, she ceases to sit. 668

Courier pheasant.—Tawney white; tail long, and shining green; a few white spots at the base of the tail. Eighteen inches long. Inhabits New Spain; is slow in flight, but so swift on foot as to outrun the fleetest horses. Mexicanus. 669

Common pheasant.—Rufous, head blue; tail wedged; cheeks papillous; bill pale, horn colour; irides yellow; cheeks red, speckled with black; in the old birds wrinkled and pendulous; a greenish-black feathered line from the nostrils to beneath the eyes; rest of the head and neck green-gold, with a gloss of violet and blue; lower part of the neck, breast, back, and rump, shining tawney; quill feathers brown, with ochreous spots; belly and vent white; tail feathers eighteen, with transverse black bars; legs dusky, armed with spurs. Female less, varied with brown, gray, rufous, and blackish; cheeks feathered; and, after she has done breeding, puts on the appearance of the male. There are several varieties. This beautiful bird is about nineteen inches long, and weighs from two pounds twelve ounces to three pounds four ounces. It is said to have been brought from the island of Colchis Colchicus.

Gallinæ. chis by the Argonauts; is a native of Africa, and very common in almost all the southern parts of the old continent, whence it was originally imported into Great Britain. Pheasants are much attached to the shelter of thickets and woods, where the grass is very long; but they also often breed in clover fields. They form their nests on the ground, and the females lay from twelve to fifteen eggs, which are smaller than those of the domestic hen. The nest is usually composed of a few dry vegetables put carelessly together, and the young follow the mother like chickens, as soon as they break the shell. The parents and their brood remain in the stubble and hedge rows, if undisturbed, for some time after the corn is ripe. If disturbed, they seek the woods, and only come forth in the mornings and evenings to feed in the stubble. Though very fond of corn, they are often obliged to content themselves with wild berries and acorns. In confinement, the female neither lays so many eggs, nor hatches and rears her brood with so much care and vigilance as in the fields. In a mew she will very rarely dispose her eggs in a nest, or sit on them at all; and the domestic hen is usually entrusted with the charge of incubation and rearing the young. The wings of the pheasant are very short, and ill adapted for considerable flights. As the cold weather approaches, these birds begin to fly at sunset among the branches of oak trees for roosting during the night; and this they do more frequently as the winter advances, and the trees lose their foliage. The male birds at these times make a noise, which they repeat three or four times, and which the sportsmen call *coketing*. The hens on flying up utter one shrill whistle, and then are silent. Poachers avail themselves of these notes, and, unless the woods are strictly watched, secure the birds with the greatest certainty. The crowing of the males, which begins in the first week of March, may be heard at a considerable distance. During the breeding season, the cocks will sometimes intermix with the common hen, and produce a hybrid breed. The pheasant does not appear to pair, for the female carefully hides her nest from the male; and where they are in plenty, and food provided for them, the two sexes are said in general not to feed together. In a domestic state, they are sometimes more or less mixed with white, and sometimes wholly so. A variety with a white ring round the neck, and thence called the *ring pheasant*, is not uncommon in some parts of England. This species rarely occurs in Scotland.

670 *Argus.* *Argus pheasant*.—Pale yellow, spotted with black; face red; hind head crested, blue; bill yellowish; orbits and whiskers black; front, chin, and throat red; hindhead and nape blue; wings gray, with eye-like spots; tail wedged, the colour of the wings; two middle feathers three feet long, with large eye-spots at the shaft; feet armed; size of a turkey. Inhabits Chinese Tartary and Sumatra. This is a most beautiful bird, though its colours are not brilliant. It is with great difficulty kept alive for any time after it has been caught in the woods. It seems to have an antipathy to the light, being quite inanimate in the open day; but when kept in a dark place, it appears to be perfectly at ease, and sometimes makes its call, which is rather planitive, and not harsh like that of the peacock. The flesh resembles that of the common pheasant.

671 *Impeyanus.* *Impeyan pheasant*.—Crested, purple glossy green, black beneath; feathers of the neck with a changeable lustre of gold, copper, and green; tail entire, rufous; larger than a common fowl. Inhabits India, but not plentifully, being brought from the hills in the northern parts of Hindostan to Calcutta, as curiosities. Lady Impey attempted, with great probability of success, to bring over with her some of them to England; but after living in health on board the ship for two months, they caught a disorder from the rest of the poultry, similar to the smallpox, and died in consequence. They bear cold, but are impatient of heat. The cock was never observed to crow, but had a strong hoarse cackle, not unlike that of a pheasant.—Described and figured by Latham.

672 *Cristatus.* Plate CCCC. fig. 3. *Crested pheasant*.—Brown above; beneath reddish-white; vent rufous; head crested; orbits red, naked; tail wedge-shaped, and tipt with yellow; bill and unarmed legs black; feathers of the crest whitish-brown; beneath black; feathers from the hind head to the lower part of the neck have a white streak down the middle; coverts of the wings at the tip and edge white; quill feathers rufous; tail ten inches long; length of the body 22 inches. Native of New Spain. Frequents trees in the neighbourhood of water, and feeds on worms, insects, and serpents.

673 *Pictus.* *Painted pheasant*.—Crest yellow; breast scarlet; secondary quill feathers blue; tail wedged; bill, irides, and armed legs, yellow; feathers of the crest silky, and hanging backwards; cheeks naked and flesh coloured; feathers of the hind head tawney, with black lines, and beneath these green ones; back and rump yellow; upper tail coverts long, narrow, and scarlet; wing-coverts varied with bay and brown; scapulars blue; quill feathers brown, with yellowish spots; tail feathers varied bay and black, and 23 inches long. Female reddish brown; yellowish brown beneath; legs unarmed; less than the common pheasants; length two feet nine inches and a half. The native country of this beautiful species is China, where it is called *Kin-ki*. It bears confinement well, and will breed readily in that state. The eggs are redder than those of the common pheasant, and somewhat resemble those of the Guinea fowl. An instance of their breeding with the common pheasant is mentioned by Buffon. Edwards informs us, that some females of this species, kept by Lady Essex, in the space of six years gradually gained the male feathers; and we are told, that it is not unusual for the hen birds, when about four or five years old, to be neglected by the cocks, and gradually to gain the plumage of the males.

674 *Superbus.* *Superb pheasant*.—Unarmed; rufous, varied with green and blue; caruncles of the front rounded; wattles awl-shaped; bill and body red; each side of the neck with long feathers turned back; crown green; the hind part with a folding blue crest; shoulders green, spotted with white; primary quill feathers blue; tail long, wedged, the feathers varied with blue and red; coverts declined, and of various mixed colours; legs yellow. Inhabits China.

Gen. 73. NUMIDA, *Pintado*, or *Guinea Fowl*. 675 NUMIDA.

676 Characters. Bill strong and short; the base covered with a caruncculated cere, receiving the nostrils; head horned, with a compressed coloured callus; tail short, bending down; body speckled.

Common

Gallinæ.

677 *Meleagris.* *Common Guinea hen.*—Caruncles at the gape double, and no gular fold; bill of a reddish horn colour; head blue; the crown with a conical, compressed, bluish red protuberance; upper part of the neck bluish ash, almost naked; lower feathered, verging to violet; body black, with round white spots; legs gray brown; gular caruncle of the male bluish; of the female red. There is a variety with the breast white, and another with the body entirely white; somewhat larger than the common hen. Inhabits Africa, and is domesticated in most parts of Europe, the West Indies, and America. It formed a part of the Roman banquets, and is now much esteemed as a delicacy, especially when young. The female lays a great number of eggs, which she frequently secretes till she has produced her young brood. The eggs are smaller than those of a common hen, and of a rounder shape, and are delicious eating. The Guinea hen is a restless and very clamorous bird, and has a harsh creaking note, which is peculiarly grating and unpleasant. Like the common domestic fowl it scrapes the ground, and rolls in the dust to free itself from insects. During the night it perches on high places, and, if disturbed, alarms the neighbourhood by its unceasing cry. In its natural state of freedom, it is said to prefer marshy places. It is easily tamed, but often abandons its young.

678 TETRAO.

Gen. 74. TETRAO.

679 Characters. Near the eyes, a spot which is either naked or papillous, or rarely covered with feathers.

The birds of this genus have a strong convex bill; grouse, partridges, and quails, agree in having a short convex bill. The grouse chiefly inhabits the colder regions, and is distinguished by small nostrils, hid under the feathers; an acute tongue; strong feet; and a pretty long tail. Partridges and quails are less in size; have a short tail; and their nostrils covered above with a callous prominent margin. They inhabit the temperate and even the warmer climates. The tinamous are a tribe peculiar to Guiana, and approach the pheasant in manners. Their bill is longer and obtuse at the apex; the nostrils are placed in the middle; their gape is very wide; the throat thinly covered with feathers; the tail very short; the back-toe short, and useless for running. The female is larger than the male.

680 *Grouse.* A. *Spot over the eyes naked; legs downy.* *Grouse.*

681 *Urogallus.* *Wood grouse, cock of the wood*, or *capercailzie.*—Tail rounded; arm-pits white; bill horn colour; spot above the eyes scarlet; irides hazel; nostrils covered with short feathers; feathers of the chin black, longer; head and neck cinereous, with fine transverse black lines; body bay with blackish lines above; breast blackish green; belly and vent black, varied with white; tail feathers 18, each side spotted with white; legs robust and brown; toes pectinated at the edge. Of the female the bill is dusky; chin red; body with alternate red and black transverse lines above; breast with a few white spots, the lower part orange; belly spotted with pale orange and black, the feathers tipt with white; shoulders black, the feathers edged with black and pale tawney, and tipt with white; tail rusty, barred with black, and tipt with white. In size, this species is little inferior to a turkey, and sometimes weighs 12 or 13, but more frequently seven or eight pounds. The male is two feet nine inches, and the female two feet two inches long. Inhabits the mountainous and woody parts of Europe and northern Asia. It is not uncommon in the pine-forests of Normandy, in Russia and Siberia, in Italy, and several parts of the Alps. In Scotland and Ireland it is nearly extinct. It feeds on the berries of the juniper and vaccinium, and on the seeds of the pine tribe and other trees. It is a solitary bird, except in the season of love, when, in the beginning of February, perched on the top of a tree, it calls the females about it with a loud voice, its tail expanded, its wings hanging down to its feet, its neck stretched out, and the feathers of its head erected. The female builds on the ground among mosses, and lays from eight to sixteen eggs. The flesh of this species is much esteemed, and its eggs are accounted preferable to those of every other bird. They are white, spotted with yellow, and larger than those of the common hen. The young follow the hen as soon as they are hatched, and sometimes with part of the shell attached to them.

Black game, black grouse, or *black cock.*—Violet 682 *Tetrix.*
black; tail forked; secondary quill feathers white towards the base; bill black; body shining glaucous-black; wing-coverts black brown; four first quill feathers black, the rest white at the base; tail feathers from 16 to 18, black; legs black brown; toes pectinated. Female less; the weight of an old cock is nearly four pounds, but that of the female is not often more than two. Length about 23 inches: there are several varieties. Inhabits mountainous and woody parts of Europe. In Britain it is chiefly confined to the northern parts of the kingdom, and especially to the Highlands of Scotland; population and culture having driven them from the south, except in a few of the more wild uncultivated parts, as in the New Forest in Hampshire, Dartmoor and Sedgemoor in Devonshire, and the heathy hills in Somersetshire contiguous to the latter. It also occurs in Staffordshire, North Wales, and the north of England. It feeds principally on the tops of heath and birch, except when the mountain berries are ripe, at which time it devours bilberries and craneberries with the greatest voracity. In the month of April the male places himself on an eminence, at morning dawn, and invites the females by crowing and clapping his wings. The males are polygamous, and fight desperately for the females. They afterwards associate peaceably in small packs, are fond of wood, heathy, and mountainous situations; but occasionally visit the corn fields in autumn, retiring wholly to woods in the winter, and perching on trees. It is somewhat remarkable that they are killed by eating cherries or pears. The female forms an artless nest on the ground, and lays six or eight eggs, of a dull yellowish white colour, marked with numerous very small ferruginous specks, and with blotches of the same towards the smaller end. The young are hatched very late in summer. The young males quit their parent in the beginning of winter, and keep together in flocks of seven or eight till the spring. They do not acquire their male garb till towards the end of autumn, when the plumage gradually changes to a deeper colour, and assumes that of a bluish-black, which it afterwards retains.

Ptarmigan, white grouse, or *white game.*—Cinereous; 683 *Lagopus.*
toes downy; quill feathers white; tail feathers black, tipt

Gallinæ. tipt with white, the middle ones white; body, in summer, cinereous, varied with white and brown, in winter nearly all white; but in all seasons the lateral tail feathers are black, tipt with white; legs and toes covered with a thick wool like a hare's. From 14 to 15 inches long. Inhabits the Alpine parts of Europe and Siberia. In this country it is met with only on the summits of our highest hills, chiefly in the Highlands of Scotland, and sometimes, but rarely, on the lofty hills of Cumberland and Wales. As the snow melts on the sides of the mountains, it constantly ascends till it gains the summit, where it forms holes, and burrows in the snow. These birds pair at the same time with the red grouse; the female lays eight or ten white eggs, spotted with brown, not in any regular nest but on the ground. In winter they fly in flocks, and are so little accustomed to the sight of man, that they are easily shot, or taken in a snare. They feed on the wild productions of the hills, as the buds of trees, the young shoots of pines, the heath, crow-berry, rhododendron, &c. They run swiftly, fly heavily, are impatient of the sun and wind, and are unsusceptible of domestication. The flesh of the young is accounted a great delicacy. That of the full-grown birds has sometimes a bitter, but not unpalatable taste: it is also dark coloured, and, according to Buffon, approaches in flavour to that of the hare.

684 Albus. *White grouse.*—Orange, varied with black bands and white blotches; toes downy; tail feathers black, tipt with white; the middle ones entirely white; bill black; belly and legs white; claws broad and flat. Upwards of 16 inches long. Inhabits the woods of Europe and Asia, and, like the preceding, grows white in winter.

685 Cupido. *Pinnated grouse.*—Back of the neck with supplemental wings, which are wanting in the female. The male is smaller than a partridge. Inhabits North America; feeds chiefly on acorns; and at sunrise erects his neck and wings, and sings for the space of half an hour.

686 Bonasia. *Hazel grouse.*—Tail feather cinereous, with black spots and a black band, except the two middle ones. Fourteen inches long. Inhabits the hazel woods of Europe; feeds on catkins; when terrified, erects the feathers of the crown.

687 Attagen or Scoticus. *Red grouse*, or *moorcock.*—Transversely streaked with rufous and blackish; six outer tail feathers blackish on each side; caruncle on the eyebrows lunated and scarlet; greater quill-feathers brown; tail feathers sixteen, the four middle ones the colour of the back, the rest blackish. Length fifteen inches; weight about nineteen ounces. This species is only to be met with in the extensive uncultivated wastes that are covered with heath, particularly the most mountainous situations, having been driven from the south by cultivation. It still occurs in the mountains of Wales, and in the moorlands of Yorkshire and the north of England, but is no where so plentiful as in the Highlands of Scotland, and in the waste moors of North Britain in general. It is also found in the Western islands, and in the mountains and bogs of Ireland; but seems to be unknown on the continent of Europe, those mentioned by Buffon as natives of France, Spain, Italy, &c. either forming a distinct species, or at least a variety. Linnæus did not seem to be acquainted with it, and Gmelin gave it as a variety of the ptarmigan. The red grouse never resort to woods, but confine themselves wholly to the open moors, feeding on the mountain and bog berries; and, in defect of these, on the tops of the heath. They pair in the spring; and the female lays from 8 to 14 eggs, much like those of the black grouse, but smaller, on the ground. The young keep with the parent birds till towards winter, and are called a *pack*, or *brood*. In November they flock together in greater numbers, sometimes to the amount of thirty or forty, and are then extremely shy and difficult to be shot. Gallinæ.

B. *Orbits granulated; legs naked.*

a. *Legs of the male armed with a spur. Partridge.* 688 Partridge.

Greek or *red partridge.*—Bill and legs blood-red; 689 Rufus. chin white, surrounded with a black band, and spotted with white; feathers of the sides with a double black stripe; tail feathers fourteen, cinereous, the five outer rufous for the last half. Rather larger than the next species. Inhabits various parts of southern Europe, Asia, Africa, and the Greek islands. A variety, called the *Guernsey* or *red-legged partridge*, has sometimes been found on the Suffolk or Norfolk coasts. It is distinguished by a single black stripe on the feathers of the sides, and sixteen tail feathers, of which the five outer are rufous on each side. The red partridge frequently perches on a tree, and will breed in confinement, which the common one is never known to do.

Common partridge.—A naked scarlet spot under the 690 Perdix. eyes; tail ferruginous; breast brown; legs white; face yellowish; cap and neck waved ash; quill feathers brown, with ferruginous bands; tail feathers eighteen, lower part of the breast with two chesnut spots. Several varieties of this species are enumerated by ornithologists, but most of them appear to be accidental. Length about 13 inches; weight 15 ounces. Inhabits Europe and Asia, though chiefly in temperate regions, the extremes of heat and cold being equally unfavourable to it. They are nowhere in greater plenty than in this island, where, in their season, they contribute to our most elegant entertainments. They haunt corn fields, and are never found at any distance from arable land. They pair early in the spring; and the female is very prolific, laying from 12 to 20 eggs. It makes no nest, but scrapes a small hole in the ground, and throws into it a few contiguous fibres, on which to deposit the eggs. The old birds sit very close on the latter when near hatching. The incubation lasts three weeks, and the young birds learn to run as soon as hatched, frequently with part of the shell sticking to them. It is no uncommon thing to introduce partridges eggs under the common hen, who hatches and rears them as her own: but, in this case, the young birds require to be fed with the larvæ of ants, which are their favourite food, and without which it is almost impossible to rear them. They likewise eat insects, and, when full grown, feed on all kinds of grain and young plants. "The affection of the partridge for her young (says Mr Bewick), is peculiarly strong and lively; she is greatly assisted in the care of rearing them by her mate: they lead them out in common, call them together, point out to them their proper food, and assist them in finding it by scratching the ground with their feet; they frequently sit close by each other, covering the chickens with their wings like the hen. In this situation they are not easily flushed; the sportsman, who is attentive to the preservation of his game, will carefully avoid giving any disturbance to a scene

Gallinæ. scene so truly interesting; but should the pointer come too near, or unfortunately run in upon them, there are few who are ignorant of the confusion that follows: the male first gives the signal of alarm by a peculiar cry of distress, throwing himself at the same moment more immediately into the way of danger, in order to deceive or mislead the enemy; he flies, or rather runs along the ground, hanging his wings, and exhibiting every symptom of debility, whereby the dog is decoyed, in the too eager expectation of an easy prey, to a distance from the covey; the female flies off in a contrary direction, and to a greater distance, but returning soon after by secret ways, she finds her scattered brood closely squatted among the grass, and, collecting them with haste, she leads them from the danger, before the dog has had time to return from his pursuit."

691 *Quail* b. *Legs without a spur. Quail.*

692 *Viridis.* *Green quail.*—Green; bill and legs reddish; wings chesnut, speckled with black; bill a little bent at the tip; hind toe unarmed; tail and vent black. Between 11 and 12 inches long.

693 *Californicus.* *Californian quail.*—Lead colour; crown with an upright crest; throat black, edged with white; belly yellowish brown, with black crescents. The female wants the black throat and whitish margin. Larger than the common quail. Inhabits California.

694 *Suscilator.* *Noisy quail.*—Varied with yellowish, rufous, black, and gray; bill longer than in others of the genus. A very clamorous bird, which inhabits the woods in Java.

695 *Sinensis.* *Chinese quail.*—Body spotted with gray; throat black, with a white arch. From four to six inches long. Inhabits China and the Philippine isles, and is carried alive by the Chinese, in the winter, between their hands, for the purpose of warming them.

696 *Coturnix.* *Common quail.*—Body spotted with gray; eyebrows white; tail feathers with a ferruginous edge and crescent; bill black; head black, varied with rufous; a yellowish streak down the middle of the crown and neck; feathers of the neck rusty brown, varied with gray; the shafts with a longitudinal yellowish streak; body beneath dirty ochreous; throat and breast reddish; quill feathers gray brown, with rufous bars on the outside; tail feathers twelve, with reddish and black lines; legs brownish. Seven inches and a half long. Inhabits Europe, Asia, and Africa. When these birds migrate to and from the north, they are found in prodigious quantities in all the islands of the Archipelago. One hundred thousand, it is said, have been taken in one day on the west coast of the kingdom of Naples. A small portion only extend their flight to this country. With us they appear about the beginning of May, in our cultivated champaign districts, though not in such numbers as formerly. On their first arrival, the males are constantly uttering a whistling note, thrice successively repeated, which being imitated by a whistle or quail-call, they are easily enticed into a net. Before the revolution, great quantities used to be sent alive from France to the London market. In confinement they fatten, and seem to lose much of their fierce and pugnacious disposition. The female deposits eight or ten yellowish eggs, blotched, or spotted with dusky, on the bare ground, and usually with us among green wheat. The young birds follow the mother as soon as hatched, but do not continue long together; for they are scarcely grown up when they separate, or, if kept together, they fight obstinately, and frequently destroy one another. From this quarrelsome disposition it was, that the Greeks and Romans used them as game cocks; and that the Chinese, and some of the Italians are, at this day, addicted to the diversion of quail-fighting. After feeding two quails very highly, they place them opposite to each other, and throw in a few grains of seed between them, when the birds rush on each other with the utmost fury, striking with their bills and heels till one of them yields.

C. *Orbits with a few feathers; legs naked, four-toed, and unarmed. Tinamous.* 697 *Tinamus.*

698 *Guianensis.* *Cayenne tinamous.*—Bill and legs brown; back ashy-brown, varied with blackish stripes; chin cinereous; belly pale orange. Eleven inches long. Inhabits Cayenne and Guiana.

Great tinamous.—Legs yellowish-brown; bill black; crown rufous; body olive; back and tail with black spots. Eighteen inches long. Inhabits the woods of South America; roosts on the lower branches of trees; feeds on worms, insects, seeds and fruits; builds twice a-year, at the root of a large tree, and lays from twelve to fifteen green eggs. 699 *Major.*

Little tinamous.—Bill and legs yellow; head and neck black; body brown above, rufous beneath; chin mixed with white; quill feathers brown. Nine inches long. Inhabits Guiana. Builds an hemispherical nest in the branches of trees. 700 *Soui.*

Order VI. PASSERES. 701 Passeres.

Bill conical, pointed; nostrils oval, pervious, and naked. 702 Characters.

The birds of this order have the feet formed for walking or hopping. They live, some at the time of breeding, and others constantly, in monogamy. Some which feed on the seeds of plants have a short bill, others that live on insects and worms are generally furnished with a longer bill. They nestle on trees, in bushes, in houses, and on the ground. They often build very artificial nests, and feed their young with their bill. This order includes all the singing birds; the males are the songsters. They are for the most part eatable.

Gen. 75. Columba, *Pigeon.* 703 Columba.

Bill straight, descending towards the tip; nostrils oblong, and half covered with a soft tumid membrane. 704 Characters.

The birds of this genus have a weak and slender bill, short feet, and many of them red toes, divided to their origin. They extend their residence even to the arctic regions. They drink much, and not at intervals like other birds, but by continuous draughts like quadrupeds. Their note is plaintive or mournful. They form the connecting link between this and the preceding order; but are more nearly related to the passerine tribes, in being monogamous, in caressing each other by their bills, in the male and female alternately hatching, in both joining to feed the young, in laying but few eggs, and in their nidification. Of upwards of seventy species which belong to this genus, only five or six are natives of of Great Britain. The eggs of all the species are white.

A. *Tail even and moderate.*

705 *Oenas.* *Common* or *stock pigeon*, or *stock dove*.—Bluish; neck above glossy green; double band on the wings, and tip of the tail blackish; throat and breast claret colour; claws black. Length 13 or 14 inches; weight 11 ounces. Inhabits Europe and Siberia; is wild in many places, but is kept in pigeon-houses every where, and is the parent stock whence all the varieties of the domestic pigeon are derived, and is on that account called the *stock-dove*. It build in towers, in caverns of rocks, and in cliffs in unfrequented islands. On the approach of winter, it migrates southward. It is gregarious; lays two eggs, and breeds several times in the year.

706 *Domestica.* *Domestic pigeon*.—Cinereous; rump white; band on the wings, and tip of the tail blackish. The varieties are, however, very numerous, and not easily reducible to distinct descriptions. Some of the more remarkable are, the *rock*, *Roman*, *Barbary*, *jacobine*, *shaker*, *tumbler*, *carrier*, *horseman*, and *turner* pigeons. From 14 to 15 inches long. Inhabits and is domesticated in almost every part of Europe and Asia, and lays from nine to 11 times a year. Though only two eggs are laid at a time, at the expiration of four years, the produce and descendants of a single pair may amount to nearly 15,000. A composition of loam, old rubbish and salt, will not only entice birds of this species to remain in a required spot, but will even decoy those belonging to other places, and is therefore prohibited by law. The carrier pigeon is easily distinguished from the other varieties, by a broad circle of naked white skin round the eyes, and by its dark blue or blackish colour. The bird is conveyed from its home to the place whence the information is intended to be sent; the letter is tied under its wing, and it is let loose. From the instant of its liberation, its flight is directed through the clouds, at an amazing height, to its home, and it darts onward in a straight line to the very spot from which it was taken, by virtue of some faculty or instinct which it is very difficult to explain. To measure their speed with some degree of exactness, a gentleman some years ago, on a trifling wager, sent a carrier pigeon from London, by the coach, to a friend at St Edmund's-bury, and along with it a note, requesting that the pigeon, two days after its arrival there, might be thrown up precisely when the town-clock struck nine in the morning. This was accordingly done, and the pigeon arrived in London, and flew into the Bull Inn in Bishop's-Gate Street, at half an hour past eleven o'clock of the same morning, having flown 72 miles in two hours and a half.

707 *Coronata.* *Great crowned Indian pigeon*.—Bluish; cinereous above; orbits black; crest; shoulders ferruginous. Size of a turkey. Inhabits New Guinea.

708 *Cristata.* *Lesser crowned pigeon*.—Eyelids white; hind head with a red gold crest; breast and belly violet; back, rump, and tail green; legs yellow; hind toe unarmed. Size of the common pigeon. Inhabits Malacca.

709 *Palumbus.* *Ring dove*.—Cinereous; tail feathers black on the hind part; primary quill feathers whitish on the outer edge; neck white on each side; bill yellowish; cere red and scurfy; irides yellowish; head, back, and wing-coverts bluish; rump and throat pale ash; breast claret colour; belly and vent whitish; neck above and at the sides green gold, with a white crescent on each side; feet rough as far as the toes. Weighs about 20 ounces; length eight inches. Inhabits Europe, and rarely Siberia. From its living in woods, and building in trees, it is not uncommonly called *wood pigeon*. It seems to be originally a native of this island, and probably migrates no farther than from the northern to the southern parts of it. Early in spring it begins to pair, at which time the male is observed to fly in a singular manner, alternately rising and falling in the air. It forms a nest of a few small sticks loosely put together. Its common food is grain and seeds of all kinds, acorns and beech-nuts, and in default of these, turnip-greens, and young clover, or even green corn, and ivy berries. Various attempts to domesticate this species have proved unsuccessful.

Green turtle.—Brass green above, purple-violet beneath. Near eight inches long. Inhabits Amboina. 710 *Viridis.*

Turtle dove.—Tail feathers tipt with white; back gray; breast flesh-coloured; a spot of black feathers, tipt with white, on each side of the neck; bill brown; irides yellow; crown olive-ash; front and chin nearly white; scapulars and coverts reddish-brown, spotted with black; throat and breast claret-coloured; belly and vent white; two middle tail feathers dusky-brown, the end and exterior side of the outermost feathers white. Subject to several varieties. About 12 inches long. Inhabits Europe, China, and India. Visits the southern parts of England in the spring, and leaves them in the beginning of September. Is very shy and retired, breeding in thick woods, and nestling on high trees. Is very destructive to fields of pease. 711 *Turtur.*

B. *Tail long and wedged.*

Passenger pigeon.—Orbits naked and sanguine; breast rufous. From 15 to 16 inches long. Inhabits North America, migrating southward in December in quest of food. The multitudes which pass in hard winters are truly astonishing, as they fly by millions in a flock, and literally intercept the light of the sun. As soon as one flock has passed, another succeeds; and these movements sometimes continue for three days without intermission. Their favourite food is acorns; but they not only eat the fruit of various kinds of trees, but also corn and rice, of which they are very unsparing in the course of their passage. 712 *Migratoria.*

Black-winged pigeon.—Body livid; wings black. Inhabits Chili. 713 *Melanoptera.*

Marginated turtle.—Breast red; tail feathers tipt with black, and edged with white; bill horny; irides rufous; front and chin reddish brown; lores white; hind head bluish-ash colour; a black spot under the ears; body above brown; shoulders spotted with black; rump cinereous; throat and breast rosy; two middle tail feathers blackish; the rest ash colour. Ten inches long. Native of America. 714 *Marginata* Plate CCCCI. fig. 1.

Bantam pigeon.—Orbits naked and flesh-coloured; neck, breast, and flanks, waved with black and white. Size of the wry-neck. Inhabits Java. 715 *Bantamensis.*

Gen. 76. ALAUDA, *Lark*. 716 ALAUDA.

717 Characters. Bill cylindrical, subulated, straight; the mandibles equal, and a little gaping at the base; tongue bifid; hind claw straight, and longer than the toe.

 Field

Passeres.

718 Arvensis. *Field* or *sky lark*.—Outer webs of the two middle tail feathers white, middle ones ferruginous on the inner side; body above varied with blackish, reddish-gray, and whitish; reddish-white beneath; bill and legs black; throat spotted with black. A variety sometimes occurs that is wholly white, another which is black-brown, and a third, which is found in Russia, and distinguished by its very long legs. This well-known species is about seven inches long, and inhabits Europe, Asia, and Africa. It is most common in the open and upland cultivated districts in which corn abounds, and is rarely seen on extended moors at a distance from arable land. The nest is placed on the ground, among grass or corn, and is formed of dry grass and other vegetable stalks, and lined with fine dry grass. The eggs are generally four, rather larger than those of a tit-lark, and of a dirty white, blotched and spotted with brown. The sky lark begins to breed in May, and will lay as late as September, if its first nests are destroyed. The incubation lasts a fortnight, and two broods are usually produced in the course of the year. When hatched, the mother watches over them with the most tender solicitude and affection. They are first fed with worms and insects; but after they are grown up, they live chiefly on seeds, herbage, and most other vegetable substances. They are easily tamed, and become so familiar as to eat off the table, and even alight on the hand. The lark becomes tuneful early in spring, and continues so during the summer. His song is chiefly heard in the morning and evening; and he is one of those few birds that chaunt their mellow notes on the wing. We need scarcely remark, that he mounts almost perpendicularly, and by successive springs into the air, where he hovers at a great height, and whence he descends in an oblique direction, unless threatened by some ravenous bird of prey, or attracted by his mate, when he drops down to the ground like a stone. When he first leaves the earth, his notes are feeble and interrupted, but, as he rises, they gradually swell to their full tone. These birds cease their strains in winter, when they assemble in flocks, grow fat, and are taken in multitudes by the bird-catchers. Four thousand dozen have been taken in the neighbourhood of Dunstable, between September and February; and Kepler informs us, that the excise on larks alone produces about 900l. a-year to the city of Leipsic, whose neighbourhood is celebrated for larks of a peculiarly delicate flavour.

719 Pratensis. *Tit lark*.—Greenish-brown, outer webs of the two outermost tail feathers white; eyebrows with a white line; bill black; body white beneath; breast ochreous yellow, with oblong black spots; legs yellowish. Length nearly five inches and three quarters. Inhabits Europe, and is very common in most parts of this island, though it seems partial to barren situations, and occurs both in mountainous and low swampy places. In Scotland, it is almost the only bird which frequents the extensive heath tracts on which it breeds. It has a fine note, and sings either sitting in trees, or on the ground.

720 Minor. *Lesser field lark*.—Reddish-brown, spotted beneath; chin and belly white; throat and breast obscure yellow; legs brownish; wing coverts edged with white; quill feathers dusky, the outer web of the first edged with white, the others with yellowish-green; hind claw short, and sometimes hooked. Somewhat larger than the preceding, with which it has been often confounded. It visits this country in spring, but is rarely seen till the beginning of May; is not plentiful, and chiefly affects enclosed situations. From the beginning of May till July, it may be seen mounting in the air in a fluttering manner, at the same time uttering a twittering note, and then descending to some neighbouring tree with motionless wing and the tail thrown up. It then sings sweetly, but never when rising. In generally nestles in the high grass or green wheat, and lays four eggs of a dirty bluish white, thickly blotched and spotted with purplish brown.

721 Arborea. *Wood lark*.—Head surrounded by a white annular fillet; body varied like the *arvensis*; legs flesh coloured. Weighs about eight drams; length six inches. Inhabits Europe and Siberia, and is met with, though sparingly, in various parts of Britain. It sings delightfully on wing, but rarely when sitting on the ground, though sometimes when perched on a tree. Its song is much more melodious than that of the sky lark, but does not consist of so great a variety of notes; but then it frequently sings in the night, and through most of the year, except in the months of June and July. It does not ascend in the air perpendicularly, and continue hovering and singing in the same spot, like the sky lark, but will sometimes soar to a great height, and keep flying in large irregular circles, singing with little intermission; and will thus continue in the air for an hour together. It is an early breeder, the eggs being sometimes found in the nest in the beginning of April.

722 Rubra. *Red lark*.—Brown; orbits blackish; two outermost tail feathers white. About the size of the sky lark. Inhabits North America, and is sometimes found near London.

723 Malabarica. Plate CCCCI. fig. 3. *Malabar lark*.—Wings and tail dirty brown colour, with reddish edges; bill black; crest long, brown and tipt with white; chin and belly reddish white; feathers of the back, and coverts of the wings, brown; the edge reddish towards the tip, and marked with a white spot; legs reddish. Five inches and a half long. Native of Malabar.

724 Trivialis. *Grasshopper lark*, or *grasshopper warbler*.—Tail feathers brown, the outer one half white, the second with a white wedged tip; wings with two whitish lines; bill dusky; legs whitish; lores white; body greenish-brown above, feathers dusky in the middle, yellowish-white beneath; breast dirty white; tail longish, and somewhat wedged. Length five inches and a half; weight about three drams and a quarter. Inhabits Europe. Though not plentiful in Britain, it perhaps appears to be much less so from its extreme shyness, and its habit of concealing itself among furze and thick hedges. Its singular note resembles the chirping of the larger species of crickets.

725 Obscura. *Rock lark*.—Olive brown, varied with blackish; yellowish beneath; sides of the neck and breast with brownish spots; outermost tail feathers obliquely half whitish, second whitish at the tip. Upwards of seven inches long. In its song, manner of flying, and general habits, is much allied to the tit lark. Inhabits some of the rocky shores of England, and seems to subsist chiefly on marine insects.

726 Nemorosa. *Lesser crested lark*.—Tail feathers black, the two outermost white on the outer edge; head crested; legs red; body pale brown. Inhabits Europe and Siberia, and is

Passeres. is common in Yorkshire. It is a solitary bird, and builds in woods and thickets.

727 Calandra. *Calandre lark.*—Outermost tail feathers totally white without, second and third tipt with white; pectoral band brown. Seven inches and a quarter long. Inhabits Italy and Russia. Builds on the ground. Sings sweetly, and imitates the notes of other birds.

728 Sturnus.

Gen. 77. Sturnus, *Stare*, or *Starling*.

729 Character. Bill subulate, angular, depressed, somewhat blunt; the upper mandible entire, and somewhat open at the edges; nostrils surrounded with a prominent rim; tongue notched and pointed.

730 Vulgaris. *Common stare* or *starling.*—Bill yellowish; body black, with white dots; quill feathers and tail dusky; the former edged with yellow on the outer side, the latter with dirty green; lesser coverts edged with yellow, and slightly glossed with green; legs reddish-brown. Male shining with purple, green, and gold. There are several varieties. Weight about three ounces; length eight inches and three quarters. Found in almost every part of the old continent. It breeds in the hollows of trees or rocks, among rubbish, or in old towers, and sometimes appropriates the nest of another bird. Myriads of this species breed among the rocks in the Orkney islands, and in the winter feed on the *cancer pulex*. Their general food is insects, earth-worms, seeds, berries, &c. They migrate in flocks, and are very noisy. In confinement it may be taught to mimic various sounds, and even to speak. So attached are they to society, that they not only join those of their own species, but also birds of a different kind; and are frequently seen in company with redwings, fieldfares, and even with pigeons, jackdaws, and owls. They chatter much in the evening and morning, both when they assemble and disperse.

731 Cinclus. *Water-ouzel*, or *crake.*—Black; breast white; chin white; tail black; belly ferruginous; legs pale blue before, black behind. Length seven inches and a half. Inhabits Europe and northern Persia. Is shy and solitary, and rarely to be seen, except on the banks of rivers, and streams of water. It is not unfrequent in the mountainous parts of Scotland and Wales, and in some districts in Devonshire. In these places it breeds, and continues the whole year. The nest is very large, formed externally of moss and water plants, and lined with dry oak leaves, resembling that of the wren, with a dome or covering. It is usually placed in some mossy bank, impending on the water, and contains five or six eggs of a transparent white. "A pair of these birds, says Mr Montagu, which had for many years built under a small wooden bridge in Caermarthenshire, we found had made a nest early in May. It was taken, but had no eggs, although the bird flew out of it at the time. In a fortnight after they had completed another nest in the same place, containing five eggs, which was taken; and in a month after we took a third nest under the same bridge with four eggs; undoubtedly the work of the same birds, as no others were seen about that part. At the time the last was taken, the female was sitting, and the instant she quitted her nest, plunged into the water, and disappeared for a considerable time; at last she emerged at a great distance down the stream. At another time we found a nest of this bird in a steep projecting bank over a rivulet clothed with moss. The nest was so well adapted to the surrounding materials, that nothing but the old bird flying in with a fish in its bill would have led to a discovery. The young were nearly full feathered, but incapable of flight, and the moment the nest was disturbed, they fluttered out and dropt into the water, and to our astonishment, instantly vanished; but in a little time made their appearance at some distance down the stream; and it was with difficulty two out of five were taken, as they dived on being approached.—The aquatic habits of this bird have not escaped the notice of ornithologists, some of whom speak of their flying under water. If, indeed, the wings being in motion can be called flying, in certainly does; but this is no more than is common to all diving birds, which, in pursuit of fish, or to escape danger, always use their wings to accelerate their motion. In this case, however, the wings are not extended, for that would retard their progress; but it is effected by short jerks from the shoulder joint. Whether these birds can run at the bottom of the water, as some have asserted, is much to be doubted, as it is requisite all birds should use a considerable exertion to keep them under water, by reason of their specific gravity being so much less. It is certainly a most curious and singular circumstance, that a bird, not apparently in the least formed for diving, should pursue its prey under water, living chiefly on small fish and aquatic insects. It cannot, however, swim on the surface."

Green stare.—Green above; bluish beneath; a tuft of black and white feathers on the front and chin. Inhabits China. 732 Viridis.

Wattled Stare.—Bill and legs black; a pendent orange wattle at each angle of the mouth. Male black, with the back and wing-coverts ferruginous. Female rusty-brown, with very small wattles. Ten inches long. Inhabits New Zealand. 733 Carunculatus.

Collared stare.—Blackish brown, spotted with brown; flanks rufous; chin white, spotted with brown. Size of the fieldfare. Inhabits Switzerland and Italy. Is solitary, wags its tail, feeds on seeds, sings with a very weak voice, and builds in the ground, or in clefts of rocks. 734 Collaris.

Gen. 78. Turdus, *Thrush*. 735 Turdus.

Bill somewhat straight; upper mandible a little bending and notched near the point; nostrils naked or half covered with a small membrane; mouth ciliated, with a few bristles at the corners; tongue jagged. 736 Characters.

Most of the numerous species of this genus feed on berries, especially those of the juniper; and many of them are excellent songsters.

Missel thrush.—Back brown; neck spotted with white; bill yellowish; body whitish-yellow beneath, with spots brown on the chin and white beneath; quill and tail feathers brown, with paler edges; the three outermost tipt with white; legs yellow; claws black. Weight near five ounces; length 11 inches. Inhabits the woods of Europe. It is by no means plentiful in Britain, and appears to be less so in winter. It begins to sing in January if the weather is mild, but ceases as soon as the thermometer sinks below 40 degrees. A- 737 Viscivorus.

bout

Passeres. bout the middle of March it makes a nest in the fork of some tree, especially if covered with lichen, and seems partial to the apple tree, frequenting orchards more than other situations in spring, and never building in a bush. The nest is made of mosses, lichens, and dry leaves, lined with withered grass, and fortified on the outside with small sticks. The eggs are four or five, rarely six; of a flesh colour, and marked with deep and light rust-coloured spots. The song of this bird is louder than that of the throstle, and superior to it. Perching on the uppermost branch of a tall tree, the missel thrush sings when its mate is making the nest, and during incubation; but becomes silent as soon as the young are hatched, and is no more heard till the beginning of the new year. If the young are taken, its song continues as before, and if the female is destroyed, it continues in song the whole summer. The missel is very bold during the breeding season, driving other birds from the neighbourhood of its nest, and even attacking the magpie and jay. Its food is insects and berries, particularly those of the misletoe, which are frequently propagated after passing through the digestive organs of this bird.

738 *Pilaris.* *Fieldfare.*—Tail feathers black, the outermost at the inner edge tipt with white; head and rump hoary; bill yellowish, tipt with black; crown and neck olive ash above; body bay above; quill feathers cinereous; throat and breast yellowish-rufous; belly and vent whitish; legs blackish. Subject to three or four varieties. Length 10 inches; weight four ounces. Inhabits Europe, Syria, and Siberia. Arrives in Britain, in large flocks, about Michaelmas, and leaves us in March. It feeds on the berries of the holly, thorn, juniper, *empetrum nigrum*, *arbutus alpina*, &c. as well as on worms and insects. In very severe weather they migrate farther south, if not prevented by a sudden fall of snow. In 1798, when a very heavy snow fell on the northern and eastern parts of England, prodigious flocks of fieldfares appeared in the west; but as that part of the island also was soon covered with snow, which lay on the ground for a considerable time, they became too weak to advance farther south, and thousands were picked up, starved to death. Though it builds in trees, and sits on them in the day time, it always roosts on the ground. When a person approaches a tree that is covered with them, they continue fearless, till one at the extremity of the bush, rising on its wings, utters a loud and peculiar note of alarm, when they all immediately fly, except one other, which remains till the person approaches still nearer, and then it also flies off, repeating the note of alarm. Fieldfares were highly esteemed by the Roman epicures, who kept them in their aviaries, and fattened them with crumbs of bread, mixed with minced figs. According to Varro and Plutarch, the flesh was sometimes bitter.

739 *Iliacus.* *Redwing* or *wind thrush.*—Wings ferruginous underneath; eyebrows whitish; bill blackish; legs pale gray; body gray-brown, whitish beneath, with brown spots; sides and inner coverts ferruginous; vent white. Weight nearly two ounces and a half; length eight inches and a half. Inhabits Europe, and is a winter guest with us, appearing a few days before the preceding, migrating in vast flocks. It breeds in Sweden, Norway, &c. where it inhabits the maple woods, and sings delightfully from their highest tops. It builds in hedges or thickets, and lays six bluish-green eggs, spotted with black. In the southern countries of Europe, it does great injury to the vineyards.

740 *Musicus.* *Throstle* or *song-thrush*; *mavis* of the Scotch.—Quill feathers ferruginous at the inner base. Resembles the missel in colour, but the inner wing coverts are yellow, irides hazel, bill brown, and the mouth yellow within. Inhabits the woods in Europe. Weight about three ounces; length nine inches. This well-known species is generally admired for its song. Every wood and grove re-echoes with its notes, which sometimes vie with those of the missel. The throstle frequently sings as early as February, if the weather is mild, and in March the female makes its nest, composed of dried grass and green moss externally, and plastered within with rotten wood, mixed with cow dung or clay, and so compactly as to hold water, a circumstance which, in a rainy season, sometimes proves fatal to the eggs. The latter are four or five, of a blue colour, and spotted with black at the larger end. The nest is sometimes placed on the stump of a tree, very near the ground, or against the side of a tree, and frequently in a hedge, or solitary bush. Though the throstle feeds on berries and insects in general, it is particularly fond of shelled snails, especially of the *helix nemoralis*, whose shell it breaks by repeated strokes against a stone. It is not uncommon to find a great many fragments of shells together, as if a number had been conveyed to one particular stone for the purpose. This species breeds twice, and sometimes thrice in the year, and consequently continues long in song. Like the preceding, it is very hurtful to vineyards.

741 *Polyglottus.* *Mocking bird*, or *mimic thrush.*—Dusky-ash above; pale ash beneath; primary quill feathers white on the outer half; bill black; irides yellow; tail four inches long; legs cinereous. Nine inches and a half long. Inhabits the moist woods of Virginia, Carolina, Jamaica, &c. In the summer is seen much more to the northward than in winter. This singular species not only possesses musical and solemn notes of its own, but can at pleasure assume the tone of every other animal in the forest, from the humming bird to the eagle, and descending even to the wolf or the raven. One of them, confined in a cage, has been heard to mimic the mewing of a cat, the chattering of a magpie, and the creaking of the hinges of a sign-post in high winds. It is said to take a pleasure in archly deceiving other birds, alluring the smaller kinds, for example, with the call of their mates, and then terrifying them with the scream of an eagle. In the warmer parts of America, it sings incessantly from March to August, both day and night, beginning with its own compositions, and frequently finishing by borrowing from the whole feathered quire, repeating its tunes with such artful sweetness as to excite both pleasure and surprise. The female frequently builds her nest in the bushes or fruit-trees about houses, but is so very shy, that if a person only looks at the nest, she immediately forsakes it. It feeds on grasshoppers, different kinds of berries, &c. and is itself eaten by the Americans, who account it very delicate food.

742 *Orpheus.* *Mocking thrush.*—Back brown; breast and lateral tail feathers whitish; eyebrows white. Eight inches and a half long; inhabits South America, and resembles the last in its fine song and imitative notes.

743 *Pagodarum.* *Pagoda thrush.*—Black; back and rump gray; vent white;

Passeres. white; head crested. Size of a finch. Inhabits Malabar and Coromandel, chiefly about the temples and pagodas.

744 *Curæus.* *Chili thrush.*—Glossy black; bill somewhat striated; tail wedged; bill, eyes, legs, and flesh black; tail five inches long. About the size of the missel; is common in Chili, where it sings sweetly; imitates the notes of other birds, and, when tamed, the voice of man. Feeds on worms, seeds, and even on smaller birds, which it kills by perforating the skull with its bill. Congregates with starlings, and makes a nest of twigs and fibres, mixed with mud, and lined with hair. Lays three bluish-white eggs.

745 *Roseus.* *Rose-coloured thrush.*—Pale rosy; head, wings, and tail black; hind head crested. About eight inches long. Inhabits Europe and Asia, and has been found, though very rarely, in England. As it feeds chiefly on locusts, it is held sacred by the Turks.

746 *Cantans.* *Musician thrush.*—Reddish-brown, varied with transverse dark streaks; whitish beneath; chin, cheeks, and throat reddish-orange; a black blotch spotted with white on each side of the neck. Four inches long. Inhabits the woods of Cayenne. Is solitary; feeds on ants and other insects, and is celebrated for its sweet and variable note.

747 *Tintinnabulatus.* *Chiming thrush.*—Brown above; under parts and rump reddish-tawney; chin white; cap and cheeks white, spotted with black; eyebrows and streaks behind the eyes black. Four inches long. Inhabits the woods of Cayenne and Guiana. Its note resembles the chiming of bells.

748 *Tinniens.* *Alarum thrush.*—Brown above; white beneath; breast spotted with black; tail even; bill black above, white beneath; legs pale plumbeous. Six inches and a half long. Inhabits Cayenne. Every morning and evening, for the space of an hour, cries with a harsh loud voice, like an alarum bell.

749 *Rex.* *King thrush.*—Reddish-brown above, paler beneath; hind head lead-coloured; front varied with white and brown. Seven inches and a half long. Inhabits South America, near the hillocks raised by the white ants, on which it feeds.

750 *Merula.* *Blackbird.*—Black; bill and eyelids yellow. Female, and the young male rusty black, and bill dark. There is a variety with the head white, another with the body white and black, and a third entirely white. Inhabits Europe and Asia. A well-known species, admired for its song, which is a shrill kind of whistle of various notes, enlivening the early days of spring. The nest is externally composed of green moss, fibrous roots, &c. having the inside plastered with earth, and then lined with fine dry grass. The female lays four or five blue eggs, thickly covered with pale ferruginous brown spots. The blackbird feeds principally on worms and shelled snails, but is also fond of insects and fruit in general. It breaks the shell of the snail with great dexterity on a stone. In confinement it readily eats crumbs of bread, and flesh either raw or prepared for the table. With us it is never observed to migrate or to congregate, but lives solitary in woods and inclosed situations. It is easily tamed, and imitates other sounds, even that of the human voice.

751 *Torquatus.* *Ring ouzel.*—Blackish; bill yellowish; collar white. Rather larger than the blackbird. Inhabits Europe, Asia, and Africa. Is migratory in some countries, but is known to remain and breed in the mountains of Scotland and Wales. When fattened, its flesh is much esteemed. In its habits it is nearly allied to the blackbird. Passeres.

Reed thrush.—Rusty brown; white testaceous beneath; quill feathers brown, tipt with reddish. Frequently varies in its markings. Inhabits the reedy marshes of Europe, builds a hanging nest among the reeds, and lays from five to six yellowish white eggs spotted with brown. The male sings while the female is sitting. 752 *Arundinaceus.*

Songster thrush.—Greenish-black, shining with blue or violet; wings and tail black. Inhabits the Philippine isles in numerous flocks; sings very sweetly, and often lays in pigeon houses. 753 *Cantor.*

Gen. 79. Ampelis, *Chatterer*. 754 Ampelis.

Bill straight, convex, somewhat incurved; each mandible notched; nostrils covered with bristles; tongue sharp, cartilaginous, and bifid; middle toe connected at the base to the outermost. 755 Characters.

Waxen or *Bohemian chatterer*.—Hind head crested; secondary quill feathers tipt with red horny appendages; bill and legs black; irides bright ruby; cheeks tawney; throat black, with a small bristly tuft in the middle; head and body reddish-ash above; ocular line and chin black; breast and belly pale purplish bay; lesser wing-coverts brown; greater remotest from the body black, tipt with white; quill feathers black, three first tipt with white; six next with half an inch of the exterior edge yellow; inner white; tail black, tipt with yellow. Length about eight inches; size nearly that of a starling. Inhabits Europe, Northern Asia, and America. Occasionally visits this country, migrating in flocks. In the month of February, it frequents the neighbourhood of Edinburgh, where it feeds on the berries of the mountain ash. It is supposed to breed farther north, and to build in the holes of rocks. Its flesh is excellent. 756 *Garrulus.*

The other species of this genus are all inhabitants of the warmer parts of America.

Gen. 80. Colius, *Coly*. 757 Colius.

Bill short, thick, convex above, and flat beneath; upper mandible bent down at the tip; nostrils small at the base of the bill, and nearly covered with feathers; tongue jagged at the tip; tail long and wedged. 758 Characters.

Cape coly.—Outermost tail feathers white on the outside; body cinereous; whitish beneath. Ten inches and a quarter long. Inhabits the Cape of Good Hope. 759 *Capensis.*

Panayan coly.—Above yellowish ash colour; beneath rufous; breast streaked with black; head crested; bill black; legs pale flesh colour; tail very long, the feathers of which are of different lengths. Native of Panay, one of the Philippine islands. 760 *Panayensis.* Plate CCCCII. fig. 2.

Green coly.—Shining green; hind head and eyelids silky black; wings and tail blackish. Twelve inches long. Inhabits New Holland. 761 *Viridis.*

Indian coly.—Cinereous above; rufous beneath; hind head and chin yellow; lores and naked orbits yellow. Fourteen inches long. Inhabits India. 762 *Indicus.*

Gen.

Gen. 81. Loxia, *Grossbeak*.

763 Loxia. 764 Characters. Bill strong, thick, convex, and rounded at the base; lower mandible bent in at the edge; nostrils small, round at the base of the bill; tongue truncated.

765 *Curvirostra.* *Crossbill*, or *sheld apple*.—Mandibles crossing each other; body varying in colour; wings and forked tail brown; varies, with a reddish head and scarlet body. Male red, varied with brown and green. Female olive green, mixed with brown. Weighs about an ounce and a half; length near six inches and a half. Inhabits Europe, Asia, and America. Is not known to breed with us, but is more or less found among fir plantations from June to the latter end of the year, feeding on the seed by dexterously dividing the scales of the cones, for which purpose the bill is admirably adapted. It is sometimes found in orchards in autumn, and will readily divide an apple to get at the kernels. Many are taken with a bird-call and birdlime; and others by a horse-hair noose fixed on a long fishing rod; for so intent are these birds on picking out the seeds of the cone, that they will suffer themselves to be taken by the noose being put over their head. The crossbill breeds in the northern countries early in the month of March, on the tops of the pine trees, making its hemispherical nest of twigs, and of the *sphagnum arboreum*, two inches and a half thick, lining it with the *lichen floridus*, and stopping up the chinks with rosin. It is capable of being tamed, and in confinement climbs up the wires of a cage by the claws and beak.

766 *Coccothraustes.* *Grossbeak*, or *hawfinch*.—Chesnut ash; wings with a white line: middle quill feathers rhombic at the tips; tail feathers black at the base of the thinner web; orbits and chin black; tail spotted with white within. The length of this species is six inches; weight about two ounces. The plumage is subject to great variety. It inhabits Europe, and usually appears in Britain in the autumn, continuing till April, and appearing in small flocks of four or five, but not commonly. It is more plentiful in France, and breeds in Burgundy in April. The nest is composed of dried fibres intermixed with liverwort, and lined with finer materials. The eggs are of a bluish green spotted with olive brown, with a few irregular black markings. This bird lives on the kernel of the almond, walnut, and cherry, breaking with the greatest ease their hard stones with its bill.

767 *Enucleator.* *Pine grossbeak*.—Wings with a double white line; tail feathers all black; head, neck, breast, and rump in the young bird, red; in the old yellow; female olive. Nine inches long. Inhabits Europe, Asia, and America, but is limited to the northern regions of these quarters of the globe, and especially to the pine forests. In this island it is only found in the north of Scotland, where it is also supposed to breed. It sings excellently, and during the night, but soon ceases. It builds in trees pretty near the ground a nest of small sticks, and lines it with feathers, laying four eggs. Its food is the seed of the pine.

768 *Pyrrhula.* *Bullfinch*.—Cinereous; head, wings, and tail black; coverts of the tail, and hindermost quill feathers white; crown black; breast cinereous; belly of the male red, of the female chesnut. Scarcely six inches long, and liable to vary in its markings. Inhabits Europe and Siberia. In summer it frequents woods, and in winter haunts orchards and gardens, where it preys on the young buds of the trees. It is not gregarious, but is usually observed in pairs, or on broods, and remains with us all the year, making a nest of small dry twigs, lined with fibrous roots, in some thick bush, either in woods or hedges, about the latter end of April or beginning of May, and laying four or five eggs of a bluish-white, speckled and streaked with purple, and rather larger than those of a linnet. The native notes of the bullfinch are few, but remarkably soft, and uttered in so low a tone as to escape a common observer; the call notes are simple, but more audible. In confinement it becomes very docile, and may be taught a great variety of tunes, and even to imitate human speech. But it also acquires harsh strains with equal facility. A friend of the Comte de Buffon saw one of this species that had never heard any person whistle but carters; and it whistled with their strength and coarseness. These birds are also susceptible of strong and durable attachments. Some have been known, after escaping and living a whole year in the woods, to recognise the voice of their mistress, and return to forsake her no more, and others have died of melancholy on being removed from the first object of their attachment.

Cardinal grossbeak.—Crested; red; frontlet black; bill and legs blood red; crest, when erect, pointed. Nearly eight inches long. Inhabits North America. From the melody of its song, some of the Americans call it *nightingale*. In spring, and during great part of summer, it sits on the tops of the highest trees, and makes the forests echo with its song. During summer, it lays up its winter provision of maize and buck-wheat. Nearly a bushel of the former grain has been found in the retreat of one of these birds, artfully covered with leaves and small branches of trees, and only a small hole left at which the bird enters. In cages it will sing with a very short interval of silence, through the whole year. 769 *Cardinalis.*

Molucca grossbeak.—Colour brownish; the head, throat, and tail feathers are black; beneath waved with white and black; bill black; hindhead, wings and legs brown; rump waved with white and black. Four inches long. Inhabits the Molucca islands. 770 *Moluccensis.* Plate CCCCL. fig. 2.

Hamburgh grossbeak.—Head and neck chesnut above; chin, band in the middle of the white throat and rounded tail brown; back, breast, and rump yellowish-brown, spotted with black; belly, vent, and two bands on the wing-coverts white. Nearly six inches long. Inhabits the neighbourhood of Hamburgh. Feeds on insects, and climbs trees like the creeper. 771 *Hamburgia.*

Greenfinch, or *green grossbeak*; provincially *green linnet*.—Yellowish-green; primary quill feathers edged with yellow; four lateral tail feathers pale yellow at the base; bill brownish; legs flesh coloured; female browner. Rather larger than the house sparrow; weight nearly eight drams; length six inches and a half. Inhabits Europe and Kamtschatka; is very common in most parts of this country in summer; becomes gregarious in winter, and associates with chaffinches and yellow hammers; but in severe weather migrates from particular districts. It is rather a late breeder. The nest is composed of small dry twigs, bents, and moss, interwoven with wool, and lined with hair and feathers. It is commonly placed among ivy surrounding a tree, or in some 772 *Chloris.*

Passeres. some thick bush. The eggs are four or five; white, speckled with rusty red at the larger end, and much like those of the linnet, but larger. The principal food of this bird is seed and grain. It is easily tamed if held on one's fingers in the dark and heated gently. Though its native song is trifling, in confinement it will catch the notes of other birds.

773 *Sulphurata.* *Brimstone grosbeak.*—Olive brown; throat and belly pale yellow; eyebrows yellow. Nearly six inches long. Inhabits in flocks near the Cape of Good Hope, frequents the banks of rivers, and builds a pendulous nest, with a long neck beneath, in trees and shrubs.

774 *Bengalensis.* *Bengal grosbeak.*—Gray; crown yellow; temples whitish; belly whitish, spotted with brown. "This bird (says Sir William Jones) is exceedingly common in Hindostan: he is astonishingly sensible, faithful and docile; never voluntarily deserting the place where his young are hatched, but not averse, like most other birds, to the society of mankind, and easily taught to perch on the hand of his master. In a state of nature he generally builds his nest on the highest tree that he can find, especially on the palmyra, or on the Indian fig tree, and he prefers that which happens to overhang a well or a rivulet; he makes it of grass, which he weaves like cloth, and shapes like a large bottle, suspending it firmly on the branches; but so as to rock with the wind, and placing it with its entrance downward to secure it from birds of prey. Its nest usually consists of two or three chambers; and it is popularly believed that he lights them with fire flies, which he is said to catch alive at night, and confine with moist clay or with cow dung. That such flies are often found in his nest, where pieces of cow dung are also stuck, is indubitable; but as their light could be of little use to him, it seems probable that he only feeds on them. He may be taught with ease to fetch a piece of paper, or any small thing that his master points out to him. It is an attested fact, that if a ring be dropt into a deep well, and a signal given to him, he will fly down with amazing celerity, catch the ring before it touches the water, and bring it up to his master with apparent exultation; and it is confidently asserted, that if a house or any other place be shown to him once or twice, he will carry a note thither immediately on a proper signal being made. One instance of his docility I can myself mention with confidence, having often been an eye witness of it. The young Hindoo women at Benares, and in other places, wear very thin plates of gold called *ticas*, slightly fixed, by way of ornament, between their eyebrows; and when they pass through the streets, it is not uncommon for the youthful libertines who amuse themselves with training these birds, to give them a signal which they understand, and send them to pluck the pieces of gold from the foreheads of their mistresses, which they bring in triumph to their lovers."

775 *Canora.* *Brown-cheeked grosbeak.*—Dirty greenish; cinereous beneath: cheeks brown, surrounded with a yellow fringe. Inhabits Mexico, and sings delightfully.

776 *Philippina.* *Philippine grosbeak.*—Brown; yellowish white beneath; crown and breast pale yellow; chin brown. Inhabits the Philippine islands. A variety found in Abyssinia, has the tail and quill feathers greenish brown, and edged with yellow. Constructs a nest like the *bengalensis*.

777 *Abyssinica.* *Abyssinian grosbeak.*—Yellowish; crown, temples, throat, and breast, black; shoulders blackish; quill and tail feathers brown, and edged with yellow; irides red; wing-coverts brown, edged with gray; legs reddish-gray. Size of the hawfinch. Inhabits Abyssinia. This bird forms a curious nest of a pyramidal shape, which is suspended from the ends of branches like the nests of some others of this tribe. The opening is on one side, facing the east; the cavity is separated in the middle by a partition of half its height; up this the bird ascends perpendicularly, and then descending on the other side, forms its nest in the further chamber. By this means the brood is defended from snakes, squirrels, monkeys, and other mischievous animals, besides being secured from the rains, which in that country last sometimes for five or six months together.

778 *Pensilis.* *Pensile grosbeak.*—Green; head and throat yellow; ocular band green; belly gray; vent rufous red; bill, legs, tail, and quill feathers, black; the last edged with green. Size of a house sparrow. Inhabits Madagascar. Constructs a hanging nest of straw and reeds, shaped like a bag with an opening beneath, on one side of which is the true nest. The bird does not choose a new situation every year, but fastens a new nest to the end of the last, so that five may sometimes be seen hanging from one another. Builds in large societies, and produces three at each incubation.

779 *Socia.* *Sociable grosbeak.*—Rufous brown; yellowish beneath; frontlet black; tail short; bill black; region of the ears yellowish; legs brown. Inhabits the interior parts of the Cape of Good Hope, where they were first discovered by Mr Paterson. They build their nests in a species of mimosa, which grows to an uncommon size; and which, from its ample head and strong wide spreading branches, is well calculated to admit and support their dwellings. The tallness and smoothness of its trunk are also a perfect defence against the invasions of the serpent and monkey tribes. In one tree described by Mr Paterson, there could not be fewer than from eight hundred to a thousand nests under one general roof. Mr Paterson calls it a *roof*, because it resembles that of a thatched house, and projects over the entrance of the nest below in a very singular manner. "The industry of these birds (says this traveller) seems almost equal to that of the bee. Throughout the day they seem to be busily employed in carrying a fine species of grass, which is the principal material they use for the purpose of erecting this extraordinary work, as well as for additions and repairs. Though my short stay in the country was not sufficient to satisfy me by ocular proof that they added to their nest as they annually increased in numbers; still, from the many trees which I have seen borne down by the weight, and others which I have observed with their boughs completely covered over, it would appear that this is really the case. When the tree which is the support of this aerial city, is obliged to give way to the increase of weight, it is obvious that they are no longer protected, and are under the necessity of building in other trees. One of these deserted nests I had the curiosity to break down, to inform myself of the internal structure of it, and found it equally ingenious with that of the external. There are many entrances, each of which forms a regular street with nests on both sides, at about two inches distance from each other. The grass with which they build is called the *Boshman's* grass; and I believe the seed of it to be their

Passeres. their principal food; though, on examining their nests, I found the wings and legs of different insects. From every appearance, the nest which I dissected had been inhabited for many years; and some parts of it were much more complete than others. This, therefore, I conceive to amount nearly to a proof, that the animals added to it at different times, as they found necessary from the increase of the family, or rather of the nation or community."

780 Oriv. *Grenadier grosbeak.*—Gray; bill, front, and belly, black; neck and rump tawney; sometimes the wings are white, and the tail is brown. Size of a sparrow; inhabits Africa, and is found chiefly in marshy and reedy grounds. The nest is formed among the reeds with small twigs, so closely interwoven with cotton, as not to be penetrated by any weather. It is also divided into two compartments, of which the upper is for the male, and the lower for the female and the young.

Among various other species which we have not room to describe, there are two or three of a very small size, which inhabit Surinam.

781 Emberiza.

Gen. 82. Emberiza, *Bunting*.

782 Characters. Bill conical; mandibles receding from each other from the base downwards, the lower with the sides contracted, the upper with a hard knob within.

783 Nivalis. *Snow bunting, snow bird, or snow flake.*—Quill feathers white, the primaries black on the outer edge; tail feathers black, the three lateral ones white; bill and legs brown. Besides the varieties induced by age, sex, and climate, there are others which seem to be more permanent. In winter, the whole body, except the back and middle coverts, often becomes nearly white. Somewhat larger than the chaffinch. In summer, inhabits in vast flocks, the north of Europe, Asia, and America. In winter, migrates to some warmer climate. Breeds in some of the mountains of Scotland, where it is sometimes mistaken for the ortolan. It builds in the fissures of rocks, constructing a nest of grass and feathers lined with the hair and wool of the arctic fox or other quadruped, and lays five eggs. It sings well, sitting on the ground, feeds on grain, and is wakeful during the night. It is taken in great numbers in winter, when it is fat, and its flesh esteemed delicate.

784 Mustelina. *Tawney bunting.*—Quill feathers dusky, white at the base, the last wholly black; tail feathers black, the middle ones at the edge, and three lateral ones, white on each side, with a dusky spot without. Nearly seven inches long. Inhabits with the last; but is more rare. In some places it is called *sea lark* and *brambling*.

785 Montana. *Mountain bunting, lesser mountain finch or brambling.*—Five first quill feathers blackish-brown, the rest white, spotted with brown at the tips; tail feathers brown, three lateral ones all white on each side; bill yellow, tipt with black; head chesnut; chin white; upper part of the neck and back cinereous; breast and belly with longitudinal flame-coloured spots. Found in Yorkshire, Lincolnshire, and Northamptonshire, but is not common.

786 Miliaria. *Common bunting.*—Brown; spotted with black beneath; orbits rufous; bill and legs brownish; quill feathers dusky; outer edges pale yellow; tail a little forked, edged with white; legs yellowish. Weight nearly two ounces; length seven inches and a half. Inhabits Europe in large flocks during the autumn and winter. Seems partial to champaign countries, abounding with corn, and is rarely found in uncultivated parts, or in grass fields remote from arable land. While the female is employed in incubation, the male sits on the branch of a neighbouring tree, and cheers her with his rude song. The nest is placed on the ground, formed externally of straw, lined with fibrous roots or dry grass, and sometimes finished with long hairs. The eggs are from four to six, of a dirty white, spotted and veined with reddish-brown and ash-colour. These birds are sometimes brought to market, and sold for larks, to which they are little or nothing inferior, but are easily distinguished by the form of the bill, and the tooth like knob in the roof of the mouth, by the most common observer.

Ortolan.—Quill feathers brown, the first three whitish at the edges; tail feathers brown, the two lateral ones black on the outer side; bill, naked eyelids and legs yellowish; head and neck olive-ash; chin yellowish, surrounded with a cinereous line; feathers of the back and scapulars brownish-bay, black in the middle; body reddish beneath. The female is distinguished by the head and neck being cinereous, and each feather with a narrow blackish line. Somewhat less than the yellow hammer; length six inches and a quarter. Inhabits several parts of Europe, but is not found in Britain. Ortolans are common in France, Italy, some parts of Germany, Sweden, &c. migrating in spring and autumn, when they are caught in great quantities, and fattened for the table. For this purpose, they are confined in a dark room, and fed plentifully with oats and millet. They are then killed for sale, and reckoned the most delicate of food. The ortolan will sometimes sing very prettily, its note being not unlike that of the yellow hammer, but finer and sweeter. In some parts, it makes its nest on a low hedge, in others on the ground, and constructs it carelessly, like that of the lark. The female lays four or five grayish eggs, and in general has two broods in the year.—There are five or six varieties. 787 Hortulana.

Yellow hammer, or yellow bunting.—Tail feathers blackish, the two outer ones on the inner edge, with a pointed white spot; bill black; crown, cheeks and body beneath yellow; eyebrows brownish; nape greenish; feathers of the neck and back blackish down the middle, rufous at the sides, and edged with gray; rump pale tawney; wings chesnut, olive or black, mostly edged with gray; lateral ones olive without; the tip edged with white; legs yellowish-brown. The weight of this species is about seven drams: length six inches. Inhabits Europe, and is one of the most common indigenous birds of this country. Its song is as little attractive as that of the common bunting, possessing only a repetition of the same note, five or six times successively, and terminating in one more lengthened and shrill. It congregates in winter, approaching houses, and picking up scattered grains. It does not breed till late in the spring. The nest is generally placed near the ground, in some low bush or hedge, and is composed of straw and various dried stalks, lined with fine dry grass, and finished with long hair. The eggs differ somewhat in colour and size, some being nearly white, and others having a purplish hue, but all more or less marked with hair-like streaks. The number is usually three, four, or five. 788 Citrinella.

Foolish bunting, or foolish sparrow.—Reddish; head with a few blackish lines; eyebrows white. Size of the yellow. 789 Cia.

Passeres. yellow hammer. Inhabits Europe and Siberia. Is so tame as to be caught in any snare. Has a trifling note, like that of a yellow hammer.

790 Cirlus. *Cirl bunting.*—Brown; breast spotted; eyebrows pale yellow; two outmost tail-feathers with a white wedged spot; bill brown ash; head olive; temples yellow; a black spot between the bill and eyes; throat black, with a yellow band; body yellow beneath; tail slightly forked, the feathers edged with gray. Female streaked with brown beneath; chin and vent white. Length six inches and a half; weight about seven drams. Inhabits France and Italy. "We first discovered this species," says Mr Montagu, near Kingsbridge in the winter of 1800, not uncommon amongst flocks of yellow buntings and chaffinches, and procured several specimens of both sexes, killed in different places six or seven miles from that place. They are indigenous to Devonshire, but seem to be confined to the southern parts of that county contiguous to the coast, having found them extending as far as Teignmouth, at both of which places we found their nests; but have never observed them far inland. It generally builds in furze or some low bush; the nest is composed of dry stalks, roots, and a little moss, and lined with long hair and fibrous roots. The eggs are four or five in number, cinereous white, with irregular long and short curved lines, terminating frequently with a spot at one end; size rather inferior to those of the yellow bunting, to which it bears great resemblance. These birds pair in April, and begin laying early in May.—The female might readily be mistaken for that sex of the yellow bunting at a little distance, but is materially different when compared, especially in the chesnut colour of the upper parts of this bird. The note is also similar to that of the yellow bunting, but shorter, not so shrill, and the latter part not drawn out to such a length.—It is remarkable, that so common a bird as the cirl bunting seems to be in the west of England, should have so long escaped the notice of British naturalists; but in all probability this has been occasioned by their locality. It is said to be only found on the continent in the warmer parts of France and Italy; so with us it seems confined to the mildest part of England; but the winter of 1800, which was severe in Devonshire, did not force them to seek a warmer climate, but on the contrary, they continued gregarious with other small birds, searching their food among the ploughed lands."

791 Familiaris. *Familiar bunting.*—Cinereous, spotted with brown; tail feathers tipt with white; hind part of the back yellow. Size of a siskin. Was found at Java by Osbeck, and was so familiar, that if the cage door was opened, it would leap on the first person's hand that was offered; if any one whistled to it, it sang very sweetly in return, and if it saw a dish of water, it went immediately and bathed in it. It was fed with rice.

792 Oryzivora. *Rice bunting,* or *rice bird.*—Black; crown reddish; belly black; tail feathers daggered. Six inches and three quarters long. Inhabits Cuba. These birds feed on the early crops of rice in the island of Cuba; but when the rice in Carolina begins to ripen, they quit the island, and proceed to Carolina, in amazing and destructive multitudes. They arrive there in September, while the rice is yet milky; and when it grows hard they return. The birds which thus migrate are all females; but both sexes make a transient visit to Carolina in the spring.

Reed bunting, or *reed sparrow.*—Head black; body gray and black; outmost tail feathers with a white wedged spot; bill brown; throat and breast black; 793 Schœniclus. belly white, streaked with black at the sides; wing coverts and quill feathers brownish red, black down the middle; tail feathers pointed, the eight middle ones black, two middle ones rufous on each edge, the rest on the outer only; legs brownish. Weight near five drams and a half; length six inches. Inhabits the marshy and reedy districts of Europe and Southern Siberia. A brown variety occurs at the Cape of Good Hope, and a white one about Astracan. "It is somewhat extraordinary," observes the intelligent ornithologist quoted above, "that the manners and habits of so common a bird should remain so long in obscurity; even modern authors tell us it is a song bird, that it sings after sunset; and describe its nest to be suspended over the water fastened between three or four reeds. There can be no doubt, however, that the nest, as well as the song, of the sedge warbler, have been taken and confounded for those of this bird; for as they both frequent the same places in the breeding season, that elegant little warbler is pouring forth its varied notes concealed in the thickest part of a bush; while this is conspicuously perched above, whose tune is not deserving the name of song, consisting only of two notes, the first repeated three or four times, the last single and more sharp. This inharmonious tune it continues to deliver with small intervals from the same spray, for a great while together when the female is sitting. The nest is most commonly placed on the ground near water; sometimes it builds in a bush some distance from the ground; at other times in high grass, reeds, sedge, or the like, and even in furze at a considerable distance from any water; in all these situations we have met with it, but never fastened or suspended as authors have related. The nest is composed of stalks of grass, or other dry vegetable substances, sometimes partly moss, and lined with fine grass; frequently finished with long hair. The eggs, which are four or five in number, weigh about 36 grains, and are of a dirty bluish-white or purplish-brown, with numerous dark-coloured spots and veins, much resembling those of the chaffinch.

Whidaw bunting.—Black; breast red; four middle 794 Paradisea. tail feathers long and pointed, two very long; bill black. The two middle tail feathers are four inches in length, very broad, and ending in a long thread; the two next are 13 inches or more in length, very broad in the middle, narrower at the end, and rather pointed; from the middle of the shaft of this last arises another long thread; the rest of the tail feathers are only two inches and a quarter long; the two middle long ones are placed somewhat vertically, appear undulated across, and are more glossy than the others; the legs are flesh-coloured. The female is wholly of a deep brown, approaching to black, but does not acquire its full plumage till the third year. This species inhabits Africa, particularly Angola. It moults in November, and also late in spring.

Shaft-tailed bunting.—Four middle tail feathers black, 795 Regia. Plate CCCCII. fig. 1. from nine to ten inches long, equal and feathered only at the tip; bill and legs red; body above, and vent, black; body beneath, and throat, temples, and orbits, rufous; neck above spotted with black. Native of Africa. Less than the linnet.

Green-headed bunting.—Brown; head and neck olive; 796 Chlorocephala. back

Passeres. back and wing-coverts varied with brown and black; tail forked. Only two instances are recorded of this species having been found in England.

797 TANAGRA. Gen. 83. TANAGRA, *Tanager*.

798 Characters. Bill conical, pointed, notched, almost triangular at the base, and a little inclining at the tip.

799 *Jacapa.* *Red-breasted tanager.*—Black; front, throat, and breast, scarlet; bill black; lower mandible silvery, and convex on the hind part; front sometimes black; legs brown. Female purplish-brown; reddish beneath; wings and tail brown. Six inches and a half long. Inhabits South America, frequenting inhabited places, building a pendulous cylindrical nest, and feeding on fruits.

800 *Episcopus.* *Bishop tanager.*—Cinereous; wings and tail blue without. Six inches and a half long. Inhabits Cayenne, especially about the skirts of the forests, and feeds on the lesser kinds of fruits. During night it roosts on the palm leaves.

801 *Jacanari.* *Jacanari tanager.*—Black violet; wings whitish beneath; tail divaricated and forked; bill and legs cinereous. Inhabits Brazil and Guiana. Is fond of newly cultivated land; haunts small trees, particularly coffee trees. The male frequently hops upwards from a branch, alighting again, first on one foot, and then on the other, accompanying each leap by a note, and spreading out the tail at the same time. The nest is hemispherical, about two inches in diameter, and composed of dried herbs of a gray colour. The eggs are two in number, of a greenish-white, marked with small numerous red spots, deepest and most in number at the large end.

802 *Siberica.* Plate CCCCII. fig. 5. *Siberian tanager.*—Black; tips of the interscapular and rump feathers fringed with white; bill short, pale, tipt with brown; bill notched at the tip; legs black. Native of Siberia; size of a thrush.

The other species, which are numerous, and not very distinctly ascertained by authors, seem to differ from one another more in their markings than their habits.

803 FRINGILLA. Gen. 84. FRINGILLA, *Finch*.

804 Characters. Bill conical, straight, and pointed.

This is a numerous and active tribe of birds, very generally dispersed over the world, and feeding principally on insects and grain.

805 *Lapponica.* *Lapland finch.*—Head black; body gray and black; eyebrows white; outmost tail feathers with a white wedged spot. Six inches and a half long. Inhabits Europe, Asia, and America. Runs along the ground like a lark, and sings on the wing.

806 *Cœlebs.* *Chaffinch;* provincially, *beech finch, horse finch, pink,* and *twink.*—Limbs black; quill feathers white on both sides, the three first without spots; two of the tail feathers obliquely white; bill white, but in spring and summer bluish, tipt with black; crown, nape, and sides of the neck hoary; temples and throat reddish; belly and vent reddish-white; wing-coverts with a white blotch, the greater with a white band besides; quill feathers yellowish at the edge, and white at the base; tail a little forked; legs brown. The female wants the red on the breast and other parts. Rather less than the sparrow. Inhabits Europe and Africa. Continues with us the whole year; but the females migrate from Sweden to Holland in the autumn, leaving their mates behind, and return in the spring. This bird makes a most elegant nest of green moss, curiously studded with lichen, interwoven with wool, and lined with feathers and hair. It builds against the side of a tree, particularly in ivy, or in some forked branch of a bush; but particularly in apple trees overgrown with moss and lichen, and, like many other birds, adapts the materials of its nest to the surrounding colour. The eggs are four or five, larger than those of the goldfinch, of a dirty white, tinged with purple, marked with streaks and spots of dark purple. Its notes are few, and scarcely deserve the name of song. Both sexes have a monotonous call-note, which seems to express the word *twink*. This species is subject to several varieties.

Mountain finch, brambling, or *bramble.*—Base of the wings fine yellow beneath; bill yellowish, tipt with black; head, neck, and back black; in the female brown; the feathers edged with reddish-brown; rump, lower part of the breast and belly white; throat and upper part of the breast reddish-tawney; in the female reddish gray; lesser wing-coverts reddish; middle ones reddish white; greater black, tipt with white; those next the body reddish at the tip; quill feathers black, edged with yellowish; tail a little forked; legs gray. Rather larger than the preceding; length about six inches. Inhabits Europe and Asia, breeding in the northern regions. Is frequently seen in large flocks in the winter, on the coasts of Kent and Sussex, when the weather is severe, when it is sometimes so exhausted as to suffer itself to be taken up. They are also found in the interior parts of the kingdom at that season, flying in company with chaffinches and yellow hammers. In hard winters, they are also frequently seen in the neighbourhood of Edinburgh. They are partial to the pine forests in the Highlands, and live on beech mast and the seeds of other trees. They build in trees a nest formed of hypnums without, and of wood and feathers within, the female laying four or five yellowish spotted eggs. Their flesh is eatable, though sometimes bitter. 807 *Montifringilla.*

Goldfinch, or thistlefinch.—Quill feathers black; and except the outmost marked with fine yellow in the middle; two outmost tail feathers in the middle, and the rest at the tips white; bill white, tipt with black; frontlet scarlet, in the female brown; cheeks, hind head, and belly white; top of the head black; wing-coverts black, in the female brown; back, rump, and breast, chesnut-brown. This beautiful species, which is subject to great variety, is rather less than the chaffinch, and inhabits Europe, Asia, and Africa. It is gregarious in winter, lives to a great age, subsists chiefly on the seeds of the thistle, hemp, and capitated plants; is docile and easily tamed, and sings delightfully, even in confinement. It sometimes builds in hedges, but most commonly in trees, especially those that are evergreen. The nest is neatly constructed of bents, moss, and lichen, woven together with wool, and sometimes lined with wool, or hair covered with thistle down, or the pappus of the willow. The eggs are four or five, of a bluish white, with a few small spots, chiefly at the larger end. The goldfinch readily breeds with the canary and other congenerous birds. 808 *Carduelis.*

Lepid finch.—Greenish-brown; band above and beneath the eyes and chin orange; breast black. Only half the size of the canary bird. Inhabits the woods of Cuba, and sings with a weak, but very sweet note. 809 *Lepida.*

Ethiopian finch.—Deep black; irides rufous. Inhabits 810 *Ethiops.*

Passeres. habits the woods of America, feeds on fruits and seeds, is easily tamed, and sings with the feathers of the head erected.

811 Caspa. *Caspa finch.*—Reddish-gray; front and chin white; wings and tail black. Inhabits Barbary and Abyssinia, frequents granaries in large flocks, and excels the canary bird in its song.

812 Elegans. *Beautiful finch.*—Green above; neck cinereous; breast yellow; frontlet, chin, rump, and tail red; belly with curved white spots; bill and legs red; rump and tail chesnut red. Five inches long. Inhabits Africa.

813 Canaria. *Canary bird, or canary finch.*—Bill and body straw colour; quill and tail feathers greenish. Is now well known over Europe, into which it was brought from the Canary islands, about the beginning of the 16th century. It is somewhat longer than the siskin, and about five inches and a half in length. With us they are kept in a state of captivity, and partake of all the differences and varieties incident to that condition. Buffon enumerates 29 varieties, and more might probably be added to his list. "The breeding and rearing of these charming birds," says Mr Bewick, "form an amusement of the most pleasing kind, and afford a variety of scenes highly interesting and gratifying to innocent minds. In the places fitted up and accommodated to the use of the little captives, we are delighted to see the workings of nature exemplified in the choice of their mates, building their nests, hatching and rearing their young, and in the impassionate ardour exhibited by the male, whether he is engaged in assisting his faithful mate in collecting materials for her nest, in arranging them for her accommodation, in providing food for her offspring, or in chanting his lively and amorous songs during every part of the important business. The canary will breed freely with the siskin and goldfinch, particularly the former; it likewise proves prolific with the linnet, but not so readily, and admits also the chaffinch, yellow bunting, and even the sparrow, though with still more difficulty. In all these instances, excepting the first, the pairing succeeds best when the female canary is introduced to the male of the opposite species. According to Buffon, the siskin is the only bird of which the male and female propagate equally with those of the male or female canaries." Great numbers of these birds are reared in the Tyrol. Four Tyrolese usually brought over to England about 1600 of them annually; and though they carried them on their backs 1000 miles, and paid 20l. for such a number, they were enabled to sell them at five shillings a-piece. It is not generally known, that the song of the canary bird is usually composed of the notes of the tit-lark or of the nightingale. Mr Barrington saw two of the species which were imported from the Canary islands, neither of which had any song; and he was afterwards informed, that a ship brought over a great many of them with the same defect. Most of those from the Tyrol have been educated under parents whose progenitors were instructed by a nightingale. Our English canary birds, however, have more of the tit-lark's than of the nightingale's notes. The canary bird lives chiefly on the seeds of *phalaris canariensis, canabis myagrum, brassica napus, avena*, &c.

814 Spinus. *Siskin, or aberdevine.*—Quill feathers yellow in the middle; the first four without spots; tail feathers yellow at the base, and tipt with black; crown black; body yellowish; greenish above, breast greenish; wings green; throat brown, of the female white; head and back, in the female, greenish-ash, spotted with brown. Four inches and three-fourths long. Inhabits Europe, and is liable to several varieties. Though migratory in most places, it does not seem to observe any regular periods, as it is sometimes seen in large, and at other times in very small numbers. Buffon remarks, that the great flights happen only once in the course of three or four years. It conceals its nest with so much art, that it is extremely difficult to discover it. Kramer informs us, that in the forests bordering on the Danube, thousands of young siskins are frequently found, which have not dropt their first feathers, and yet it is rare to meet with a nest. It is not known to breed in this island; nor is it known whence they come over to us. In some parts it is called the *barley bird*, from its appearing when that grain is sown. Its song, though not so loud as that of the canary, is pleasing and various. It is docile and familiar in captivity, and will imitate the notes of other birds, even to the chirping of a sparrow. Like the goldfinch, it may easily be taught to draw up its little bucket with water and food. It drinks frequently, and seems fond of throwing water over its feathers. The male breeds freely with the hen canary, and is assiduous in his attention to her, carrying materials for the nest, and arranging them, and during the time of incubation, regularly supplying her with food.

815 Barbata. *Bearded finch.*—Pale yellow: wings green, spotted with black and red; chin bearded. Size of the canary bird. Inhabits the mountains of Chili, except in winter, when it descends into the plains. It is easily tamed, sings charmingly, and imitates the notes of other birds.

816 Canabina. *Greater redpole, or red-headed linnet.*—Chesnut brown; reddish-white beneath; wings with a longitudinal white band; tail feathers edged with white on each side; bill black; head and neck cinereous; sides yellow; middle of the belly white; tail forked, dusky, both sides edged with white. Head of the female ash-colour, spotted with black; crown and breast without the red; breast dirty yellow with black lines. Subject to considerable variety in the markings. Five inches and a half long. Inhabits Europe and America. These birds fly in flocks during winter, at which time the males have little or none of the red markings, which in the return of spring they put forth. In many parts they haunt the sea shore, and in the breeding season, often resort to furzy commons. The nest is composed of moss and bents interwoven with wool, and lined with wool and hair. The eggs are four or five, of a bluish-white, with purplish specks and short lines. The redpole sings nearly the whole year, is very familiar, and so easily tamed, as to be cheerful in five minutes after it is taken.

817 Linota. *Common or brown linnet.*—Chesnut brown; whitish beneath; wings with a longitudinal white band; tail feathers edged with white on each side. Though this is usually described as a distinct species, it seems to be only a variety of the preceding.

818 Linaria. *Lesser redpole or lesser red-headed linnet.*—Brown, varied with gray; reddish-white beneath; wings with a double white band; crown and breast red; bill and legs brown; back black, the feathers edged with chesnut; sides with narrow dusky lines; quill feathers dusky, edged with dirty white; legs dusky. Female with a saffron spot on the front. Weight about two drams and a half; length

Passeres. length five inches. Inhabits Europe, Asia, and America. It is gregarious in winter, when many are taken by the bird-catchers near London, &c. under the name of *stone redpole*. It breeds in Scotland and the north of England; building in the trunk of the alder a nest of dry sticks and wool, lined with hair and feathers, or willow down. Lays four eggs of a light bluish-green, thickly sprinkled with reddish spots, especially at the larger end.

819 *Montium.* *Mountain linnet*, or *twite*.—Black, varied with reddish; whitish beneath; feathers of the lower part of the neck black in the middle; wings with a white band; rump red; feathers of the throat and breast black, edged with white; middle quill feathers edged; secondary tipt with white. Rather larger than the greater redpole; length about six inches and a half. Inhabits Europe. Is gregarious, and has much the habits of the other linnets, with which it associates.

820 *Coccinea.* *Scarlet finch*.—Bright orange; wings and even tail black; quill feathers orange at the outer edge, the primaries tipt with black; bill brownish; legs black. Four inches and a half long. Inhabits the Sandwich islands.

821 *Domestica.* *House sparrow*.—Quill and tail feathers brown; body gray and black; wings with a single white band; bill black; crown gray; a black spot under each eye; a broad bay mark surrounding the hind part of the head; cheeks white; chin and under side of the neck black, the latter edged with white; lesser wing-coverts bright bay; the last row black, tipt with white. The lower mandible of the female white, and a white line beyond each eye. The most remarkable varieties are, 1. white, 2. yellow, clouded with chesnut above, and 3. blackish. Weighs nearly seven drams; length about six inches. Inhabits Europe, Asia, and Africa. This well known species inhabits the dwellings of the rich and the poor, and is rarely seen far from the habitation of man. It lives on seeds and fruits, and often cunningly avoids the snares that are laid for it. In autumn it is often gregarious, but more frequently so in winter. It does not sing, except when tamed, and then the male will imitate the song of a linnet, or other bird within hearing. It makes a nest conformable to the place which it chooses for incubation, whether in a hole of a wall, in thatch, under the tiles of a house, or in the nest of a martin, or other bird; but when it builds in a tree, the nest is of a large size, and covered at the top, composed of hay and straw, lined warmly with feathers and fragments of thread or worsted, bits of cloth, or any refuse material of that sort found about houses. The female lays six eggs of a whitish colour, spotted with dusky and cinereous, and usually breeds thrice in the year. Mr Smellie relates a pleasing anecdote of the affection of these birds towards their young. "When I was a boy," says he, "I carried off a nest of young sparrows, about a mile from my place of residence. After the nest was completely removed, and while I was marching home with them in triumph, I perceived, with some degree of astonishment, both parents following me at some distance, and observing my motions in perfect silence. A thought then struck me, that they might follow me home, and feed their young according to their usual manner. When just entering the door, I held up the nest, and made the young utter the cry which is expressive of the desire of food. I immediately put the nest and the young in the corner of a wire cage, and placed it on the outside of a window. I chose a situation in the room where I could perceive all that should happen, without being myself seen. The young animals soon cried for food. In a short time both parents, having their bills filled with small caterpillars, came to the cage; and after chatting a little, as we would do with a friend through the lattice of a prison, gave a small worm to each. This parental intercourse continued regularly for some time, till the young were completely fledged, and had acquired a considerable degree of strength. I then took one of the strongest of them, and placed him on the outside of the cage, in order to observe the conduct of the parents after one of their offspring was emancipated. In a few minutes both parents arrived, loaded as usual with food. They no sooner perceived that one of their children had escaped from prison, than they fluttered about, and made a thousand noisy demonstrations of joy both with their wings and their voices. These tumultuous expressions of unexpected happiness at last gave place to a more calm and soothing conversation. By their voices and their movements it was evident that they earnestly entreated him to follow them, and to fly from his present dangerous state. He seemed to be impatient to obey their mandates; but, by his gestures, and the feeble sounds he uttered, he plainly expressed that he was afraid to try an exertion he had never before attempted. They, however, incessantly repeated their solicitations; by flying alternately from the cage to a neighbouring chimney top, they endeavoured to show him how easily the journey was to be accomplished. He at last committed himself to the air, and alighted in safety. Upon his arrival, another scene of clamorous and active joy was exhibited. Next day I repeated the same experiment, by exposing another of the young on the top of the cage. I observed the same conduct with the remainder of the brood, which consisted of four. I need hardly add, that not one either of the parents or children ever afterwards revisited the execrated cage."—Few birds are more persecuted by the farmers, and, perhaps, more unjustly so, than sparrows; as it has been proved, that they are more useful than noxious. Mr Bradley, in his Treatise on Husbandry and Gardening, shows, that a pair of sparrows, during the time that they have their young to feed, destroy, on an average, every week 3360 caterpillars. He discovered that the two parents carried to the nest 40 caterpillars in an hour. He supposed the sparrows to enter the nest only during 12 hours each day, which would cause a daily consumption of 480 caterpillars. This sum gives 3360 caterpillars extirpated weekly from a garden. But the utility of these birds is not limited to this circumstance alone; for they likewise feed their young with butterflies and other winged insects, each of which, if not destroyed in this manner, would be the parent of hundreds of caterpillars.

Tree or *mountain sparrow*, *Hamburgh grosbeak* of Latham, &c.—Quill and tail feathers brown; body gray and black; wings with a double white band; bill, chin, and spot on the ears black; head and nape bay; body above reddish-brown, spotted with black; whitish beneath; wing coverts black, edged with rufous; tail feathers blackish, edged with rufous; legs yellowish. Female without the black spots. Five inches and a half long, and rather smaller than the preceding. Inhabits Europe and North America, and is said to be very plentiful 822 *Montana.*

 tiful in Lincolnshire, Yorkshire, and Lancashire. It is local, and very gregarious.

823 *Ultramarina.* *Ultramarine finch.*—Blue; bill white; legs red. Size of a canary bird. Inhabits Abyssinia, and sings well.

824 Phytotoma.

Gen. 85. Phytotoma.

825 Characters. Bill conical, straight, serrated; nostrils oval; tongue short, and obtuse; feet four-toed.

826 *Rara.* *Rara phytotoma*, or *four-toed plant-cutter.*—Bill thick, half an inch long, and toothed on each side like a saw; irides brown; body ash above; paler beneath; quill and tail feathers spotted with black; tail rounded; hind toe shorter than the fore ones. Inhabits Chili, where it is not uncommon. Has a rough voice, and utters at intervals, the syllable *ra*, *ra*, very distinctly. Feeds on vegetables, digging and cutting about their roots with its bill as with a saw, and thus making great havock in gardens. Builds in lofty trees, in retired situations.

827 Muscicapa.

Gen. 86. Muscicapa, *Fly-catcher.*

828 Characters. Bill nearly triangular, notched on each side, bent in at the tip, and beset with bristles at the root; toes in most cases divided to their origin.

The birds of this genus live on insects, particularly flies. Of 92 species, two only inhabit Britain.

829 *Paradisi.* *Paradise fly-catcher*, or *pied bird of Paradise.*—Crested; head black; body white; tail wedged; two middle feathers very long; head, neck, and chin greenish-black; back, rump, throat, and body white beneath; wing coverts and quill feathers black, edged with white; two middle tail feathers 15 inches long; legs lead-coloured. Eight inches and a quarter long. Of this species there are several varieties. Inhabits Asia and Africa.

830 *Tyrannus.* *Forked-tail fly-catcher.*—Tail very long and forked; body black; white beneath. Fourteen inches long. Inhabits Canada and Surinam.

831 *Malachura.* *Soft-tailed fly-catcher.*—Brown; ferruginous beneath; throat of the male blue; tail long, wedged, with loose webbed feathers. Inhabits New Holland, being found about Sidney and Botany Bay, in marshy places, abounding with long grass and rushes, which afford it a hiding place, and where, like the bearded titmouse, it is supposed to make its nest. When disturbed, its flight is very short; but it runs on the ground with great swiftness. This singular bird, which is but three inches long, is well represented in the fourth volume of the Linnæan Transactions.

832 *Pygmaea.* Plate CCCCI. fig. 4. *Dwarf fly-catcher.*—Straw-coloured beneath; head and neck rufous, spotted with black; feathers of the back and wing coverts cinereous; edged with greenish; quill feathers black, edged with gray; tail black and short. Hardly three inches long. Inhabits Cayenne.

833 *Rubricollis.* *Purple-throated fly-catcher.*—Black; chin and throat with a large purple red spot. Twelve inches long. Inhabits woods in South America, is gregarious, feeds on fruits and insects, and often associates with the toucan.

834 *Atricapilla.* *Pied fly-catcher.*—Black above; under parts, spot on the front, and shield on the wings, white; lateral tail feathers white without; bill and legs black; tail coverts spotted with white. Female brown; white beneath, and wants the frontal spot. About the size of a linnet, and nearly five inches long. There are three or four varieties, and the young birds at first resemble the female. It is local, and by no means plentiful in this island, affecting wild and uncultivated tracts of furze. According to Dr Latham, it builds in some hole of a tree, not very near the ground, making a nest of a few fibres, mixed with moss, and laying six eggs.

Chattering fly-catcher.—Green; yellow beneath; belly and vent whitish; eyebrows and spot under the eyes whitish; tail brown. Seven inches and three quarters long. Haunts unfrequented places in Carolina; is very shy, and flies with its legs extended. 835 *Viridis.*

Azure fly-catcher.—Blue; hind head and breast with a black spot; belly and vent bluish-white; quill and tail feathers dusky-blue. Five inches long. Inhabits the Philippine islands. 836 *Caerulea.*

Fan-tailed fly-catcher.—Olive above, ferruginous beneath; eyebrows, chin, throat, sides of the neck, and lateral tail feathers white; middle tail feathers, head, and collar black. Six inches and a half long. Inhabits New Zealand. Flies with its tail expanded like a fan; and is easily tamed. 837 *Flabellifera.*

Black fly-catcher.—Totally black; bill, head, and legs dusky black. Inhabits Society islands. 838 *Nigra.*

Active fly-catcher.—Olive-brown; whitish beneath; quill and tail feathers black, and edged with olive-brown. Four inches and a half long. Inhabits Cayenne. Is continually hunting after insects, which it picks out from under the bark of trees. 839 *Agilis.*

Spotted fly-catcher.—Brownish whitish beneath; neck longitudinally spotted; vent pale-rufous; bill black, whitish at the base; inside of the mouth yellow; head large, brownish, and spotted with black; back mouse-coloured; wings and tail black; the former edged with white; chin spotted with red; legs black. About the size of the tit-lark; length five inches and a half. Inhabits Europe. This bird visits us in spring, and departs in September. It frequents orchards and groves, and will make its nest on the limb of some fruit-tree nailed against the wall, or in a hole, sometimes in out-buildings, on the end of a beam or rafter, and at other times against the body of a large tree, on the stump of a decayed branch. The nest is formed of bents, moss, and such materials, interwoven with spiders webs, and lined with feathers. The female lays four or five eggs, not much unlike those of the redbreast, but rather less, and the rust-coloured spots more distinct, and not so much confined to the larger end. Its food seems to be entirely winged insects, though it is said to be particularly fond of cherries, probably from the circumstance of its frequenting the cherry tree for the sake of flies that are attracted by the fruit. As soon as the young birds leave the nest, they are led by the old ones to some neighbouring wood or grove where insects abound, and where they may be seen darting in every direction in pursuit of flies, and frequently returning to the same station. The note of this species is a simple weak chirp, not frequently used till after the young are fled, so that the bird, though not uncommon, is not readily discovered. 840 *Grisola.*

Desert fly-catcher.—Body ferruginous and sooty; wings and tail blackish; bill yellowish. Inhabits the deserts of Arabia. 841 *Deserti.*

Gen.

Passeres.

Gen. 87. Motacilla.

842 Motacilla. Bill subulated, straight; the mandibles nearly equal; nostrils obovate; tongue lacerated at the end.

843 Characters. Most of this genus feed on insects; a few are gregarious; and on the approach of winter, migrate to warmer climates.

844 Luscinia. *Nightingale.*—Rufous-ash, white-ash beneath; tail feathers rufous-brown; bracelets cinereous; bill brown; head and back pale mouse-colour, with olive spots; tail red-mouse colour; legs and quill feathers brown-ash, the latter chesnut on the outer edge. About the size of the sky-lark, but of a more slender and elegant form. Weighs six drams; and measures between six and seven inches in length. There is a variety with the body somewhat larger, and another that is entirely white. Inhabits Europe, Asia, and Africa. Appears in England sometimes in April, but most commonly not till the beginning of May. The females do not arrive till a week or ten days after the males; so that on the first arrival of these birds none but males are caught, a circumstance which has given rise to the supposition, that the proportion of males exceeds that of females. The nightingale is said to be found as far north as Yorkshire, and certainly not farther west than the eastern borders of Devonshire; it is plentiful both in Somersetshire and Dorsetshire. This bird resides wholly in woods and thickets, and is seldom seen. About the latter end of May it prepares a nest of dry leaves, generally of the oak, and lined with dry grass, usually placed on the ground, among the same materials of which it is composed, so that it is not readily discovered. The eggs are four or five, of an uniform brown colour, and rather larger than those of the hedge-sparrow. As soon as the young are hatched, the song of the nightingale ceases; and it is a mistaken notion that this, or any of the later breeding birds, have a second brood in the same season, except when some accident has befallen the first. The young are not easily reared in confinement. At first they are fed with meal-worms, and afterwards with boiled sheep's heart. The winter residence of this bird is said to be in Asia. The sweetness and variety of its notes have been universally admired, and the more so, perhaps, because they are uttered in the silence of night. In a wild state, it does not sing above ten weeks in the year, while those confined in a cage continue their song for nine or ten months. The honourable Daines Barrington once kept a very fine nightingale for three years, during which time he paid particular attention to its song. Its tone was infinitely more mellow than that of any other bird, though at the same time, by a proper exertion, it could be very brilliant. When it *sung its song round*, in its whole compass, he observed sixteen different beginnings and closes; at the same time that the intermediate notes were commonly varied in their succession with so much judgment as to produce the most pleasing variety. Sometimes it would continue its song twenty seconds without a pause; whenever respiration, however, became necessary, it was taken as skilfully as by an opera singer. Nightingales will also adopt the notes of other birds, may be instructed to sing by turns, with a chorus, and even to articulate words. The London bird-catchers take them by net-traps, baited with meal-worms from the bakers shops. It is with great difficulty that the old birds are induced to sing after being taken; for a considerable time they refuse to eat; but by great attention to their treatment, and avoiding every thing that might agitate them, they at length resume their song, and continue it during the greater part of the year.

Hang-nest warbler.—Greenish-brown above, tawney beneath; ocular line, and one beneath, black. Size of a robin-redbreast. Inhabits Jamaica, and builds a hanging nest. 845 Calidris.

Hedge-sparrow, or *hedge-warbler.*—Gray-brown above; wing-coverts tipt with white; breast bluish-ash; bill blackish; cheeks striped with white; feathers of the back and wing-coverts edged with chesnut; wings and tail dusky; rump greenish brown; chin and breast cinereous; belly whitish; vent yellowish; legs flesh-coloured Length five inches and three quarters; weight nearly six drams. Inhabits Europe; and is one of the few of the warbler tribe that remains with us the whole year. It has a pleasing plaintive song, which it begins with the new year, if the weather is mild, breeds early, making, in March, a nest composed of green moss and wool, and lined with hair, which is placed in some low evergreen shrub, thick bush, or cut hedge, and sometimes in faggot piles. The female lays four or five blue eggs. In default of insects and worms, the hedge-sparrow will pick up crumbs of bread, and seems to prefer situations near the habitation of man. The cuckoo frequently makes choice of this bird's nest for the purpose of depositing its egg. 846 Modularis.

Lesser petty-chaps.—Greenish-ash above, yellowish beneath; belly whitish; limbs brown; eyebrows whitish; upper mandible black, lower bluish; inside of the mouth red; a yellowish line above and beneath the eyes; quill and tail feathers mouse-coloured, and edged with greenish; the shafts black; lower wing-coverts yellow; belly silvery. Weight about two drams; length rather more than four inches and a half; size inferior to that of the yellow wren, which it much resembles in plumage, and with which, and the wood-wren, it has been often confounded. It is the first of the warblers that visits us in the spring, being generally heard on or before the first of April, repeating its song, if so it may be called; for it consists only of two notes, which seem to express the words *chip*, *chop*, four or five times successively. It is a busy, restless bird, always active among the trees and bushes, in search of insects. The nest is oval, with a small hole near the top, composed externally of dry leaves and coarse dry grass, and lined with feathers. For the most part, it is placed on, or near the ground, frequently on a ditch-bank, or in a tuft of grass or low bush. The eggs are five or six, white, speckled with purplish-red at the larger end only, with here and there a single speck on the sides. This species is found in almost every part of the country where wood or hedges can shelter it. Its note is heard long after the yellow wren is silent; and it remains with us, not unfrequently, till the latter end of October. 847 Hippolais.

Wood-wren.—Olive-green above; throat and cheeks yellow; belly and vent fine silvery; tail feathers brown, and, except the first, green on the outer webs, and white on the inner; bill horn-colour; irides hazel; breast pale-yellow; a yellow line through the eye; tail somewhat forked, and brown; under part of the shoulder bright yellow; legs horn-colour. Weight about two drams 848 Sylvatica.

Passeres. drams and forty grains; length five inches and a quarter. The female is rather larger. This is a migrative species, appearing about the end of April, and departing in September. The females arrive ten days or a fortnight after the males. From its great similitude to the yellow wren, it has been little noticed as a distinct species, but is far from uncommon in some parts of England. It seems partial to oak and beech woods, where it may be found by its singular note, expressive of the word *twee*, drawn out to some length, and repeated five or six times in succession, terminating with the same notes, delivered in a hurried manner, and accompanied by a shaking of the wings. The nest, which is oval with a small hole near the top, is constructed of dry grass, a few dead leaves, and a little moss, and is invariably lined with finer grass and a few long hairs. It is placed on the ground, and contains six white eggs, sprinkled all over with purplish spots.

849 *Hortensis.* *Petty-chaps*, or *greater petty-chaps*.—Gray-brown above, white beneath; eyebrows whitish; quill feathers brown-ash, edged with gray, the outmost on the outer web, and near the tip on the inner, whitish; bill blackish; lateral tail feathers edged with gray-brown; legs brown. Length six inches; weight about five drams. Inhabits Europe; and occurs during summer in Lancashire, and in some of the southern counties of England. It chiefly frequents thick hedges, where it makes a nest composed of goose-grass, and other fibrous plants, flimsily put together, with sometimes an addition of a little green moss externally. It usually contains four eggs, about the size of the hedge-sparrow's, of a dirty white, blotched all over with light brown, especially at the larger end, where spots of ash-colour also appear. The song of this species is little inferior to that of the nightingale. Some of the notes are sweetly and softly drawn, others quick, lively, loud, and piercing, reaching the distant ear with pleasing harmony, not unlike the blackbird's whistle, but in a more hurried cadence. It frequently sings after sunset.

850 *Salicaria.* *Sedge warbler*.—Cinereous above, white beneath; eyebrows white; bill black; head brown, with dusky streaks; hind part of the neck and back reddish-brown; back spotted with black; tail coverts tawney; wing-coverts dusky, edged with pale brown; tail brown and wedged; legs dusky. Weight about three drams; length five inches and a half. Inhabits sedgy situations in Europe. It comes to us about the middle of April, and leaves us again in September. It has a variety of notes, which it utters in a hurried manner, and which partake of those of the sky-lark and swallow, as well as of the chatter of the house-sparrow. It is frequent by the sides of rivers and watery places, where sedges and reeds grow, among which it makes a nest, composed of a little moss, intermixed with dry stalks, and lined with dried grass, and occasionally a few hairs, sometimes fastened between two or three reeds, sometimes placed on a tuft of rushes, and fastened round the bottom of them, and at other times, in a low bush, or on the trunk of a willow. The eggs are five or six, of a light-brown colour, mottled with darker shades of the same. Various authors have erroneously ascribed the song of this warbler to the reed-bunting, which has no notes that deserve the name of song, a mistake which has originated from both species breeding in the same places, and the reed-bunting being conspicuous on the upper branches of a tree, while the little warbler, concealed in the thickest part, is heard aloud. It has been remarked, that if it be silent, a stone thrown into the bush, will make it begin singing instantly, and that it will also sing during a moon-light night.

White-throat.—Cinereous above, white beneath; first tail feathers longitudinally half-white, the second tipt with white; bill black, white at the base; head brownish-ash; back reddish. Female, with the breast and belly snowy. There is a variety that is reddish-ash above, and reddish-white beneath, with the throat white; the outmost tail feathers on the upper part of the inner side, and whole of the outer side white. Weight about four drams; length five inches and three quarters. Inhabits Europe, and is very common in our inclosed countries. It arrives about the middle of April, and enlivens our hedges with its song, when it erects the feathers on the crown of the head. The nest is made of goose-grass, lined with fibres, and sometimes a few long hairs, but is of so flimsy a texture that it can afford little warmth to the eggs or young. It is generally placed in some low bush, among nettles or other luxuriant plants. The eggs are four or five, of a greenish-white, and speckled all over with light brown or ash-colour. The white-throat feeds on insects and berries, and frequents our gardens in the summer, for the sake of cherries and currants. 851 *Sylvia.*

Lesser white-throat.—Brown-ash, dirty-white beneath; two middle tail feathers shorter and subulated; bill dusky, the base beneath yellowish; irides dusky; crown deeper than the body; legs brown. Scarcely five inches long. Though not so common as the preceding, it occurs in many of the hedges of Gloucestershire and Wiltshire; builds in low shrubs, and has a shrill whistling note. 852 *Sylviella.*

Epicurean warbler.—Brownish, white beneath; breast spotted with cinereous. About five inches long. Inhabits Europe. Its flesh is reckoned delicious. 853 *Ficedula.*

Dartford warbler.—Chesnut above, ferruginous beneath; middle of the belly, edge of the quill feathers, spurious wings, and outside of the outmost tail feather white; eyebrows red; bill black, the base beneath white; irides scarlet; tail black, and as long as the body; legs yellow. Inhabits Provence, and rarely England. A pair were shot on a common near Dartford in 1773, and others have since been observed about Falmouth, Wandsworth, &c. As yet the nest and eggs are unknown. It is rather larger than the common wren, and five inches and a half in length. It is a shy bird, concealing itself among the thickest furze, on the least alarm, and creeping from bush to bush. The shortness of the wing, and length of tail give it a singular manner of flying, which is in short jerks, with the tail thrown up. Its note is a weak but shrill piping noise, several times repeated. 854 *Provincialis.*

Pensile warbler.—Gray, yellow beneath; belly and eyebrows white; lores spotted with yellow; wing coverts with alternate white and black bands. Nearly five inches long. Inhabits St Domingo, and some of the West India islands, where it feeds chiefly on insects and fruits; and has a very delicate song, which is continued throughout the year. "The sagacity displayed by this bird (says Mr Bingley), in building and placing its nest, is truly remarkable. She does not fix it at the forking of the branches, as is usual with most other birds, 855 *Pensilis.*

birds, but suspends it to binders hanging from the netting, which she forms from tree to tree, especially those which fall from branches that hang over the rivers and deep ravines. The nest consists of dry blades of grass, the ribs of leaves, and exceedingly small roots interwoven with the greatest art; it is fastened on, or rather it is worked into, the pendant strings. It is in fact a small bed rolled into a ball, so thick and compact as to exclude the rain; and it rocks in the wind without receiving any harm. But the elements are not the only enemies against which this bird has to struggle; with wonderful sagacity it provides for the protection of its nest from other accidents. The opening is not made on the top nor side of the nest, but at the bottom. Nor is the entrance direct. After the bird has made its way into the vestibule, it must pass over a kind of partition, and through another aperture before it descends into the abode of its family. This lodgment is round and soft, being lined with a species of lichen, which grows on the trees, or with the silky down of plants."

856 *Alba.* *White* or *water wagtail;* provincially, *dishwasher*, or *washerwoman.*—Breast black; two lateral tail feathers obliquely half white; bill, hind head, nape, throat, and legs black; front, orbits, sides of the neck, and belly white; body cinereous above; greater quill feathers blackish; secondary, and wing-coverts dusky, and edged with gray; middle tail feathers black, and edged with gray. Female with the crown brown. Weight nearly six drams; length seven inches and a half. This species inhabits almost every where; is a very active bird, and continually in motion, running after flies. In this country, as the weather becomes severe, it is apt to haunt marshes that are subject to the flow of the tide. Early in spring they return to their usual summer situation; and from the number which are sometimes seen together at this time attending sheepfolds and newly ploughed fields, we may presume that they are gregarious in their flights. In the breeding season they seem to prefer pleasure grounds that are constantly mowed, on which they run unencumbered, and where the insects have not sufficient cover to evade their sight. The nest is found in various places, sometimes on the ground, in a heap of stones, the hole of a wall, or on the top of a pollard tree. It is composed of moss, dried grass, and fibres, put together with wool, and lined with feathers or hair. The eggs are four or five, white, and spotted all over with light brown and ash-colour; weighing about forty grains, and much resembling that of the cuckoo, which bird frequently makes choice of the wagtail's nest, in which to deposit her egg. It sings very prettily early in spring, and frequently gives the alarm on the appearance of a hawk, which it pursues in company with the swallows. The young birds have no black on the throat till the returning spring, and the old ones lose it in winter. In this state they have been erroneously described as a variety.

857 *Flava.* *Yellow wagtail.*—Breast and belly yellow; two lateral tail feathers obliquely half white; bill and legs black; hind claw very long; body olive above; band through, and one beneath the eyes, black; throat with a few black spots; middle and greater wing-coverts black, edged with yellowish; tail black. Female with whitish eyebrows. Length six inches and a half. Inhabits Europe and Asia. Visits this country in April, and departs in September. It frequents arable land, especially in the more champaign parts, and sometimes uncultivated ground, interspersed with furze. It is also partial to bean fields; and breeds in all such situations, being more negligent of water than the white or gray wagtail. The nest is always placed on the ground, composed of dried stalks and fibres, and lined with hair. The eggs are four or five; not very unlike those of the sedge warbler. Its note is more shrill than that of the white, and less so than that of the gray wagtail.

858 *Oenanthe.* *Wheatear.*—Back hoary; front, line above the eyes, rump, and base of the tail white; a black band through the eyes; crown, neck, and back reddish-gray; eyebrows, rump, upper tail coverts, and upper half of the tail white; lower half, legs, and quill feathers black, the latter edged with reddish-brown; body yellowish-white beneath. The female wants the line over the eyes. There are, however, several varieties. Weighs about six drams and a half; length near six inches and a half. Inhabits Europe, Asia, and Africa. This bird visits England annually in the middle of March, and leaves it again in September. In some parts they are found in great plenty, and are much esteemed. About Eastbourne in Sussex, they are taken in snares made of horse-hair, placed beneath a long turf. Being naturally very timid, the motion even of a cloud, or the appearance of a hawk, will immediately drive them into the traps. These last are first set, every year on St James's day, the 25th of July; soon after which they are caught in astonishing numbers, considering that they are not gregarious, and that more than two or three are scarcely ever seen flying together. The number annually ensnared in the district of Eastbourne alone, is said to amount to nearly two thousand dozen. The birds caught are chiefly young ones; and they are invariably found in the greatest number when an easterly wind prevails. They are very fat in autumn, and esteemed a great delicacy, little inferior to the ortolan. They live chiefly on insects and earth worms, frequent open stony places, warrens, downs, &c. and breed in stone walls, old rabbit holes, or under stones, making a large nest of dry grass, rabbit's down, feathers, and horse-hair. The female lays five or six eggs, of a uniform pale-blue colour. The wheatear sings prettily, and not unfrequently on wing, hovering over the female.

859 *Rubetra.* *Whinchat.*—Blackish; eyebrows white; wings with two white spots; chin and breast yellowish; bill and legs black; chin white; tail white; the lower third part blackish; two middle feathers all blackish. Weighs about four drams and a half; length full five inches. Inhabits Europe, and appears in this island about the middle of April, frequenting the same places with the stonechat, and corresponding with it in most of its habits.

860 *Rubicola.* *Stonechat*, or *moor titling.*—Gray, pale rufous beneath; throat with a white band; lores black; bill and legs blackish; head and neck nearly black; body above blackish, varied with pale rufous; breast and belly reddish yellow; vent and rump white; tail feathers black, the two outmost, on the outer edge and tip, pale ferruginous; quill feathers black, edged with ferruginous; those next the body at the base, and wing-coverts, with a white spot. Female varied with blackish and reddish. Weight about five drams; length five inches and a quarter. Inhabits hedges and dry moors in Europe and Siberia. Feeds on insects and worms, and frequently

Passeres. ly sits on the uppermost sprays, darting at every fly that passes. The nest is placed on, or very near the ground, at the bottom of a furze bush, or some similar situation, is composed of moss and bents, lined with hair, and sometimes mixed with small feathers. The eggs are five, of a blue colour, with small rufous spots at the larger end. When the young leave the nest, the old birds are extremely bold and clamorous, and are as artful in enticing any one from their young as they are in concealing their nest. In the early part of the spring, the stonechat sings very prettily, springing into the air, and suspending itself for some time on wing. But as it breeds so early, its song is of short duration.

861 Atricapilla. *Blackcap.*—Brick-colour above, cinereous beneath; cap dusky-black; bill brown; crown black, in the female chesnut; body greenish-ash above, gray beneath, gradually growing white; temples gray; quill and tail feathers brown-ash, edged with greenish-ash, the middle ones very short; legs lead colour. Of this species there are at least three or four varieties. Length full six inches. Inhabits Europe. It is a migrative bird, visiting us early in the spring and retiring in September. It frequents woods and thick hedges, and seems very partial to orchards and gardens, where it delights us with its charming melodious song, which is very little inferior to that of the nightingale, except in variety of notes. It makes a nest in some low bush or shrub, composed of dried stalks, generally of goose-grass, put together with a little wool, and sometimes a little green moss on the outside, and lined with fibrous roots, on which are frequently placed a few long hairs. The eggs are four or five, of a pale reddish-brown, mottled with a deeper colour, and sometimes sprinkled with a few ash-coloured spots. On the first arrival of this bird it feeds greedily on ivy berries, but forsakes that food as soon as the vernal sun has roused the insect tribe.

862 Spinicauda. *Thorn-tailed warbler.*—Chesnut, white beneath; crown spotted with yellow; face and eyebrows yellow; wing coverts rufous, varied with brown; the greater and quill feathers brown; tail wedged, the feathers daggered. Four inches and a half long. Inhabits Terra del Fuego.

863 Minima. *Least warbler.*—Pale brown, whitish beneath; bill and very short tail yellowish. Three inches long. Inhabits New Holland.

864 Phœnicurus. *Redstart.*—Throat black; belly and tail rufous; head and back hoary; front white; bill, cheeks, and legs, black; belly white; rump, breast, and lateral tail feathers rufous; the middle ones brown; wings brown. Female with the crown and back gray-ash; and chin white. Five inches and a quarter long. Inhabits Europe. It is seen in this country only in spring and summer. It builds in holes of walls, or even of houses, or in hollow trees; and lays four or five eggs. It sings prettily, and imitates the notes of other birds. It is less than the redbreast, and moves its tail horizontally.

865 Suecica. *Blue-throated warbler.*—Breast ferruginous, with a blue band; tail feathers brown, ferruginous towards the tip. Size of the redbreast. Inhabits Europe and Siberia. Sings sweetly, and does not migrate.

866 Cyanea. *Superb warbler.*—Black blue above, white beneath; feathers of the head long, lax, and turgid; front, cheeks, and lunule on the neck fine blue. Five inches and a half long. Inhabits New Holland.

867 Arundinacea. *Reed wren.*—Olive-brown above, whitish beneath; lores and orbits whitish-brown; band in the middle of the wings tawney-yellow beneath; tail brown, slightly wedged; under part of the toes greenish-yellow. Upper mandible horn-colour, lower flesh-colour; mouth orange; irides brown; chin white; legs pale-olive. Length scarcely five inches and a half; weight nearly three drams. Has often been confounded with the sedge warbler, to which it is nearly allied in form, size, and habits; but it may at once be distinguished by the greater broadness of the base of the bill, by the want of a light stroke over the eye, and having the upper parts of one plain colour. The nest and eggs are also different. The former is composed of long grass, and the seed-branches of reeds, and lined with the finer parts of the latter. It is very deep, and is generally fastened by long grass to several reeds, which are drawn together for that purpose. The eggs are four or five, rather larger than those of the sedge-warbler, of a greenish-white, blotched all over with dusky brown. This species inhabits near Uxbridge, in the fens of Lincolnshire, and in many parts of the south of England and Wales; arriving about the end of April, or beginning of May, and departing again in September.

868 Rubecola. *Redbreast*, or *robin redbreast.*—Gray; throat and breast ferruginous; bill and legs dusky; tail feathers terminating in an acute angle; belly white; edges of the quill feathers inclining to yellow. There is a variety with a white chin; wing-coverts varied with white, black, and rufous; quill and tail feathers black, and edged with rufous; and another that is entirely white. This well-known species is a constant inhabitant of most parts of the European continent, and appears about our dwellings in winter, when the woods and fields are destitute of insects. "When the cold grows more severe (says Buffon), and thick snow covers the ground, it approaches our houses, and taps on the window with its bill, as if to entreat an asylum, which is cheerfully granted; and it repays the favour by the most amiable familiarity, gathering the crumbs from the table, distinguishing affectionately the people of the house, and assuming a warble, not indeed so rich as that of the spring, but more delicate. This it retains through all the rigours of the season; to hail each day the kindness of its host, and the sweetness of its retreat. There it remains tranquil till the returning spring awakens new desires, and invites to other pleasures: it now becomes uneasy, and impatient to recover its liberty." The redbreast generally builds its nest by the roots of trees, in some concealed spot near the ground, composing it of dried leaves mixed with hair and moss, and lined with feathers. The female lays from five to seven eggs, which are whitish, and spotted with rust-colour, and cinereous. In order the more successfully to conceal its nest, we are told, that it covers it with leaves, suffering only a narrow winding entrance under the heap to be left. This bird feeds principally on insects and worms: and its delicacy in preparing the latter is somewhat remarkable. It takes a worm by one extremity, in its beak, and beats it on the ground, till the inner part comes away; then taking it in the same manner by the other end, it cleanses the outer part, which alone it eats. Besides insects, it is fond of the seeds of the spindle tree. It is a solitary and quarrelsome species, insomuch that two are never seen on the same tree.

869 Troglodytes. *Wren.*—Gray; eyebrows white; wings waved with black

Passeres. black and cinereous; bill dark green; head and body deep reddish brown above; quill feathers alternately barred with black and red; throat yellowish-white; belly and sides crossed with narrow, dusky, and pale reddish-brown lines; tail with dusky bars; legs brownish. Length nearly four inches and a quarter; weight about two drams and three quarters. Inhabits Europe and Asia. Its nest is curiously constructed, and not begun at the bottom, as is the case in most instances, but first traced, as it were, in oval frame-work, and equally fastened in all its parts to a tree, or other support, and afterwards inclosed on the sides and top, a small hole only being left near the latter, for entrance. If the nest is placed under a bank, the top is first begun, and well secured in some small cavity by which the fabric is suspended. The materials are generally adapted to the place; if built against the side of a hay-rick, for example, the nest is composed of hay, if against the side of a tree covered with lichen, it is made of that species of moss, &c. The lining is invariably feathers. The eggs are seven or eight, and sometimes more, white, and sparingly marked with small reddish spots. The song of the wren is much admired, being, though short, a very pleasing warble, and louder than could be expected from the size of the bird. This it continues throughout the year; and it has been heard to sing, with apparent unconcern, even during a fall of snow. It also sings very late in the evening, though not like the nightingale, after dark. The wren feeds on insects, which it finds in sufficient abundance to support life, even in the severest winters.

870 Regulus. *Golden-crested wren.*—Greenish; secondary quill feathers yellow on the outer edge, and white in the middle; crown orange; bill black; crest orange (of the female yellow), each side edged with black; body yellowish-green above, reddish white beneath; wing-coverts dark brown, with two transverse white bars; legs yellow. Inhabits every quarter of the globe. This is the smallest British bird; its weight seldom exceeding eighty grains, and its length three inches and three quarters. It migrates from the Shetland islands in winter, but continues in the Orkneys the whole year. Its song is like that of the common wren, but its voice is weaker. It builds a nest nearly of a round form, with a hole in the side; and lays from six to eight eggs. It erects or depresses the crest at pleasure. Though not uncommon, it often escapes observation, from the smallness of its size. It has also been remarked, that the female, from some cause which has not yet been discovered, is frequently destroyed during the time of incubation; and the nest, with the eggs, left to decay. Mr Montagu communicates the following interesting details relative to a young family of this beautiful species. "When first I discovered the nest, I thought it a favourable opportunity to become acquainted with some of the manners of this minute species, and to endeavour to discover whether the male ever sung by way of instructing the young ones. Accordingly I took the nest when the young were about six days old, placed it in a small basket, and by degrees enticed the old ones to my study window; and after they became familiar with that situation, the basket was placed within the window; then at the opposite side of the room. It is remarkable, that although the female seemed regardless of danger from her affection to her young, yet the male never once ventered within the room; and yet would constantly feed them while they remained at the outside of the window; on the contrary, the female would feed them at the table at which I sat, and even when I held the nest in my hand, provided I remained motionless. But on moving my head one day, while she was on the edge of the nest, which I held in my hand, she made a precipitate retreat, mistook the open part of the window, knocked herself against the glass, and laid breathless on the floor for some time. However, recovering a little, she made her escape, and in about an hour after I was agreeably surprised by her return, and would afterwards frequently feed the young while I held the nest in my hand. The male bird constantly attended the female in her flight to and fro, but never ventured beyond the window-frame; nor did he latterly ever appear with food in his bill. He never uttered any note but when the female was out of sight, and then only a small chirp. At first there were ten young in the nest, but probably for want of the male's assistance in providing food two died. The visits of the female were generally repeated in the space of a minute and a half or two minutes, or upon an average, thirty-six times in an hour; and this continued full sixteen hours in a day, and which, if equally divided between the eight young ones, each would receive 72 feeds in the day; the whole amounting to 576. From examination of the food, which by accident now and then dropt into the nest, I judged from those weighed that each feed was a quarter of a grain upon a medium; so that each young one was supplied with 18 grain weights in a day; and as the young birds weighed about 77 grains at the time they began to perch, they consumed nearly their weight of food in four days at that time. I could always perceive by the animation of the young brood when the old one was coming; probably some low note indicated her near approach, and in an instant every mouth was open to receive the insect morsel. But there appeared no regularity in the supply given by the parent bird; sometimes the same was fed two or three times successively; and I generally observed that the strongest got most, being able to reach farthest, the old one delivering it to the mouth nearest to her, and after each feed she waited a while to see if any *muted*."

Yellow wren.—Dusky green above, yellowish-white beneath; wings and tail brown, and edged with green; 871 Trochilus. eyebrows yellow. Four inches and a half long. Inhabits Europe and America. Frequents wooded and inclosed situations, especially where willows abound. Visits us early in April, and soon begins its usual song, which is short, with little variety. Makes an oval nest, with a small opening near the top, composed of moss and dried grass, and lined with feathers, either in the hollow of a ditch, or in a low bush, close to the ground. The eggs are six or seven, white, and spotted with light rust colour. Has often been confounded with the lesser prettychaps, and the wood wren.

Tailor warbler, or *tailor bird*.—Entirely yellow, and 872 Sutoria. very small, scarcely exceeding three inches in length. Inhabits India. Its nest is composed of two leaves, the one generally dead, which it fixes, at the end of some branch, to the side of a living one, by sewing both together with little filaments (its bill serving as a needle), in the manner of a pouch or purse, and open at the top. Sometimes, instead of a dead and a living leaf, two living

Passeres. ing ones are sewed together, and, when thus connected, seem rather the work of human art than of an uninstructed animal. After the operation of sewing is finished, the cavity is lined with feathers and soft vegetable down. The nest and birds are together so very light, that the leaves of the exterior and more slender twigs of the trees are chosen for the purpose; and, thus situated, the brood is completely secured from the depredations of every invader.

873 Boarula. *Gray wagtail.*—Cinereous above, yellow beneath; first tail feathers entirely, second on the inner side, white; bill and legs brown; chin and throat black; wing-coverts brown, and edged with ash; quill feathers brown, the secondaries white at the base; middle tail feathers black, and edged with greenish. Weighs about five drams; and measures seven inches and three quarters in length. This elegant species inhabits Europe; visits us about the latter end of September, and departs in April. It is much in motion, constantly flirts the tail, seldom perches, frequents waters, makes its nest on the ground, and sometimes on the banks of rivulets, and lays from six to eight eggs, of a dirty white, marked with yellow spots.

874 Pipra.

Gen. 88. Pipra, *Manakin.*

875 Characters. Bill shorter than the head, hard, nearly triangular at the base, and slightly incurved at the tip; nostrils naked; feet gressorial; tail short.

876 Rupicola. Plate CCCCII. fig. 4. *Crested* or *rock manakin.*—Crest erect, edged with purple; body saffron; tail coverts truncated.—Size of a small pigeon; from 10 to 12 inches long; is shy, but may be tamed, if taken young; feeds on small wild fruits, and builds in the clefts of the most remote rocks, laying two white eggs. Inhabits the rocky parts of South America.

877 Manacus. *Black-capped manakin.*—Black above, white beneath; spot on the neck above, and on the wings, white; bill black; legs yellow. Inhabits the woods of Guiana. Is restless and gregarious.

878 Minuta. *Little manakin.*—Gray; head black, speckled with white. Size of a small wren. Inhabits India.

879 Musica. *Tuneful manakin.*—Black above, orange beneath; front and rump yellow; crown and nape blue; chin and throat black. Four inches long. Inhabits St Domingo. Is very shy, and easily eludes the vigilance of such as attempt to take it. Its note is musical, and forms a complete octave, one note succeeding another.

880 Parus.

Gen. 89. Parus, *Titmouse.*

881 Characters. Bill very entire, narrow, somewhat compressed, strong, hard pointed, and covered at the base with bristles; tongue truncated, and bristly at the end; toes divided at the origin, the hind ones large and strong.

This is a numerous and prolific tribe, some of the species laying from 18 to 20 eggs at a time. Most of them feed on seeds, fruits, and insects, and some on flesh. They are particularly fond of the brains of other birds, which they get at by cleaving the skulls of such as they find dead. They are restless, bold, cruel to birds less than themselves, and will attack such as are three times their own size. Their note is generally unpleasant.

882 Cristatus. Plate CCCCI. fig. 5. *Crested titmouse.*—Head crested; collar black; belly white. Nearly five inches long. Inhabits Europe, chiefly in fir woods. Is solitary, and not easily tamed.

Great titmouse, or *ox-eye.*—Head black; temples white; nape yellow; bill, chin, and tail black; back and wings olive; rump blue gray; belly greenish yellow, divided in the middle by a band of black, extending to the vent; quill feathers dusky, edged partly with blue, partly with white; exterior sides of the outmost tail feathers white, of the others bluish; inner sides dusky; legs lead-coloured. This species weighs about 10 drams; length five inches and three quarters. It inhabits Europe, Asia, and Africa; and is common in many parts of Britain, frequenting gardens and orchards, where it does much mischief by picking off the tender buds of trees. The nest is made of moss, lined with hair, and placed in the hole of a wall, or of a tree. The female sometimes lays eight or ten eggs, but more commonly six, which are white, spotted with rust-colour, and so exactly like those of the nuthatch, as not to be distinguished from them. The common note of the great titmouse is a sort of chatter; but in the spring it assumes a greater variety, a shrill whistle, and a very singular noise, something like the whetting of a saw: but these cease with incubation. A variety was once killed near Feversham in Kent, that had the bill crossed, as in *loxia curvirostra*. Its characters were olive brown above; dirty yellowish beneath; head black; temples cinereous, and bill forked. 883 Major.

Creeping titmouse.—Bluish; temples, breast, and back yellowish; flanks purplish. Four inches and three quarters long. Inhabits Carolina and Canada. Is constantly running up and down trees in search of insects. 884 Americanus.

Blue titmouse, or *tomtit.*—Quill feathers bluish, the primaries white on the outer edge; front white; crown blue; bill blackish; line from the bill to the eyes, and one surrounding the temples black; back yellowish-green; wing coverts blue; quill feathers black, with dusky edges; tail blue, the middle feathers longer; body whitish-yellow beneath; legs and claws black. Length about four inches and a half; weight three drams. Inhabits Europe. This species would probably be more admired for its beauty, if it was less common. In winter it frequents houses for the sake of plunder, and will devour flesh greedily, whether fresh or putrid. It is also a constant attendant where horse-flesh is kept for hounds, and in the farm-yard, being partial to oats, which it plucks out, and retiring to a neighbouring bush fixes the grain between its claws, and hammers it with the bill, to break the husk. In summer, it feeds chiefly on insects, in search of which it plucks off a number of young buds from the trees. The nest is always made in some hole, either of a tree or wall, composed of moss, and lined with feathers and hair. The eggs are white, and speckled with rust-colour at the larger end. The female is so tenacious of her nest, that she will often suffer herself to be taken rather than quit it, and will frequently return again after being taken out. It menaces every intruder in a singular manner, hissing like a snake, erecting all its feathers, and uttering a noise like the spitting of a cat, biting at the same time, severely, if handled. It has no song, but utters a shrill note quickly repeated. 885 Caeruleus.

Colemouse or *cole titmouse.*—Head black; back cinereous; hind head and breast white; bill and chin black; 886 Ater.

a

Passeres. a broad black stripe beneath the eyes, from the bill to the neck; belly and vent reddish white; wing-coverts gray, tipt with white; quill and tail feathers brownish-ash, edged with gray; legs and claws lead coloured. Weight about two drams and a quarter; length four inches and a quarter. Has frequently been confounded with the *palustris;* but it is not so plentiful a species; keeps more to woods; seems to live entirely on insects, and has also a diffrent note.

887 *Palustris.* *Marsh titmouse.*—Head black; back cinereous; temples white. The markings are, however, very subject to vary; the length is about four inches and a half; and the weight two drams and a half. Inhabits Europe. With the blue species it partakes of flesh, and haunts the oat-ricks. It seems to be partial to low wet ground, where old willow trees abound, in the holes of which it frequently nestles.

888 *Caudatus.* *Long-tailed titmouse.*—Crown white; tail longer than the body; weighs only two drams, and measures five inches and a quarter in length. This very elegant and singular species is confined chiefly to the woods and thickets of Europe and Siberia, where it makes a curious oval nest of lichens, firmly woven together with wool; and having only a small hole on the side, placed in the fork of some bush or branch of a tree. The female lays from nine to seventeen eggs, which are white, and sparingly marked with small rust-coloured spots towards the larger end.

889 *Capensis.* *Cape titmouse.*—Gray ash; quill feathers black, edged with white; tail black above; bill and legs black. Inhabits the Cape of Good Hope. Constructs a luxurious nest of the down of a species of asclepias; near the upper end projects a small tube, about an inch in length, with an orifice about three-fourths of an inch in diameter. Immediately under the tube is a small hole in the side, that has no communication with the interior of the nest. In this hole the male sits at night; and thus both male and female are screened from the weather.

890 *Biarmicus.* *Bearded titmouse.*—Rufous; crown hoary; tail longer than the body; head bearded; vent black; bill pale orange; irides yellow; legs black; tail wedged; whiskers composed of long black feathers; three outer tail feathers black at the base, and whitish at the tips; middle of the breast flesh coloured; sides and thighs pale orange; six inches and a quarter long. Inhabits marshy situations in Europe. Though it breeds with us, and continues the whole year, its history is little known; and authors differ not only with respect to the shape and composition of the nest, but even with respect to the place of nidification.

891 *Pendulinus.* *Penduline titmouse,* or *remiz.*—Head ferruginous; ocular band black; quill and tail feathers brown, and edged on each side with ferruginous; four inches and a half long. Inhabits Europe and Siberia, frequenting watery places for the sake of aquatic insects, on which it feeds. The most curious fact in the history of these birds is the exquisite art displayed in the construction of their nest. They employ the light down found on the buds of the willow, the poplar, and the asper, on thistles, dandelion, &c. With their bill they entwine this filamentous substance, and form a thick close web, almost like cloth. This they fortify externally with fibres and small roots, which penetrate into the texture, and, in some measure, compose the basis of the nest. They line the inside with the same down, but not woven, that their young may lie soft; they shut it above to confine the warmth, and they suspend it with hemp, nettles, &c. from the cleft of a small pliant branch over some stream, that it may rock more gently, assisted by the spring of the branch. In this situation the brood are well supplied with insects, which constitute their chief food, and are at the same time protected from their enemies. The nest sometimes resembles a bag, and sometimes a short purse. The aperture is made in the side, and is almost always turned towards the water. It is nearly round, and only an inch and a half in diameter, or even less, and is often, though not always, surrounded by a brim. These nests are found in the fens of Bologna, Tuscany, Lithuania, Poland, and Germany. The peasants regard them with superstitious veneration, one of them being usually suspended near the door of each cottage, as a charm against lightning. Passeres.

Languedoc titmouse.—Rufous gray; crown hoary; wings and tail blackish, edged with rufous; primary quill feathers edged with white; four inches long. Inhabits France. Builds a strong pendulous nest on the forked branch of a tree. 892 *Narbonensis.*

Amorous titmouse.—Blackish blue; longitudinal spot on the middle of the wings, half yellow and rufous; five inches and a half long. Inhabits Northern Asia, and is remarkable for the mutual affection of the sexes. 893 *Amatorius.*

Gen. 90. HIRUNDO, *Swallow.* 894 Hirundo.

Bill small, weak, curved, subulated, depressed at the base; gape larger than the head; tongue short, broad, cleft; wings long; tail mostly forked. 895 Characters.

The birds of this genus are readily distinguished, not only by their structure, but by their twittering voice, and their manner of life. They fly with great rapidity, seldom walk, and perform all their functions either on the wing or sitting. By means of their wide mouth they easily catch insects (their principal food) in the air, or on the surface of the water. Naturalists have been much divided in their opinions respecting the migration of the swallow tribe. The Hon. Daines Barrington and others have supposed that they do not leave this country, but that they lie concealed and torpid, during winter, under water, in crevices of rocks, holes in sand banks, &c. In confirmation of this opinion they quote instances which appear to be sufficiently well authenticated. But a migration of the greater part of the birds is not to be contradicted, by what seems to be rather the effect of chance than design. Those that have been hatched late, and have not acquired sufficient strength to accompany their companions in their journey, may alone have supplied the above-mentioned instances. Were all to remain, we should undoubtedly be furnished with more numerous and more generally known examples than have hitherto been recorded. The ingenious Mr John Hunter, on dissecting several swallows, observed in them nothing different from other birds in the organs of respiration, and hence inferred, perhaps too hastily, that none of them can remain, for any length of time, under water. That the migration of swallows does, however, really take place, appears to have been fully proved by a variety of well-attested facts, most of which have been observed by navigators, who were eye-witnesses of the flights of these birds, and whose ships have sometimes afforded

Passeres. forded to them resting places in the course of their toilsome progress.

A. *Three toes before, and one behind.*

896 *Rustica.* *Chimney or common swallow.*—Front and chin chesnut; tail feathers, except the two middle ones, with a white spot; bill black; body blackish blue above, whitish beneath; tail very much forked; legs short and blackish; weight between five and six drams; length six inches and a half. Inhabits all the quarters of the world; visits us early in April, if the weather be mild, and retires about the end of September or beginning of October. It is supposed to winter in Senegal, and other warm countries. It has got the name of *Chimney swallow*, from the circumstance of breeding in chimneys. It also nestles on the beams or rafters of out-houses, and sometimes on rocks. The nest is made of mud, plastered together, and lined with feathers, and is open at top. The eggs are four or five, white, and speckled with rusty red. Its velocity of wing and quickness of sight are truly astonishing, and enable it to pursue its prey with precision and effect. When a fly is taken, a smart snap from the bill is to be heard, not unlike the noise of the shutting of a watch case; but the motion of the mandibles is too quick for the eye. Wonderful is the address with which this bird ascends and descends through the passages of a chimney. When hovering over the roof of the funnel, the vibrations of its wings acting on the confined air, occasion a rumbling like distant thunder. It is not improbable that the female submits to the inconvenience of having her nest low down in the shaft, in order to secure her offspring from the birds of prey, particularly from owls, which are frequently found to fall down chimneys, probably in their attempts to get at the nestlings. The progressive method by which the young are introduced to their proper habits, deserves to be noted. They first, though not without difficulty, emerge from the shaft, and, for a day or two, are fed on the chimney top, thence they are conducted to the dead leafless bough of some neighbouring tree, where, sitting in a row, they are attended by the parents with great assiduity. In a day or two after this they are strong enough to fly, but continue still unable to take their own food; they therefore play about near the place where the females are watching for flies; and, when a mouthful is collected, on a certain signal, the dam and the nestling advance, rising towards each other, and meeting at an angle, the young all the while, uttering a short quick note of gratitude and complacency. As soon as the mother has disengaged herself from the first brood, she immediately commences her operations for a second, which is produced about the middle or latter end of August.

897 *Esculenta.* *Esculent swallow.*—Blackish, whitish beneath; all the tail feathers with a white spot; bill black; tail tipt with white; legs brown. Two inches and a quarter in length; in size rather less than the wren. Inhabits China and the islands of the Indian ocean. Many of our readers must have heard of the curious eatable nests of this species. The following is the account given of them by Sir George Staunton. "In the Cass, a small island near Sumatra, were found two caverns, running horizontally into the side of the rock; and in these were a number of those birds nests so much prized by the Chinese epicures. They seem to be composed of fine filaments, cemented together by a transparent viscous matter, not unlike what is left by the foam of the sea upon stones alternately covered by the tide, or those gelatinous animal substances found floating on every coast. The nests adhere to each other, and to the sides of the caverns; mostly in rows, without any break or interruption. The birds that build these nests are small gray swallows, with bellies of a dirty white. They were flying about in considerable numbers; but were so small, and their flight was so quick, that they escaped the shot fired at them. The same sorts of nests are said to be also found in deep caverns at the foot of the highest mountains in the middle of Java, at a distance from the sea: from which source it is thought that the birds derive no materials, either for their food, or the construction of their nests; as it does not appear probable they should fly in search of either, over the intermediate mountains, which are very high, or against the boisterous winds prevailing thereabout. They feed on insects, which they find hovering over stagnated pools between the mountains, and for the catching of which their wide-opening beaks are particularly adapted. They prepare their nests from the best remnants of their food. Their greatest enemy is the kite, who often intercepts them in their passage to and from the caverns, which are generally surrounded with rocks of gray limestone, or white marble. The nests are placed in horizontal rows, at different depths, from 50 to 500 feet. The colour and value of the nests depend on the quantity and quality of the insects caught, and perhaps also on the situation where they are built. Their value is chiefly ascertained by the uniform fineness and delicacy of their texture; those that are white and transparent being most esteemed, and fetching often in China their weight in silver.—These nests are a considerable object of traffic among the Javanese, many of whom are employed in it from their infancy. The birds, after having spent nearly two months in preparing their nests, lay each two eggs, which are hatched in about 15 days. When the young birds become fledged, it is thought the proper time to seize upon their nests, which is done regularly three times a-year, and is effected by means of ladders of bamboo and reeds, by which the people descend into the caverns: but when these are very deep, rope-ladders are preferred. This operation is attended with much danger, and several perish in the attempt. The inhabitants of the mountains, generally employed in this business, begin always by sacrificing a buffalo; which custom is observed by the Javanese, on the eve of every extraordinary enterprise. They also pronounce some prayers, anoint themselves with sweet-scented oil, and smoke the entrance of the cavern with gum-benjamin. Near some of the caverns a tutelar goddess is worshipped, whose priest burns incense, and lays his protecting hands on every person preparing to descend. A flambeau is carefully prepared at the same time, with a gum which exudes from a tree growing in the vicinity, and which is not easily extinguished by fixed air or subterraneous vapours."—The nest of this species generally weighs about half a ounce; and is in shape something like a half lemon. The consistency of the several layers of component matter approaches to that of isinglass, or of fine gum-dragon. Such of these nests as are perfectly free from dirt, are dissolved in broth to thicken it, and are said to give it an exquisite flavour; or they are soaked in

Passeres. in water to soften them, then pulled in pieces, and, after being mixed with ginseng, are put into the body of a fowl. The whole is then stewed in a pot, with a sufficient quantity of water, and left on the coals all night. On the following morning it is ready to be eaten.

898 Urbica. *Martin, martlet, martinet*, or *house martin*.—Bluish-black above, white beneath; tail feathers without spots; bill black; mouth yellow; rump white; legs covered with a short white down. There is a variety that has the quill and tail feathers tipt with white. About five inches and a half, and rather inferior in size to the chimney swallow. Inhabits Europe, Asia, and North America. Visits Britain in spring, rather later than the common swallow, making its first appearance in low, warm situations, and if the weather is fine, beginning to build early in May. It builds a close nest made of straw and clay, and lined with feathers, with a hole at top for admission, in windows, under the eaves of houses, the projecting ornaments of steeples and churches, &c. and sometimes against rocks or cliffs, contiguous to the sea. The eggs are four or five, and pure white. The manners and habits of this well-known species nearly resemble those of the common swallow.

899 Riparia. *Sand martin, bank martin, or shore bird*.—Cinereous; chin and belly white; bill blackish; throat encircled with a mouse-coloured ring; legs black, and downy behind. Four inches and three quarters long. Inhabits Europe and America, in which last country it is called *ground swallow*. In this country it is not so plentiful as the preceding, with which it associates, and which in its manners it much resembles, except that it nestles in the banks of rivers or sand pits, and makes a nest of straw and dried fibres, lined with feathers.

900 Purpurea. *Purple swallow*.—Entirely violet; tail forked; bill black; legs blackish. Female brown. Seven inches and three quarters long. Inhabits Carolina and Virginia, during summer. Is much valued by the inhabitants for its use in alarming poultry on the approach of birds of prey, which it does not only by shrieking, but attacking them with the greatest fury.

901 Subis. Plate CCCCII. fig. 3. *Canada swallow*.—Bluish black; beneath and mouth whitish-ash; belly white, clouded with brown; quill and tail feathers blackish, edged with brown; legs and claws dusky. Eight or nine inches long. Native of Hudson's bay.

902 Ambrosiaca. *Ambergrise swallow*.—Grayish-brown; bill blackish; legs brown. Five inches and a half long. Inhabits Senegal. Smells strongly of ambergrise.

903 Erythrocephala. *Red-headed swallow*.—Dusky-black, the feathers edged with white; under part of the body white; head red. Size of the least humming bird. Inhabits India.

904 Nigra. *Black swallow*.—Entirely black. Six inches long. Inhabits the interior parts of South America, and builds in a deep hole in the ground, with a long entrance.

905 Apus. *Swift, black martin*, &c.—Blackish; chin white. Weight nearly an ounce; length about eight inches. Inhabits almost every where. The swift makes its appearance with us later than any of the other species, being seldom seen till May. It frequents steeples, towers, and other lofty buildings, in the holes of which, or under the tiles of houses and barns, it makes a nest of dried grass, lined with feathers, which it collects on wing, sweeping them off the ground in a dexterous manner. Like the swallow, it sips the water, and at the same time, picks up flies as it skims over the surface. The female lays only two white eggs of an oblong shape, larger than that of the swallow; and while she is sitting, the male is continually flying to and from the spot, making a screeching noise, which is its only note. At night, both sit on the nest, or at least roost in the same hole. In very warm weather, these birds soar to a great height; but in cold or moist weather, fly low in search of flies and other winged insects, which at that time cannot ascend. This species disappears about the middle of August, remaining here no longer than is necessary for its breeding. It is remarkable that it disappears soonest in the best and warmest weather; and that in the very inclement season of 1782, numbers of them were seen in the neighbourhood of Edinburgh, so late as the 25th of August, flying about with their usual spirit and vivacity, when the thermometer stood at 36°. It is neither cold, therefore, nor the want of food, which disposes them to quit us so early. They have the process of moulting to undergo, which cannot be performed in a state of torpor. Their place of retirement, however, has not been ascertained.

White-collared swift.—Blackish-violet; head black; collar bifid; ocular band and thighs white. Five inches and one quarter long. Inhabits Cayenne. Builds a long conical nest, with a division in the middle. 906 Cayennensis.

Gen. 91. Caprimulgus, *Goatsucker*. 907 Caprimulgus.

908 Characters. Bill slightly curved, very small, subulated and depressed at the base; mouth extremely wide, and furnished at the sides with a series of bristles; ears very large; tongue pointed and entire; tail unforked, with 10 feathers; legs short, middle claw with a broad serrated edge.

The birds of this family seldom appear in the day time, except they are disturbed, or in dark cloudy weather, but wander about in the evening, in search of insects. They lay two eggs on the naked ground. The lateral toes are connected to the middle one by a small membrane.

European or *nocturnal goatsucker*; provincially *night or dorrhawk, churn* or *goatowl, wheelbird, nightjarr*, &c.—Black, varied with cinereous, brown, ferruginous and white; beneath reddish-white, with brown bands; irides hazel; legs short, scaly, and feathered below the knees. The male is distinguished from the female by a large oval white spot near the end of the three first quill feathers, and another on the outmost tail feathers. Inhabits Europe, Asia, and America. With us this bird is only a summer visitant, appearing about the middle of May, and departing again the latter end of September, or beginning of October. It makes no nest, but lays two eggs on the bare ground, among fern, heath, or long grass, sometimes in woods or furze, but at all times contiguous to woods, in which it chiefly conceals itself by day. The eggs are larger than those of a blackbird, oblong oval, whitish, and elegantly marbled with light brown and ash-colour. It generally sits on the ground, but if molested, frequently perches on the limb of a tree, most commonly lengthwise, and not across, as is common with most birds. In the dusk of the evening, it begins its flight in pursuit of the larger insects, particularly *scarabæus melolontha*, and *solstitialis*, which rise from their earthy abode about that time. It is also fond of the large-bodied moths, and indeed allows few winged 909 Europæus.

Passeres. winged insects to escape its wide extended gape. It makes a singular noise, like the sound of a large spinning wheel, and which it is observed to utter perched with the head lowermost; besides which, it utters a sharp squeak, as it flies. It has its name from the ancient, but erroneous belief, that it sucked the teats of goats.

910 Grandis. *Great goatsucker.*—Blackish, with small brown spots and streaks; area of the eyes yellowish; legs white; middle claw not serrated. Nearly two feet long. Inhabits Cayenne. The gape of its mouth can readily admit a man's fist.

911 Novæ Hollandiæ. *Crested goatsucker.*—Waved with brown, black, and whitish; whitish beneath; neck and breast with dusky bands; crest on the front erect, and setaceous. Nine inches and a half long. Inhabits New Holland. No account has hitherto been procured of its manners, except that it appears about our settlement at Port Jackson in March.

912 Longipennis. *Leone goatsucker.*—Variegated gray; wings spotted with rufous and black; a very long naked-shafted feather on each shoulder. "This singular species," says Dr Latham, "is about the size of the *European* one, and not far different from it in the general markings: the length from the bill to the end of the tail is eight inches and a quarter; but the remarkable circumstance belonging to it, is the having a single feather springing out of the middle part of the coverts of each wing, full 29 inches in length: this continues as a plain unwebbed shaft for 14 inches and three quarters, having a few solitary hairs, on the inside only; from thence it expands into a broad web for the remaining five inches and a quarter of its length. This part is mottled, not unlike the darker part of the rest of the plumage, and crossed with five dusky bars; the web or blade has almost the whole of its breadth on the inner side, being there more than one inch broad, but very narrow on the outer part of the shaft; the legs are small. Inhabits Sierra Leona in Africa; several of them have been brought into England," &c.—The same bird is described by Dr Shaw in his *Naturalists Miscellany*.

913 Menura. We have purposely reserved for an Appendix, the following description of *menura superba*, a bird of New South Wales, by Major-general Thomas Davies, F. R. and L. S.

"Menura.

Char. gen. *Rostrum* validiusculum, convexo-conicum.
Nares ovatæ in medio rostri.
Rectrices elongatæ, pinnulis decompositis; intermediæ duæ longiores angustæ, exteriores ad apicem patulæ, revolutæ.
Pedes validi ambulatorii.

Menura Superba.

"The total length of this singular bird, from the point of the bill to the end of the broad tail feathers, is 43 inches; 25 of which are in the tail alone. The bill rather exceeds an inch in length, is strong, formed much like that of a peacock, and black, with the nostrils, which are long open slits, rather large, placed near the middle of its length; the head, which is somewhat crested at the hind part, neck, shoulders, back, upper tail coverts, and upper surface of the tail-feathers, of a dark brownish-black; throat rufous, reaching some way down the middle of the neck; breast, belly, and vent gray; the feathers of the latter are long, very soft, and of a silky texture; thighs nearly of the same colour, rather long, and feathered down to the knee; scapulars of a brownish tinge; upper tail coverts and prime quill feathers, which are somewhat curved at the ends, brown black; edges of the quills gray; the legs long and very strong, covered with large scales, especially in front; the feet, which are likewise large, and the nails, are black; the last somewhat crooked, convex above and flat beneath; the hind nail near three quarters of an inch long.

Appendix.

"The tail consists in the whole of 16 feathers; all of which, except the two upper or middle ones, and the two exterior on each side, have long slender shafts furnished on each side with delicate long filaments, four inches or more in length, placed pretty close towards the rump, but more distant from each other as they approach the extremity, and resemble much those of the greater Paradise bird. The two middle or upper ones are longer than the rest, slender, narrow at the base, growing wider as they approach the ends, which are pointed; webbed on the inner edge all the way, and furnished with some distant hair like threads near the end on the outer side, of a pale gray colour beneath, and brown black above, as is the rest of the tail. The two exterior feathers on each side are of an extraordinary construction, rather more than an inch wide at the base, and growing wider as they proceed to the ends, where they are full two inches broad and curve outwardly; the curved part is black with a narrow white border; the quills of these feathers are double for two-thirds down from the rump. The general colour of the under sides of these two feathers is of a pearly hue, elegantly marked on the inner web with bright rufous coloured crescent-shaped spots, which from the extraordinary construction of the parts, appear wonderfully transparent, although at first sight seemingly the darkest; they are also elongated into slender filaments of an inch or more, especially towards the extremities.

"The figure of the male, which accompanies this description, was taken from a specimen sent from New South Wales as a present to Lady Mary Howe. I have also seen two other specimens in the possession of the right hon. Sir Joseph Banks, which I believe have since been deposited in the British Museum.

"Since I had the honour of communicating to the Linnæan Society the foregoing description of the *menura*, I have been favoured with both male and female of that extraordinary bird from my friend Governor King, by the Buffalo store ship; and I am thereby enabled to lay before the society a description of the different sexes. I find, indeed, that, with a little deviation, the same characters and colours will serve for both of them. The female, however, is somewhat smaller, being in length, from the crown of the head to the end of the tail, only 31 inches. The general plumage of the whole bird is of a dull blackish colour, a little rufous under the chin and throat, and of a brownish cast on the scapulars, as in the male. The plumage of the whole body, from the breast to the vent, and from the shoulders to the rump, is composed of long, slender, thread-like, silky feathers, resembling fringe, of a dull grayish-black; lighter on the breast, belly, and vent. The bill and legs, which are strong and furnished with large scales, as in the cock, are black. From the head to the rump 14 inches; the tail 18 inches, also of a dull brown black colour

Appendix. colour above and gray beneath; the two upper tail feathers are sharp-pointed at the ends; the rest are rounded and darker in colour, and shorter by degrees, as they approach the rump, so as to appear cuneated; the two outer feathers are shorter than the rest, but in form like those of the male, brown black above, of a pearly gray beneath; and the crescents, which are of a deeper rufous colour, are not so visible nor so large, but more transparent, if posible, than those of the cock. They are about an inch and a half broad, and not black or longer at the ends as in the other sex.

"From these birds being found in the hilly parts of the country, they are called by the inhabitants the *mountain pheasant.* With respect to their food or manners, I have not as yet obtained any particular account. In my specimens, there is a nakedness round the eyes, but whether this is from the feathers having fallen off I know not. I rather think otherwise, and that it may be brightly coloured as in many other birds."

For the most recent additions to Ornithology, see ZOOLOGY and VERTEBROSA, SUPPLEMENT.

INDEX.

ORNITHOMANCY, a species of divination performed by means of birds; being the same with augury. See DIVINATION and AUGURY.

ORNITHOPUS, a genus of plants belonging to the diadelphia class; and in the natural method ranking under the 32d order, *Papilionaceæ*. See BOTANY *Index*.

ORNITHORYNCHUS PARADOXUS, one of the most extraordinary animals of the mammalia class yet known, particularly for the singular conformation of its head, which is the perfect resemblance of the beak of a duck ingrafted on the head of a quadruped. See MAMMALIA *Index*.

ORNUS FRAXINUS, is that species of the ash tree, in the Linnæan system, which, according to Dr Cirillo of Naples, produces the manna. See MATERIA MEDICA *Index*.

OROBANCHE, a genus of plants belonging to the didynamia class; and in the natural method ranking under the 40th order, *Personatæ*. See BOTANY *Index*.

OROBIO, DON BALTHASAR, a celebrated Jew of Spain. He was carefully educated in Judaism by his parents, who were Jews, though they outwardly professed themselves Roman Catholics; abstaining from the practice of their religion in every thing, except only the observation of the fast of expiation, in the month Tisis or September. Orobio studied the scholastic philosophy usual in Spain, and became so skilled in it, that he was made professor of metaphysics in the university of Salamanca. Afterwards, however, applying himself to the study of physic, he practised that art at Seville with success, till, accused of Judaism, he was thrown into the inquisition, and suffered the most dreadful cruelties, in order to force a confession. He himself tells us, that he was put into a dark dungeon, so strait that he could scarce turn himself in it; and suffered so many hardships, that his brain began to be disturbed. He talked to himself often in this way: "Am I indeed that Don Balthasar Orobio, who walked freely about in Seville, who was entirely at ease, and had the blessings of a wife and children?" Sometimes, supposing that his past life was but a dream, and that the dungeon where he then lay was his true birth-place, and which to all appearance would also prove the place of his death. At other times, as he had a very metaphysical head, he first formed arguments of that kind, and then resolved them; performing thus the three different parts of opponent, respondent, and moderator, at the same time. In this whimsical way he amused himself from time to time, and constantly denied that he was a Jew. After having appeared twice or thrice before the inquisitors, he was used as follows: At the bottom of a subterraneous vault, lighted by two or three small torches, he appeared before two persons, one of whom was judge of the inquisition, and the other secretary; who, asking him whether he would confess the truth? protested, that in case of a criminal's denial, the holy office would not be deemed the cause of his death if he should expire under the torments, but that it must be imputed entirely to his own obstinacy. Then the executioner stript off his clothes, tied his feet and hands with a strong cord, and set him upon a little stool, while he passed the cord through some iron buckles which were fixed in the wall; then drawing away the stool, he remained hanging by the cord, which the executioner still drew harder and harder, to make him confess, till a surgeon assured the court of examinants, that he could not possibly bear more without expiring. These cords put him to exquisite tortures, by cutting into the flesh, and making the blood burst from under his nails. As there was certainly danger that the cords would tear off his flesh, to prevent the worst, care was taken to gird him with some bands about the breast, which however were drawn so very tight, that he would have run the risk of not being able to breathe, if he had not held his breath in while the executioner put the bands round him; by which device his lungs had room enough to perform their functions. In the severest extremity of his sufferings, he was told that this was but the beginning of his torments, and that he would better confess before they proceeded to extremities. Orobio added further, that the executioner, being on a small ladder, in order to frighten him, frequently let it fall against the shinbones of his legs; so that the staves being sharp, created exquisite pain. At last, after three years confinement, finding themselves baffled by his perseverance in denying his religion, they ordered his wounds to be cured, and discharged him. As soon as he had got liberty,

liberty, he resolved to quit the Spanish dominions; and, going to France, was made professor of physic at Thoulouse. The theses which he made as candidate for this place were upon putrefaction; and he maintained them with so much metaphysical subtlety, as embarrassed all his competitors. He continued in this city for some time, still outwardly professing popery; but at last, weary of dissembling, he repaired to Amsterdam, where he was circumcised, took the name of Isaac, and professed Judaism; still continuing, however, to practise physic, in which he was much esteemed. Upon the publication of Spinoza's book, he despised a system the falseness of which he quickly discovered; and when Bredenbourg's answer to it came to his hands, Orobio, being persuaded that the writer in refuting Spinoza, had also admitted some principles which tended to Atheism, took up his pen against them both, and published a piece to that purpose, intitled, *Certamen philosophicum adversus J. B. Principia*. But the dispute which he held with the celebrated Philip Limborch against the Christian religion made the greatest noise. Here he exerted the utmost force of his metaphysical genius, and carried himself with great temper. The three papers which he wrote on the occasion were afterwards printed by his antagonist, in an account which he published of the controversy, under the title of *Amica Collatio cum Judæo*. Orobio died in 1687.

OROBUS, Bitter Vetch, a genus of plants belonging to the diadelphia class; and in the natural method ranking under the 32d order, *Papilionaceæ*. See Botany *Index*.

ORODES, a prince of Parthia, who murdered his brother Mithridates, and ascended his throne. He defeated Crassus the Roman triumvir, and poured melted gold down the throat of his fallen enemy, to reproach him for his avarice and ambition. He followed the fortune of Cassius and Brutus at Philippi. It is said, that when Orodes became old and infirm, his 30 children disputed in his presence the right to the succession. Phraates, the eldest of them, obtained the crown from his father; and, to hasten him out of the world, he attempted to poison him. The poison had no effect; and Phraates, still determined on his father's death, strangled him with his own hands, about 36 years before the Christian era. Orodes had reigned about 50 years.

ORONOKO, or Orinoco, a large river of South America, which rises in Spanish Guiana, about 5° N. Lat. Its course has a spiral form, running first east, then south, then west, then north, and at last east again. It falls into the Atlantic ocean in N. Lat. 9° after a course of 1400 miles, during which it is joined by several large rivers, which flow eastward from the Andes.

ORONSA, a small fertile island of Scotland, one of the Hebrides, seven miles west of Jura. Here are the ruins of an abbey, with many sepulchral statues, and some curious ancient sculpture.

ORONTIUM, a genus of plants belonging to the hexandria class; and in the natural method ranking under the second order, *Piperitæ*. See Botany *Index*.

ORPHAN, a fatherless child or minor; or one that is deprived both of father and mother.

ORPHEUS, a celebrated poet and musician of antiquity. His reputation was established as early as the time of the Argonautic expedition, in which he was himself an adventurer; and is said by Apollonius Rhodius not only to have excited the Argonauts to row by the sound of his lyre, but to have vanquished and put to silence the Sirens by the superiority of his strains. Yet, notwithstanding the great celebrity he had so long enjoyed, there is a passage in Cicero, which says, that Aristotle, in the third book of his *Poetics*, which is now lost, *doubted if such a person as Orpheus ever existed*. But as the work of Cicero, in which this passage occurs, is in dialogue, it is not easy to discover what was his own opinion upon the subject, the words cited being put into the mouth of Caius Cotta. And Cicero, in other parts of his writings, mentions Orpheus as a person of whose existence he had no doubts. There are several ancient authors, among whom is Suidas, who enumerate five persons of the name of *Orpheus*, and relate some particulars of each. And it is very probable that it has fared with Orpheus as with Hercules, and that writers have attributed to *one* the actions of *many*. But, however that may have been, we shall not attempt to collect all the fables that poets and mythologists have invented concerning him; they are too well known to need insertion here. We shall, therefore, in speaking of him, make use only of such materials as the best ancient historians, and the most respectable writers among the moderns, have furnished towards his history.

Dr Cudworth, in his *Intellectual System* *, after examining and confuting the objections that have been made to the being of an Orpheus, and with his usual learning and abilities clearly establishing his existence, proceeds, in a very ample manner, to speak of the opinions and writings of our bard, whom he regards not only as the first musician and poet of antiquity, but as a great mythologist, from whom the Greeks derived the Thracian religious rites and mysteries.

* Book i. sect. 17.

"It is the opinion (says he) of some eminent philologers of latter times, that there never was any such person as Orpheus, except in Fairy land; and that his whole history was nothing but a mere romantic allegory, utterly devoid of truth and reality. But there is nothing alleged for this opinion from antiquity, except the one passage of Cicero concerning Aristotle; who seems to have meant no more than this, that there was no such poet as Orpheus anterior to Homer, or that the verses vulgarly called *Orphical*, were not written by Orpheus. However, if it should be granted that Aristotle had denied the existence of such a man, there seems to be no reason why his single testimony should preponderate against the universal consent of all antiquity; which agrees that Orpheus was the son of Oegar, by birth a Thracian, the father or chief founder of the mythological and allegorical theology amongst the Greeks, and of all their most sacred religious rites and mysteries; who is commonly supposed to have lived before the Trojan war, that is, in the time of the Israelitish judges, or at least to have been senior both to Hesiod and Homer; and to have died a violent death, most affirming that he was torn in pieces by women, because their husbands deserted them in order to follow him. For which reason, in the vision of Herus Pamphilius, in Plato, Orpheus's soul passing into another body, is said to have chosen that of a swan, a reputed musical animal, on account of the great hatred he had conceived for all women, from the death which they had inflicted on him. And the historic truth of Orpheus was not only acknowledged by Plato, but also by Isocrates, who lived before Aristotle,

stotle, in his oration in praise of Busiris; and confirmed by the grave historian Diodorus Siculus, who says, that Orpheus diligently applied himself to literature, and when he had learned τα μυθολογυμενα, or the mythological part of theology, he travelled into Egypt, where he soon became the greatest proficient among the Greeks in the mysteries of religion, theology, and poetry. Neither was his history of Orpheus contradicted by Origen, when so justly provoked by Celsus, who had preferred him to our Saviour: and, according to Suidas, Orpheus the Thracian was the first inventor of the religious mysteries of the Greeks, and that religion was thence called Θρησκεια, *Threskeia*, as if a Thracian invention. On account of the great antiquity of Orpheus, there have been numberless fables intermingled with his history; yet there appears no reason that we should disbelieve the existence of such a man."

Cudworth is also of opinion, that the poems ascribed to Orpheus were either written by him, or that they were very ancient, and contained his doctrines. He farther argues, that though Orpheus was a polytheist, and asserted a multiplicity of gods, he nevertheless acknowledged one supreme unmade deity, as the original of all things; and that the Pythagoreans and Platonists not only had Orpheus in great esteem, being commonly called by them the *Theologer*, but were also thought in great measure to have owed their theology and philosophy to him, deriving it from his principles and traditions.

The bishop of Gloucester* speaks no more doubtfully of the existence of Orpheus than of Homer and Hesiod, with whom he ranks him, not only as a poet, but also as a theologian, and founder of religion.

* Warburton.

The family of Orpheus is traced by Sir Isaac Newton for several generations · "Sesac passing over the Hellespont, conquers Thrace; kills Lycurgus king of that country; and gives his kingdom and one of his singing women to Oeagrus, the son of Tharops, and father of Orpheus; hence Orpheus is said to have had the muse Calliope for his mother.

He is allowed by most ancient authors to have excelled in poetry and music, particularly the latter; and that to such a degree, that he is represented as taming the most ferocious animals, changing the course of the winds by his melody, and as causing the trees of the forest to dance in concert with his lyre. This account, though we must suppose it fabulous, yet proves his excellence to have been great before he could have given rise to such fictions. He is said to have early cultivated the lyre, in preference to every other instrument: so that all those who came after him were contented to be his imitators; whereas, according to Plutarch, he adopted no model; for before his time no other music was known, except a few airs for the flute. Music was so closely connected in ancient times with the most sublime sciences, that Orpheus united it not only with philosophy, but with theology and legislation. He abstained from eating animal food; and held eggs in abhorrence as aliment, being persuaded that the egg subsisted before the chicken, and was the principle of all existence: both his knowledge and prejudices, it is probable, were acquired in Egypt, as well as those of Pythagoras many ages after.

Burney's Hist. of Music.

With respect to his abstaining from the flesh of oxen, Gesner supposes it may have proceeded from the veneration shown to that animal so useful in tillage, in the Eleusinian mysteries instituted in honour of Ceres, the goddess of agriculture. He might have added, that, as those mysteries were instituted in imitation of those established in Egypt in honour of Osiris and Isis, this abstinence from animal food was of the like origin, and a particular compliment to Apis. But Abbé Fragnir, in an ingenious dissertation upon the *Orphic Life*, gives still more importance to the prohibition; for as Orpheus was the legislator and humanizer of the wild and savage Thracians, who were cannibals, a total abolition of eating human flesh could only be established by obliging his countrymen to abstain from every thing that had life.

With respect to theology, Diodorus Siculus tells us, that his father Oeagrus gave him his first instructions in religion, imparting to him the mysteries of Bacchus, as they were then practised in Thrace. He became afterwards a disciple of the Idæi Dactyli in Crete, and there acquired new ideas concerning religious ceremonies. But nothing contributed so much to his skill in theological matters, as his journey into Egypt; where being initiated into the mysteries of Isis and Osiris, or of Ceres and Bacchus, he acquired a knowledge concerning initiations, expiations, funeral rites, and other points of religious worship, far superior to any one of his age and country. And being much connected with the descendants of Cadmus, the founder of Thebes in Bœotia, he resolved, in order to honour their origin, to transport into Greece the whole fable of Osiris, and apply it to the family of Cadmus. The credulous people easily received this tale, and were much flattered by the institution of the ceremonies in honour of Osiris. Thus Orpheus, who was held in great veneration at the Grecian Thebes, of which he was become a citizen, admirably adapted this fable, and rendered it respectable, not only by his beautiful verses and manner of singing them, but by the reputation he had acquired of being profoundly skilled in all religious concerns. Diodorus Siculus also says that he was a most attentive student in all kinds of literature, whether sacred or profane.

Diod. Siculus, lib. iv. cap. 25.

At his return into Greece, according to Pausanias, he was held in the highest veneration by the people, as they imagined he had discovered the secret of expiating crimes, purifying criminals, curing diseases, and appeasing the angry gods. He formed and promulgated an idea of a hell, from the funeral ceremonies of the Egyptians, which was received throughout all Greece. He instituted the mysteries and worship of Hecate among the Eginetes, and that of Ceres at Sparta.

Justin Martyr says, that he introduced among the Greeks near 360 gods; Hesiod and Homer pursued his labours, and followed the same clue, agreeing in the like doctrines, having all drank at the same Egyptian fountain.

Profane authors look upon Orpheus as the inventor of that species of magic called *evocation of the manes*, or raising ghosts; and indeed the hymns which are attributed to him are mostly pieces of incantation, and real conjuration. By all accounts he was an admirable musician: he is said to have received a lyre from Apollo, or according to some from Mercury, upon which he played with such a masterly hand, that even the most rapid rivers ceased to flow, the savage beasts of the forest

Orpheus. rest forgot their wildness, and the mountains came to listen to his song. All nature seemed charmed and animated, and the nymphs were his constant companions. Eurydice was the only one who made a deep impression on the melodious musician, and their nuptials were celebrated. Their happiness, however, was but short; for Aristæus became enamoured of her; and as she fled from her pursuer, a serpent that was lurking in the grass bit her foot, and she died of the poisoned wound. Her loss was severely felt by Orpheus, and he resolved to recover her or perish in the attempt. With his lyre in his hand, he entered the infernal regions, and gained an easy admission to the palace of Pluto. The king of hell was charmed with the melody of his strains; and according to the beautiful expressions of the poets, the wheel of Ixion stopped; the stone of Sisyphus stood still; Tantalus forgot his perpetual thirst, and even the furies relented. Pluto and Proserpine were moved with his sorrow, and consented to restore him Eurydice, provided he forbore looking behind him till he had come to the extremest borders of hell. The conditions were gladly accepted, and Orpheus was already in sight of the upper regions of the air, when he forgot his promise, and turned back to look at his long lost Eurydice.

All dangers past, at length the lovely bride
In safety goes, with her melodious guide;
Longing the common light again to share,
And draw the vital breath of upper air:
He first, and close behind him followed she;
For such was Proserpine's severe decree.
When strong desires th' impatient youth invade;
By little caution, and much love betrayed:
A fault which easy pardon might receive,
Were lovers judges, or could hell forgive.
For near the confines of etherial light,
And longing for the glimm'ring of a sight,
Th' unwary lover cast a look behind,
Forgetful of the law, nor master of his mind.
Straight all his hopes exhal'd in empty smoke;
And his long toils were forfeit for a look.

DRYDEN's Virgil.

He saw her, but she instantly vanished from his eyes: He attempted to follow her, but he was refused admission; and the only comfort he could find was to soothe his grief at the sound of his musical instrument in grottoes or on the mountains. He totally separated himself from the society of mankind; and the Thracian women, whom he had offended by his coldness to their amorous passion, or, according to others, by his unnatural gratifications and impure indulgencies, attacked him while they celebrated the orgies of Bacchus; and after they had torn his body to pieces, they threw his head into the Hebrus, which still articulated the words Eurydice! Eurydice! as it was carried down the stream into the Ægean sea. Others think, that, as he attempted to conjure his wife from the dead, which they understand by the story of his going down to hell, he thought he saw her; and when afterwards, on looking back he missed her, he died of grief. There is certainly some reason for supposing this to be the case: for there were persons and temples publicly appointed for the purpose; and Pausanias really speaks of that temple which was in Thesprotia, and where Orpheus went to call up the ghost of Eurydice. Poets often mention this subject; and instances of it occur in history both sacred and profane. The witch of Endor is well known to those who read the historical part of the Bible. But to particularise instances, whether sacred or profane, would be endless. Some maintain that he was killed by a thunderbolt. He was buried at Pieria in Macedonia, according to Apollodorus. The inhabitants of Dion boasted that his tomb was in their city, and the people of Mount Libethrus in Thrace claimed the same honour; and farther observed that the nightingales which built their nests near his tomb, sang with greater melody than all other birds. Orpheus, as some report, after death received divine honours; the muses gave an honourable burial to his remains, and his lyre became one of the constellations in the heavens.

Tzetzes explains the fable of his drawing his wife Eurydice from hell, by his great skill in medicine, with which he prolonged her life, or, in other words, snatched her from the grave. Æsculapius, and other physicians, have been said to have raised from the dead those whom they had recovered from dangerous diseases.

The bishop of Gloucester, in his learned, ample, and admirable account of the Eleusinian mysteries, says, "While these mysteries were confined to Egypt their native country, and while the Grecian lawgivers went thither to be initiated, as a kind of designation to their office, the ceremony would be naturally described in terms highly allegorical. This way of speaking was used by Orpheus, Bacchus, and others: and continued even after the mysteries were introduced into Greece, as appears by the fables of Hercules, Castor, Pollux, and Theseus's descent into hell; but the allegory was so circumstanced, as to discover the truth concealed under it. So Orpheus is said to get to hell by the power of his harp:

Threicia fretus cithara, fidibusque canoris.
VIRG. Æn. vi. ver. 119.

That is, in quality of lawgiver; the harp being the known symbol of his laws, by which he humanized a rude and barbarous people.—Had an old poem, under the name of *Orpheus*, intitled *A descent into Hell*, been now extant, it would perhaps have shown us, that no more was meant than Orpheus's *initiation*." See MYSTERIES.

Many ancient writers, in speaking of his death, relate, that the Thracian women, as hinted at above, enraged at being abandoned by their husbands, who were disciples of Orpheus, concealed themselves in the woods, in order to satiate their vengeance; and notwithstanding they postponed the perpetration of their design some time through fear, at length, by drinking to a degree of intoxication, they so far fortified their courage as to put him to death. And Plutarch assures us, that the Thracians stigmatized their women, even in his time, for the barbarity of this action.

Our venerable bard is defended by the author* of the *Divine Legation*, from some insinuations to his disadvantage in Diogenes Laertius. "It is true (says he), if uncertain report was to be believed, the mysteries were corrupted very early; for Orpheus himself is said to have abused them. But this was an art the debauched mystæ of later times employed to varnish their enormities;

* Warburton.

mities; as the detested pæderasts of after ages scandalized the blameless Socrates. Besides, the story is so ill laid, that it is detected by the surest records of antiquity; for in consequence of what they fabled of Orpheus in the mysteries, they pretended he was torn in pieces by the women; whereas it appeared from the inscription on his monument at Dium, in Macedonia, that he was struck dead with lightning, the envied death of the reputed favourites of the gods."

This monument at Dium, consisting of a marble urn on a pillar, was still to be seen in the time of Pausanias. It is said, however, that his sepulchre was removed from Libethra, upon Mount Olympus, where Orpheus was born, and from whence it was transferred to Dium by the Macedonians, after the ruin of Libethra by a sudden inundation which a dreadful storm had occasioned. This event is very minutely related by Pausanias.

Virgil bestows the first place in his Elysium upon the legislators, and *those who brought mankind from a state of nature into society:*

Magnanimi heroës, nati melioribus annis.

At the head of these is Orpheus, the most renowned of the European lawgivers, but better known under the character of a poet: for the first laws being written in measure, to allure men to learn them, and, when learnt, to retain them, the fable would have it, that by the force of harmony Orpheus softened the savage inhabitants of Thrace:

——*Threïcius longa cum veste sacerdos*
Obloquitur numeris septem discrimina vocum:
Jamque eadem digitis jam pectine pulsat eburno.
Æn. lib. vi. ver. 645.

The seven strings given by the poet in this passage to the lyre of Orpheus, is a circumstance somewhat historical. The first Mercurian lyre had, at most, but four strings. Others were afterwards added to it by the second Mercury, or Amphion: but, according to several traditions preserved by Greek historians, it was Orpheus who completed the second tetrachord, which extended the scale to a heptachord, or *seven sounds* implied by the *septem discrimina vocum.* For the assertion of many writers, that Orpheus added two new strings to the lyre, which before had seven, clashes with the claims of Pythagoras to the invention of the octachord, or addition of the sound *proslambanomenos* to the heptachord, of which almost all antiquity allows him to have been the inventor. And it is not easy to suppose, that the lyre should have been represented in ancient sculpture with four or five strings only, if it had had nine, so early as the time of Orpheus, who flourished long before sculpture was known in Greece. See the article Lyre.

With respect to the writings of Orpheus, he is mentioned by Pindar as author of the Argonautics, and Herodotus speaks of his Orphics. His hymns, says Pausanias, were very short, and but few in number: the Lycomides, an Athenian family, knew them by heart, and had an exclusive privilege of singing them, and those of their old poets, Musæus, Onomacritus, Pamphus, and Olen, at the celebration of the Eleusinian mysteries; that is, the priesthood was hereditary in this family.

Jamblicus tells us, that the poems under the name of *Orpheus* were written in the Doric dialect, but have since been transdialected, or modernised. It was the common opinion in antiquity that they were genuine; but even those who doubted of it, gave them to the earliest Pythagoreans, and some of them to Pythagoras himself, who has frequently been called the *follower of Orpheus*, and has been supposed to have adopted many of his opinions.

Of the poems that are still subsisting under the name of *Orpheus*, which were collected and published at Nuremberg 1702, by Andr. Christ. Eschenbach, and which have been reprinted at Leipsic 1764, under the title of ΟΡΦΕΩΣ ΑΠΑΝΤΑ, several have been attributed to Onomacritus, an Athenian, who flourished under the Pisistratidæ, about 500 years before Christ. Their titles are, 1. The Argonautics, an epic poem. 2. Eighty-six hymns; which are so full of incantations and magical evocation, that Daniel Heinsius has called them *veram Satanæ liturgiam*, "the true liturgy of the devil." Pausanias, who made no doubt that the hymns subsisting in his time were composed by Orpheus, tells us, that though less elegant, they had been preferred for religious purposes to those of Homer. 3. *De lapidibus*, a poem on precious stones. 4. Fragments, collected by Henry Stevens. Orpheus has been called the *inventor*, or at least the *propagator*, of many arts and doctrines among the Greeks. 1. The *combination of letters*, or the art of writing. 2. *Music*, the lyre, or *cithara*, of seven strings, adding three to that of Mercury. 3. *Hexameter verse*. 4. *Mysteries* and *theology*. 5. *Medicine*. 6. *Magic* and *divination*. 7. *Astrology*. Servius upon the sixth Æneid, p. 450. says, Orpheus first instituted *the harmony of the spheres*. 8. He is said likewise to have been the first who imagined a *plurality of worlds*, or that the moon and planets were inhabited.

Orpheus, in *Ichthyology*, the name of a fish caught in the Archipelago. It is of a broad and flat figure, and of a fine purple colour; its eyes are large and prominent, and its teeth serrated; it has only one fin on the back and the anterior rays of that are prickly, the others soft to the touch; its anus is small, and is said to have no passage for the semen.

This was the fish called *orpheus* by the ancients, but the modern Greeks call another fish by that name. It is a species of the sparus, of a flat figure, but very thick, has a small mouth, and is covered with small but very rough scales, which adhere very firmly to the flesh; the tail is not forked; it has fleshy lips, and very small teeth; its back and sides are black; its belly white: it has a large black spot at the root of the tail; its head is reddish, and its fins are very elegantly diversified with various colours; it has only one back-fin, and that has the anterior ray prickly, the hinder ones not at all so. It grows sometimes to 20 pounds weight, and is much esteemed among the modern Greeks.

ORPIMENT (*auripigmentum*), in *Natural History*, a mineral which is composed of sulphur and arsenic, found native in the earth, and constituting one of the ores of arsenic, but sometimes artificially prepared. It is of two kinds, red and yellow. See Arsenic, Mineralogy *Index*, and Arsenic under Ores, *Reduction of*.

ORPINE. See Sedum, Botany *Index*.

ORRERY, a curious machine for representing the motions or phases of the heavenly bodies. See ASTRONOMY, p. 171.

The reason of its being called an *Orrery* was this: Mr Rowley, a mathematical instrument maker, having got one from Mr George Graham, the original inventor, to be sent abroad with some of his own instruments, he copied it, and made the first for the earl of Orrery. Sir Richard Steele, who knew nothing of Mr Graham's machines, thinking to do justice to the first encourager, as well as to the inventor of such a curious instrument, called it an *Orrery*, and gave Mr Rowley the praise due to Mr Graham.

ORRERY, *Earls of.* See BOYLE.

ORRICE. See IRIS, BOTANY *Index*.

ORTEGAL, CAPE, the most northern promontory of Spain, where there is also a castle of the same name. W. Long. 8. 20. N. Lat. 44. 0.

ORTELIUS, ABRAHAM, a celebrated geographer born at Antwerp, in 1527, was well skilled in the languages and the mathematics, and acquired such reputation by his skill in geography, that he was surnamed the *Ptolemy of his time*. Justus Lipsius, and most of the great men of the 16th century, were Ortelius's friends. He resided at Oxford in the reign of Edward VI. and came a second time into England in 1577. His *Theatrum Orbis* was the completest work of the kind that had ever been published, and gained him a reputation equal to his immense labour in compiling it. He also wrote several other excellent geographical works; the principal of which are his *Thesaurus*, and his *Synonyma Geographica*. The world is likewise obliged to him for the *Britannia*, which he persuaded Camden to undertake. He died at Antwerp in 1598.

ORTHEZ, a city in France, in the department of the lower Pyrenees, and before the Revolution, a bishop's see. Its population in 1800 was 6738. The cathedral is a wretched edifice, very ancient, built in a barbarous style, and almost in ruins. The remains of the castle of Orthez are very noble, and its situation is fine, on a hill which commands the town and a great extent of country. The people call it *Le Chateau de la Reine Jeanne*, because that queen resided in it during many years, in preference to the castle of Pau. The princess Blanche, daughter to John king of Arragon and Navarre, was shut up, and died here, in 1464. Her brother being dead, she became heiress to the crown of Navarre; but her father having delivered her into the hands of her younger sister Leonara countess of Foix, she confined the unhappy Blanche in the castle of Orthez, and, after am imprisonment of two years, caused her to be poisoned.

ORTHODOX, in church history, an appellation given to those who are sound in all the articles of the Christian faith.

ORTHOGRAPHIC PROJECTION *of the* SPHERE, that wherein the eye is supposed to be at an infinite distance; so called, because the perpendiculars, from any point of the sphere, will all fall in the common intersection of the sphere with the plane of the projection. See GEOGRAPHY and PROJECTION.

ORTHOGRAPHY, that part of grammar which teaches the nature and affections of letters, and the just method of spelling or writing words, with all the proper and necessary letters, making one of the four greatest divisions or branches of grammar. See GRAMMAR.

ORTHOGRAPHY, in *Geometry*, the art of drawing or delineating the fore-right plan of any object, and of expressing the heights or elevations of each part. It is called *Orthography*, for its determining things by perpendicular lines falling on the geometrical plane.

ORTHOGRAPHY, in *Architecture*, the elevation of a building.

ORTHOGRAPHY, in *Perspective*, is the fore-right side of any plane, i. e. the side or plane that lies parallel to a straight line, that may be imagined to pass through the outward convex points of the eyes, continued to a convenient length.

ORTHOPNOEA, a species or degree of asthma, where there is such a difficulty of respiration that the patient is obliged to sit or stand upright in order to be able to breathe. See MEDICINE *Index*.

ORTIVE, in *Astronomy*, the same with eastern. The ortive or eastern amplitude, is an arch of the horizon intercepted between the place where a star rises, and the east point of the horizon, or point where the horizon and equator intersect.

ORTNAU or ORTENAU, a district or canton in Germany, in Suabia, lying along the Rhine opposite Strasburg. It included eight or ten small towns, of which Offenburg, Gegensbach, and Zell, were the most considerable: these towns formed a small federation, and held immediately of the empire. At the distribution of the indemnities, after the peace of Luneville, this territory, with the Brisgaw, was assigned to the duke of Modena; but the greater part of it was afterwards annexed to the grand duchy of Baden.

ORTOLAN. See EMBERIZA, ORNITHOLOGY *Index*.

ORTYGIA, the birthplace of Diana, was a beautiful grove of trees of various kinds, chiefly cypresses, near Ephesus; on the coast, a little up from the sea. This place was filled with shrines and images. The priests of the goddess were eunuchs, and exceedingly respected by the people. A general assembly was held there yearly, and splendid entertainments were provided, and mystic sacrifices solemnized. The Cenchrius, probably a crooked river, ran through it; and above it was the mountain Solmissus, on which, it was fabled, the Curetes stood, and rattled on their shields, to divert the attention of Juno. The improved face of a country is perishable like human beauty. Not only the birthplace of Diana and its sanctity are forgotten, but the grove and buildings which adorned it appear no more; and perhaps, says Dr Chandler, the land has encroached on the sea, and the valley, in which Arvisia is, was once Ortygia. See EPHESUS, and DIANA, &c.

ORVIETO, a town of Italy, in the patrimony of St Peter, with a bishop's see, and a magnificent palace. It is the capital of the province of Orvietano, in the ecclesiastic state, in E. Long. 12. 5. Lat. 42. 50. It is a large strong town, situated at the conflux of the Paglia and the Chiane, on a steep hill, surrounded on every side with rocks and precipices. To this situation it is owing that it has no springs; but there is a very surprising well cut into the rock, to supply it with fresh water. The mules, which bring up the water on their backs, go down by a staircase of 150 steps, and 60 windows, and come up by another, without meeting. The architect

of

of this singular building was the famous Antonio de San Gallo, employed by Clement VII. At the entrance is this inscription, *Quod natura munimento inviderat, industria adjecit.* This city, called *Herbanum* by Pliny, and *Urbecetanum* by Procopius, is the see of a bishop suffragan of Rome. The cathedral, which is of Gothic architecture, is a handsome building, which was begun in 1260 by Nicolo Pisano. The front is adorned with fine statues, among the rest the Virgin Mary and the four Evangelists, with a basso-relievo of the last judgement, by the said Nicolo Pisano, and others representing some histories of the Old Testament. The other half of the front is a surprising work in mosaic, by Scalzi, expressing the history of the New Testament. In the church there is a very fine organ, and a basso-relievo of Raphael da Monte Lupo. Here is also a chapel, which was begun to be painted by F. Angelo, a dominican, and finished by Luke Signorelli, where you see a very beautiful representation of the last judgment. Orvieto was once a potent and populous city, but is now much upon the decline.

ORYZA, Rice, a genus of plants belonging to the hexandria class, and in the natural method ranking under the 4th order, *Gramina*. See Botany *Index*.

There is but one species, namely the sativa, or common rice. This plant is greatly cultivated in most of the eastern countries, where it is the chief support of the inhabitants; and great quantities of it are brought into England and other European countries every year, where it is much esteemed for puddings, &c. it being too tender to be produced in these northern countries without the assistance of artificial heat; but from some seeds which were formerly sent to Carolina there have been great quantities produced, and it is found to succeed as well there as in the east.

This plant grows upon moist soils, where the ground can be flowed over with water after it is come up. So that whoever would cultivate it in this country should sow the seeds upon a hot-bed; and when the plants are come up, they should be removed into pots filled with light rich earth, and placed in pans of water, which should be plunged into a hot-bed; and, as the water wastes, it must from time to time be renewed again. In July these plants may be set abroad in a warm situation, still preserving the water in the pans, otherwise they will not thrive; and, toward the latter end of August, they will produce their grain, which will ripen tolerably well, provided the autumn proves favourable. The leaves of rice are long, like the reed, and fleshy; the flowers blow on the top like barley; but the seed which follows is disposed in clusters, each of which is inclosed in a yellow husk, ending in a spiral thread. The seed is oblong, or rather oval, and white.

Rice is the chief commodity and riches of Damietta in Egypt. Dr Hasselquist gives the following description of the manner in which they dress and separate it from the husks. "It is pounded by hollow iron pestles of a cylindrical form, lifted up by a wheel worked by oxen. A person sitting between the two pestles, pushes forward the rice when the pestles are rising; another sifts, winnows, and lays it under the pestles. In this manner they continue working it until it is entirely free from chaff and husks. When clean, they add a 30th part of salt, and pound them together; by which the rice, formerly gray, becomes white. After this purification, it is passed through a fine sieve to part the salt from the rice; and then it is ready for sale." Damietta sells every year 60,800 sacks of rice, the greatest part of which goes to Turkey, some to Leghorn, Marseilles, and Venice.

ORYZIVORA, called the rice-bird of Catesby, a species of emberiza, which see, Ornithology *Index*.

OSCHOPHORIA, a festival celebrated by the Athenians, which receives its name απο του φερειν τας οσχας, "from carrying boughs hung up with grapes," called οσχαι. The original institution is thus mentioned by *Plut. in Thes.* Theseus, on returning from Crete, forgot to hang out the white sail, by which his father was to be apprized of his success. This neglect proved fatal to Ægeus, for he threw himself into the sea, and perished. Theseus no sooner reached the land, than he sent a herald to inform his father of his safe return, and in the mean time he began to make the sacrifices which he had vowed to make when he first set sail from Crete. The herald, on his entrance into the city, found the people in great agitation. Some lamented the king's death, while others, elated at the sudden news of the victory of Theseus, crowned the herald with garlands in token of their joy. The herald carried back the garlands on his staff to the sea shore; and, after waiting till Theseus had finished his sacrifice, he related the melancholy account of the king's death. Upon this the people ran in crowds to the city, showing their grief by cries and lamentations. From this circumstance, therefore, at the feast of Oschophoria, not the herald but his staff is crowned with garlands, and all the people that are present always exclaim ελελευ, ιυ, ιυ, the first of which expresses haste, and the others a consternation or depression of spirits. The historian further mentions, that Theseus, when he went to Crete, did not take with him the usual number of virgins, but that in the place of two of them, he took two youths of his acquaintance, whom he caused to pass for women, by disguising their dress, and by accustoming them to the ointments and perfumes of women, as well as by a long and successful imitation of their voice. The imposition succeeded; their sex was not discovered in Crete; and when Theseus had triumphed over the Minotaur, he with these two young men led a procession, with branches in their hands in the same habit, which is still used at the celebration of the festival. The branches which were carried were in honour of Bacchus or Ariadne, or because they returned in autumn, when the grapes were ripe. Besides this procession, there was also a race, in which young men only whose parents were both alive were permitted to engage. It was customary for them to run from the temple of Bacchus to that of Minerva, which was on the sea shore. The place where they stopped was called οσχοφοριον, because the boughs which they carried in their hands were deposited there. The reward of the conqueror was a cup called πενταπλοα, "five-fold," because it contained a mixture of five different things, wine, honey, cheese, meal, and oil.

OSCILLA, small images of wax or clay made in the shape of men or women, and consecrated to Saturn, to render him propitious. The word is sometimes used to signify a kind of masks scooped from the bark of trees, and worn by the performers of comedy in the ruder ages of Rome. In this sense we find it in Virg. Georg. ii. 386. It also signifies little heads or images of

Bacchus, which the country men of old hung upon trees, that the face might turn every way, out of a notion that the countenance of this god gave felicity to themselves, and fertility to their vineyards. An allusion to this opinion and custom is also found in Virgil, Georg. ii. 388.

OSENEY-ISLAND, in England, is formed by the river Isis, in the meadows near Oxford, where a magnificent abbey was erected, at the instigation of a concubine of King Henry I. to atone for her sins; and the said king built a palace there, wherein King Richard I. was born, which Edward II. converted into a monastery.

OSIRIS, in *Mythology*, one of the gods of ancient Egypt, and very generally believed to have been the sun, or at least the mind actuating that luminary.

The Egyptians derived all things from two principles, an *active* and a *passive*. Their active principle, according to the learned Jablonski*, was an infinite and eternal *spirit;* and their passive principle was *night*. This spirit they considered sometimes as a *male*, sometimes as a *female*, divinity, and occasionally they attributed to it *both sexes;* but it does not appear to have been the object of their worship. It shall be shown elsewhere (see POLYTHEISM), that the earliest objects of pagan adoration were the sun, moon, and planets: and that the philosophers and priests of ancient Egypt worshipped the sun by the name of *Osiris*, may be proved by numberless testimonies from the most authentic records of antiquity. Diogenes Laertius affirms, that they held the sun and moon for divinities, and that they called the latter *Isis;* and Macrobius says expressly, "Nec in occulto est, neque aliud esse *Osirin* quam *solem*, nec *Isim* aliud esse quam *terram*." The same writer informs us, that in the hieroglyphic writings of ancient Egypt, "Osiris was represented by a sceptre and an eye," to denote that this god was the *sun* looking down from heaven on all things upon earth.

* Panth. Ægypt.

It must not, however, be concealed, that some of the ancients, and a few of the most learned moderns, have contended, that by *Osiris* the Egyptians understood the Nile or spirit of the Nile, whilst others have confounded him with the Grecian Bacchus. Scaliger and Selden have adopted the former of these opinions, and Servius on Virgil has given his countenance to the latter. But that they are all mistaken, has been evinced by Jablonski in such a manner as to enforce the fullest conviction: "When the Egyptians, in their sacred books, sometimes gave the name of *Osiris* to the Nile and its wonderful increase during the heat of summer, they mean nothing more (says he) but to attribute to their god Osiris the gift which fertilizes their country." This they would the more readily do that they believed the Nile to have its source in heaven. Hence Eusebius tells us †, Οσιρις εστιν ὁ Νειλος, ὃν εξ ουρανου καταφερεσθαι οιονται, *Osiris is the Nile, because they think it is sent down from heaven.* In one sense Osiris might be Bacchus, because the original Bacchus was himself the sun (see MYSTERIES, N° 12.); but that the Egyptian god could not be worshipped as the inventor of wine is indeed undeniable, if, as Jablonski labours to prove, the primitive religion of that country inculcated upon its votaries, that wine was the gift, not of a benevolent god, but of an evil genius, the enemy of the human race. In support of this opinion our learned author quotes a passage from Plutarch, from which it appears, that, before the era of Psammetichus, the Egyptians neither drank wine themselves, nor offered it in libations to the gods, because they believed that the first vine sprung from the earth was impregnated by the blood of those giants who perished in the war with the gods. It is indeed true, that the Greeks, who borrowed their religion as well as the first principles of science from Egypt, attributed to their Bacchus many of the actions of Osiris; but it is likewise true, that they gave him other attributes, which the Egyptian god could not possess, consistently with the known superstitions of that country. Salmasius, however, attempts to prove, from the import of the name, that the *Osiris* of Egypt must have been the Bacchus of Greece. Σηρ or Σιρι, he says, signifies a *son* in the Egyptian language; and hence he concludes that the god was by that people called *Osiris*, for the same reason that by the Greeks he was called Κουρος, and by the Romans *Liber*. But this seems all to be a mistake. *Siris* makes a part of many Egyptian proper names, as *Bu-siris*, *Termo-siris*, *Tapo-siris*, &c. and is in all probability derived from the Hebrew word *Sar*, *Sur*, or *Sir*, which signifies a *prince*, *potentate*, or *grandee*. As the name of the god was in Egypt not *Osiris*, but *Isiris* or *Ysiris*, it was probably made up of *Sir* or *Siris*, and the Hebrew prefix *I* or *ish*, denoting *strength;* so that the whole word will signify the *strong* or *mighty prince*. If so, we cannot doubt, as Diodorus Siculus, Eusebius, Sextus Empiricus, &c. all affirm, that the Egyptians worshipped the sun by the name of *Osiris*, but that by this name they meant the *power* or *governing mind* of the sun, as the Greeks and Romans seem to have done by their *Phœbus* and *Apollo*.

† Prepar. Evangel.

But though the original Osiris was undoubtedly the sun, or the intelligence actuating the sun, yet there is reason to believe that there was a *secondary Osiris*, who at a very early period reigned in Egypt, and was deified after his death for the benefits he had rendered to his country (see POLYTHEISM). This is indeed so generally admitted, as to have occasioned great controversies among the learned respecting the time when he flourished, and whether he was the civilizer of rude barbarians or the victorious sovereign of a polished nation. The illustrious Newton it is well known, has adopted the latter opinion; and with much plausibility endeavoured to prove, that *Osiris* was the same with *Sesostris* or *Sesac:* but it must be confessed, that his conclusion is contrary to all the most authentic records of antiquity; and that it would be easy, by the same mode of arguing, to give a show of identity to two persons universally known to have flourished in very distant ages (A). The annals of Egypt, as may be seen in the writings of Herodotus, Diodorus Siculus, Strabo, Plutarch, and others, who copied

(A) This has been in fact done by Warburton; who employs Newton's mode of reasoning with equal plausibility, and perhaps superior force, to prove the identity of King Arthur and William the Conqueror. See *Divine Legation of Moses*, vol. iii. book. iv. sect. v.

pied from those annals, expressly asserted the distinct personality of Osiris and Sesostris, and placed them in æras vastly distant from each other. Osiris, if any credit be due to those historians, was the founder of the Egyptian monarchy; and, as was customary in those days, having either received the name of the sun, or communicated his own to that luminary, was after his death deified for the benefits which he had rendered to his country: and being at first worshipped only as a demigod, was in process of time advanced to full divinity, and confounded with his heavenly godfather. The Greeks, who, though original in nothing, were always prompted by their vanity to hold themselves out as the first of the nations, claimed this Osiris as their own, and pretended that he was the son of Jupiter and Niobe. He reigned, say they, over the Argives; but afterwards delivered his kingdom to his brother Algialeus, and took a voyage into Egypt, of which he made himself master, and married Io or Isis. He established good laws there; and they were both after their deaths worshipped as gods. That this is a ridiculous fiction needs no proof; since every one knows, that good laws were established in Egypt long before the Argives had any king, or indeed existed either as a tribe or nation.

OSMUNDA, Moonwort; a genus of plants belonging to the cryptogamia class. See Botany *Index*.

OSNABURG, a bishopric of Germany, situated in the centre of the circle of Westphalia, between the Weser and the Ems, having Minden on the east, Munster on the west, Diepholt on the north-east, and Ravensburg on the south-west. It is about 45 miles long and 25 broad, producing some rye, several sorts of turf, coals, marble, and good pasturage. The inhabitants, who are a mixture of Protestants and Roman Catholics, breed a considerable number of cattle, especially hogs, of which they make excellent bacon and hams; but a great part of the country consists of heaths. By the treaty concluded here in 1648, the bishopric was to be an alternative between the Roman Catholics and Lutherans; and the Lutheran bishop was to be a younger prince of the house of Brunswick Lunenburg, or in failure thereof, of Brunswick Wolfenbuttle. In consequence of this settlement, it has been twice held by a British prince since the accession of the family of Hanover. In 1802 this bishopric was secularized and added to Hanover on certain conditions, and now forms a part of that kingdom. The bishopric had a population of about 130,000 souls. Of the peasants, 6000 go yearly to Holland, where they mow, till, cut turf, and do other work for hire. The meanest of them brings home twenty, and the best workmen seventy florins. Bishop Ernest established a salt-work at Dissen; and the same bishop opened a silver mine, but this undertaking was not prosecuted. The chief manufactures of the country are a coarse kind of linen cloth and yarn, which are said to bring into it annually about 1,000,000 of rixdollars. There are also some woollen manufactures in Osnaburg and Bramsche. The land estates of the bishopric were, the chapter, the knights, and the four towns. The diets were held at Osnaburg, when called together by the bishop. The count of Bar was hereditary seneschal or steward, and president of the college of knights. The bishop was a prince of the empire; and in the matricula is rated at six horse and 36 foot, or 216 florins monthly, in lieu of them. To the chamber of the empire he contributed each term 81 rixdollars, 14 kruitzers and a half. The capital of this bishopric is

Osnaburg, or *Osnabruck*. It was formerly an imperial city, and one of the Hanse towns. It has its name from a bridge over the river Hase, or Ose, which divides it into the Old and New Town, and stands 75 miles west of Hanover, and 30 north-east of Munster, being surrounded with walls and ditches, but commanded by a mountain within cannon shot. It stands in a fine plain, and is adorned with several good buildings, and on the mountain there is an abbey. The magistracy of this city, which is rechosen yearly on the 2d of January, is Lutheran; and the churches belong, some to the Lutherans, and some to the Papists. Both parties have the full and free exercise of their religion, whether the bishop be Protestant or Papist. The bishop's palace, called *Petersburgh*, was built by Bishop Ernest Augustus, brother to King George I. It is well fortified and separated from the town by a bridge. It is a hexagon, with a court in the middle, and at each corner a turret. In the town-house are still preserved the pictures of the plenipotentiaries that assisted at the conferences there for the famous treaty of Westphalia. In the treasury of the cathedral are still to be seen some ornaments given by Charlemagne, as also his crown, which is only of silver gilt, and his comb and batoon, six feet in length, both of ivory; together with other curiosities. Charlemagne is said to have erected here a school for Latin and Greek, which the Jesuits in 1625 converted into an academy. They have the best bread and beer that is to be met with in all Westphalia, and have a pretty good trade in bacon and linen; as also by brewing a palatable thick sort of beer called *buse*. This city is noted for a treaty betwixt the emperor and the king of Sweden in 1648, wherein the affairs of the Protestants were regulated, which was a branch of the treaty of Westphalia. In 1613 the greatest part of it was destroyed by fire. In 1630 Bishop Francis William erected an academy here, consisting of thirteen seminaries, which were also confirmed by the emperor Ferdinand II., and Pope Urban VIII.; but the capture of the place by the Swedes in 1733 put an end to it. In 1634 the crown of Sweden created Count Gustavus Wasaburg lord of the bishopric of Osnaburg; but at the peace of Osnaburg he renounced all his right obtained over this place during the war, in consideration of receiving 80,000 rix dollars. The town toll was by the town, in the year 1431, given to the bishop, with a reserve of exemption from toll to the burghers, in order to get rid of the Jews, who were that year banished. The cathedral is in the hands of the Roman Catholics, with the church and monastery of the Dominicans in the old city, and the collegiate church of St John in the new. The Protestants are masters of the great parochial church of St Mary in the old city; and both religions have a voice in the election of the magistrates. The bishop's palace is fortified like a castle: here it was that George I. was born on the 28th of May 1660, his father Ernest Augustus being then bishop and prince of the place; and here also he died in the night of the 10th of June 1727, and, as some say, in the very room in which he was born. The inhabitants have considerable manufactures

nufactures of linen and a good breed of cattle; and of their hogs, for which they are remarkable, is made the best Westphalia bacon. Not far from this city are to be seen the ruins of an old church and castle called *Beclem*, which some say was built by King Witekind upon his conversion; and about two miles from it lies the monastery of Rulle, on the bank of a lake so deep, that report says it could never yet be fathomed. This was the first town in Westphalia which received the Lutheran doctrine.

Osnaburg Island, one of the islands in the South sea, discovered by Captain Wallis in 1767. It is a high, round island, not above a league in circuit; in some parts covered with trees, in others a naked rock. S. Lat. 22. 48. W. Long. 14. 34.

OSORIUS, Jerome, a Portuguese ecclesiastic, was born of a noble family at Lisbon, in 1500. He was educated at the university of Salamanca, and afterwards studied at Paris and Bologna. On his return to Portugal he gradually rose to the bishopric of Sylves, to which he was appointed by Catharine of Austria, regent of the kingdom in the minority of Sebastian. At the request of Cardinal Henry of Portugal, he wrote his history of King Emanuel, and the Expedition of Gama; which his great contemporary Camoens made at the same time the subject of his immortal Lusiad; a poem which has at length appeared with due lustre in our language, being translated with great spirit and elegance by Mr Mickle. It is remarkable that the history of Osorius, and the epic poem of Camoens, were published in the same year, 1572: but the fate of these two great authors were very different; the poet was suffered to perish in poverty, under the reign of that Henry who patronised the historian: yet allowing for the difference of their professions, they possessed a similarity of mind. There appear many traces of that high heroic spirit even in the priest Osorius, which animated the soldier Camoens; particularly in the pleasure with which he seems to describe the martial manners of his countrymen under the reign of Emanuel. "In that age (says the historian in the close of his manly work), poverty and sadness were banished from Portugal. Complaints were never heard; but every place, from the court to the cottage, resounded with mirth and music. Illicit love was unknown; nor would the ladies listen to the most honourable addresses of such youths as had not signalized themselves in war. No young man about court, however noble by birth, was permitted to wear the dress of manhood till he had passed over into Africa, and thence brought back with him some animal esteemed for its rarity; and such was the hardy education of the nobility in that age, that many of them travelled everywhere in quest of adventures." This is a striking picture of the manners of chivalry, to which Portugal owed much of its glory in that splendid period. There is one particular in the character of Osorius, which, considering his age and country, deserves the highest encomium; and that is his tolerating spirit. In the first book of his history, he speaks of Emanuel's cruel persecution of the Jews in the following generous and exalted language: "This (says he) was authorized neither by law nor by religion. Can men be compelled to believe what they reject with abhorrence? Do you take upon you to restrain the liberty of the will, or to fetter the understanding? Such an attempt must be unsuccessful; and is not acceptable to Christ, who expects from man devotion of the heart, and not that formal worship which is the offspring of pains and penalties. He wishes them to study his religion, and accept it from conviction, not from terror: for who does not see that forced belief is mere hypocrisy?" Osorius is said to have used many arguments to dissuade Sebastian from his unfortunate expedition into Africa, and to have felt so deeply the miseries which befel the Portuguese after that fatal event, that his grief was supposed to accelerate his death. He expired in 1580, happy, says De Thou (who celebrates him as a model of Christian virtue), that he died just before the Spanish army entered Portugal, and thus escaped being a witness to the desolation of his country.—His various works were published at Rome in 1592, by his nephew Osorius, in four volumes folio, with a life of their author. Among these are two remarkable productions; the first, An Admonition to our Queen Elizabeth, exhorting her to return into the Church of Rome; the second, An Essay on Glory, written with such classical purity, as to give birth to a report, that it was not the composition of Osorius, but the last work of Cicero on that subject.

OSPREY. See Falco, Ornithology *Index*.

OSSA, a lofty mountain of Thessaly, near the Peneus, which runs between this mountain and Olympus; famous in the fabulous story of the giants (Homer, Virgil, Horace, Seneca, Ovid). The bending and unbending of its pines, on the blowing of a strong north wind, formed a clashing sound like thunder (Lucan). It was once the residence of the Centaurs, and was formerly joined to Mount Olympus; but Hercules, as some report, separated them, and made between them the celebrated valley of Tempe. The separation of the two mountains was more probably effected by an earthquake which happened about 1885 years before the Christian era. Its greatest celebrity arises from its being one of those mountains which the giants in their wars against the gods heaped up one on the other to scale the heavens with more facility. A town of Macedonia.

OSSAT, Arnauld de, a learned French ecclesiastic, was born in the diocese of Auch in 1536, of mean parentage, and was taken notice of by a gentleman in the diocese, who made him study with his ward the Lord of Castlenan de Magnoac. He studied the law at Dijon under Cujace, and applied himself to the bar at Paris. He was secretary at Rome to M. de Foix, archbishop of Thoulouse; to Cardinal Este; and afterwards to Cardinal de Joyeuse, by the French king's express command. After rising to the highest dignities both in church and state, in 1599 he was created a cardinal by Pope Clement VIII. He died in 1604. An eminent French writer gives him the following character: "He was a man of prodigious penetration; applied himself so closely to affairs, and especially was so judicious in forming his resolutions, and it is almost impossible to find out one false step in the many negociations in which he was concerned. His works, and especially his letters, have been much esteemed in the learned world.

OSSIAN, the son of Fingal, a celebrated Celtic poet, who flourished about the end of the second and

Ossian. beginning of the third century. Several incidents in his poems point out this as his æra: particularly the engagement of Fingal with Caracul, or Caracalla, the son of the emperor Severus, styled by Ossian, *The Son of the King of the World*. M. Tillemont fixes the elevation of Caracalla to a share in the government to the year 198, and the association of his brother Geta to 208. About which time Gibbon fixes the Caledonian war, and speaks thus upon the subject: "This Caledonian war, neither marked by decisive events, nor attended with any important consequences, would ill deserve our attention; but it is supposed, not without a considerable degree of probability, that the invasion of Severus is connected with the most shining period of the British history or fable. Fingal, whose fame, with that of his heroes and bards, has been revived in our language by a recent publication, is said to have commanded the Caledonians in that memorable juncture, to have eluded the power of Severus, and to have obtained a signal victory on the banks of the Carun, in which the *son of the King of the World*, Caracul, fled from his arms along the fields of his pride †. Something of a doubtful mist still hangs over these Highland traditions; nor can it be entirely dispelled by the most ingenious researches of modern criticism (A); but if we could with safety indulge the pleasing supposition that Fingal lived, and that Ossian sung, the striking contrast of the situation and manners of the contending nations might amuse a philosophic mind. The parallel would be little to the advantage of the more civilized people, if we compared the unrelenting revenge of Severus with the generous clemency of Fingal; the timid and brutal cruelty of Caracalla, with the bravery, the tenderness, the elegant genius of Ossian; the mercenary chiefs who, from motives of fear or interest, served under the imperial standard, with the free-born warriors who started to arms at the voice of the king of Morven: if, in a word, we contemplated the untutored Caledonians glowing with the warm virtues of nature, and the degenerate Romans polluted with the mean vices of wealth and slavery."

† *Ossian's Poems*, vol. i. p. 175.

The date of this action, if the poems be true, is rather confounding; for the next expedition, which is produced to fix the time in which Ossian flourished, was conducted by Oscar (against the usurper Carausius, the Caros of Ossian), who did not assume the purple till so late as the year 287. This account indeed corresponds pretty well with the account given by Irish histories, which place the death of Fingal in the year 283, and that of Oscar (who died many years before his father Ossian) in the year 296. These hints are not thrown out because we think they militate against the authenticity of the poems; for distant though these dates be, it is yet possible to reconcile them. Old age was and is very common in those regions; and Ossian himself, we are told, was an instance of great longevity. Indeed at such a distance of time, it cannot be expected that we should give either a very particular or a very exact account of Ossian and his heroes. Were there no doubts remaining of the truth of the facts, it is still natural to suppose that they must have suffered obscurity through the rust of time, and above all through the neglect of the poems, which till lately were unknown.

The first expedition on which Ossian's father sent him was, to raise a stone on the banks of Crona, to perpetuate the memory of a victory which the king of Morven had obtained at that place. The Highlanders talk of this as being emblematical of that immortality which heroes were to receive from his future compositions. In this expedition he was accompanied by Toscar, father of the beautiful Malvina, the amiable companion of his grief, after the death of her beloved Oscar, his son. It appears from his poems, that in one of his early expeditions to Ireland, he had fallen in love with and married Evirallin, daughter to Branno, petty king of Lego. "I went in suit of the maid of Lego's sable surge; twelve of my people were there, the sons of streamy Morven. We came to Branno, friend of strangers; Branno of the sounding mail.—'From whence (he said) are the arms of steel? Not easy to win is the maid that has denied the blue-eyed sons of Erin. But blest be thou, O son of Fingal! happy is the maid that waits thee. Though twelve daughters were mine, thine were the choice, thou son of fame.'—Then he opened the hall of the maid; the dark-haired Evirallin †." This Evirallin was the mother of his son Oscar, whose exploits he celebrates in many of his poems, and whose death he laments in the first book of Temora. Evirallin died some time before Oscar (FINGAL, B. iv.), who seems to have been her only child; and Ossian did not marry afterwards; so that his posterity ended in the death of Oscar; who seems to have died as he was about to be married to Malvina, the daughter of Toscar. Several of her lamentations for her lover are recorded by Ossian, which paint her grief in the strongest and most beautiful colours. "It is the voice of my love! few are his visits to my dreams.—But thou dwellest in the soul of Malvina, son of mighty Ossian. My sighs arise with the beams of the east; my tears descend with the drops of night. I was a lovely tree in thy presence, Oscar, with all my branches round me: but thy death came like a blast from the desert, and laid my green head low; the spring returned with its showers, but no green leaf of mine arose." *Poem of* COMRA.

† *Fingal*, B iv.

The principal residence of Ossian was in the vale of Cona, now Glenco, in Argyleshire. See FINGAL.

His poems relate many of his expeditions to Ireland,

(A) "That the *Caracul* of Ossian is the *Caracalla* of the Roman history, is perhaps the only point of British antiquity in which Mr Macpherson and Mr Whitaker are of the same opinion; and yet the opinion is not without difficulty. In the Caledonian war, the son of Severus was known only by the appellation of *Antoninus;* and it may seem strange that the Highland bard should describe him by a nickname, invented four years afterwards, scarcely used by the Romans till after the death of that emperor, and seldom employed by the most ancient historians. See Dion. lib. lxxvii. p. 1317. Hist. August. p. 89. Aurel. Victor. Euseb. in Chron. ad ann. 214.

land, Scandinavia, Clyde, and Tweed or Teutha. His exploits on these occasions, after making a large allowance for poetical exaggeration, show him to have been no less a warrior than a poet: (See OSSIAN'S WORKS, in the poems *Calthon and Colmal*, *Lathmon*, *Berrathon*, &c.). By these xpeditions, which were always undertaken for the relief of the distressed, the mind of Ossian seems to have been cultivated and enlarged beyond what is usually to be met with in so rude a period of society as that in which he lived. His poems breathe, throughout, such a spirit of generosity and tenderness, especially towards the fair sex, as is seldom or never to be met with in the compositions of other poets who lived in a more advanced state of civilization. He lived to an extreme old age; having survived all his family and friends, many of whom perished by a fatal accident, recorded in one of his poems called the *fall of Tura* *. Malvina alone, the love of his son Oscar, remained with him till within a few years of his death, and paid him every attention that could be expected from the tender relation in which she stood to him. To her he addresses many of his poems, which seem to have been composed for the most part in his old age. Her death is pathetically lamented by him in the poem of *Berrathon*: towards the close of which, he gives the presages of his own departure; an event which he often wishes for, under the blindness and other calamities of his declining years. "Roll on, ye dark brown years, for ye bring no joy on your course. Let the tomb open to Ossian, for his strength has failed. The sons of the song are gone to rest: my voice remains, like a blast, that roars lonely, on the sea surrounded rock, after the winds are laid. The dark moss whistles there, and the distant mariner sees the waving trees †."—"But Ossian is a tree that is withered. Its branches are blasted and bare; no green leaf covers its boughs. From its trunk no young shoot is seen to spring. The breeze whistles in its gray moss: the blast shakes its head of ages.—The storm will soon overturn it, and strew all its dry branches with thee, O Dermid! and with all the rest of the mighty dead, in the green winding vale of Cona ‡."

* See *Gaelic Antiquities*.

† Poem of *Berrathon*.

‡ *Gaelic Antiquities*, poem of *Dermid*.

It is not certain at what age Ossian died; but from his having been long blind with years, and from the many contrasts between his present and past situations, in poems composed, as it would appear, at a considerable distance of time from each other, it is most likely he lived to an extreme old age. The current tradition is, that he died in the house of a Culdee, called the *Son of Alpin*, with whom he is said to have held several conferences about the doctrines of Christianity. One of these dialogues is still preserved, and bears the genuine marks of a very remote antiquity; (*Dissertation* prefixed to *Ossian's Works*). Several of Ossian's poems are addressed to this son of Alpin, who was probably one of those Christians whom the persecution under Dioclesian had driven beyond the pale of the Roman empire.

The poems of Ossian, though always held in the highest esteem by those who knew them, were allowed to remain in the obscurity of their original Gaelic, till Mr Macpherson, above 40 years ago, translated a collection of them into English, which immediately attracted the attention of every person who had a true taste for poetry. Dr Blair, in particular, introduced these poems into the world with those critical remarks which do no less honour to himself than to the poet. According to that eminent critic, the two great characteristics of Ossian's poetry are tenderness and sublimity. Ossian is, perhaps, the only poet who never relaxes, or lets himself down into the light and amusing strain. He moves perpetually in the high region of the grand and pathetic. The events which he records are all serious and grave; the scenery wild and romantic. We find not in him an imagination that sports itself, and dresses out gay trifles to please the fancy. His poetry, more perhaps than that of any other, deserves to be styled the *poetry of the heart*. It is a heart penetrated with noble sentiments, with sublime and tender passions; a heart that glows and kindles the fancy; a heart that is full, and pours itself forth. Of all the great poets, Homer is the one whose manner and whose times come the nearest to Ossian's Homer's ideas were more enlarged, and his characters more diversified, Ossian's ideas fewer, but of the kind fittest for poetry; the bravery and generosity of heroes, the tenderness of lovers, and the attachment of friends. Homer is diffuse; Ossian abrupt and concise. His images are a blaze of lightning, which flash and vanish. Homer has more of impetuosity and fire; Ossian of a solemn and awful grandeur. In the pathetic, Homer has a great power; but Ossian exerts that power much oftener, and has the character of tenderness more deeply imprinted on his works. No poet knew better how to seize and melt the heart. With regard to dignity of sentiment, we must be surprised to find that the pre-eminence must clearly be given to the Celtic bard. This appears nowhere more remarkable than in the sentiments which he expresses towards his enemies. "Uthal fell beneath my sword, and the sons of Berrathon fled.—It was then I saw him in his beauty, and the tear hung in my eye. Thou art fallen, young tree, I said, with all thy beauty round thee. Thou art fallen on thy plains, and the field is bare. The winds come from the desert, and there is no sound in thy leaves! Lovely art thou in death, son of car-borne Larthmore *." His supposition, that all the little feuds and differences of this life should be forgotten in a future state, and that those who had once been foes would "stretch their arms to the same shell in Loda," gives us the highest idea of the man as well as of the poet. "Daughter of beauty, thou art low! A strange shore receives thy corse. But the ghosts of Morven will open their halls when they see thee coming. Heroes around the feast of dim shells, in the midst of clouds shall admire thee; and virgins shall touch the harp of mist †."——"The feuds of other years by the mighty dead are forgotten. The warriors now meet in peace, and ride together on the tempest's wing. No clang of the shield, no noise of the spear, is heard in their peaceful dwellings. Side by side they sit, who once mixed in battle their steel. There, Lochlin and Morven meet at the mutual feast, and listen together to the song of their bards ‡."

* *Ossian's Works*, poem of *Berrathon*.

‡ *Ib.* poem of *Dargo*.

But the sublimity of moral sentiments, if they wanted the softening of the tender, would be in hazard of giving a stiff air to poetry. It is not enough that we admire. Admiration is a cold feeling in comparison of that deep interest the heart takes in tender and pathetic scenes. With scenes of this kind Ossian abounds;

and

and his high merit in these is incontestable. He may be blamed for drawing tears too often from our eyes; but that he has the power of commanding them, no man who has the least sensibility can question. His poems awake the tenderest sympathies, and inspire the most generous emotions. No reader can rise from him without being warmed by the sentiments of humanity, virtue, and honour.

But the excellency of these poems occasioned in many persons a doubt of their authenticity. Their genuineness, however, has been very ably defended by Dr Blair and Lord Kames, and warmly supported by the author of the *Gaelic Antiquities*, who has given the public some more remains of Ossian's poetry.

As the nature of our work will not allow us to treat this matter at full length, we shall only give a brief view of the arguments offered in support of the authenticity of these poems, referring our readers to the authors just now mentioned and others, for fuller satisfaction.

"In every period of society (says Dr Blair), human manners are a curious spectacle; and the most natural pictures of ancient manners are exhibited in the ancient poems of nations. These make us acquainted with the notions and feelings of our fellow-creatures in the most artless ages; discovering what objects they admired, and what pleasures they pursued, before those refinements of society had taken place, which enlarge indeed, and diversify the transactions, but disguise the manners of mankind.

"Besides this, ancient poems have another merit with persons of taste. They promise some of the highest beauties of poetical writing. That state, in which human nature shoots wild and free, though unfit for other improvements, certainly encourages the high exertions of fancy and passion.

"In the infancy of societies the passions of men have nothing to restrain them; their imagination has nothing to check it. And as their feelings are strong, so their language of itself assumes a poetical turn. Men never have used so many figures of style, as in those rude ages, when, besides a warm imagination to suggest lively images, the want of proper and precise terms for the ideas they would express, obliged them to have recourse to circumlocution, metaphor, comparison, and all those substituted forms of expression, which give a poetical air to language. An American chief, at this day, harangues at the head of his tribe in a more bold metaphorical style than a modern European would venture to use in an epic poem.

"Poetry has been said to be more ancient than prose, which, in a qualified sense, is true. Music or song has been found coeval with society among the most barbarous nations; and the only subjects which could prompt men, in their first rude state, to utter their thoughts in compositions of any length, were such as naturally assumed the tone of poetry; praises of their gods, or of their ancestors; commemorations of their own warlike exploits; or lamentations over their misfortunes. And before writing was invented, no other compositions, except songs or poems, could take such hold of the imagination and memory, as to be preserved by oral tradition, and handed down from one race to another.

"Hence we may expect to find poems among the antiquities of all nations. It is probable, too, that an extensive search would discover a certain degree of resemblance among all the most ancient poetical productions, from whatever country they have proceeded. In a similar state of manners, similar objects and passions operating upon the imaginations of men, will stamp their productions with the same general character. Some diversity will, no doubt, be occasioned by climate and genius. But mankind never bear such resembling features as they do in the beginnings of society. What we call the *oriental vein* of poetry, because the earliest poetical productions have come to us from the east, is probably no more *oriental* than *occidental*; it is characteristical of an age rather than a country; and belongs, in some measure, to all nations at a certain period. Of this the works of Ossian seem to furnish a remarkable proof.

"He appears clearly to have lived in a period which enjoyed all the benefit I have just now mentioned of traditionary poetry. The exploits of Trathal, Trenmor, and the other ancestors of Fingal, are spoken of as familiarly known. Ancient bards are frequently alluded to. In one remarkable passage, Ossian describes himself as living in a sort of classical age, enlightened by the memorials of former times, conveyed in the songs of bards, and points at a period of ignorance which lay beyond the reach of tradition. Ossian himself appears to have been endowed by nature with exquisite sensibility; prone to that tender melancholy which is so often an attendant on great genius; and susceptible equally of strong and of soft emotions. He was not only a professed bard, but a warrior also, and the son of the most renowned hero and prince of his age. This formed a conjunction of circumstances, uncommonly favourable towards exalting the imagination of a poet.

"The manners of Ossian's age were favourable to a poetical genius. Covetousness and effeminacy were unknown. The cares of men were few. The great object pursued by heroic spirits, was, 'to receive their fame,' that is, to become worthy of being celebrated in the songs of bards; and 'to have their names on the four gray stones.' To die unlamented by a bard was deemed so great a misfortune as even to disturb their ghosts in another state. In such times as these, in a country where poetry had been so long cultivated, and so highly honoured, is it any wonder that, among the race and succession of bards, one Homer should arise: a man who, endowed with a natural, happy genius, favoured by peculiar advantages of birth and condition, and meeting, in the course of his life, with a variety of incidents proper to fire his imagination, and to touch his heart, should attain a degree of eminence in poetry, worthy to draw the admiration of more refined ages?"

Besides, his compositions, when viewed in themselves, have, we are told, all the internal marks of antiquity so strongly impressed upon them, that no reader of taste and judgment can deny their claim to it. They exhibit so lively a picture of customs which have disappeared for ages, as could be drawn only from nature and real life. The features are so distinct, that few portraits of the life continually passing before us are found to be drawn with so much likeness. The manners uniformly relate to a very early stage of society; and no hint, no allusion to the arts, customs, or manners, of a more advanced

vanced period, appears throughout the poems. To that distinction of ranks, which is always found in adult societies, the poet appears to have been a perfect stranger. The first heroes prepare their own repasts, and indiscriminately condescend to the most menial services. Their quarrels arise from causes generally slight, but in such a period extremely natural. A rivalship in love, an omission at a feast, or an affront at a tournament, are often the foundation of a quarrel among single heroes. And the wars in which whole tribes are engaged, are carried on with a view, not to enlarge their territory, but to revenge perhaps the killing of a few deer on their mountains, or the taking forcibly away one of their women. Their occupation was war and hunting; and their chief ambition was to have their fame in the songs of the bards.

The notions of a future state, exhibited in these poems, are likewise strongly marked with the character of antiquity. A creed so uncommon, that the imagination of a modern could not be supposed to grasp so strong an idea of it from mere fancy, is uniformly supported throughout. This creed is extremely simple, but admirably suited to the times.

The language, too, and the structure, of these poems, bear the most striking characters of antiquity. The language is bold, animated, and metaphorical, such as it is found to be in all infant states; where the words, as well as the ideas and objects, must be few; and where the language, like the imagination, is strong and undisciplined. No abstract, and few general, terms appear in the poems of Ossian. If objects are but introduced in a simile, they are always particularized. It is "the young pine of Inishuna:" it is "the bow of the showery Lena." This character, so conspicuous in the poems of Ossian, is a striking feature in the language of all early states; whose objects and ideas are few and particular, and whose ordinary conversation is of course highly figurative and poetical. A picture, therefore, marked with such striking features, could not be drawn without an original.

The whole texture of the composition is also, like the language, bold, nervous, and concise; yet always plain and artless; without any thing of that modern refinement, or elaborate decoration, which attend the advancement of literature. No foreign ornaments are hunted after. The wild and grand nature which lay within the poet's view, is the only source from which he draws his ornaments. Beyond this circle, his imagination, though quick and rapid, seldom made any excursion. We perceive his language always to be that of a person who saw and felt what he describes; who bore a part in the expeditions which he celebrates, and who fought in the battles which he sings. Such is the nature of the internal proof adduced in the present case, which unquestionably has weight, and that not inconsiderable; but unsupported by external proof, or contrary to facts, however forcible it may be in itself, when considered in this connection, and found wanting, it will neither silence the querulous sceptic, nor, in all probability, will it ever convince those who have truth for their object, and who wish to investigate, and, if possible, discover it on surer grounds. Internal proof is of the greatest service in a variety of excellent causes; but it comes in rather as a succedaneum than as direct evidence; and without something more to the purpose, it may excite admiration, but will seldom enforce belief. Of the customs and manners of ancient times we know but little, and of that little we have often but a confused notion. There is therefore room for genius and ability to exert itself in deceiving; and in proportion to the darkness in which the subject is involved, the deception will generally be the more complete, and the secret windings of error less easy to be developed.

Destitute of external proof, authenticity may appear to be probable, but cannot be certain; and in such circumstances, on many occasions, and especially with respect to ancient writings, we may, without any offence to truth or to sound reasoning, give them up as spurious. In the present instance, therefore, it is just and proper to add to what has been already said, the more external and positive proofs of the authenticity of the poems in question, by the strength or weakness of which the subject must be finally determined. It is observed, therefore, That there have been in the Highlands of Scotland, for some ages back, a vast many poems ascribed to Ossian: That these poems have been held in the highest veneration, repeated by almost all persons, and on all occasions. These are facts so well known, that nobody as yet has been hardy enough to deny them. There is not an old man in the Highlands, who will not declare, that he heard such poems repeated by his father and grandfather as pieces of the most remote antiquity. There is not a district in the Highlands where there are not many places, waters, isles, caves, and mountains, which from time immemorial are called after the names of Ossian's heroes.—There is not a lover of ancient tale or poetry, however illiterate, who is not well acquainted with almost every single name, character, and incident, mentioned in those translations of Ossian's poems, which he may have never heard of.—Bards, who are themselves several centuries old, quote those poems, imitate them, and refer to them.—The ordinary conversation and comparisons of the Highlanders frequently allude to the customs and characters mentioned in them;—and many of their most common proverbs, established by the most ancient use, are lines borrowed from the poems of Ossian *.—The most ancient of the clans boast of deriving their pedigree, each from some one of Ossian's heroes;—and many of the signs armorial assumed by them, are drawn from the feats ascribed to their predecessors in those poems †. Manuscripts are mentioned, in which some of those have been preserved for several centuries ‡; and a list of living names, in different part of the Highlands, is appealed to, as persons who still repeat a part of these poems ‖. Whilst Mr Macpherson was engaged in the translation, many respectable persons, gentlemen and clergymen, avowed to the public, that these were Ossian's poems, with which they had long been acquainted, and that the translation was literal §. This appears also from the large specimens of the originals published and compared by proper judges. The originals lay a considerable time in the hands of the bookseller, for the inspection of the curious; they have been afterwards shown frequently to many of the best judges, and offered for publication if the editor had been favoured with subscriptions. The editor of the pamphlet, in which their authenticity is attested by many respectable names of undoubted veracity, observes, by way of conclusion, "that more testimonies might have been produced by a more enlarged correspondence

Ossian.

correspondence with the Highland counties: But I apprehend, if any apology is necessary, it is for producing so many names in a question where the consenting silence of a whole country was, to every unprejudiced person, the strongest proof that spurious compositions, in the name of that country, had not been obtruded upon the world." It is likewise argued in support of the authenticity of these poems, that candid sceptics, on hearing some of them repeated by illiterate persons, who had never seen the translation, caused them to give the meaning of what they repeated, by an extempore translation into English, and by this means had all their doubts of the authenticity of Ossian removed *. They urge further, that such passages of Ossian's works as are still repeated by some old men, are among the most beautiful parts of Ossian's poems; such as the battle of Lora, the most affecting parts of Carthon, Berrathon, the death of Oscar, and Darthula, or the children of Usnoth, &c.; which gives a credibility to his being equal to the other parts of the collection, none of it being superior to these in merit.

* Pref. to Dr Percy's *Reliques of Old English Poetry.* 1st edit.

To these and the like arguments advanced in support of the authenticity of the poems ascribed to Ossian, many objections have been urged. Those of Johnson and his friend Shaw are universally known. A later writer objects to them in the following manner: No fragments of British poetry in Scotland are to be found. Many specimens of Irish poetry in Scotland have been published; but none older than a century or two. Translations have also appeared; but, in general, of no fidelity. Those of the poems ascribed to Ossian in particular, have deservedly drawn much of the public attention; but they will only mislead any reader who wishes to form an idea of Celtic poetry. He that believes Ossian to have flourished about the year 300, and his writings preserved by oral tradition for 1460 years, large is his faith, and he might move mountains! Gentlemen of the Highlands of Scotland, with whom our author conversed on the subject, assured him, that they looked upon nine-tenths of Mr Macpherson's work as his own; and upon the other tenth, as so much changed by him, that all might be regarded as his own composition. There are positive evidences, he says, which convince him that not one of the poems given to Ossian, and probably not one passage of them is older than the 15th century. The very first author we know who mentions Fingal, is Barbour, a Scotch poet, who wrote in 1375. Fingal was an Irish hero: and one Good, a schoolmaster of Limerick, sent some account of Ireland to Camden, in 1566, in which mention is made of some strange fables, that the people amuse themselves with, about the "giants *Fin Mac Huyle*, and *Other Mac Oshin*," of which we shall speak more largely presently. In the mean time, to these and such like objections, it has been answered, That poetry has been cultivated with most success in the earliest ages of society; that in Greece, Orpheus, Linus, Hesiod, and Homer, wrote their admirable poems some ages before any thing had been written in prose in the Greek language; that the book of Job, written in a very early period of society, is highly poetical; that among the tribes of Lapland and America, there have been found, in the earliest state, some excellent pieces of poetry. That the Caledonians, in particular, had some peculiar institutions, which tended to improve their poetry: their druids were among the most learned philosophers which perhaps any age or country produced; their bards or poets were the disciples of those druids, and were always a standing order, to which none but the most promising geniuses were admitted. This standing college of poets was furnished, not only with the fruits of their own long study and observation, but also with as much as merited to be preserved of the compositions of their predecessors in office, since the "light of the song" first dawned. They had the advantage of one another's conversation; which would excite their emulation, and make them aspire to eminence: They were always present, and generally engaged, in every grand operation that was transacted; which could not fail to inspire their muse with the truest poetic fire.

Pinkerton.

The case of Ossian was particularly favourable. He lived in an age when manners came to a considerable degree of refinement under the care of the bards and druids. Poetry in his day was considerably advanced; and the language, though strong and figurative, had undergone some degree of cultivation, and learned to flow in regular numbers, adapted to the harp, the favourite instrument of the times. As a prince and a warrior, his mind must have been expanded and much enlarged by his excursions to other countries. At home he had Ullin, Alpin, Carril, and Ryno, to converse with; all of them poets of eminence, who would have advanced him greatly by their example and conversation. All these advantages, meeting with a native fire and enthusiasm of genius, as in the case of Ossian, may well be supposed to have produced poems that might challenge the veneration of ages.

But it is not to their merit alone that we owe the preservation of these poems so long by oral tradition. Other circumstances concurred; of which, the institution of the Bards deserves particular notice. In a country, the only one perhaps in the world in which there was always, from the earliest period almost to the present age, a standing order of poets, we cannot reasonably be surprised, either at finding excellent poems composed, or, after being composed, carefully preserved from oblivion. A great part of the business of this order was to watch over the poems of Ossian. In every family of distinction there was always one principal bard, and a number of disciples, who vied with each other in having these poems in the greatest perfection. Should the institution of the bards last for ever, the poems of Ossian could never perish.

Nor were they only the bards of great families who took an interest in these poems; the vassal, equally fond of the song with his superior, entertained himself in the same manner. This, with a life free from care, a spirit unbroken by labour, and a space of time unoccupied by any other employment or diversion, contributed to render the Highlanders a nation of singers and poets. From such a people, the superior merit of Ossian's poems would naturally procure every encouragement, which they always retained as long as the manners of the people remained unchanged.

Many other reasons conspired to preserve the poems of Ossian. The martial and intrepid spirit which they breathed, made it the interest of the chieftains to preserve them: the strain of justice, generosity, and humanity, which runs through them, recommended them to the superintendants of religion, who well knew how

Ossian. much the morals of a people must be tinctured with those songs which they are continually repeating, and which have all the advantages of poetry and of music. In superstitious ages, the people revered these poems, from their being addressed generally to some "son of the rock," supposed to be the tutelar saint of the place, or the great Irish apostle St Patrick. Besides, every hill and dale which the natives of the Highlands walked over, was classic ground. Every mountain, rock, and river, was immortalized in the song. This song would naturally be suggested by the sight of these objects, and everybody would hum it as he walked along. All the proverbs and customs to which these poems gave rise, would operate in the same manner. The son would ask what they meant, and the father would repeat the song from which they were taken. The distinct and unsubdued state in which the Highlanders remained for so long a course of ages, every clan, one generation after another, inhabiting the same valley, till towards the present century, contributed much to preserve their traditions and their poems; and the constant and general custom of repeating these in the winter nights, kept them always alive in their remembrance.

To these causes and customs the preservation of Ossian's poems, for so many ages, has been ascribed. But these causes and customs have ceased to exist; and the poems of Ossian, of course, have ceased to be repeated.—Within a century back, the Highlands of Scotland have undergone a greater revolution than it had done for ten before that period. With a quicker pace the feudal system vanished; property fluctuated; new laws and new customs stept in, and supplanted the old: and all this, with such sudden and such violent convulsions, as may well account for the shaking of a fabric which had stood so many ages, that it seemed to have bidden defiance to all the injuries of time. Even since Mr Macpherson gathered the poems in his collection, the amusements, employments, and taste of the Highlanders are much altered. A greater attention to commerce, agriculture, and pasturage, has quite engrossed that partial attention which was paid, even then, to the song of the bard. In twenty years hence, if manners continue to change so fast as they do at present, the faintest traces will scarce be found of those tales and poems. "Ossian himself is the last of his race; and he too shall soon be no more, for his gray branches are already strewed on all the winds."

Among the causes which make these poems vanish so rapidly, poverty and the iron rod should come in for a large share. From the baneful shade of those *murderers of the muse*, the light of the song must fast retire. No other reason needs be given why the present Highlanders neglect so much the songs of their fathers.—Once, the humble, but happy vassal, sat at his ease, at the foot of his grey rock or green tree. Few were his wants, and fewer still his cares; for he beheld his herds, sporting around him, on his then unmeasured mountain. He hummed the careless song, and tuned his harp with joy, while his soul in silence blessed his children.—Now, we were going to draw the comparison:

————sed Cynthius aurem
Vellit et admonuit.

It is more agreeable to remark, as another cause for the neglect of ancient poems and traditions, the growth of industry, which fills up all the blanks of time to more advantage, and especially the increase of more useful knowledge.—But above all, the extinction of the order of the bards hastened the catastrophe of Ossian's poems. By a happy coincidence Macpherson overtook the last that remained of this order, (Macvaurich, bard to Clanronald), and got his treasure. This fact (with the *red book* furnished by Mr Macdonald of Croidart, and some other MSS.) accounts for Mr Macpherson's having found these poems in greater number and perfection, than they could ever since be met with. The fragments, however, which have since been gathered, give a credibility to every thing that has been said of the original grandeur of the building.

Although this disquisition has already extended to a length which readers not partial to Scottish antiquities will perhaps think too great, we cannot dismiss it without observing, that Fingal and Ossian have been claimed by the Irish as well as by the Caledonians. On this double claim, as well as on the controversy concerning the authenticity of the poems, there is so much candour and good sense in the following remarks of T. F. Hill, published in the 53d volume of the Gentleman's Magazine, that we cannot deny ourselves the pleasure of making them conclude the article.

Mr Hill travelled through the Highlands of Scotland during the summer months of 1780. He seems to have been very ardent in his inquiries concerning Ossian, and to have conducted those inquiries with great judgment. The consequence was, that he received different accounts in different places, and picked up various songs relating to Fingal and his heroes.

"From this collection, it is evident (says he) that there are many traditional songs preserved in the Highlands relating to Fingal and his heroes, as well as to several other subjects. It is also evident, that these songs contain portions of the very poems published by Mr Macpherson and Mr Smith, under the name of *Ossian*. We may therefore justly conclude, that these poems are not wholly the forgery of their editors, but compiled at least from original songs. I by no means think it worth my while to notice the various concessions in favour of this conclusion, which the minor antagonists of Ossian have of late been forced to make. I myself have given proofs of it, which need I hope no external confirmation. To these proofs might be added, that I met with many traditional preservers of these songs, in every different part of the Highlands: some of whom, especially in Argyleshire, Lochaber, and on the rest of the western coast, were said to possess various poems attributed to Ossian, although I had neither leisure nor opportunity to collect copies from them.—But enough has already been said on this subject, if my testimony deserves regard.

"These principles being established, it remains to be considered how far the poems published by Macpherson and Smith deserve to be considered as the works of Ossian.

"The songs attributed to that bard, which contain passages of the Ossian of Macpherson and Smith, are by no means uniformly consistent with the poems in which the

the parallel passages are found, but frequently relate to different events, and even contain different circumstances. From hence it seems most probable, that Mr Macpherson and Mr Smith compiled their publications from those parts of the Highland songs which they most approved, combining them into such forms as according to their ideas were most excellent, and preserving the old names and the leading events. In this process they were supported and encouraged by the variety of songs preserved in the Highlands upon the same subject, and by the various modes in which the same event is related. Mr Macpherson may indeed have MSS. of all the poems he has published; which MSS. may either have been compiled by himself, or by some former collector; or they may possibly contain entire poems really ancient. But Mr Smith has honestly acknowledged, that he himself compiled his Ossian in the manner above described. 'After the materials were collected (says he), the next labour was to compare the different editions; to strike off several parts that were manifestly spurious; to bring together some episodes that appeared to have a relation to one another, though repeated separately; and restore to their proper places some incidents that seemed to have run from one poem to another:—and hence it was unavoidably necessary to throw in sometimes a few lines or sentences to join some of the episodes together.—I am sensible that the form of these poems is considerably altered from what is found in any one of the editions from which they are compiled. They have assumed somewhat more of the appearance of regularity and art —than that bold and irregular manner in which they are originally delivered.'

"Mr Smith also speaks of the Ossian of Mr Macpherson in a somewhat similar manner: 'That we have not the whole of the poems of Ossian, or even of the collection translated by Mr Macpherson, we allow: yet still we have many of them, and of almost all a part. The building is not entire, but we have still the grand ruins of it.'

"What portion, therefore, of the Ossian of Macpherson and Smith is original, no man can determine except themselves. Smith indeed says, that he has mentioned all his *material* alterations, transpositions, and additions, in his notes; and that, *for the most part*, he was guided in them by the Sgeulachds, or traditionary tales accompanying the songs; but there are few such notes in his book, and perhaps as few *such* Sgeulachds in the mouths of the Highlanders. In Macpherson and Smith also we see these poems divested of their idiomatic peculiarities and fabulous ornaments; which renders it impossible to discover what manners and opinions are really ancient, and what are of modern invention. Yet it is remarkable, that in spite of all the objections to their authenticity, necessarily produced by such a treatment of them, they still possess an internal evidence of originality which has enabled them hitherto to withstand all the torrent of opposition.

"The Ossian of Macpherson and Smith appears therefore to be a mutilated work, even though we should suppose that the songs they originally compiled from were the undoubted works of that celebrated bard. But this is far from being the case; for even allowing that an Ossian ever existed and wrote, yet time must have introduced such material changes in his works if preserved merely by tradition during so long a period, that their own author would hardly know them again. I think it however doubtful, whether such a being as Ossian ever appeared in the world.

"All the songs which I met with in the Highlands relative to the Feinne or Fingalians were attributed to Ossian: his name seems merely a common title, which is ascribed to all the poetic annals of his race.

"From these considerations, we seem authorized finally to conclude, that the Ossian of Macpherson and Smith is a mutilated compilation from Highland songs, ascribed indeed to that bard, yet very little likely to be his composition. Out of these they selected the best parts, and rejected such as they thought might discredit the character of Highland antiquity; attributing them to later times, and the ignorant bards of the fifteenth century. Perhaps even the works of Homer himself, which had so many different editions, very considerably varying from each other, were compiled by a somewhat similar process from the ancient Greek songs.

"Another question remains to be considered: Whether these songs are the compositions of the Highlands or of Ireland; and, whether Ossian was an Irish or a Caledonian Scot? It is my opinion, that the songs in this collection evidently manifest a connection with Ireland, though their traditional preservation in Scotland has sometimes introduced the name of Scotland in its stead. One of their principal personages is St Patrick, the peculiar apostle of Ireland, which alone seems sufficient to mark their origin (A). If therefore we may reason from a part to the whole, it is just to conclude, that all the other songs preserved in the Highlands relative to the Fingalians are also Irish. They are wholly confined to the western coast of the Highlands, opposite Ireland; and the very traditions of the country themselves acknowledge the Fingalians to be originally Irish. The genealogy of Fingal was there given me as follows: Fion Mac Coul, Mac Trathal, Mac Arsht Riogh Erin, or king of Ireland; thus attributing the origin of his race to the Irish. I am inclined to believe that these notions about Fingal were common to the Scots in the most ancient times, and brought by them from Ireland to Scotland, the hereditary superstition of both races; for, notwithstanding it may appear most probable that Ireland should receive colonies from Scotland than the contrary, we have direct historic evidences that Scotland received them from Ireland; and no bare theoretic probability deserves to be opposed to the positive assertions of history.

"With regard to the Erse manuscripts, about which so much has been said, it becomes me to acknowledge, that

(A) "The Scots indeed lay claim to the birth of St Patrick, and boast also his burial-place. Camden, edit. Gibson, 1695, pp. 921, 1014. And so also do the Britons, ib. p. 631, 1014; but his life and miracles all agree to attribute it to Ireland. In Gough's edition of Camden, the account of St Patrick is in vol. iii. p. 612, 618. See PATRICK, *St*.

that I have never seen enough of them to give any decided opinion: those which I have seen induced me to think they principally owe their existence to Ireland.

"I shall not repeat what others have said to prove the Fingalians Irish; though the connection of Fingal with Ireland has been already warmly asserted.

"But an unnoticed though curious, passage in Camden affords us the most remarkable, and perhaps the most convincing proof that Fingal is an Irish hero, which demonstrates at least that he was indisputably claimed by the Irish 200 years ago. It is contained in an extract (already mentioned) made by Camden, from an account of the manners of the native Irish, written by one Good, a schoolmaster at Limerick, in 1566. 'They think,' says he, speaking of Ireland and its inhabitants, 'the souls of the deceased are in communion with famous men of those places, of whom they retain many stories and sonnets; as of the giants Fin-Mac-Huyle, Oskir-Mac-Oschin, or Oschin-Mac-Owim; and they say, through illusion, that they often see them.'

"The very material importance of this curious passage, with relation to the present subject, it is unnecessary to urge; for every eye must see it. We also obtain from it new information in respect to the last part of the history of Fingal and his heroes; as it enables us to determine who they were with a precision which must otherwise have been wanting, to complete these remarks on the Highlands songs.

"The singular agreement of this passage with the accounts of Ossian which were taught me in Scotland is worthy particular remark; it confirms them even in the most novel and peculiar instances. The Fingalians were generally represented as giants: but the most remarkable occurrence is in the mythologic character attributed by both to Fingal, Oscar, and Ossian. In proof of this, I have to observe, that Mac Nab described Fingal as the Odin of the Scots, and that a song called *Urnigh Ossian* evidently speaks of him as such. This curious passage represents him exactly in the same character; a hero with whom the spirits of the deceased are in communion, who is their chieftain, and the lord of their feasts. The gods of all the northern nations seem to have been of this class; mighty heroes, esteemed once to have been invincible on earth, though perhaps not ever strictly men, nor yet constantly regarded as giants. Such are Odin, Thor, and the other Teutonic gods; such are Fingal, Oscar, and the rest of the Fingalians among the ancient Scots; such are Hercules, Bacchus, and even Jupiter himself, with all his sons and daughters, among the original Greeks, a people who agreed in many particulars with our own ancestors in northern Europe. The notions entertained about ghosts, as an intermediate order of beings between men and divinities, endowed with some share of power to do evil, is also remarkably congruous with this mythology.

"As Fingal was a divine hero, so Ossian seems to have been a divine bard. Some of the gods of the Teutons were bards in like manner; the god Niord and his wife Skada quarrelled in elegant verse of their own composition; and Odin is the relator of his own Edda. Apollo, the poetic deity of Greece, likewise sung the history of his fellow-deities to men on earth, as well as Orpheus his son. The bards and traditional preservers of songs in Scotland and Ireland have ever been fond of ascribing all ancient poems to this Ossian, and especially those relating to his own race; and from this cause the poems ascribed to Ossian are become so voluminous. The ancient Egyptians had a similar custom of ascribing their works to Hermes: οἱ ἡμέτεροι προγονοι τα αὑτων της σοφιας ευρηματα αυτῳ ανετιθεσαν Ἑρμου παντα τα οικεια συγγραμματα επονομαζοντες, says Jamblichus, S. I. c. 1. which rendered the Hermetic writings equally voluminous. The Egyptians, who possessed the art of writing, deposited their works in the adyta of their temples; as the Arabians deposited their poems of old in the temple of Mecca: but because the Egyptians affixed to them no author's name, except that of Hermes, to him, as to the Scottish Ossian, almost all the national literature was attributed by religious flattery.

"I sincerely wish, that some gentleman possessed of adequate abilities and acquaintance with the Erse language, would undertake to collect these Ossianic songs in their simple original state; as they undoubtedly contain much curious knowledge, accumulated in the various ages through which they have descended to us, and would probably afford much new information on subjects at present very ill understood. I own, however, that I should rather choose to seek for them in Ireland than in Scotland; but neither country should be unexplored.

"After having thus freely, though I hope not uncandidly, delivered my sentiments on the Ossian of Mr Macpherson, it becomes me to acknowledge myself deeply indebted to it for the pleasure in perusal it has frequently afforded me. I am willing, and indeed happy, thus publicly to declare myself a warm admirer of it as a literary composition. The novelty of its manner, of its ideas, and of the objects it describes, added to the strength and brilliancy of genius which frequently appears in it, have enabled me to read it with more delight, and to return to it more frequently, than almost any other work of modern times. And let it be regarded in what light it may, the praise of elegant selection and composition certainly belongs to its editor. If I had not entertained these opinions of its merit, I should never have taken so much pains to investigate its authenticity; nor indeed can I believe, if the general opinion had not concurred with mine, that the world would ever have wasted so much time in disputing about it."

Since what has now been said concerning the authenticity of the poems of Ossian was written, the same subject has been again brought under discussion, and more keenly and ably agitated than at any former period of the controversy. Among those who have entered the lists in this controversy, Mr Laing the historian appears by far the most powerful opponent of the authenticity of these celebrated poems. In a historical and critical dissertation* on this subject, Mr Laing roundly asserts, that the poems, as ascribed to Ossian, a bard of the third century, are forgeries, and charges Macpherson, as well as Smith (in our opinion too hastily and rashly), with direct fraud in imposing on the world their own productions as the genuine translations of ancient Gaelic poems. The arguments for the detection of these forgeries are arranged under eight different heads: 1. The Roman History of Britain with which Macpherson has connected the poems by false and incorrect allusions. 2. The traditionary poems in the Highlands refer to the middle ages,

* Hist. of Scotland.

ages, that is, about the 9th and 10th centuries. 3. The difficulty or impossibility of preserving poems by oral tradition for a period of 1500 years. 4. The remarkable diversity in the manners of the Highlanders at the period in which Fingal lived, as described by historians, and as they are represented by Ossian; and the contradiction of great refinement at an early age and extreme barbarism in a future age, are considered by Mr Laing as strong and decisive proofs of forgery. 5. From tracing the origin of the poems to other works of Macpherson, particularly to an epic poem entitled the Highlander, published at Edinburgh in 1758, which, being unsuccessful, appeared afterwards as fragments of ancient poetry, Mr Laing thinks another proof of detection is derived. 6. A sixth source of detection, in his opinion, may be traced to the imitation of the classics, scripture, and other writings. 7. Mr Laing asserts that the specimens of the original produced by Macpherson were either written or translated into Erse from the English original, by the supposed translator himself. 8. From the ambiguous language which Macpherson seems to have employed at different times during the progress of the numerous editions of the poems, Mr Laing infers a distinct avowal of fraud. But for the illustration of the arguments now noticed we must refer the reader to the dissertation itself.

It was not to be expected that charges so formally adduced, and so keenly supported, would pass altogether unnoticed by the admirers of the poems of Ossian, or the believers in their authenticity. Accordingly, we find that Mr Laing's arguments have been combated by different writers with various success. Among the works on this side of the question which have fallen in our way, the Essay on the Authenticity of the Poems of Ossian by the Rev. Dr Graham, holds the most respectable place. But our limits absolutely preclude us even from stating his arguments. We refer therefore to the work itself which, the reader will not dislike to find, is written with some degree of elegance, and, what is not usual in controversy, with a great degree of temper and moderation. The reader who wishes to pursue this investigation, may consult also a Treatise on the same subject by Mr Macdonald, the Report on Ossian by a Committee of the Highland Society of Scotland; and the Gaelic scholar has now an opportunity of perusing the Originals, which have been published by Sir John Sinclair.

OSSIFICATION, in the animal economy, the formation of the bones, but more particularly the conversion of parts naturally soft to the hardness and consistency of bones. Bones, Dr Drake contends, are formed out of the most comminute or broken parts of the blood; since we see that the blood of old men, which by a long course of circulation becomes in a manner unfit for the common office of nutrition, will however ossify, and convert into bones, many of the tendons and ligaments, and even the coats of the vessels themselves, whose substance being next to the bones the most compact, admits only of the smallest particles of the blood, which therefore soonest become osseous, as they are frequently found. Dr Nisbet's opinion of ossification is, that in the blood, or a fluid secreted from it, there is an ossifying juice, having particles which are not apparent: that whenever nature designs an ossification between membranes, or within a cartilage, she occasions a more than usual afflux of this fluid; which so much distends the vessels which were before invisible, as to make them capable of receiving the red globules of blood, which is always to be seen near to the place where ossification is begun. In this blood gritty bony particles may be felt by the point of a knife, which have been formed by the attraction and cohesion of the particles of the ossifying juice obstructed, along with the other grosser fluids, in the beginning of the vessels prepared to receive refluent juices. The blood being capable of forming fine membranes, the membranous parts of a bone, which acts as a gluten to keep these particles and fibres together, if there be any such, that do not arise from the coats of its vessels, are produced by a cohesion round the cretaceous particles of a part of the fluid, in which they were generated and contained. Thus the membranes of cartilages serve as a bed, between or within which the bony particles are deposited, or shoot; but without any intermixture of the particles of the bone and cartilage, or continuation of the fibres of the one substance to those of the other, as is evident in cartilages containing bones kept long enough in water, and then slit; for the bone will, as soon as the large vessels that enter its substance are divided, slip as easily, and perhaps easier, from it than an acorn does out of its cup: and there is a smoothness and polish of the parts of both cartilage and bone, which show there is no conjunction of the fibres of the two substances. While the bones are increasing within cartilages, the cartilages are extended and spread out; by which, with the pressure which they suffer, and the great influx of various fluids, and the nutritious matter being hindered to flow freely into them, they decrease continually, and at last may truly be said to be entirely destroyed. Dr Buddeus endeavours to prove, that the preternatural ossifications, which are commonly said to be formed in different parts of the body, do not deserve that name; for that these hard substances have scarcely any other properties of bone except whiteness and hardness.

OSSORY, the west division of Queen's-county in Ireland.

OSSORY, *Bale, bishop of*. See BALE.

OSSUNA, an ancient and considerable town of Andalusia in Spain, with an university, an hospital, and the title of a duchy. N. Lat. 37. 8. W. Long. 4. 18.

OSTADE, ADRIAN VAN, an eminent Dutch painter, born at Lubec in 1610. He was a disciple of Francis Hals, in whose school Brouwer was cotemporary with him, where they contracted an intimate friendship. The subjects of his pencil were always of a low kind, he having nearly the same ideas as Teniers; diverting himself with clowns and drunkards in stables, ale-houses, and kitchens. His pictures are so transparent and highly finished, that they have the polish and lustre of enamel: they have frequently a force superior to Teniers; yet it were to be wished that he had not designed his figures so short. He is perhaps one of the Dutch masters who best understood the *chiaro obscuro*; and he was often employed to paint figures for the best landscape painters of his countrymen. He died in 1685. His works, especially those of his best time and manner, are very scarce; so that when they are to be purchased, no price is thought too much for them. His prints etched by himself, large and small, consist of 54 pieces.

OSTALRIC, a town of Catalonia, in Spain, having a strong castle, and seated on the river Tordera, in E. Long. 2. 45. N. Lat. 24. 44.

OSTEND,

Ostend, Osteocolla.

OSTEND, a very strong sea-port town of the Netherlands, with a good harbour and a magnificent town-house, and containing 10,288 inhabitants in 1800. It is not very large, but it is well fortified. It was much more considerable before the long siege of the Spaniards, which continued from 1601 to 1604, when it was almost entirely reduced to ashes. The Dutch lost 50,000 men, and the Spaniards 80,000. Isabella Eugenia, governante of the Netherlands, made a vow she would not shift her smock before Ostend surrendered; but before the town was taken it had greatly changed its colour. However, the ladies of the court, to keep her in countenance, had theirs dyed, that they might be like that of their mistress. This place was taken by the Dutch in 1706, but restored to the emperor in 1724, when an East India company was established here, but entirely suppressed by treaty in 1731. It was taken by the French in August 1745, after 10 days siege, but restored by the treaty of Aix-la-Chapelle. It was taken again by the French republicans, under Dumourier, but was quickly recovered by the allies. The French repossessed it in 1794. Here the British landed a body of troops in May 1798, who blew up and destroyed the works of the Bruges canal; but the wind shifting before they could re-embark, they were under the necessity of surrendering to the French. In 1814 it separated from France with the Netherlands. It is 10 miles W. of Bruges, eight N. E. of Newport, 22 N. E. of Dunkirk, and 60 N. W. of Brussels. E. Long. 2. 56. N. Lat. 51. 14.

OSTEOCOLLA, οστεοκολλα, in *Natural History*, a white or ash-coloured sparry substance, in shape like a bone, and by some supposed to have the quality of uniting broken bones, on which account it is ordered in some plasters; a supposition, we fear, which is not warranted by experience. It is found in long, thick, and irregularly cylindric pieces, which are in general hollow, but are sometimes filled up with a marly earth, and sometimes contain within them the remains of a stick, round which the osteocolla had been formed; but though it is plain from thence that many pieces of osteocolla have been formed by incrustations round sticks, yet the greater number are not so, but are irregularly tubular, and appear to be formed of a flat cake, rolled up in a cylindric shape. The crusts of which these are composed do not form regular concentric circles round the internal cavity, as must have been the case had they been formed by incrustation. On the other hand, they plainly show that they were once so many thin strata, composing a flat surface, which has afterwards been rolled up, as one might do a paper three or four times doubled, into two, three, or more spiral lines; in which case, each single edge of the paper would be everywhere a regular point of a continued spiral line drawn from a given point; but they would by no means be so many detached concentric circles. The osteocolla is found of different sizes, from that of a crow-quill to the thickness of a man's arm. It is composed of sand and earth, which may be separated by washing the powdered osteocolla with water, and is found both in digging and in several brooks, in many parts of Germany, and elsewhere. It is called hammosteus in many parts of Germany. It has this name in these places from its always growing in sand, never in clay, or any solid soil, nor even in gravel. Where a piece of it any where appears on the surface, they dig down for it, and find the branches run ten or twelve feet deep. They usually run straight down, but sometimes they are found spreading into many parts near the surface, as if it were a subterraneous tree, whose main stem began at 12 feet depth, and thence grew up in a branched manner till met by the open air. The main trunk is usually as thick as a man's leg, and the branches that grow out from it are thickest near the trunk, and thinner as they separate from it. The thinnest are about the size of a man's finger. The people employed to collect it, when they cannot find any mark of it on the surface, search after the specks of white or little lumps of whitish soft matter, which they find lying in various parts on the top of the sand. These always lead them either to a bed of perfect osteocolla, or to some in the formation. If they miss of it, they still find a substance like rotten wood; which when traced in its course, is found to proceed from a main trunk, at the depth of that of the osteocolla, and to spread itself into branches in the same manner. The diggers call this substance the flower of osteocolla, or hammosteus.

Osteocolla || Ostervald.

The osteocolla found in the earth is at first soft and ductile, but in half an hour's time, if exposed to the air, it becomes as hard as we find it in the shops. The method to take up a perfect piece for a specimen is to open the ground, clear away the sand, and leave it so for an hour or thereabouts: in this time it will harden, and may be taken out whole. It is certain, that the osteocolla is produced at this time; for if a pit be cleared of it, there will more grow there in a year or two, only it will be softer, and will not harden so easily in the air as the other. What the rotten substance resembling the decayed branches of trees is, we cannot determine, unless it really be such; but the opinion of the common people, that it is the root of something, is absurd, because its thickest part always lies at the greatest depth, and the branches all run upwards. The osteocolla is a marly spar, which concretes round this matter; but what it is that determines it to concrete no where on the same ground but about these branches, it is difficult to say. The rottenness of this substance, which forms the basis of the osteocolla, renders it very liable to moulder and fall away; and hence it is that we usually see the osteocolla hollow. Sometimes it is found solid; but in this case there will be found to have been a vegetable matter serving as its basis, and instead of one branch, it will be found in this case to have concreted about a number of fibres, the remains of which will be found in it on a close examination. See Phil. Trans. N° 39.

OSTEOLOGY, that part of anatomy which treats of the bones. See ANATOMY, Part I.

OSTERVALD, JOHN FREDERIC, a famous Protestant divine, was born at Neufchattel in 1663; and made such rapid progress in his studies, that he became master of arts at Samur before he was 16 years of age. He afterwards studied at Orleans and at Paris. At his return to Neufchattel in 1699, he became pastor of the church there; and contracted a strict friendship with the celebrated John Alphonsus Turretin of Geneva, and the illustrious Samuel Werenfels of Basil. The union of these three divines, which was called the *Triumvirate of the divines of Swisserland*, lasted till his death. Mr Ostervald acquired the highest reputation, by his virtues, his zeal in instructing his disciples, and restored ecclesiastical

siastical discipline. He wrote many books in French; the principal of which are, 1. A Treatise concerning the Sources of Corruption, which is a good moral piece. 2. A Catechism, or Instruction in the Christian Religion; which has been translated into German, Dutch, and English; and the Abridgement of the Sacred History, which he prefixed to it, was translated and printed in Arabic, in order to be sent to the East Indies, by the care of the Society for the Propagation of the Gospel; and that Society established in London, paid him a high compliment, by admitting him an honorary member. 3. A treatise against impurity. 4. An edition of the French Bible of Geneva, with Arguments and Reflections, in folio. 5. *Ethica Christiana*. 6. *Theologiæ Compendium*, &c. He died in 1747, regretted by all who knew him.

OSTIA, a town situated at the mouth of the Tiber, about 12 miles to the westward of Rome. It was built by Ancus Martius, the fourth king of Rome, and was called *Ostia Tiberina*, in the plural number, *i. e.* the two mouths of the Tiber, which were separated by the Holy Island, an equilateral triangle, whose sides were each of them computed at about two miles. The colony of Ostia was founded immediately beyond the left or southern, and the port immediately beyond the right or northern branch of the river; and the distance between their remains measures something more than two miles on Cingolani's map. In the time of Strabo, the sand and mud deposited by the Tiber had choked the harbour of Ostia; the progress of the same cause has added much to the size of the Holy Island, and gradually left both Ostia and the port at a considerable distance from the shore. The dry channels (*fiumi morti*), and the large estuaries (*stagno di Ponente, de Levante*), mark the changes of the river, and the efforts of the sea. Its port was one of the most stupendous works of Roman magnificence, and it was a long time one of the best towns on the coast; but having been destroyed by the Saracens, and the harbour choked up, as mentioned above, it has not been able since to recover itself. Though it be an inconsiderable place, and but poorly inhabited by reason of the badness of the air, yet it is the see of a bishop, who is always deacon of the cardinals, and crowns the Pope. The old Ostia, where are seen the ruins of the ancient harbour, is beyond New Ostia, towards the sea; the latter is but a little cluster of houses, with a small castle. It is 12 miles S. W. of Rome. E. Long. 12. 24. N. Lat. 41. 44. There were saltworks in Ostia, called *Salina Ostiensis*, as early as the times of Ancus Martius (Livy); from which the *Via Salaria*, which led to the Sabines, took its name, (Varro). It gave name to one of the gates of Rome, which was called *Ostiensis* (Ammian).

OSTIACKS, a people of Siberia in Asia. They live upon the banks of the rivers Oby and Yeuisey, and on those of some other rivers which fall into these. These people are very poor, and very lazy, and in the summer time live mostly upon fish. They are of a middle size, with broad faces and noses, and yellowish or red hair. All their garments from top to toe are made of fish skins, for they have neither linen nor woollen: and indeed they might almost as well go naked. Their greatest diversion is hunting; and they go together in crowds, with a weapon like a large knife fastened in a stick. In summer they take and dry the fish which serves them in winter; and when that season begins, they go into the woods with their bows and arrows, their dogs and nets, to kill sables, ermines, bears, reindeer, elks, martens, and foxes. Part of the furs of these is paid as a tax to the empress of Russia, and the rest are sold at a stated price to the Russian governors, but sometimes they are allowed to dispose of them to private persons.

They chiefly live upon venison, wild fowl, fish, and roots, for they have neither rice nor bread. They drink for the most part water, and it is said they can very well relish a draught of train oil. They are immoderately fond of tobacco, and of swallowing the smoke, which soon intoxicates them. In the winter they build their huts in woods and forests, where they find the greatest plenty of game, and dig deep in the earth to secure themselves from the cold, laying a roof of bark or rushes over their huts, which are soon covered with snow. In summer they build above ground on the banks of the rivers, to enjoy the convenience of fishing, and make no difficulty of forsaking their habitations. They have a sort of princes among them, in one of whose houses some European travellers found four wives (A). One of these had a red cloth coat on, and was set off with all sorts of glass beads. There was no other furniture than cradles and chests, made of the bark of trees sewed together. Their beds consisted of wood shavings, almost as soft feathers, and their children lie naked upon them in cradles. They can neither read nor write, nor do they cultivate the land; and seem totally ignorant of times past. They have neither temples nor priests; and their boats are only made of the bark of trees sewed together. Their religion is Pagan; and they have some little brazen idols, tolerably well cast, representing men and animals, made of wood and earth, all of which are dressed in silks in the manner of Russian ladies. In general, however, they are ill made, every man being his own carver. They place them on the tops of hills, in groves, and in the pleasantest places their country affords, and sometimes before their huts; yet they have no set time for performing religious worship, but apply to their gods for success in all their undertakings. As they have no regular priests, every old man may devote himself to that service, and the office is frequently performed by the masters and heads of families. Strahlenberg says, that when he was among them he saw one of their temples, which was built of wood in an oblong form, like a great barn, covered at the

(A) They may have as many wives as they please, and make no scruple of marrying their nearest relations. They purchase a wife of her relations for three or four rein-deer, and take as many as they please, returning them again if they do not like them, only losing what they gave for the purchase. Upon the birth of their children, some give them the name of the first creature they happen to see afterward. Thus the child has frequently the name of an animal, and you hear a man call his son perhaps *Sabatski*, or my little dog; others call their children according to the order of their birth, as *First*, *Second*, *Third*, &c.

the top with birch bark. At the end of the wall supporting the gable was a kind of altar, made of timber, on which were placed two idols, representing a man and woman, dressed in all sorts of rags; and round these were other small figures, as deer, foxes, and hares, all which were roughly carved in wood, and also clothed in rags. They did not appear to have much devotion, nor any great reverence for their idols. When they offer sacrifices, they present the beast to the idol; and having bound it, an old man puts up the petitions of those who brought the offering; he then lets fly an arrow at the beast, and the people assist in killing it. It is then drawn three times round the idol; and the blood being received into a vessel, they sprinkle it on their houses; they afterwards dress the flesh and eat it, rejoicing and singing their country songs: they also besmear the idol with the blood of the sacrifice, and grease their mouths with the fat. What they cannot eat they carry home to their families, and make presents of it to their neighbours: they as often sacrifice a fish as a beast. At the conclusion of the feast they shout, to show their gratitude to the idol for his attending and accepting their devotions; for they are persuaded that the saint or hero represented by the image always attends their sacrifices, which when over he returns to his abode in the air. There is nothing more surprising, nor, if properly improved, is there any thing more instructing, than the history of superstition. It is with this view that we have given so enlarged a view of the Ostiacks, longer, some may imagine, than their importance demands. It would, however, in our opinion, be improper to let such an opportunity slip of exhibiting the extreme weakness of unassisted reason, and the consequent necessity of a divine revelation. That the religion of these ignorant and misguided Pagans is the corruption of a primitive revelation, we think at least probable; nor do we see any way of so satisfactorily accounting for the universal use of sacrifices. The Ostiacks are obliged to take an oath of fidelity to the Russian government; and on these occasions they use the following ceremony. After laying down a bear skin and an axe, and holding over it a piece of bread and a knife, they say, "In case I do not to my life's end prove true and faithful to the supreme government of the country, or if I knowingly and willingly break through my allegiance, or be wanting in the duty I owe to the said supreme government, may the bear tear me to pieces in the wood; may the bread I eat stick in my throat and choke me; may the knife stab me, and the axe cut off my head." The like ceremony is used among them in the deposition of a witness.

OSTRACION, a genus of fishes belonging to the order *Cartilaginei*. See Ichthyology, p. 103.

OSTRACISM, in Grecian antiquity, denotes the banishment of such persons whose merit and influence gave umbrage to the people of Athens, lest they should attempt any thing against the public liberty. This punishment was called *ostracism*, from the Greek word ὀστρακον, which properly signifies a "shell;" but when applied to this object, it is used for the billet on which the Athenians wrote the names of the citizens whom they intended to banish. The learned are divided with regard to the substance of which this billet was formed: some insist that it was a small stone, or a piece of brick; some that it was a piece of bark; and others assert, that it was a shell. The word admits most of these interpretations. But what determines its true sense, is the epithet given it by ancient authors, of *ceramitè mastix;* which words signify, "The punishment of potter's clay;" and this expression seems to us a proof, that the word ὀστρακον, when applied on this occasion, signifies a "piece of baked earth, in the form of a shell;" and undoubtedly the Latin authors had this idea of the word here, for they translated it by *testula*.

The ancients are likewise divided with regard to the time when ostracism was instituted. But they all agree, that the person who moved the law was its first victim. But as to the name of its patron, and the time of its establishment, they differ extremely. Many are of opinion, that ostracism owes its origin to very remote times.

However that be, the punishment of ostracism was inflicted by the Athenians when their liberty was in danger. If, for instance, jealousy or ambition had sowed discord among the chiefs of the republic; and if different parties were formed, which threatened some revolution in the state; the people assembled to propose measures proper to be taken in order to prevent the consequences of a division which in the end might be fatal to freedom. Ostracism was the remedy to which they usually had recourse on these occasions; and the consultations of the people generally terminated with a decree, in which a day was fixed for a particular assembly, when they were to proceed to the sentence of ostracism. Then they who were threatened with banishment, omitted no assiduity or art which might gain them the favour of the people. They made harangues to evince their innocence, and the great injustice that would be done them if they were banished. They solicited, in person, the interest of every citizen; all their party exerted themselves in their behalf: they procured informers to vilify the chiefs of the opposite faction. Some time before the meeting of the assembly, a wooden inclosure was raised in the forum, with ten doors, i. e. with as many as there were tribes in the republic; and when the appointed day was come, the citizens of each tribe entered at their respective door, and threw into the middle of the inclosure the small brick on which the citizen's name was written whose banishment they voted. The archons and the senate presided at this assembly, and counted the billets. He who was condemned by 6000 of his fellow citizens, was obliged to quit the city within ten days; for 6000 voices, at least, were requisite to banish an Athenian by the ostracism.

The Athenians, without doubt, foresaw the inconveniences to which this law was subject; but they chose rather, as Cornelius Nepos hath remarked, sometimes to expose the innocent to an unjust censure, than to live in continual alarms. Yet as they were sensible that the injustice of confounding virtue and vice would have been too flagrant, they softened, as much as they could, the rigour of ostracism. It was not aggravated with the circumstances which were most dishonourable and shocking in the ordinary mode of exile. They did not confiscate the goods of those who were banished by ostracism. They enjoyed the produce of their effects in the places into which they were banished; and they were banished only for a certain time. But in the common banishment, the goods of the exiles were always confiscated, and no hopes were given them of ever returning to Athens.

The scholiast of Aristophanes informs us of a third difference betwixt ostracism and the common banishment. He says, that a particular place of retirement was assigned to those who were banished by ostracism, which was not appointed to the other exiles. We suspect, however, the truth of this observation; for Themistocles was certainly not limited in his banishment. That great man, as we are told by Thucydides, though his chief residence was at Argi, travelled over all the Peloponnesus.

This punishment, far from conveying the idea of infamy, became, at Athens, a proof of merit, by the objects on which it was inflicted; as Aristides the sophist justly observes, in his second declamation against the Gorgias of Plato, where he says, that ostracism was not an effect of the vindictive spirit of the people against those whom it condemned; that the law, whether good or bad, (for he enters not into an examination of the question), was only meant to prune the luxuriant growth of transcendent merit: that it condemned to an exile of ten years, only those illustrious men who were accused of being exalted far above other citizens by their conspicuous virtue; and that none of that public indignation was shown to the exiles by ostracism, which commonly breaks out against criminals.

Such were the mitigations with which this law was introduced among the Athenians: and by them we see that they were sensible of all the inconveniences to which it was subject. They were indeed too enlightened a people, not to foresee the many instances of injustice which it might produce; that if in some respects it would be favourable to liberty, in others it would be its enemy, by condemning citizens without allowing them a previous defence, and by making a capricious and envious people arbiters of the fate of great men; that it might even become pernicious to the state, by depriving it of its best subjects, and by rendering the administration of public affairs an odious employment to men of capital talents and virtue.

However great the inconveniences of ostracism were, it would not have been impossible to avoid them; and we may add, that this law would have been of service to the state, if the people by whom it was instituted had always had discernment enough only to give it force on such occasions as endangered liberty. But its fate was like that of almost all other laws which the wisest legislators have planned for the good of communities. Destined by their institution to maintain order, to repress injustice, and to protect innocence, men have found ways to pervert their application, and have made them instruments to gratify their private passions. Thus ostracism was established to prevent the dangerous enterprises of the great, and to preserve the vigour of the democracy; but the people of Athens, naturally jealous and envious, exerted that law, to remove men of eminent merit from the state, by whose presence they were reproved and intimidated. The fear of tyranny was commonly but a specious pretext with which they veiled their malignity. The repeated victories which they had gained over the Persians, had rendered them, says Plutarch, proud and insolent. Intoxicated with their prosperity, they arrogated all its glory to themselves; they were jealous of those citizens whose political and military talents were the subjects of public eulogium. They thought the glory acquired by great men diminished their own reputation. An Athenian no sooner distinguished himself by a splendid action, than he was marked out as a victim by public envy. His reputation was a sufficient reason for his banishment.

OSTRACITES, in *Natural History*, a name used for the fossil oysters, common in many parts of England. They are of various shapes and kinds; and the name is by some authors made to signify the shell itself, when preserved in its native state and condition; as is the case with those about Woolwich and Blackheath; and by others, the stones cast or formed in those shells, or in cavities from whence they have been washed away.

OSTREA, the OYSTER, a genus of shell-fish belonging to the order of vermes testacea. See OSTREA, CONCHOLOGY *Index*.

OSTRICH. See STRUTHIO, ORNITHOLOGY *Index*.

OSTROVIZZA, in Dalmatia (see DALMATIA), supposed by some to be the Arauzona, and by others the Stlupi of the ancients, though probably it has no connection with either the one or the other. It was purchased in 1410 by the republic of Venice, for 5000 ducats, and some pieces of land besides. Its fortress, which was seated on a rock, perpendicularly cut all round, and deservedly reckoned impregnable before the use of artillery, was taken by Soliman in 1524, but soon after restored to the dominion of Venice. At present, no traces of its fortification remain, and it is only a bare and isolated mass. It now belongs to Austria.

OSTUNI, a town of Italy, in the kingdom of Naples, and in the Terra di Otranto, with a bishop's see. Its territory is well cultivated, and abounds with olives and almonds. It is seated on a mountain near the gulf of Venice, in E. Long. 17. 49. N. Lat. 49. 59.

OSWEGO, a fort of North America, seated on the east side of a river of the same name, and on the south side of the lake Ontario, in W. Long. 76 30. N. Lat. 43. 15.

OSWEIZEN, a town of Austrian Poland, in the palatinate of Cracovia, formerly having the title of a duchy. It carries on a great trade in salt, and is seated on the river Vistula. E. Long. 19 47. N. Lat. 50. 1.

OSWESTRY, an old town of Shropshire, in England, 172 miles from London, with a castle, a wall, and a ditch, and was anciently a borough. It is a place celebrated in Saxon history and legendary piety. On this spot, August 5. 642, was fought the battle between the Christian Oswald, king of the Northumbrians, and the pagan Penda, king of the Mercians, in which Oswald was defeated, and lost his life. The barbarian victor cut the body of the slain prince in pieces, and stuck them on stakes dispersed over the field as so many trophies; but, according to others, his head and hands only were thus exposed. A prince so dear to the church as Oswald, and so attached to the professors of the monastic life, received every posthumous honour they could bestow. He was raised to the rank of a saint, and his sanctity confirmed by numberless miracles, which are too numerous and too trifling to admit of particular description. Its church, which is of no great antiquity, was formerly a monastery, and was called Blancminster. It is, however, spacious, and has a handsome plain tower. In 1542 and 1567, it suffered much by fire. It is governed by two bailiffs, burgesses, &c. and once had a great trade in Welch cottons and flannels; but this is

Oswestry, Osymandes.

now much decayed. Its population in 1801 was 2672, and in 1811 it was 3479. But besides a good grammar school, it is noted for an excellent charity-school for 40 boys, besides girls, which has the best methods for exciting the emulation of the children in their learning; for 20 of the boys are set to strive against 20 others for shoes, and the 20 who perform their task best have shoes first; then 10 of the boys are set against 10 others for the like premium, and so on till they are all shod: so in the girls school a shift is put up for the best spinner, a head-dress for the best sempstress, a pair of stockings for the best knitter, a Bible for the best reader, and a copy-book for the best writer. In the wall with which the town was fortified there were four gates. That called the *Block-gate* is demolished; the New-gate, Willow-gate, and the Beatrice-gate, still remain. The last is a handsome building, with a guard-room on both sides. There are only two fragments of the castle remaining. It stood on an artificial mount, surrounded by a fosse, extending to the Willow-gate.

OSYMANDES, a famous king of Egypt, was, according to some authors, the first monarch who collected a great number of books for the purpose of forming a library. To this curious collection he gave the title of *Pharmacy of the Soul*. Of all the monuments of the kings of Thebes, that of Osymandes is one of the most magnificent. "He appears (says an elegant author) to have been a prince of great elegance and taste in his day. Diodorus Siculus describes many sumptuous edifices erected by him; among those edifices his palace or mausoleum, whichsoever it was, has been eminently distinguished for the paintings and sculptures with which it was adorned. When we look to the subject of those works, we shall have reason to think that no man in any age could discover a fairer and more enlightened judgment than he did in the employment of the genius around him, which was not tamely devoted to dull or contracted objects, nor lavished on scenes of savage life, nor wholly engrossed in allusions to himself, but sensibly enlarged to a variety of contemplation which might become a great sovereign; and in each of those parts the subject was characteristically great.

Bromley's Hist. of the Fine Arts, vol. i.

"* In one place was represented, in a multitude of sculptures, his expedition against the Bactrians, a people of Asia, whom he had invaded with 400,000 foot, and 20,000 horse, and whom he conquered. In another part was displayed the variety of fruits and productions, with which Pan, the great source of all things, had enriched the fertile land over which Osymandes reigned. A third group of figures represented the monarch himself, as the high priest of the country, offering to the gods the gold and silver which he drew every year from the mines of Egypt. In another part of the edifice was exhibited, in an infinite number of figures, an assembly of judges, in the midst of a great audience attentive to their decisions; the president or chief of those judges, surrounded by many books, wore on his breast a picture of Truth with her eyes shut—these emphatic emblems, beyond which no age could go for the impression of that wisdom and impartiality which ought to prevail in administrative justice."

* *Diod. Sic.* lib. i. p. 45. edit. Rhodom.

In short, we cannot without astonishment read the account which Diodorus Siculus gives of the almost incredible magnificence of this prince, and of the immense sums which he spent upon those grand works. Amongst a variety of other surprising curiosities, was to be seen a statue in the attitude of sitting, which was the largest in all Egypt, the length of one of the feet being seven cubits. Not only the art of the sculptor, but also the beauty of the stone, which was perfect in its kind, contributed to render this a masterpiece of sculpture. It bore the following inscription: *I am OSYMANDES, king of kings; whoever will dispute with me this title, let him surpass me in any of my works.*

Osymandes ‖ Otaheite.

Indeed (to use the words of the same elegant author quoted above) "the palace or mausoleum of this accomplished prince must give us a striking assurance of the progress which had been made in the arts at that time; whether he lived, as some have thought * the immediate successor of the first Busiris, which was somewhat later than the period of Semiramis; or, as others have conceived †, subsequent to Sesostris, which would be 400 years later. Diodorus Siculus, who describes that edifice, says nothing of the age in which Osymandes lived; every opinion, therefore, on that point must be conjecture. We shall only remark, that there is nothing in the works of art in that edifice which should appear too much for the earliest age in which that monarch has been placed, when we look back to what was done of those works in a period full as early by Semiramis in Assyria."

OTACOUSTIC INSTRUMENT, or *Auricular Tube*, an instrument to facilitate the hearing. See ACOUSTICS.

OTAHEITE, a celebrated island of the South sea, situated in W. Long. 149. 13. S. Lat. 17. 46. It was discovered by Captain Wallis in 1767; afterwards Mr Bougainville touched here; and it was visited by Captain Cook in 1773 and 1774, who had in 1769 sailed round the island in a boat to observe the transit of Venus.

The island consists of two distinct kingdoms, which are united by a narrow neck of land; the larger being called by the natives *Tiarrabou*, or *O-Taheitee Nue*; the smaller one *Opoureonou*, or *O-Taheitee-Ete*. The circumference of both islands is about 40 leagues; the larger kingdom being divided into 43 districts. The country has a delightful romantic appearance. The coast, viewed from the sea, presents a most beautiful prospect, being elevated like an amphitheatre. The island is skirted with a reef of rocks, and towards the sea is level, being covered with fruit trees of various kinds, particularly the cocoa-nut. At the distance of about three miles from the shore, the country rises into lofty hills that are covered with wood, and terminate in peaks, from which large rivers are precipitated into the sea. The stones everywhere appear to have been burnt, not one being found which did not give manifest signs of fire; so that there is great reason for supposing that this and the neighbouring islands are either the shattered remains of a continent, or were torn from rocks, which from the creation of the world have been the bed of the sea, and thrown up in heaps to a height which the waters never reach. What is farther extraordinary, the water does not gradually grow shallow as we approach the shore, but is of immense depth close by the land; and the islands in this neighbourhood are almost everywhere surrounded by reefs which appear to be rude and broken in the manner that some violent concussion would naturally leave the solid substance of the

1 Appearance of the country.

Otaheite. the earth; and Mr Foster saw a rock with projecting longitudinal angles of black compact basaltes. The exterior ranges of hills are sometimes entirely barren, and contain a great quantity of yellowish clay, mixed with iron ochre; but others are covered with mould and wood like the mountains in the internal parts of the country. Pieces of quartz are sometimes met with here; but no indications of precious minerals or metals of any kind have been observed, iron only excepted.

2 Climate. The air is extremely healthy and pleasant; the heat is not troublesome; and fresh meat will keep very well for two days, and fish one day. The winds do not blow constantly from the east, but generally a little breeze from east to south-south-east. The tide rises very little; and, being governed by the winds, is very uncertain. "The climate," says M. Bougainville, "is so healthy, that notwithstanding the hard labour of the ships companies while on shore, though the men were continually in the water, and exposed to the meridian sun, though they slept upon the bare soil, and in the open air, none of them fell sick; those who were afflicted with the scurvy, and were sent on shore, regained their strength: although they were obliged to assist in the erecting of a fort, and had scarce one uninterrupted night, yet they were so far recovered in the short space of time they continued there, that they were afterwards perfectly cured on board."

3 High mountains. Notwithstanding the great height of the inland mountains of Otaheite, none of their rocks have the appearance of barrenness, every one of them being covered with woods. "We hardly believed our eyes," says M. de Bougainville, "when we saw a peak covered with woods up to its highest summit, which rises above the level of the mountains in the interior parts of the southern quarter of this island. Its apparent size seemed to be more than 30 toises in diameter, and grew less in breadth as it rose higher. At a distance it might have been taken for a pyramid of immense height, which the hand of an able sculptor had adorned with garlands and foliage." One of the mates of the Dolphin, with a party of marines and seamen, penetrated into the interior parts of the island; and having ascended, with great difficulty, a mountain which they supposed to be a mile high, they discovered mountains before them so much higher, that with respect to them they seemed to be in a valley: towards the sea the view was enchanting, the sides of the hills were beautifully clothed with wood, villages were everywhere interspersed, and the valleys between them afforded a still richer prospect; the houses stood thicker, and the verdure was more luxuriant; and Mr Foster, with other gentlemen, ascended to the summit of one of the highest mountains in the island, from whence they had a prospect of the island of Huahine, and some others lying at the distance of 40 leagues; from which we may form some judgment of the prodigious height of that mountain. The view of the fertile plain below them, and of a river making innumerable meanders, was delightful in the highest degree. The vegetation on the upper part of the mountains was luxuriant, and the woods consisted of many unknown sorts of trees and plants.

4 Soil and produce. The soil of this island is a rich fat earth, of a blackish colour. It produces spontaneously, or with the slightest culture imaginable, a great variety of the most excellent fruits; such as bread-fruit, cocoa nuts, bananas of 13 sorts, plantains, potatoes, yams, a fruit known here by the name of *jambu*, and reckoned most delicious; sugar-canes, which the inhabitants eat raw; ginger; turmeric; a root of the salep kind, called by the inhabitants *pea*; a plant called *ethee*, of which the root only is eaten; a fruit that grows in a pod like that of a large kidney bean, by the natives called *ahee*; a tree called *wharra*, which produces fruit something like the pine-apple, and which is known in the East Indies by the name of *pandanus*; a shrub called *nono*; the *morinda*, which also produces fruit; a species of fern; a plant called *theve*; and the Chinese paper-mulberry, of the bark of which they make their cloth; an herb which the inhabitants eat raw, its flavour somewhat resembling that of the West India spinage called *calletoon*, but its leaf very different; a plant which the natives call *ava* or *eava*, from the root of which they express a liquor, which, if drank to excess, intoxicates like wine or distilled spirits. Here are a sort of shady trees covered with a dark green foliage, bearing golden-coloured apples, which, in juiciness and flavour, resemble the ananas or pine-apple. One of the most beautiful trees in the world received here the name of *Barringtonia*; it had a great abundance of flowers larger than lilies, and perfectly white, excepting the tips of their numerous chives, which were of a deep crimson. Such a quantity of these flowers were seen dropped off, that the ground underneath the tree was entirely covered with them. The natives called the tree *buddov*; and said, that the fruit, which is a large nut, when bruised and mixed up with some shell-fish, and thrown into the sea, intoxicates the fish for some time, so that they come to the surface of the water, and suffer themselves to be taken with people's hands. Several other maritime plants in tropical climates are found to have the same quality. Mr Dalrymple describes the method of catching fish with these plants as follows: the plant is thrust under the coral rocks or hollows where the fish haunt; the effect is most sensible in still water, though it is effectual in the open sea; for the same gentleman says, he has seen fish soon after float on the surface of the water half dead, and some totally without life; and where the effect is less violent, the fish will be seen under the water to have lost their poise, without coming up to the surface. Fish caught in this manner are not in the least noxious or ill tasted.

In this island they have domestic poultry exactly resembling those of Europe: besides which there are wild ducks; also beautiful green turtle doves; large pigeons of a deep blue plumage and excellent taste; a small sort of paroquets, very singular on account of the various mixture of red and blue in their feathers; also another sort of a greenish colour, with a few red spots; the latter are frequently tamed, and are valued on account of their red feathers. Here is a kingfisher of a dark green, with a collar of the same hue round his white throat; a large cuckoo, and a blue heron. Small birds of various kinds dwell in the shady trees; and, contrary to the generally received opinion that birds in warm climates are not remarkable for their song, have a very agreeable note. There were no quadrupeds but dogs, hogs, and rats: and for these last the natives were said to have a scrupulous regard, insomuch that they would by no means kill them; however, 5 Animals.

Otaheite. however, Captain Cook, in 1773, turned about 14 cats on the island, which have probably reduced the number of these vermin. No frogs, toads, scorpions, centipedes, or any kind of serpent, have been found here; the ants, however, are troublesome, but not very numerous. When the Endeavour first arrived here in 1769, the flies were found excessively troublesome; but musqueto nets and fly-flaps in some measure removed the inconvenience. Sydney Parkinson, in his journal, says, that notwithstanding these flies are so great a nuisance, the natives, from a religious principle, will not kill them. But there is a strange disagreement in the accounts of different voyagers concerning this matter. For M. Bougainville says, "this island is not infested with those myriads of troublesome insects that are the plague of other tropical countries." And Mr Forster says, "not a gnat or musqueto hummed unpleasantly about us, or made us apprehensive of its bite." This inconvenience must therefore be felt at certain seasons of the year, and in certain districts of the country, more sensibly than at other times and places. There is great variety of excellent fish; and according to Aitourou, a native who embarked with M. de Bougainville, there are sea-snakes on the shore of Otaheite, whose bite is mortal.

6 Description of the inhabitants, &c. The inhabitants of Otaheite are a stout, well-made, active, and comely people. The stature of the men, in general, is from five feet seven to five feet ten inches; the tallest man seen by Captain Wallis measured six feet three inches and a half; and Captain Cook, in his second voyage, describes O-Too, the king of Otaheite, to be of that height. "In order to paint a Hercules or a Mars," says M. de Bougainville, "one could nowhere find such beautiful models." They are of a pale brown complexion; in general their hair is black, and finely frizzled; they have black eyes, flat noses, large mouths, and fine white teeth; the men wear their beards in many fashions, all of them plucking out a great part, and have prominent bellies. Most of them smell strong of the cocoa-nut oil. The women in general are much smaller, especially those of the lower rank or tawtows, which is attributed to their early and promiscuous intercourse with the men; whilst the better sort who do not gratify their passions in the same unbridled manner, are above the middle stature of Europeans. Their skin is most delicately smooth and soft: they have no colour in their cheeks; their nose is generally somewhat flat, but their eyes are full of expression, and their teeth beautifully even and white. "The women," says M. de Bougainville, "have features not less agreeable than the generality of Europeans, and a symmetry of body and beautiful proportion of limbs which might vie with any of them. The complexion of the men is tawney; but those who go upon the water are much more red than those who live on shore. Some have their hair brown, red, or flaxen, in which they are exceptions to all the natives of Asia, Africa, and America, who have their hair black universally; here, in the children of both sexes, it is generally flaxen. The strongest expression is painted in the countenances of these people; their walk is graceful, and all their motions are performed with great vigour and ease." "I never beheld statelier men, (says Sydney Parkinson). The men of consequence on the island wear the nails of their fingers long, which they consider as a very honourable badge of distinction, since only such people as have no occasion to work can suffer them to grow to that length. This custom they have in common with the Chinese; but the nail of the middle finger on the right hand is always kept short, the meaning for which peculiarity could not be learned. Only one single cripple was met with among them, and he appeared to have been maimed by a fall. The women always cut their hair short round their heads. Both sexes have a custom of staining their bodies, which they call *tattowing*; both men and women have the hinder part of their thighs and loins marked very thick with black lines in various forms; these marks are made by striking the teeth of an instrument somewhat like a comb just through the skin, and rubbing into the punctures a kind of paste made of soot and oil, which leaves an indelible stain. The boys and girls under twelve years of age are not marked; a few of the men, whose legs were marked in chequers by the same method, appeared to be persons of superior rank and authority. Mr Banks saw the operation of tattowing performed upon the backside of a girl about thirteen years old. The instrument used upon this occasion had thirty teeth; and every stroke, of which at least a hundred were made in a minute, drew an ichor or serum a little tinged with blood. The girl bore it with most stoical resolution for about a quarter of an hour; but the pain of so many hundred punctures as she had received in that time, then became intolerable. She first complained in murmurs, then wept, and at last burst into loud lamentations, earnestly imploring the operator to desist. He was, however, inexorable; and when she began to struggle, she was held down by two women, who sometimes soothed and sometimes chid her; and now and then, when she was most unruly, gave her a smart blow. Mr Banks staid in a neighbouring house an hour, and the operation was not over when he went away; yet it was performed but upon one side, the other having been done some time before; and the arches upon the loins, in which they most pride themselves, and which gave more pain than all the rest, were still to be done. Both men and women are not only decently but gracefully clothed, in a kind of white cloth that is made of the bark of a shrub, and very much resembles coarse China paper. Their dress consists of two pieces of this cloth; one of them, having a hole made in the middle to put the head through, hangs from the shoulders to the mid-leg before and behind; another piece, which is between four and five yards long, and about one yard broad, they wrap round the body in a very easy manner: This cloth is not woven; but is made like paper, of the macerated fibres of the inner bark spread out and beaten together. Their ornaments are feathers, flowers, pieces of shell, and pearls; the pearls are worn chiefly by the women. In wet weather they wear matting of different kinds, as their cloth will not bear wetting. The dress of the better sort of women consists of three or four pieces: one piece, about two yards wide and eleven long, they wrap several times round their waist, so as to hang down like a petticoat as low as the middle of the leg; and this they call *paroo*. This simple drapery affords the sex an opportunity of displaying an elegant figure to the greatest advantage, according to the talents and taste of the wearer: no general fashions force them to disfigure instead of adorning themselves, but an innate gracefulness is the companion of simplicity.

Otaheite. simplicity. To this cloth they give a very strong perfume.

7 Of their houses. The chief use which they make of their houses is to sleep in them; for unless it rains, they eat in the open air under the shade of a tree. These houses are no other than sheds, all built in the wood between the sea and the mountains; they are erected on an oblong square; their width is nearly half of their length; they are nothing more than a roof, not quite four feet from the ground, raised on three rows of pillars, one row on each side, and one in the middle. The roof resembles our thatched houses in England, and consists of two flat sides inclining to each other. Their thatch consists of palm-leaves. The floor of their dwelling is covered with hay, over which they spread mats. Some of these erections are furnished with a stool, which is appropriated solely to the use of the master of the family; they consist of no other furniture except a few blocks of wood, which being square, one side is hollowed into a curve; and these they use as pillows, and with their apparel they cover themselves. In these open dwellings the whole family repose themselves at night. The size of the house is proportioned to the number that constitutes the family. The established order in these dormitories is, for the master and his wife to sleep in the middle; round them the married people; in the next circle the unmarried women; and in the next, at the same distance, the unmarried men; and the servants at the extremity of the shed; but in fair weather the latter sleep in the open air. Some few dwellings, however, constructed for greater privacy, are entirely inclosed with walls of reeds, connected together with transverse pieces of wood, so as to appear somewhat like large bird cages closely lined; in these houses there is commonly a hole left for the entrance, which can be closed up with a board.

Their candles are made of the kernels of a kind of oily nut, which they stick one above another on a skewer that is thrust through the middle of them; the upper one being lighted burns to the second, at the same time consuming that part of the skewer that goes through it; the second taking fire burns in the same manner down to the third, and so to the last; they burn a considerable time, and afford a pretty good light. The natives generally retire to rest about an hour after it is dark.

8 Food, method of cookery. The food of the common people entirely consists of vegetables. These are, the bread-fruit, with bananas, plantains, yams, apples, and a sour fruit, which, though not pleasant by itself, gives an agreeable relish to roasted bread-fruit, with which it is frequently beaten up. The flesh, which is reserved for the tables of the great, is either poultry, hogs, or dogs; the flesh of their fowls is not well-tasted, but that of dogs is esteemed by the natives beyond pork. The smaller fish are generally eaten raw, as we eat oysters: every thing that can be procured from the sea is made an article of their food; for they will eat not only sea-insects, but what the seamen call *blubbers*, though some of them are so tough that they are obliged to suffer them to become putrid before they can be chewed. A very large shark being caught by the Dolphin's people was given to the natives; who soon cut it to pieces, and carried it away with great satisfaction.

They kill the animals they intend for food by suffocating them, which is done by stopping the mouth and nose with their hands; they then singe off the hair, by holding the animal over a fire, and scraping him with a shell: with this instrument they cut him up, and take out the entrails; which are washed, and put into cocoa-nut shells, together with the blood. Dogs are eaten that are fed wholly upon bread-fruit, cocoa-nuts, yams, and other vegetables, and are never suffered to taste any animal food; and those who have tasted the flesh of a dog thus fed, have declared it to be little inferior to English lamb. In order to dress their food, they kindle a fire, by rubbing the end of one piece of dry wood upon the side of another, in the same manner as a carpenter with us whets a chisel. They then dig a pit about half a foot deep, and two or three yards in circumference; they pave the bottom with large pebble stones, which they lay down very smooth and even, and then kindle a fire in it with dry wood, leaves, and the husks of cocoa-nuts. When the stones are sufficiently heated, they take out the embers, and rake up the ashes on every side; they then cover the stones with a layer of green cocoa-nut leaves, and wrap up the animal that is to be dressed in the leaves of the plantain. If it is a small hog, they wrap it up whole; if a large one, they split it. When it is placed in the pit, they cover it with the hot embers, and lay upon them bread-fruit and yams, which are also wrapped up in the leaves of plantain. Over these they spread the remainder of the embers, mixing among them some of the hot stones, with more cocoa-nut tree leaves upon them, and then close up all with earth, so that the heat is kept in; the oven is kept thus closed a longer or shorter time according to the size of the meat that is dressed. The meat, when taken out, is said to be better dressed than any other way. They use shells for knives; and carve very dexterously with them, always cutting from themselves. One of the principal attendants on Oberea, attempting the use of the knife and fork, could not feed himself therewith; but by the mere force of habit, his hand came to his mouth, and the victuals at the end of his fork went away to his ear.

They are quite unacquainted with the method of boiling water, as they have no vessels among them that will bear the fire. Whilst the noble Oberea was one morning at breakfast with Captain Wallis on board the Dolphin, the surgeon filled the tea-pot by turning the cock of a vase that stood upon the table. One of the lady's attendants observed this practice very attentively, and soon after turning the cock himself, received the water upon his hand; he no sooner felt himself scalded, than he roared and danced about in an extravagant manner. The other Indians, unapprised of the cause of these emotions, stood gazing at him in amazement, and not without some mixture of terror: but the gentlemen in company, who soon perceived the cause of the outcry, dispelled the apprehensions of their visitants; and some ointment being applied to the scald, good humour and confidence were again restored. The gunner of the ship, who was appointed comptroller of the market which was established on shore with the natives, used to dine on the spot; the astonishment of these people was very great to see him dress his pork and poultry in a pot; at length an old man, who was extremely serviceable in bringing down provisions to be exchanged, was put into possession of an iron pot, and from that time

Otaheite. time he and his friends ate boiled meat every day. Several iron pots were likewise given to Oberea and some of the chiefs: which were in constant use, and drew every body to see them; but although the particulars of two successive voyages of Captain Cook to this island are circumstantially related, we hear no more of this improvement in the culinary art, or of the further assistance which has been rendered those people in supplying them with pots for boiling; but however desirous the natives might be to eat boiled meat, it was not adviseable to have such an article for barter as iron kettles, when a few spike nails, or a common hatchet, would procure one of their largest hogs.

Salt water is the usual sauce to their food; those who live near the sea have it furnished as it is wanted, others at a distance keep it in large bamboos. The kernels of the cocoa-nuts furnish them with another sauce; these, made into a paste something of the consistence of butter, are beat up with salt water, which has a very strong flavour; but though at first it seemed very nauseous, yet when the taste became familiar, it was much relished.

Their general drink is water, or the milk of the cocoa-nut. They showed in general an aversion to strong liquors; and whenever any one of them happened to drink so freely with any of the ship's company as to be intoxicated, he resolutely refused to taste any thing that was likely to produce the same effect again; but they have a plant which they call *ava ava*, from the root of which they procure a liquor which has an inebriating quality. Their manner of preparing this strong drink is as simple as it is disgusting to an European. Several of the people take some of the root, and chew it till it is soft and pulpy; they then spit it out into a platter or other vessel, every one into the same: into this general receptacle water is poured according to the quantity prepared. The juice thus diluted is strained through some fibrous stuff like fine shavings, after which it is fit for drinking, and it is always prepared for present use: it has a pepperish taste; drinks flat, and rather insipid; and though it intoxicates, yet Captain Cook saw but one instance where it had that effect, as the natives generally drink it with great moderation, and but little at a time. Sometimes they chew this root as Europeans do tobacco, and sometimes they will eat it wholly.

They eat alone, or at least only in company with a guest that happens to call in; and the men and women never sit down together to a meal: the shade of a spreading tree serves them for a parlour; broad leaves spread in great abundance serve for a table-cloth; and if a person of rank, he is attended by a number of servants who seat themselves round him: before he begins his meal, he washes his mouth and hands very clean, and repeats this several times whilst he is eating. The quantity of food which these people eat at a meal is prodigious. Captain Cook says, he has seen one man devour two or three fishes as big as a perch; three bread-fruits, each bigger than two fists; 14 or 15 plantains, or bananas, each six or seven inches long and four or five round, and near a quart of the pounded bread-fruit. Men of rank are constantly fed by their women; and one of the chiefs who dined on board the ships in 1769, showed such reluctance to feed himself, that one of the servants was obliged to feed him to prevent his returning without his meal. In one of the excursions which the gentlemen of the ships made into the country in 1773, they arrived at a neat house, where a very fat man, who seemed to be a chief of the district, was lolling on his wooden pillow; before him two servants were preparing his dessert, by beating up with water some bread-fruit and bananas in a large wooden bowl, and mixing with it a quantity of fermented sour paste called *mahie*. While this was doing, a woman, who sat down near him, crammed down his throat by handfuls the remains of a large baked fish, and several bread-fruits, which he swallowed with a voracious appetite: his countenance was the picture of phlegmatic insensibility, and seemed to testify that all his thoughts centered in the gratification of his appetite. He scarce deigned to look at the strangers; and a few monosyllables which he uttered, were extorted from him to remind his feeders of their duty, when by gazing at them they grew less attentive to him.

That these people, who are remarkably fond of society, and particularly that of their women, should exclude its pleasures from the table, where, among all other nations, whether civil or savage, they have been principally enjoyed, is truly inexplicable. How a meal, which everywhere else brings families and friends together, comes to separate them here, was a singularity much inquired about, but never accounted for. "They ate alone (they said), because it was right;" but why it was right to eat alone, they never attempted to explain. Such, however, was the force of habit in this instance, as it is in every other, that they expressed the strongest dislike, and even disgust, at their visitants eating in society, especially with women, and of the same victuals. "At first (says Captain Cook) we thought this strange singularity arose from some superstitious opinion; but they constantly affirmed the contrary. We observed also some caprices in the custom, for which we could as little account as the custom itself. We could never prevail with any of the women to partake of the victuals at our table, when we were dining in company; yet they would go five or six together into the servants apartments, and there eat very heartily of whatever they could find: nor were they in the least disconcerted if we came in while they were doing it. When any of us have been alone with a woman, she has sometimes eaten in our company; but then she has expressed the greatest unwillingness that it should be known, and always extorted the strongest promises of secrecy. Among themselves, even two brothers and two sisters have each their separate baskets of provisions, and the apparatus of their meal. When they first visited us at our tents, each brought his basket with him; and when we sat down to table, they would go out, sit down upon the ground, at two or three yards distance from each other, and turning their faces different ways take their repast without exchanging a single word. The women not only abstain from eating with the men, and of the same victuals, but even have their victuals separately prepared by boys kept for that purpose, who deposit it in a separate shed, and attend them with it at their meals. But though they would not eat with us, or with each other, they have often asked us to eat with them, when we have visited those with whom we were particularly acquainted at their houses; and we have often upon such

such occasions eaten out of the same basket, and drank out of the same cup. The elder women, however, always appeared offended at this liberty; and if we happened to touch their victuals, or even the basket that contained it, they would throw it away."

After meals, and in the heat of the day, the middle-aged people of the better sort generally sleep. They are indeed extremely indolent; and sleeping and eating are almost all that they do. Those that are older are less drowsy, and the boys and girls are kept awake by the natural activity and sprightliness of their age.

9 Diseases.

These islanders, who inhabit huts exposed to all the winds, and hardly cover the earth, which serves them for a bed, with a layer of leaves, are remarkably healthy and vigorous, and live to an old age without enduring any of its infirmities; their senses are acute, and they retain their beautiful teeth to the last. M. de Bougainville describes an old man, whom they saw on their landing, who had no other character of old age, than that respectable one which is imprinted on a fine figure. His head was adorned with white hair, and a long white beard; all his body was nervous and fleshy; he had neither wrinkles, nor showed any other tokens of decrepitude. This venerable man seemed displeased at the arrival of these strangers; he even retired without making any returns to the courtesies they paid to him; but he gave no signs either of fear, astonishment, or curiosity: very far from taking any part in the raptures which the multitude expressed, his thoughtful and suspicious air seemed to indicate, that he feared the arrival of a new race of men would interrupt the happiness he had so long enjoyed. From whence it may be inferred, that his mind was not a whit more impaired than his body. There are, however, several sorts of leprous complaints on this island, which appear in cutaneous eruptions of the scaly kind; some were seen that had ulcers upon different parts of their bodies; yet they seemed little regarded by those who were afflicted with them, and no application whatever was used to them, not so much as to keep off the flies. But instances of them are rare, as the excellency of their climate, and the simplicity of their vegetable food, prevent almost all dangerous and deadly disorders. They are sometimes afflicted with the cholic, and coughs are not unknown among them; and the chiefs, who fare more sumptuously, as a punishment for their voluptuousness are sometimes attacked with a disorder similar to the gout, in which the legs are swelled and excessively painful. M. de Bougainville's surgeon assured him, that he had seen many with marks of the smallpox.

The usual method employed here to restore the sick to health, is by pronouncing a set form of words; after which the exorcist applies the leaves of the cocoa-tree plaited to the fingers and toes of the sick; so that nature is left to conflict with the disease, without being assisted with any salutary application of art. But though they seem utterly destitute of medical knowledge, they appear to be no inconsiderable proficients in surgery, which they had an opportunity of proving while the Dolphin lay here. One of the seamen, when on shore run a large splinter into his foot; and the surgeon not being at hand, one of his comrades endeavoured to take it out with a pen-knife: but after putting the poor fellow to a great deal of pain, he was obliged to give it over; an old native, who had been very active and successful in establishing a good understanding between the ship's company and his countrymen, happening to be present, called a man from the other side of the river, who having examined the lacerated foot, fetched a shell from the beach, which he broke to a point with his teeth; with which instrument he laid open the wound, and extracted the splinter. Whilst this operation was performing, the old man went a little way into the wood, and returned with some gum, which he applied to the wound upon a piece of the cloth that was wrapped round him, and in two days time it was perfectly healed. This gum was produced by the apple-tree; the surgeon of the ship procured some of it, and used it as a vulnerary balsam with great success. Captain Cook, in 1769, saw many of the natives with dreadful scars; one man, in particular, whose face was almost entirely destroyed; his nose, including bone, was perfectly flat; and one cheek and one eye were so beaten in, that the hollow would almost receive a man's fist; yet no one ulcer remained.

The venereal disease is said to have been entailed upon these people by the crew of M. de Bougainville's ships, who visited this island a short time after Captain Wallis had left it. In 1769, more than one-half of the crew in Captain Cook's ship had contracted it, during a month's stay here. The natives distinguished it by a name of the same import with rottenness, but of a more extensive signification. They described, in the most pathetic terms, the sufferings which the first victims to its rage endured; and told him that it caused the hair and the nails to fall off, and the flesh to rot from the bones; that it spread universal terror and consternation among the inhabitants, so that the sick were abandoned by their nearest relations, lest the calamity should spread by contagion, and were left to perish alone in such misery as till then had never been known among them. But there seems to be some reason to hope that they had found out a specific cure for it, as none were seen on whom it had made a great progress; and one who went from the ship infected, returned, after a short time, in perfect health. Both Captain Cook and Mr Forster, in their relations of their voyage in the Resolution, endeavour to establish the opinion that this scourge of licentiousness was felt in the South sea islands previous to any of the modern voyages that have been made thither, and that it was an indigenous disease there. But if that conclusion be well founded, how comes it, that at all the places where the Resolution touched in 1773, which had before been visited by the Endeavour in 1769, such as New Zealand, for instance, the crew, more or less, became infected by their commerce with the women, and not at all so at places which they visited, for the first time, in the Resolution?

10 Manufactures.

The principal manufacture among the Otaheiteans is their cloth. This is made of the bark of trees, which are of three kinds, viz. the Chinese mulberry-tree, or *aouta;* the bread-fruit tree, or *ooroo;* and one that is described by Dr Hawkesworth as resembling the wild-fig tree of the West Indies. Of all these the paper mulberry affords the best cloth; what is made from that being both finer, softer, whiter, and better suited to take a colour; the *ooroo* produces cloth much inferior in contexture; and the last is very coarse, in colour

Otaheite.

colour resembling the darkest brown paper; but this last is the only kind that withstands water: (See the article BARK).—They likewise prepare a red dye; which is made by mixing the yellow juice of a small species of fig, which the natives call *mattee*, with the greenish juice of a sort of fern or bindweed, or of several other plants, which produce a bright crimson: and this the women rub with their hands, if the piece is to be uniformly of a colour; or they make use of a bamboo reed if the piece is to be marked or sprinkled into different patterns. The colour fades very soon, and becomes of a dirty red; but notwithstanding this defect, and its being liable to be spoiled by rain, the cloth thus stained is highly valued, and is worn only by the principal inhabitants of the country. The inhabitants perfume their cloths with certain plants; concerning which, Mr Forster made all possible inquiry. Tahea, a friendly native, showed him several plants which are sometimes used as substitutes; but the most precious sort, he either could not, or would not, point out: and from the account of Omai it appears that there are no less than 14 different sorts of plants employed for this purpose.

Matting is another Otaheitean manufacture: and in this they are so dexterous, that they produce finer mats, than any made in Europe. Rushes, grass, the bark of trees, and the leaves of a plant called *wharrou*, are the materials which they work up for this purpose. Their matting is applied to various uses: the coarser kind is employed for sleeping on in the night, or sitting on through the day; the finer sort is converted into garments in rainy weather, their cloth being soon penetrated by wet. They are very dexterous in making basket and wicker-work: their baskets are of a vast number of different patterns, many of them exceedingly neat; and the making them is an art practised by every one, both men and women.

Instead of hemp, they make ropes and lines of the bark of a tree; and thus they are provided with fishing nets; the fibres of the cocoa-nut furnish them with thread, with which they fasten the different parts of their canoes, &c. The bark of a nettle which grows in the mountains, and is called *orawa*, supplies them with excellent fishing lines, capable of holding any kind of fish; and their hooks are made of mother-of-pearl, to which they fix a tuft of hair, made to resemble the tail of a fish. Instead of making them bearded, the point is turned inwards. They make also a kind of seine of a coarse broad grass, the blades of which are like flags. These they twist and tie together in a loose manner, till the net, which is about as wide as a large sack, is from 60 to 80 fathoms long. This they haul in smooth shoal water; and its own weight keeps it so close to the ground, that scarcely a single fish can escape. They make harpoons of cane, and point them with hard wood; with which they can strike fish more effectually than an European can with one headed with iron.

11
Working tools.

The tools used by the Otaheiteans for all their purposes are, an adze made of stone; a chisel or gouge made of bone, generally the bone of a man's arm between the wrist and elbow; a rasp of coral, and the skin of a sting-ray; also coral and sand, as a file or polisher: and with these they fell timber, cleave and polish it, and hew stone. The stone which makes the blade of their adzes is a kind of basaltes, of a gray or blackish colour, not very hard, but of considerable toughness; they are formed of different sizes; some that are intended for felling, weigh from six to eight pounds; others that are used for carving, not more than as many ounces: but it is necessary to sharpen these rude tools almost every minute; for which purpose a cocoa-nut shell full of water and a stone are always at hand. With such tools they generally take up several days in felling a tree; but after it is down, and split into planks, they smooth them very dexterously and expeditiously with their adzes, and can take off a thin coat from a whole plank without missing a stroke.

12
Weapons.

Their weapons are slings, which they use with great dexterity; pikes headed with the skins of sting-rays; and clubs of about six or seven feet long, made of a very hard wood. Thus armed, they are said to fight with great obstinacy; and to give no quarter to man, woman, or child, who happens to fall into their hands during the battle, nor for some time afterwards, till their passion subsides. They have likewise bows and arrows; but the arrows are good for nothing except to bring down a bird, being headed only with stone, and none of them pointed. They have targets of a semicircular form, made of wicker-work, and plaited strings of the cocoa-nut fibres, covered with glossy, bluish-green feathers belonging to a kind of pigeon, and ornamented with many shark's teeth, arranged in three concentric circles.

13
Canoes.

Their boats or canoes are of three different sorts. Some are made out of a single tree, and hold from two to six men. These are principally employed in fishing: the others are constructed of planks very dexterously sewed together; they are of different sizes, and will hold from 10 to 40 men: they generally lash two of these together, and set up two masts between them; or if they are single, they have an out-rigger on one side, and only one mast in the middle; and in these vessels they will sail far beyond the sight of land. The third sort seems to be principally designed for pleasure or shew. These are very large, but have no sail; and in shape resemble the gondolas of Venice. The middle is covered with a large awning; and some of the people sit upon it, and some under it. The plank of which these vessels are constructed, is made by splitting a tree, with the grain, into as many thin pieces as possible. The boards are brought to the thickness of about an inch, and are afterwards fitted to the boat with the same exactness that might be expected from an expert joiner. To fasten these planks together, holes are bored with a piece of bone, fixed into a stick for that purpose. Through these holes a kind of plaited cordage is passed, so as to hold the planks strongly together. The seams are caulked with dry rushes; and the whole outside of the vessel is painted over with a kind of gummy juice, which supplies the place of pitch.

14
Character, manners, &c.

The Otaheiteans are a very industrious people, and friendly in their dispositions; but like all other nations not fully civilized, their passions are extremely violent, and they are very fickle. The manner of singling out a man here for a chosen friend is by taking off a part of your clothing and putting it upon him. Their usual manner of expressing their respect to strangers, or their

4

Otaheite. their superiors, at a first meeting, is by uncovering themselves to the middle. They have a custom of saluting those who sneeze, by saying *evaroeia-eatoua*, "May the good eatoua awaken you," or "May not the evil eatoua lull you asleep!"

Their propensity to theft is very great, insomuch, that M. Bougainville says, "even in Europe itself one cannot see more expert filchers than the people of this country; and indeed, in all the voyages made by Captain Cook and others, they had abundant experience of this disposition of the natives, which often produced quarrels, and sometimes even fatal effects. In their behaviour they are extremely lascivious, almost beyond credibility. A woman of distinction who visited Mr Banks, used the following ceremony on her first approach to the stranger. After laying down several young plantain leaves, a man brought a large bundle of cloth; which having opened, he spread it piece by piece on the ground, in the space between Mr Banks and his visitants. There were in all nine pieces: having spread three pieces one upon another, the lady came forward, and, stepping upon them, took up her garments all around her to her waist; she then turned three times round, after which she dropped the veil: when other three pieces were spread, she practised the same ceremony; and so the third time, when the last three pieces were laid out; after which the cloth was again rolled up, and delivered to Mr Banks as a present from the lady, who with her attending friend came up and saluted him. From the unbridled licentiousness of these people, the French gave this island the name of the *New Cythera*. Nay, to such a degree do they carry their libidinous excesses, that a number of the principal people, it is related, have formed themselves into a society, in which every woman is common to every man. This society is distinguished by the name of *Arreoy*, the members of which have meetings from which all others are excluded. At these meetings the passions are excited by a studied course of sensuality, and the coarsest and most brutal pleasures are enjoyed by the whole company. If, however, notwithstanding these excesses, any of the female members of this community should prove with child, unless she can procure some man to adopt the child as his own, not all the strong affections of a mother, if such are not entirely eradicated by a course of life subversive of the feelings as well as the modesty of nature, can save the life of the precondemned innocent; but the child as soon as born is smothered, and the mother is left at liberty to renew her former course of execrable prostitution. Should any man be found to cooperate with a woman in saving the life of a child, they are both excluded for ever from the *arreoy*, and are considered as man and wife. The woman from that time is distinguished by the term *whannow-now*, "the bearer of children;" which in this part of the world only is considered as a term of reproach; and so depraved are those people, that being a member of such a society is boasted of as being a privilege, instead of being stigmatized as the foulest crime. The arreoys enjoys several privileges, and are greatly respected throughout the Society islands, as well as at Otaheite; nay, they claim a great share of honour from the circumstance of being childless. Tupia, one of the most intelligent natives, when he heard that the king of England had a numerous offspring, declared that he thought himself much greater, because he belonged to the arreoys. That this society indulge themselves in promiscuous embraces, and that every woman is common to every man, is contradicted by Mr Forster. He says, that these arreoys choose their wives and mistresses from among the prostitutes; and from this circumstance, as well as their extreme voluptuousness, they have seldom any reason to dread the intrusion of children. He had the following circumstances related to him by Omi or Omiah, one of the natives, who was brought to England. He said, that the pre-eminence and advantages which a man enjoyed as arreoy were so valuable as to urge him against his own feelings to destroy his child; that the mother was never willing to consent to the murder; but that her husband and other arreoys persuaded her to yield up the child; and that where entreaties were not sufficient, force was sometimes made use of. But, above all, he added, that this action was always perpetrated in secret; insomuch, that not even the *totows* or attendants of the house were present; because, if it were seen, the murderers would be put to death.

Both men and women constantly wash their whole bodies three times a-day in running water, and are remarkably cleanly in their clothes. They are most expert swimmers, being accustomed to the water from their infancy. Captain Cook relates the following remarkable instance of their expertness. On a part of the shore where a tremendously high surf broke, insomuch that no European boat could live in it, and the best European swimmer, he was persuaded, would have been drowned, as the shore was covered with pebbles and large stones, yet here were 10 or 12 Indians swimming for their amusement. Whenever a surf broke near them, they dived under it, and rose again on the other side. The stern of an old canoe added much to their sport. This they took out before them, and swam with it as far as the outermost breach; when two or three getting into it, and turning the square end to the breaking wave, were driven in towards the shore with incredible rapidity, sometimes almost to the beach; but generally the wave broke over them before they got half way; in which case they dived, and rose to the other side with the canoe in their hands, and swimming out with it again were again driven back. This amazing expertness drew the Captain's attention for more than half an hour; during which time none of the swimmers attempted to come ashore, but seemed to enjoy the sport in the highest degree. At another time, one of the officers of the quarter-deck intending to drop a bead into a canoe for a little boy of six years of age, it accidentally missed the boat, and fell into the sea; but the child immediately leaped overboard, dived after it, and recovered it. To reward him for this feat, some more beads were dropped to him; which excited a number of men and women to amuse the officers with their amazing feats of agility in the water, and not only fetched up several beads scattered at once, but likewise large nails, which, from their weight, descended quickly to a considerable depth. Some of these people continued a considerable time under water; and the velocity with which they were seen to go down, the water being extremely clear, was very surprising. Here a green branch of a tree is used as an emblem of peace, in

Otaheite. in exact conformity to the custom of the ancient nations. We shall add an extract here from Captain Cook's last voyage to the Pacific ocean.

"Nothing could make a stronger impression at first sight, on our arrival here, than the remarkable contrast between the robust make and dark colour of the people of Tongataboo*, and a sort of delicacy and whiteness which distinguish the inhabitants of Otaheite. It was even some time before that difference could preponderate in favour of the Otaheiteans; and then only, perhaps, because as we became accustomed to them, the marks which had recommended the others began to be forgotten. Their women, however, struck us as superior in every respect; and as possessing all those delicate characteristics which distinguish them from the other sex in many countries. The beard, which the men here wear long, and the hair, which is not cut so short as is the fashion at Tongataboo, made also a great difference; and we cannot help thinking, that on every occasion they showed a greater degree of timidity and fickleness. The muscular appearance, so common amongst the Friendly islanders, and which seems a consequence of their being accustomed to much action, is lost here, where the superior fertility of their country enables the inhabitants to lead a more indolent life; and its place is supplied by a plumpness and smoothness of the skin; which, though perhaps more consonant with our ideas of beauty, is no real advantage, as it seems attended with a kind of languor in all their motions, not observable in the others. This observation is fully verified in their boxing and wrestling, which may be called little better than the feeble efforts of children, if compared to the vigour with which these exercises are performed at the Friendly islands.

* One of the Friendly islands.

"Personal endowments being in great esteem amongst them, they have recourse to several methods of improving them, according to their notions of beauty. In particular, it is a practice, especially amongst the *arreoy*, or unmarried men of some consequence, to undergo a kind of physical operation, to render them fair. This is done by remaining a month or two in the house; during which time they wear a great quantity of clothes, eat nothing but bread-fruit, to which they ascribe a remarkable property in whitening them. They also speak, as if their corpulence and colour, at other times, depended upon their food; as they are obliged, from the change of seasons, to use different sorts at different times.

"The graceful air and firm step with which these people walk are not the least obvious proof of their personal accomplishments. They consider this as a thing so natural, or so necessary to be acquired, that nothing used to excite their laughter sooner, than to see us frequently stumbling upon the roots of trees, or other inequalities of the ground.

"Their countenances very remarkably express the abundant mildness or good nature which they possess, and are entirely free from that savage keenness which marks nations in a barbarous state. One would, indeed, be apt to fancy that they had been bred up under the severest restrictions to acquire an aspect so settled, and such a command of their passions, as well as steadiness in conduct. But they are at the same time frank, cheerful, and good-humoured, though sometimes, in the presence of their chiefs, they put on a degree of gravity, and such a serious air, as becomes stiff and awkward, and has an appearance of reserve. Otaheite.

"Their peaceable disposition is sufficiently evinced from the friendly reception all strangers have met with who have visited them. Instead of offering to attack them openly or clandestinely, as has been the case with most of the inhabitants of these seas, they have never appeared in the smallest degree hostile, but on the contrary, like the most civilized people, have courted an intercourse with their visitors by bartering, which is the only medium that unites all nations in a sort of friendship. They understand barter (which they call *fukkatou*) so perfectly, that at first we imagined they might have acquired the knowledge of it by commercial intercourse with the neighbouring islands; but we were afterwards assured, that they had little or no traffic except with Feejee, from which they get the red feathers, and some few other articles which they esteem. Perhaps no nation in the world traffic with more honesty, and less distrust. We could always safely permit them to examine our goods, and to hand them about one to another; and they put the same confidence in us. If either party repented of the bargain, the goods were re-exchanged with mutual consent and good humour. Upon the whole, they seem possessed of many of the most excellent qualities that adorn the human mind, such as industry, ingenuity, perseverance, affability, and perhaps other virtues which our short stay with them might prevent our observing.

"The only defect sullying their character that we know of is their propensity to thieving, to which we found those of all ages and both sexes addicted, and to an uncommon degree. It should, however, be considered, that this exceptionable part of their conduct seemed to exist merely with respect to us; for in their general intercourse with one another, I had reason to be of opinion, that thefts do not happen more frequently (perhaps less so) than in other countries, the dishonest practices of whose worthless individuals are not supposed to authorize any indiscriminate censure on the whole body of the people. Great allowances should be made for the foibles of these poor natives of the Pacific ocean, whose minds we overpowered with the glare of objects, equally new to them as they were captivating. Stealing, amongst the civilized and enlightened nations of the world, may well be considered as denoting a character deeply stained with moral turpitude, with avarice unrestrained by the known rules of right, and with profligacy producing extreme indigence, and neglecting the means of relieving it. But at the Friendly and other islands which we visited, the thefts so frequently committed by the natives, of what we had brought along with us, may be fairly traced to less culpable motives. They seemed to arise solely from an intense curiosity or desire to possess something which they had not been accustomed to before, and belonging to a sort of people so different from themselves. And, perhaps, if it were possible that a set of beings seemingly as superior in our judgment as we are in theirs should appear amongst us, it might be doubted, whether our natural regard to justice would be able to restrain many from falling into the same error. That I have assigned the true motive for their propensity to this practice, appears from their stealing every thing indiscriminately at first sight,

sight, before they could have the least conception of converting their prize to any one useful purpose. But I believe, with us, no person would forfeit his reputation, or expose himself to punishment, without knowing before-hand how to employ the stolen goods. Upon the whole, the pilfering disposition of these islanders, though certainly disagreeable and troublesome to strangers, was the means of affording us some information as to the quickness of their intellects. For their small thefts were committed with much dexterity; and those of greater consequence with a plan or scheme suited to the importance of the objects. An extraordinary instance of the last sort was, in their attempts to carry away one of the Discovery's anchors at mid-day.

Their common diet is made up of at least nine-tenths of vegetable food; and I believe more particularly the *mahee*, or fermented bread-fruit, which makes part almost of every meal, has a remarkable effect upon them, preventing a costive habit, and producing a very sensible coolness about them, which could not be perceived in us who fed on animal food. And it is, perhaps, owing to this temperate course of life that they have so few diseases among them. See N° 8.

"They only reckon five or six which might be called chronic or national disorders; amongst which are the dropsy, and the *fesai*, or indolent swellings, before mentioned as frequent at Tongataboo. But this was before the arrival of the Europeans; for we have added to this short catalogue a disease which abundantly supplies the place of all the others, and is now almost universal. For this they seem to have no effectual remedy. The priests, indeed, sometimes give them a medley of simples, but they own that it never cures them. And yet they allow that in a few cases nature, without the assistance of a physician, exterminates the poison of this fatal disease, and a perfect recovery is produced. They say, that if a man is infected with it he will often communicate it to others in the same house, by feeding out of the same utensils, or handling them, and that, in this case, they frequently die, while he recovers; though we see no reason why this should happen. See N° 9.

"Their behaviour on all occasions seems to indicate a great openness and generosity of disposition. Omai, indeed, who, as their countryman, should be supposed rather willing to conceal any of their defects, has often said that they are sometimes cruel in punishing their enemies. According to his representation, they torment them very deliberately; at one time tearing out small pieces of flesh from different parts; at another taking out the eyes; then cutting off the nose; and lastly, killing them by opening the belly. But this only happens on particular occasions. If cheerfulness argues a conscious innocence, one would suppose that their life is seldom sullied by crimes. This, however, I rather impute to their feelings, which, though lively, seem in no case permanent; for I never saw them in any misfortune labour under the appearance of anxiety after the critical moment was past. Neither does care ever seem to wrinkle their brow. On the contrary, even the approach of death does not appear to alter their usual vivacity. I have seen them when brought to the brink of the grave by disease, and when preparing to go to battle; but in neither case ever observed their countenances overclouded with melancholy or serious reflection. Such a disposition leads them to direct all their aims only to what can give them pleasure and ease. Their amusements all tend to excite and continue their amorous passions; and their songs, of which they are immoderately fond, answer the same purpose. But as a constant succession of sensual enjoyments must cloy, we found that they frequently varied them to more refined subjects, and had much pleasure in chanting their triumphs in war, and their occupations in peace; their travels to other islands and adventures there; and the peculiar beauties, and superior advantages of their own island over the rest, or of different parts of it over other less favourite districts. This marks that they receive great delight from music; and though they rather expressed a dislike to our complicated compositions, yet were they always delighted with the more melodious sounds produced singly on our instruments, as approaching nearer to the simplicity of their own. Neither are they strangers to the soothing effects produced by particular sorts of motion, which in some cases seem to allay any perturbation of mind with as much success as music. Of this I met with a remarkable instance. For, on walking one day about Matavai Point, where our tents were erected, I saw a man paddling in a small canoe so quickly, and looking about with such eagerness on each side, as to command all my attention. At first I imagined that he had stolen something from one of the ships, and was pursued; but on waiting patiently saw him repeat his amusement. He went out from the shore till he was near the place where the swell begins to take its rise; and, watching its first motion very attentively, paddled before it with great quickness till he found that it overtook him, and had acquired sufficient force to carry his canoe before it, without passing underneath. He then sat motionless, and was carried along at the same swift rate as the wave, till it landed him upon the beach. Then he started out, emptied his canoe, and went in search of another swell. I could not help concluding, that this man felt the most supreme pleasure, while he was driven on so fast and so smoothly by the sea; especially as, though the tents and ships were so near, he did not seem in the least to envy, or even to take any notice of the crowds of his countrymen collected to view them as objects which were rare and curious. During my stay, two or three of the natives came up, who seemed to share his felicity, and always called out when there was an appearance of a favourable swell, as he sometimes missed it, by his back being turned, and looking about for it. By them I understood that this exercise, which is called *ehorooe*, was frequent amongst them; and they have probably more amusements of this sort, which afford them at least as much pleasure as skaiting, which is the only one of ours with whose effects I could compare it."

15 Language, &c.

The language of these islanders is soft and melodious; it abounds with vowels, and the pronunciation of it is easily acquired: but it was found excessively difficult to teach the natives to pronounce a single English word; probably not only from its abounding with consonants, but from some peculiarity in its structure; for Spanish and Italian words, if ending in a vowel, they pronounced with the greatest ease. A sufficient acquaintance has not been formed with it to determine whether it is copious or not; but it is certainly very imperfect, being totally without inflexion either of nouns or verbs. Few of the nouns have more than one case, and few of the verbs

Otaheite. verbs more than one tense. It was impossible to teach the islanders to pronounce the names of their guests. They called Captain Cook *Toote*; Mr Hicks, the first lieutenant, *Hete*, &c. and in this manner they formed names for almost every man in the ship. In some, however, it was not easy to find any traces of the original; and they were perhaps not mere arbitrary sounds, formed upon the occasion, but signified words in their own language; and it seems that they could perfectly remember these appellations at the distance of four years, by their enquiries after such gentlemen as were absent on the second voyage by name. Mr Monkhouse, a midshipman, they called *Matte*, which in their language signifies *dead;* because he commanded a party that killed a man for stealing a musket. The nearest imitation they could reach of King George, was by calling him *Kihiargo*. We have the following observations on this subject, in vol. ii. of Cook's last voyage to the Pacific ocean: "The language of Otaheite, though doubtless radically the same with that of New Zealand and the Friendly islands, is destitute of that guttural pronunciation, and of some consonants, with which those latter dialects abound. The specimens we have already given are sufficient to mark wherein the variation chiefly consists, and to show, that, like the manners of the inhabitants, it has become soft and soothing. During the former voyage, I had collected a copious vocabulary, which enabled me the better to compare this dialect with that of the other islands; and during this voyage I took every opportunity of improving my acquaintance with it, by conversing with Omai before we arrived, and by my daily intercourse with the natives while we now remained there (A). It abounds with beautiful and figurative expressions, which, were it perfectly known, would, I have no doubt, put it upon a level with many of the languages that are most in esteem for their warm and bold images. For instance, the Otaheiteans express their notions of death very emphatically, by saying, "that the soul goes into darkness; or rather into night." And, if you seem to entertain any doubt, in asking the question, "if such a person is their mother?" they immediately reply with surprise, "yes, the mother that bore me." They have one expression that corresponds exactly with the phraseology of the scriptures, where we read of the "yearning of the bowels."—They use it on all occasions, when the passions give them uneasiness, as they constantly refer pain from grief, anxious desire, and other affections, to the bowels, as its seat; where they likewise suppose all operations of the mind are performed. Their language admits of that inverted arrangement of words which so much distinguishes the Latin and Greek from most of our modern European tongues, whose imperfections require a more orderly construction, to prevent ambiguities. It is so copious, that for the bread-fruit alone, in its different states, they have above 20 names; as many for the taro root; and about 10 for the cocoa-nut. Add to this, that, besides the common dialect, they often expostulate in a kind of stanza or recitative, which is answered in the same manner."

A map of Otaheite, engraved for Captain Cook's first voyage, was taken out, and laid before Tuahow the high-admiral, without informing him of what it was; however, he immediately found it out, and was overjoyed to see a representation of his own country. He pointed out all the districts of it, naming every one of them in their order.

These people have a remarkable sagacity in foretelling the weather, particularly the quarter from whence the wind will blow. In their long voyages they steer by the sun in the day, and in the night by the stars; all of which they distinguish by separate names, and know in what part of the heaven they will appear in any of the months during which they are visible in their horizon. They also know the times of their annual appearing and disappearing, with more precision than would easily be believed by an European astronomer. Their time they seem to reckon by moons, 13 of which make a year. The day they divide into six parts, and the night into an equal number. They judge of the time of the day by the height of the sun, but they cannot ascertain the time of the night by the stars. In numeration, the greatest length they can go is 200; that is, when they have counted each of their fingers and toes ten times over. When they take the distance from one place to another, they express it by the time which is required to pass it.

15 Government. The government of the Otaheiteans seems greatly to resemble the early state of the European nations under the feudal system. Their orders of dignity are *eareerahie*, which answers to the king; *earee*, baron; *manahouni*, vassal; and *towtow*, villein. There are two kings in the island, one being the sovereign of each of the peninsulas of which it consists. Each of them is treated with great respect by all ranks, but does not appear to be invested with so much power as is exercised by the earees in their own districts. When the king, whom they called *O-Too*, made a visit to Captain Cook, the chiefs, who happened to be there before him, immediately stripped themselves in great haste. Captain Cook took notice of it; upon which they said *earee, earee*, signifying, that it was on account of O-Too being present; but this was the only outward token of respect they paid him, for they never rose from their seats, or made any other obeisance.

The *earees* are lords of one or more of the districts into which each of the peninsulas is divided, and of which there are 43 in the larger one. These parcel out their territories to the *manahounis*, who superintend the cultivation of the ground. The lowest class, called *towtows*, seem to be nearly under the same circumstances with the villeins in feudal governments. They do all the laborious work, cultivate the land, catch fish, fetch wood and water, &c. Each of the earees keeps a kind of court, and has a great number of attendants, chiefly the younger brothers of their own tribe, and among these some hold particular offices, but of which little more is known than some of their names.

In this country a child succeeds to his father's titles and authority as soon as he is born: and thus the king no sooner has a son born, than his sovereignty ceases.

A

(A) See this vocabulary at the end of the second volume of Captain Cook's second voyage. Many corrections and additions to it were now made by this indefatigable inquirer; but the specimens of the language of Otaheite, already in the hands of the public, seem sufficient for every useful purpose.

A regent is then chosen; and the father generally retains his power under that title, until his child becomes of age. The child of the baron succeeds to the titles and honours of its father, as soon as it is born, as well as the son of the king; so that a baron who was yesterday called *earee*, and was approached with the ceremony of lowering their garments, so as to uncover the upper part of the body, is to-day, if his wife happens to be delivered of a child, reduced to the rank of a private man; all marks of respect being transferred to the child, if it is suffered to live, though the father still continues possessor and administrator of his estate. But the acquiescence which the lower class of people, or *towtows*, yield to the command of their chiefs, is very remarkable. They are not suffered to taste any animal food, although they are employed in feeding it for their lords. They endure patiently very severe blows, if, when collected into a large body, they in any manner press upon or annoy the king or a chief in his progress; and all this passive spirit is preserved without any power being lodged in the hands of the king to exact it; for he uses no military force, nor is even attended with body guards.

There are but few actions which are reckoned crimes among the Otaheiteans. Adultery, however, is sometimes punished with death: but in general, the woman escapes with a severe beating, and the gallant passes unnoticed. The regulation of public justice is not confined to the magistrate; for the injured party redresses his own wrong by inflicting whatever punishment he can upon the offender: but in matters of notorious wrong the chiefs sometimes interpose. The nobility have livery for their servants; and in proportion as the master's rank is more or less elevated, these sashes are worn higher or lower, being fastened close under the arms of the servants belonging to the chiefs, and going round the loins of those belonging to the lowest class of nobility. Several parts of the island seem to be private property, which descend to the heir of the possessor on his death, and the descent seems to fall indifferently on man or woman. Captain Cook was of opinion that the number of inhabitants on the whole island amounted to 204,000 including women and children.

The religious language of the Otaheiteans, like that of the Gentoo Bramins, is different from what is used in common discourse; but, according to the accounts we
