1823.

ENCYCLOPÆDIA BRITANNICA.

NICANDER of COLOPHON, a celebrated grammarian, poet, and physician, who lived about the 160th Olympiad, 140 years before Christ, in the reign of Attalus king of Pergamus, who overcame the Gallo-Greeks. He lived many years in Etolia, of which country he wrote a history. He wrote also many other works, of which only two are now remaining. The one is entitled *Theriaca*, describing in verse the accidents attending wounds made by venomous beasts, with the proper remedies; the other bearing the title of *Alexipharmaca*, wherein he treats poetically of poisons and their antidotes. This Nicander is not to be confounded with Nicander of Thyatira.

NICANDRA, a genus of plants belonging to the decandria class; and in the natural method ranking under the 30th order, *Contortæ*. See BOTANY *Index*.

NICARAGUA, a large river of South America, in a province of the same name, whose western extremity lies within five miles of the South sea. It is full of dreadful cataracts, and falls at length into the North sea.

NICARAGUA, a maritime province of South America, in Mexico, bounded on the north by Honduras, on the east by the North sea, on the south-east by Costa Rica, and on the south-west by the South sea; being 400 miles in length from east to west, and 120 in breadth from north to south. It is one of the most fruitful and agreeable provinces in Mexico, and is well watered with lakes and rivers. The air is wholesome and temperate; and the country produces plenty of sugar, cochineal, and fine chocolate. One of the lakes is 200 miles in circumference, has an island in the middle, and, as some say, has a tide. Leon de Nicaragua is the capital town.

NICARIA, an island of the Archipelago, between Samos and Tine, about 50 miles in circumference. A chain of high mountains runs through the middle, covered with wood, and supplies the country with springs. The inhabitants are very poor, and of the Greek communion. The productions of the island are wheat, a good deal of barley, figs, honey, and wax.

NICASTRO, an episcopal town of Italy, in the kingdom of Naples, and in the Farther Calabria; 16 miles south of Cosenza. E. Long. 16. 21. N. Lat. 39. 15.

NICE, an ancient, handsome, and considerable town on the confines of France and Italy, and capital of a county of the same name, with a strong citadel, a bishop's see. It had formerly a senate, and was a kind of a democracy. It was united to France during the late revolution, but was disjoined from it in 1814, and is now included in the dominions of Sardinia. It is very agreeably situated, four miles from the mouth of the river Var, 83 miles S. by W. of Turin. E. Long. 6. 22. N. Lat. 43. 42.

NICE, a province formerly belonging to the duke of Savoy, but now annexed to France. The inhabitants supply Genoa with timber for building ships; and carry on a trade in linen cloth, paper, oil, wine, and honey. —" Although the county of Nice be on this side of the mountains, geographers have always considered it as a province of Italy, since they have given to this beautiful part of Italy the river Var for a western limit, which is also the boundary of the county, and flows into the sea at a league distance from the capital. This province is partly covered by the maritime Alps; and is bordered on the east by Piedmont, and the states of Genoa; on the south by the Mediterranean; on the west by the Var; and on the north by Dauphiny. Its length is about 20 leagues of the country, which make about 36 English miles; its breadth is 10 leagues; and its population is about 120,000 souls.

Historical and Picturesque Description of the County of Nice.

" The city of Nice is the capital, and the seat of the bishopric, and government. It has become, within these few years, a delightful abode, by the number of strangers who assemble there in the winter, either to re-establish their health, or to enjoy the mildness of the climate, and the beauty of the country, where an unceasing verdure presents eternal spring.

" The town is situated on the sea shore, and is backed by a rock entirely insulated, on which was formerly a castle, much esteemed for its position; but it was destroyed in the year 1706 by Marechal Berwick, the garrison being too thin to defend the extent of the works. There is a distinction between the old and the new town; this last is regular, the houses are well built, and the streets are wide. Its position is by the side of the sea, and it is terminated, on one side, by a charming terrace, which serves for a promenade.

" Any person may live peaceably in this province, without fear of being troubled on points of faith, provided he conducts himself with decorum. The town has three suburbs. 1st, That of St John, which conducts to Cimier, about three leagues north from Nice, &c. The promenades this way are very delightful, and may be enjoyed in a carriage. 2d, That of the Poudriere. 3d, 3d, That of the *Croix de Marbre*, or Marble Cross. This suburb is new; and the English almost all lodge in it, being very near the town. The houses are commodious, facing on one side the great road which leads to France, and on the other a fine garden, with a prospect of the sea. All the houses are separate from each other: the company hire them for the season, i. e. from October till May. Apartments may be had from 15 to 250 louis. The proprietors commonly furnish linen, plate, &c. There are also in the town very large and commodious houses; as well as the new road, which is opened from the town to the port, by cutting that part of the rock which inclined toward the sea. The situation is delightful, and warmest in winter, being entirely covered from the north wind, and quite open to the south.

"The company is brilliant at Nice, and the amusements of the Carnival are, in proportion to the size of the town, as lively as in any of the great ones in France. There is always an Italian opera, a concert and masked ball, alternately; and the company play rather high.

"It is impossible to find a happier climate than Nice, both for summer and winter. Reaumur's thermometer, in 1781, never fell more than three degrees below the freezing point, and that only for two days; whilst at Geneva it fell ten; and in the course of the winter of 1785 it fell only two degrees; while at Geneva it fell 15. The month of May is rarely so fine in France as February at Nice. The summer is not so hot as might be expected. The thermometer never rises more than 24 degrees (86° Fahren.) above temperate in the shade; and there is always an agreeable sea breeze from ten in the morning till sunset, when the land breeze comes on. There are three chains of graduated mountains, the last of which confound their summits with the Alps; and to this triple rampart is owing the mild temperature so sensibly different from that of the neighbouring parts.

"The cultivation of the ground is as rich as can be desired. There are alternately rows of corn and beans, separated by vines attached to different fruit-trees, the almond and the fig; so that the earth being incessantly cultivated, and covered with trees, olive, orange, cedar, pomegranate, laurel, and myrtle, causes the constant appearance of spring, and forms a fine contrast with the summits of the Alps, in the back ground, covered with snow."

Nice, an ancient town of Asia, in Natolia, now called *Isnic*, with a Greek archbishop's see. It is famous for the general council assembled here in 325, which endeavoured to suppress the doctrines of Arius. It was formerly a large, populous, and well built place, and even now is not inconsiderable. See Isnic.

Nicene Creed, was composed and established, as a proper summary of the Christian faith, by the council at Nice in 325, against the Arians.—It is also called the *Constantinopolitan creed*, because it was confirmed with some few alterations, by the council of Constantinople in 381. See Creed.

NICEPHORUS, Gregoras, a Greek historian, was born about the close of the 13th century, and flourished in the 14th, under the emperors Andronicus, John Palæologus, and John Cantacuzenus. He was a great favourite of the elder Andronicus, who made him librarian of the church of Constantinople, and sent him ambassador to the prince of Servia. He accompanied this emperor in his misfortunes, and assisted at his death; after which he repaired to the court of the younger Andronicus, where he seems to have been well received; and it is certain that, by his influence over the Greeks, that church was prevailed on to refuse entering into any conference with the legates of Pope John XXII. But in the dispute which arose between Barlaam and Palamos, taking the part of the former, he maintained it zealously in the council that was held at Constantinople in 1351, for which he was cast into prison, and continued there till the return of John Palæologus, who released him; after which he held a disputation with Palamos, in the presence of that emperor. He compiled a history, which in 11 books contains all that passed from 1204, when Constantinople was taken by the French, to the death of Andronicus Palæologus the younger, in 1341.—The best edition of this work is that of the Louvre, in Greek and Latin, in 1702.

Nicephorus, *Calistus*, a Greek historian, who flourished in the 14th century under the emperor Andronicus Palæologus the elder, wrote an ecclesiastical history in 23 books; 18 of which are still extant, containing the transactions of the church from the birth of Christ to the death of the emperor Phocas in 610.—We have nothing else but the arguments of the other five books, from the commencement of the reign of the emperor Heraclius, to the end of that of Leo the Philosopher, who died in the year 911. Nicephorus dedicated his history to Andronicus Palæologus the elder. It was translated into Latin by John Langius; and has gone through several editions, the best of which is that of Paris, in 1630.

NICERON, John Francis, a French philosopher, was born at Paris in 1613. Having finished his academical studies, with a success which raised the greatest hopes of him, he entered into the order of the Minims, and took the habit in 1632; and, as is usual, he changed the names given him at his baptism for that of Francis, the name of his paternal uncle, who was also a Minim, or Franciscan. The inclination and taste which he had for mathematics appeared early. He began to apply himself to that science in his philosophical studies, and devoted to it all the time he could spare from his other employments, after he had completed his studies in theology. All the branches of the mathematics, however, did not equally engage his attention; he confined himself particularly to optics, and only learned of the rest as much as was necessary for rendering him perfect in this. There remain still, in several houses wherein he dwelt, especially at Paris, some excellent performances, which discover his skill in this way, and which make us regret that a longer life did not suffer him to carry it to that perfection which he desired; since one cannot help being surprised that he proceeded so far as he did, in the midst of those occupations and travels by which he was forced from it during the short space of time which he lived. He hath himself observed in the preface to his *Thaumaturgus Opticus*, that he went twice to Rome; and that, on his return home, he was appointed teacher of theology. He was afterwards chosen to accompany Father Francis de la Noue, vicar general of the order, in his visitation of the convents throughout all France. But the eagerness of of his passion for study put him upon making the best of all the moments he had to spare for books: and that wise economy furnished him with as much as satisfied him. Being taken sick at Aix in Provence, he died there Sept. 22. 1646, aged 33. He was an intimate acquaintance of Des Cartes. The following are his principal works: *L'Interpretation des chiffres, ou regles pour bein entendre et expliquer facilement toutes sortes des chiffres simples*, &c. 2. *La perspective curieuse, ou magie artificielle des effets merveilleux de l'optique, catoptrique, et dioptrique*. This is only an essay to the following work: 3. *Thaumaturgus opticus, sive, Admiranda opticcs, catoptrices, et dioptrices, pars prima*, &c. Two other parts were intended to complete the latter work, but were unfinished at his death.

NICERON, *John Peter*, so much celebrated on account of his Memoirs of Men illustrious in the Republic of letters, was born at Paris March 11. 1685. He was of an ancient and noble family, who were in very high repute about 1540. He studied with success in the Mazarine college at Paris, and afterwards at the college Du Plessis. In a short time, resolving to forsake the world, he consulted one of his uncles who belonged to the order of Barnabite Jesuits. This uncle examined him; and not diffident of his election, introduced him as a probationer to that society at Paris.—He was received there in 1702, took the habit in 1703, and made his vows in 1704, at the age of 19.

After he had professed himself, he was sent to Montarges, to go through a course of philosophy and theology; thence he went to Loches in Touraine to teach those sciences. He received the priesthood at Poitiers in 1708. As he was not arrived at the age to assume this order, a dispensation, which his uncommon piety had merited, was obtained in his favour. The college of Montarges having recalled him, he was their professor of rhetoric two years, and of philosophy four.—In spite of all these avocations, he was humanely attentive to every call and work of charity, and to the instruction of his fellow creatures, many of whom heard him deliver out fit rules of conduct for them, not only from the pulpits of most of the churches within the province, but even from those of Paris. In 1716, his superiors invited him to that city, that he might have an opportunity of following, with the more convenience, those studies for which he always had expressed the greatest inclination. He not only understood the ancient but the modern languages; a circumstance of infinite advantage in the composition of those works which he has given to the public, and which he carried on with great assiduity to the time of his death, which happened, after a short illness, July 8. 1738, at the age of 53. His works are, 1. *Le grand Febrifuge;* or, a Dissertation to prove that common water is the best remedy in fevers, and even in the plague; translated from the English of John Hancock minister of St Margaret's, London; in 12mo. This little treatise made its appearance, amongst other pieces relating to this subject, in 1720; and was attended with a success which carried it through three editions; the last came out in 1730, in 2 vols. 12mo, entitled, A Treatise on Common Water; Paris, printed by Cavelier. 2. The Voyages of John Ouvington to Surat, and divers parts of Asia and Africa, containing the history of the revolution in the kingdom of Golconda, and some observations upon silk worms; Paris, 1725, 2 vols. 12mo. 3. The Conversion of England to Christianity, compared with its pretended Reformation, a work translated from the English; Paris 1729, 8vo. 4. The Natural History of the Earth, translated from the English of Mr Woodward, by M. Nogues, doctor in physic; with an answer to the objections of Dr Camerarius; containing also several letters written on the same subject, and a methodical distribution of fossils, translated from the English by Niceron; Paris, 1735, 4to. 5. Memoirs of Men illustrious in the Republic of Letters, with a critical account of their works; Paris, 12mo. The first volume of this great work appeared in 1727; the others were given to the public in succession, as far as the 39th, which appeared in 1738. The 40th volume was published after the death of the author, in 1739.

NICETAS, David, a Greek historian, a native, as some relate, of Paphlagonia, who lived about the end of the 9th century. He wrote The Life of St Ignatius, patriarch of Constantinople, which was translated into Latin by Frederic Mutius bishop of Termoli: he composed also several panegyrics in honour of the apostles and other saints, which are inserted in the last continuation of the *Bibliotheca Patrum* by Combesis.

NICETAS, surnamed *Serron*, deacon of the church of Constantinople, cotemporary with Theophylact in the 11th century, and afterwards bishop of Heraclea, wrote a Catena upon the book of Job, compiled from passages of several of the fathers, which was printed at London in folio, 1637. We have also, by the same writer, several *catenæ* upon the Psalms and Canticles, Basil, 1552; together with a Commentary on the poems of Gregory Nazianzen.

NICETAS, *Arhominates*, a Greek historian of the 13th century, called *Coniates*, as being born at Chone, or Colossus, in Phrygia. He was employed in several considerable affairs at the court of Constantinople; and when that city was taken by the French in 1204, he withdrew, with a young girl taken from the enemy, to Nice in Bithynia, where he married his captive, and died in 1206. He wrote a History, or Annals, from the death of Alexius Comnenus in the year 1118, to that of Badouin in 1205; of which work we have a Latin translation by Jerome Wolfius, printed at Basil in 1557; and it has been inserted in the body of the Byzantine Historians, printed in France at the Louvre.

NICHE, in *Architecture*, a hollow sunk into a wall, for the commodious and agreeable placing of a statue. The word comes from the Italian *nechia*, "sea-shell;" in regard the statue is here enclosed in a shell, or perhaps on account of the shell wherewith the tops of some of them are adorned.

NICHOLLS, Dr Frank, physician and anatomist, was born in London in the year 1699. His father was a barrister at law; and both his parents were of good families in Cornwall. After receiving the first rudiments of his education at a private school in the country, where his docility and sweetness of temper endeared him equally to his master and his school fellows, Frank was in a few years removed to Westminster, and from thence to Oxford, where he was admitted a commoner (or sojourner) of Exeter college, under the tuition of Mr John Haviland, on March 4. 1714. There he applied himself diligently to all the usual academical studies, but particularly to natural philosophy and polite literature, of which the fruits were most conspicuous in his subsequent lectures on physiology. After reading a few books on anatomy, in order to perfect himself in the nomenclature of the animal parts then adopted, he engaged in dissections, and then devoted himself to the study of nature, perfectly free and unbiassed by the opinions of others.

On his being chosen reader of anatomy in that university, he employed his utmost attention to elevate and illustrate a science which had there been long depressed and neglected; and by quitting the beaten track of former lecturers, and minutely investigating the texture of every bowel, the nature and order of every vessel, &c. he gained a high and just reputation. He did not then reside at Oxford; but when he had finished his lectures, used to repair to London, the place of his abode, where he had determined to settle. He had once an intention of fixing in Cornwall, and for a short time practised there with great reputation; but being soon tired of the fatigues attendant on that profession in the country, he returned to London, bringing back with him a great insight, acquired by diligent observation, into the nature of the miliary fever, which was attended with the most salutary effects in his subsequent practice at London.

About this time he resolved to visit the continent, partly with a view of acquiring the knowledge of men, manners, and languages; but chiefly to acquaint himself with the opinions of foreign naturalists on his favourite study. At Paris, by conversing freely with the learned, he soon recommended himself to their notice and esteem. Winslow's was the only good system of physiology at that time known in France, and Morgagni's and Santorini's of Venice in Italy, which Dr Nicholls likewise soon after visited. On his return to England, he repeated his physiological lectures in London, which were much frequented, not only by students from both the universities, but also by many surgeons, apothecaries, and others. Soon after, his new and successful treatment of the miliary fever, then very prevalent in the southern parts of England, added much to his reputation. In 1725, at a meeting of the Royal Society, he gave his opinion on the nature of *aneurisms*, in which he dissented from Dr Freind in his History of Physic.

At the beginning of the year 1728, he was chosen a fellow of the Royal Society, to which he afterwards communicated the description of an uncommon disorder (published in the Transactions), viz. a polypus, resembling a branch of the pulmonary vein (for which Tulpius has strangely mistaken it), coughed up by an asthmatic person. He also made observations (in the same volume of the Transactions) on a treatise, by M. Helvetius of Paris, on the lungs. Towards the end of the year 1729, he took the degree of doctor of physic at Oxford. At his return to London, he underwent an examination by the president and censors of the College of Physicians, previous to his being admitted a candidate, which every practitioner must be a year before he can apply to be chosen a fellow. Dr Nicholls was chosen into the college on June 26. 1732; and two years after, being chosen Gulstonian reader of Pathology, he made the structure of the heart, and the circulation of the blood, the subject of his lectures. In 1736, at the request of the president, he again read the Gulstonian lecture; taking for his subject those parts of the human body which serve for the secretion and discharge of the urine; and the causes, symptoms, and cure of the diseases occasioned by the stone. In 1739, he delivered the anniversary Harveian oration. In 1743, he married Elizabeth, youngest daughter of the celebrated Dr Mead, by whom he had five children, two of whom died young. Two sons and a daughter survived him. In 1748, Dr Nicholls undertook the office of chirurgical lecturer, beginning with a learned and elegant dissertation on the *Anima Medica*. About this time, on the death of Dr John Cuningham, one of the elects of the college, Dr Abraham Hall was chosen to succeed him in preference to our author, who was his senior, without any apparent reason. With a just resentment, he immediately resigned the office of chirurgical lecturer, and never after attended the meetings of the fellows, except when business of the utmost importance was in agitation.

In 1751, he took some revenge in an anonymous pamphlet, entitled "The petition of the Unborn Babes to the Censors of the Royal College of Physicians of London);" in which Dr Nesbit (*Pocus*), Dr Maule (*Maulus*), Dr Barrowby (*Barebone*), principally, and Sir William Brown, Sir Edward Hulse, and the Scots incidentally, are the objects of his satire.

In 1753, on the death of Sir Hans Sloane, Bart. in his 94th year, Dr Nicholls was appointed to succeed him as one of the king's physicians, and held that office till the death of his royal master in 1760; when this most skilful physician was superseded with something like the offer of a pension, which he rejected with disdain.

The causes, &c. of the uncommon disorder of which the late king died, viz. a rupture of the right ventricle of the heart, our author explained in a letter to the earl of Macclesfield, president of the Royal Society, which was published in the Philosophical Transactions, vol. l.

In 1772, to a second edition of his treatise *De Anima Medica*, he added a dissertation *De motu cordis et sanguinis in homine nato et non nato*, inscribed to his learned friend and coadjutor the late Dr Lawrence.

Tired at length of London, and also derious of superintending the education of his son, he removed to Oxford, where he had spent most agreeably some years in his youth. But when the study of the law recalled Mr Nicholls to London, he took a house at Epsom, where he passed the remainder of his life in a literary retirement, not inattentive to natural philosophy, especially the cultivation of grain, and the improvement of barren soils, and contemplating also with admiration the internal nature of plants, as taught by Linnæus.

His constitution never was robust. In his youth, at Oxford, he was with difficulty recovered from a dangerous fever by the skill of Doctors Frampton and Frewen; and afterwards at London he had frequently been afflicted with a catarrh, and an inveterate asthmatic cough, which, returning with great violence at the beginning of the year 1778, deprived the world of this valuable man on January 7th, in the 80th year of his age.

Dr Lawrence, formerly president of the college of physicians, who gratefully ascribed all his physiological and medical knowledge to his precepts, and who, while he he lived, loved him as a brother, and revered him as a parent, two years after printed, and gave to his friends, a few copies of an elegant Latin Life of Dr Nicholls (with his head prefixed, a striking likeness, engraved by Hall from a model of Gosset, 1779; from which, through the medium of the Gentleman's Magazine, the above particulars are chiefly extracted.

NICIAS, a celebrated painter of Athens, flourished about 322 years before the Christian era; and was universally extolled for the great variety and noble choice of his subjects, the force and relievo of his figures, his skill in the distribution of the lights and shades, and his dexterity in representing all sorts of four-footed animals, beyond any master of his time. His most celebrated piece was that of Tartarus or Hell, as it is described by Homer, for which King Ptolemy the son of Lagus offered him 60 talents, or 11,250l. which he refused, and generously presented it to his own country. He was much esteemed likewise by all his cotemporaries for his excellent talent in sculpture.

NICKEL, a metallic substance; for the nature of which, see CHEMISTRY *Index*; and for an account of its ores, see MINERALOGY *Index*.

NICOBAR ISLANDS, the name of several islands in Asia, lying at the entrance of the gulf of Bengal. The largest of these islands is about 40 miles long and 15 broad, and the inhabitants are said to be a harmless sort of people, ready to supply the ships that stop there with provisions. The south end of the great Nicobar is placed in east longitude 94° 23′ 30″; and we collect from Mr Rennel's Memoir, that it is within the 12th degree of north latitude.

Of the northernmost island, which is called *Carnicobar*, we have, in the second volume of the Asiatic Researches, some interesting information respecting both the produce and natural history of the country, and the manners of its inhabitants. The author of the memoir is Mr G. Hamilton, who, in his account of this island, says, "It is low, of a round figure, about 40 miles in circumference, and appears at a distance as if entirely covered with trees: however, there are several well cleared and delightful spots upon it. The soil is a black kind of clay, and marshy. It produces in great abundance, and with little care, most of the tropical fruits, such as pine apples, plantains, papayes, cocoa-nuts, and areca-nuts; also excellent yams, and a root called *cachu*. The only four-footed animals upon the island are, hogs, dogs, large rats, and an animal of the lizard kind, but large, called by the natives *tolonqui*; these frequently carry off fowls and chickens. The only kind of poultry are hens, and those not in great plenty. There are abundance of snakes of many different kinds, and the inhabitants frequently die of their bites. The timber upon the island is of many sorts, in great plenty, and some of it remarkably large, affording excellent materials for building or repairing ships.

"The natives are low in stature, but very well made, and surprisingly active and strong; they are copper-coloured, and their features have a cast of the Malay, quite the reverse of elegant. The women in particular are extremely ugly. The men cut their hair short, and the women have their heads shaved quite bare, and wear no covering but a short petticoat, made of a sort of rush or dry grass, which reaches half way down the thigh. This grass is not interwoven, but hangs round the person something like the thatching of a house. Such of them as have received presents of cloth petticoats from the ships, commonly tie them round immediately under the arms. The men wear nothing but a narrow strip of cloth about the middle, in which they wrap up their privities so tight that there hardly is any appearance of them. The ears of both sexes are pierced when young; and by squeezing into the holes large plugs of wood, or hanging heavy weights of shells, they contrive to render them wide, and disagreeable to look at. They are naturally disposed to be good humoured and gay, and are very fond of sitting at table with Europeans, where they eat every thing that is set before them; and they eat most enormously. They do not care much for wine, but will drink bumpers of *arack* as long as they can see. A great part of their time is spent in feasting and dancing. When a feast is held at any village, every one that chooses goes uninvited, for they are utter strangers to ceremony. At those feasts they eat immense quantities of pork, which is their favourite food. Their hogs are remarkably fat, being fed upon the cocoa-nut kernel and sea water; indeed all their domestic animals, fowls, dogs, &c. are fed upon the same. They have likewise plenty of small sea fish, which they strike very dexterously with lances, wading into the sea about knee deep. They are sure of killing a very small fish at 10 or 12 yards distance. They eat the pork almost raw, giving it only a hasty grill over a quick fire. They roast a fowl, by running a piece of wood through it, by way of spit, and holding it over a brisk fire until the feathers are burnt off, when it is ready for eating, in their taste. They never drink water; only cocoa-nut milk, and a liquor called *soura* which oozes from the cocoa-nut tree after cutting off the young sprouts or flowers. This they suffer to ferment before it be used, and then it is intoxicating; to which quality they add much by their method of drinking it, by sucking it slowly through a small straw. After eating, the young men and women, who are fancifully dressed with leaves, go to dancing, and the old people surround them smoking tobacco and drinking *soura*. The dancers, while performing, sing some of their tunes, which are far from wanting harmony, and to which they keep exact time. Of musical instruments they have only one kind, and that the simplest. It is a hollow bamboo about two feet and a half long and three inches in diameter, along the outside of which there is stretched from end to end a single string made of the threads of a split cane, and the place under the string is hollowed a little to prevent it from touching. This instrument is played upon in the same manner as a guitar. It is capable of producing but few notes; the performer, however, makes it speak harmoniously, and generally accompanies it with the voice.

"Their houses are generally built upon the beach, in villages of 15 or 20 houses each; and each house contains a family of 20 persons and upwards. These habitations are raised upon wooden pillars about 10 feet from the ground; they are round, and, having no windows, are like bee-hives, covered with thatch. The entry is through a trap door below, where the family mount by a ladder, which is drawn up at night. This manner of building is intended to secure the houses from being infested with snakes and rats; and for that purpose the pillars are bound round with a smooth kind of leaf, Nicobar.

leaf, which prevents animals from being able to mount: besides which, each pillar has a broad round flat piece of wood near the top of it, the projecting of which effectually prevents the further progress of such vermine as may have passed the leaf. The flooring is made with thin strips of bamboos, laid at such distances from one another as to leave free admission for light and air; and the inside is neatly finished and decorated with fishing lances, nets, &c.

"The art of making cloth of any kind is quite unknown to the inhabitants of this island; what they have is got from the ships that come to trade in cocoanuts.

"They purchase a much larger quantity of cloth than is consumed upon their own island. This is intended for the Choury market. Choury is a small island to the southward of theirs, to which a large fleet of their boats sails every year about the month of November, to exchange cloth for canoes; for they cannot make these themselves. This voyage they perform by the help of the sun and stars, for they know nothing of the compass.

"In their disposition there are two remarkable qualities. One is their entire neglect of compliment and ceremony; and the other, their aversion to dishonesty. A Carnicobarian travelling to a distant village, upon business or amusement, passes through many towns in his way without speaking to any one; if he is hungry or tired, he goes into the nearest house, and helps himself to what he wants, and sits till he is rested, without taking the smallest notice of any of the family unless he has business or news to communicate. Theft or robbery is so very rare amongst them, that a man going out of his house never takes away his ladder or shuts his door, but leaves it open for any body to enter that pleases without the least apprehension of having any thing stolen from him.

"Their intercourse with strangers is so frequent, that they have acquired in general the barbarous Portuguese so common over India; their own language has a sound quite different from most others, their words being pronounced with a kind of stop, or catch in the throat, at every syllable.

"They have no notion of a God, but they believe firmly in the devil, and worship him from fear. In every village there is a high pole erected with long strings of ground rattans hanging from it, which, it is said, has the virtue to keep him at a distance. When they see any signs of an approaching storm, they imagine that the devil intends them a visit, upon which many superstitious ceremonies are performed. The people of every village march round their own boundaries, and fix up at different distances small sticks split at the top, into which split they put a piece of cocoa nut, a whisp of tobacco, and the leaf of a certain plant; whether this is meant as a peace offering to the devil or a scarecrow to frighten him away, does not appear.

"When a man dies, all his live stock, cloth, hatchets, fishing lances, and in short every moveable thing he possessed, is buried with him, and his death is mourned by the whole village. In one view this is an excellent custom, seeing it prevents all disputes about the property of the deceased amongst his relations. His wife must conform to custom by having a joint cut off from one of her fingers; and if she refuses this, she must submit to have a deep notch cut in one of the pillars of her house.

"I was once present at the funeral of an old woman. When we went into the house which had belonged to the deceased, we found it full of her female relations; some of them were employed in wrapping up the corpse in leaves and cloth, and others tearing to pieces all the cloth which had belonged to her. In another house hard by, the men of the village, with a great many others from the neighbouring towns, were sitting drinking *soura* and smoking tobacco. In the mean time two stout young fellows were busy digging a grave in the sand near the house. When the women had done with the corpse, they set up a most hideous howl, upon which the people began to assemble round the grave, and four men went up into the house to bring down the body; in doing this they were much interrupted by a young man, son to the deceased, who endeavoured with all his might to prevent them; but finding it in vain, he clung round the body, and was carried to the grave along with it: there, after a violent struggle, he was turned away and conducted back to the house. The corpse being now put into the grave, and the lashings which bound the legs and arms cut, all the live stock which had been the property of the deceased, consisting of about half a dozen hogs, and as many fowls, was killed and flung in above it; a man then approached with a bunch of leaves stuck upon the end of a pole, which he swept two or three times gently along the corpse, and then the grave was filled up. During the ceremony, the women continued to make the most horrible vocal concert imaginable: the men said nothing. A few days afterwards, a kind of monument was erected over the grave, with a pole upon it, to which long strips of cloth of different colours were hung.

"Polygamy is not known among them; and their punishment of adultery is not less severe than effectual. They cut, from the man's offending member, a piece of the foreskin proportioned to the frequent commission or enormity of the crime.

"There seems to subsist among them a perfect equality. A few persons, from their age, have a little more respect paid to them; but there is no appearance of authority one over another. Their society seems bound rather by mutual obligations continually conferred and received; the simplest and best of all ties."

It is our wish to take all opportunities of laying before our readers every authentic fact which can throw light upon the philosophy of the human mind. In this narrative of Mr Hamilton's respecting the natives of Carnicobar, there is however one circumstance at which we stumble. It is known to the learned, that the philosophers of Greece and Rome, as well as the magi of Persia, admitted two self-existent beings, a good and an evil (see POLYTHEISM); but we never before read of any people who had no notion of a God, and yet firmly believed in the devil. We could give instances of men worshipping the evil principle from fear, and neglecting the worship of the benevolent principle from a persuasion that he would do them all the good in his power without being bribed by sacrifices

crifices and oblations; but this is the only instance of which we have ever heard, of a people, under the influence of religion, who had *no notion of a God!* As good is at least as apparent in the world as evil, it appears to us so very unnatural to admit an *evil* and deny a *good* principle, that we cannot help thinking that Mr Hamilton, from his ignorance of the language of Carnicobar, (which he acknowledges to be different from most others), has not a perfect acquaintance with the religious creed of the natives: and that they believe in a good as well as in an evil principle, though they worship only the latter, from a persuasion, that to adore the former could be of no advantage either to him or to themselves.

Nancowry or Soury, and Comerty, two other of the Nicobar islands, are said to be the best peopled, containing not less than 800 inhabitants. Between these islands there is a safe and spacious harbour. On the north point of Nancowry, within the harbour, the Danes have long retained a small settlement, protected by a sergeant and a few soldiers and slaves.

NICODEMUS, a disciple of Jesus Christ, a Jew by nation, and by sect a Pharisee (John iii. 1. &c.) The Scripture calls him a ruler of the Jews, and our Saviour gives him the name of a master of Israel. When our Saviour began to manifest himself by his miracles at Jerusalem, at the first passover that he celebrated there after his baptism, Nicodemus made no doubt but that he was the Messiah, and came to him by night, that he might learn of him the way of salvation. Jesus told him, that no one could see the kingdom of heaven except he should be born again. Nicodemus taking this in the literal sense, made answer, "How can a man that is old be born again? Can he enter the second time into his mother's womb?" To which Jesus replied, "If a man be not born of water and of the spirit, he cannot enter into the kingdom of God. That which is born of the flesh is flesh, and that which is born of the spirit is spirit." Nicodemus asks him, "How can these things be?" Jesus answered, "Are you a master of Israel, and are you ignorant of these things? We tell you what we know, and you receive not our testimony. If you believe not common things, and which may be called earthly, how will you believe me if I speak to you of heavenly things? Nobody has ascended into heaven but the Son of God, who came down from thence. And just as Moses lifted up the brazen serpent in the wilderness, so must the Son of Man be lifted up on high. For God so loved the world that he has given his only Son, so that no man who believes in him shall perish, but shall have eternal life."

After this conversation Nicodemus became a disciple of Jesus Christ; and there is no doubt to be made, but he came to hear him as often as our Saviour came to Jerusalem. It happened on a time, that the priests and Pharisees had sent officers to seize Jesus (John vii. 45, &c.), who returning to them, made their report, that never man spoke as he did; to which the Pharisees replied, "Are you also of his disciples? Is there any one of the elders or Pharisees that have believed in him?" Then Nicodemus thought himself obliged to make answer, saying, "Does the law permit us to condemn any one before he is heard?" To which they replied, "Are you also a Galilean? Read the Scriptures, and you will find that never any prophet came out of Galilee." After this the council was dismissed. At last Nicodemus declared himself openly a disciple of Jesus Christ (*Id.* xix. 39, 40.), when he came with Joseph of Arimathea to pay the last duties to the body of Christ, which they took down from the cross, embalmed, and laid in a sepulchre.

We are told, that Nicodemus received baptism from the disciples of Christ; but it is not mentioned whether before or after the passion of our Lord. It is added, that the Jews being informed of this, deposed him from his dignity of senator, excommunicated him, and drove him from Jerusalem: but that Gamaliel, who was his cousin-german, took him to his country house, and maintained him there till his death, when he had him buried honourably near St Stephen. There is still extant an apocryphal gospel under the name of Nicodemus, which in some manuscripts bears the title of the *Acts of Pilate*.

NICOLAITANS, in church history, Christian heretics, who assumed this name from Nicholas of Antioch; who, being a Gentile by birth, first embraced Judaism and then Christianity; when his zeal and devotion recommended him to the church of Jerusalem, by whom he was chosen one of the first deacons. Many of the primitive writers believe that Nicholas was rather the occasion than the author of the infamous practices of those who assumed his name, who were expressly condemned by the Spirit of God himself, Rev. ii. 6. And indeed their opinions and actions were highly extravagant and criminal. They allowed a community of wives, and made no distinction between ordinary meats and those offered to idols. According to Eusebius, they subsisted but a short time; but Tertullian says that they only changed their name, and that their heresies passed into the sect of the Cainites.

NICOLAS, St, an island of the Atlantic ocean, and one of the most considerable of those of Cape Verd, lying between Santa Lucia and St Jago. It is of a triangular figure, and about 75 miles in length. The land is stony, mountainous, and barren; there are a great many goats in a valley inhabited by the Portuguese. W. Long. 33. 35. N. Lat. 17. 0.

NICOLO, St, the most considerable, strongest, and best peopled of the isles of Tremeti in the gulf of Venice, to the east of St Domino, and to the south of Capparata. It has a harbour defended by several towers; and a fortress, in which is an abbey, with a very handsome church. E. Long. 15. 37. N. Lat. 42. 10.

NICOMEDES, the name of several kings of the ancient Bithynia. See BITHYNIA.

NICODEMES I. had no sooner taken possession of his father's throne, before Christ 270, than, according to the custom which has in all ages been too prevalent among the despots of the east, he caused two of his brothers to be put to death. The youngest, Zibœas, having saved himself by timely flight, seized on the coast of Bithynia, which was then known by the names of *Thracia Thyniccia*, and *Thracia Asiatica*, and there maintained a long war with his brother. Nicomedes being informed that Antiochus Soter, king of Syria, was making great preparations to attack him at the same time, called in the Gauls to his assistance; and on this occasion that people first passed into Asia.—Nicomedes having with their assistance repulsed Antiochus,

chus, overcome his brother, and acquired the possession of all his father's dominions, bestowed upon them that part of Asia Minor which from them was called *Gallo-Græcia*, and Gallatia. Having now no enemies to contend with, he applied himself to the enlarging and adorning of the city of Astacus, which he called after his own name *Nicomedia*. He had two wives, and by one of them he was persuaded to leave his kingdom to her son, in preference to his elder brothers; but when or how he died is not certainly known.

NICOMEDES II. the grandson of the former, began his reign like him, by sacrificing his brothers to his jealousy, after having waded to the throne in the blood of Prusias his father. He assumed the name of *Epiphanes*, or "the Illustrious," though he performed nothing worthy of this title, or even of notice, during the whole time of his long reign. He was succeeded by his son——

NICOMEDES III. surnamed, by antiphrasis, *Philopater*, because he had murdered his father to get possession of his crown. This monarch having entered into alliance with Mithridates the Great king of Pontus, invaded Paphlagonia; and having seized on that country, he attempted likewise to make himself master of Cappadocia. This country, however, was at that time subject to his powerful ally; who thereupon marching into Bithynia at the head of an army, drove Nicomedes from the throne, and raised his brother Socrates to it in his room. The dethroned prince had recourse to the Romans, who expelled the usurper, and restored him to his hereditary dominions. For this favour they pressed him, and at length prevailed upon him, contrary to his own inclination, and the opinion of his friends, to make inroads into the territories of Mithridates, with whom Rome wanted a subject of dispute. The king of Pontus bore for some time the devastations committed by Nicomedes with great patience, that he might not seem to be the aggressor; but at last he routed his army on the banks of the Amnius, drove him a second time from his dominions, and obliged him to seek for shelter in Paphlagonia, where he led a private life till the time of Sylla, who replaced him on the throne. He was succeeded by his son——

NICOMEDES IV. who performed nothing which the many writers who flourished in his time have thought worth transmitting to posterity. As he died without issue male, he left his kingdom by his last will to the Romans, who reduced it to the form of a province. Sallust, disagreeing with the ancients, tells us, that Nicomedes left a son named *Musa* or *Mysa*; and introduces Mithridates as complaining of the Romans to Arsaces king of Parthia, for seizing on the kingdom of Bithynia, and excluding the son of a prince who had on all occasions shown himself a steady friend to their republic. But this Musa was the daughter and not the son of Nicomedes, as we are told in express terms by Suetonius, Velleius Paterculus, and Appian. All we know of her is, that upon the death of her father she claimed the kingdom of Bithynia for her son, as the next male heir to the crown, but without success; no motives of justice being of such weight with the ambitious Romans as to make them part with a kingdom.

NICOMEDIA, in *Ancient Geography*, a metropolis of Bithynia, built by Nicomedes the grandfather of Prusias. It is situated on a point of the Sinus Astacenus, (Pliny); surnamed the *Beautiful*, (Athenæus): the largest city of Bithynia, (Pausanias), who says it was formerly called *Astacus;* though Pliny distinguishes Astacum and Nicomedia as different cities. Nicomedia was very famous, not only under its own kings, but under the Romans: it was the royal residence of Dioclesian, and of Constantine while Constantinople was building, if we may credit Nicephorus. It is still called *Nicomedia*, at the bottom of a bay of the Propontis in the Hither Asia. E. Long. 30. 0. N. Lat. 41. 20. It is a place of consequence; carries on a trade in silk, cotton, glass, and earthen ware, and is the see of a Greek archbishop.

NICOMEDUS, a geometrician, famous on account of the invention of the curve called *conchoid*, which is equally useful in resolving the two problems of doubling the cube and trisecting the angle. It appears that he lived soon after Eratosthenes, for he rallied that philosopher on the mechanism of his mesolabe. Geminus, who lived in the second century before Jesus Christ, has written on the conchoid, though Nicomedus was always esteemed the inventor of it. Those who place him four or five centuries after Jesus Christ must be ignorant of these facts, by which we are enabled to ascertain pretty nearly the time in which he lived.

NICON, a native and patriarch of Russia, was born in 1613, in a village of the government of Nishnei Novogorod, of such obscure parents, that their names and station are not transmitted to posterity. He received at the baptismal font the name of *Nikita*, which afterwards, when he became monk, he changed to *Nicon*, the appellation by which he is more generally known. He was educated in the convent of St Macarius, under the care of a monk. From the course of his studies, which were almost solely directed to the Holy Scriptures, and the exhortations of his preceptor, he imbibed at a very early period the strongest attachment to a monastic life; and was only prevented from following the bent of his mind by the persuasions and authority of his father. In conformity, however, to the wishes of his family, though contrary to his own inclination, he entered into matrimony; and, as that state precluded him from being admitted into a convent, he was ordained a secular priest. With his wife he continued ten years, partly in the country, and partly at Moscow, officiating as a parish priest. The loss of three children, however, gave him a total disgust to the world: in consequence of which, his wife was persuaded to take the veil, and he became a monk; his retreat was in an island of the White sea, and a kind of ecclesiastical establishment was formed, as remarkable for the austerities of its rules as the situation was for its solitude. There were about 12 monks, but they all lived in different cells. Such a system, combined with the most gloomy ideas, occasioned so much cloistered pride as tarnished his character, when he was afterwards called up to fulfil the duties of a public and exalted station. Our limits do not permit us to be minute in our account of his life, we must therefore be contented with barely reciting general facts. Within less than the space of five years, Nicon was successively

successively created archimandrite, or abbot of the Novospatskoi convent, archbishop of Novogorod, and patriarch of Russia. That he was worthy of these rapid promotions, few will doubt who are acquainted with his character; for he was possessed of very extraordinary qualities, such as even his enemies allow and admire. His courage was undaunted, his morals irreproachable, his charity extensive and exalted, his learning deep and comprehensive, and his eloquence commanding. When archbishop, he obtained the respect of the inhabitants by his unwearied assiduity in the discharge of his trust; and conciliated their affections by acts of unbounded charity: Nor was he less conspicuous in the discharge of the office of patriarch, to which dignity he was appointed in 1652, in the 39th year of his age.

Nor was he only distinguished in his own profession, for he shone even as a statesman. At length, however, he fell a victim to popular discontents; which misfortune, though he was far from deserving it, was certainly the effect of imprudence. He abdicated the office of patriarch, which would otherwise have been taken from him, in July 1658, and bore his reverse of fortune with heroic magnanimity: he returned to a cell, and commenced his former austerities. His innocence, however, could not protect him from further malice: his enemies obtained him to be formally deposed in 1666. This degradation was followed by imprisonment, which was for some time very rigorous, because he, conscious of his own innocence, refused to accept pardon for crimes of which he was not guilty. In 1676, however, he was removed to the convent of St Cyril, and enjoyed perfect liberty.

Nicon survived his deposition 15 years. In 1681, he requested and obtained permission to return to the convent of Jerusalem, that he might end his days in that favourite spot; but he expired upon the road near Yaroslaf, in the 66th year of his age. His remains were transported to that convent, and buried with all the ceremonies used at the interment of patriarchs.

NICOPOLI, a town of Turkey in Europe, and in Bulgaria, famous for being the place where the first battle was fought between the Turks and Christians in 1396; and where the latter were defeated with the loss of 20,000 men. E. Long. 25. 33. N. Lat. 43. 46.

NICOSIA, the capital of the island of Cyprus, where a Turkish bashaw resides. It is delightfully situated between the mountains of Olympus and a chain of others, and was formerly well fortified by the Venetians; but the works are now in ruins. It was once nine miles in circumference, but was reduced to three by the Venetians. There are plantations of olives, almonds, lemons, oranges, mulberries, and cypress trees, interspersed among the houses, which give the town a delightful appearance. The church of Sancta Sophia is an old Gothic structure, which the Turks have turned into a mosque, and destroyed the ornaments. It is 100 miles west of Tripoli, and 160 south-west of Aleppo. E. Long. 34. 45. N. Lat. 34. 54.

NICOT, John, lord of Villemain, and master of request of the French king's household, was born at Nismes, and was sent ambassador to Portugal in 1559; whence he brought the plant which, from his name,

was called *Nicotiana*, but is now more generally known by the name of *Tobacco*. He died at Paris in 1603. He wrote a French and Latin dictionary in folio; a treatise on navigation; and other works.

NICOTIANA, Tobacco, a genus of plants belonging to the pentandria class, and in the natural method ranking under the 28th order, *Luridæ*. See Botany *Index*.—There are seven species, of which the most remarkable is the *tabacum*, or common tobacco plant. This was first discovered in America by the Spaniards about the year 1560, and by them imported into Europe. It had been used by the inhabitants of America long before; and was called by those of the islands *yoli*, and *petun* by the inhabitants of the continent. It was sent into Spain from Tabaco, a province of Yucatan, where it was first discovered, and from whence it takes its common name. Sir Walter Raleigh, it is generally said, first introduced it into England about the year 1585, and taught his countrymen how to use it. Dr Cotton Mather, however, (in his Christian Philosopher) says, that in the above year one Mr Lane carried over some of it from Virginia, which was the first time it had ever been seen in Europe. Tobacco is commonly used among the oriental nations, though it is uncertain by whom it was introduced among them. Considerable quantities of it are cultivated in the Levant, on the coasts of Greece and the Archipelago, in Italy, and in the island of Malta.

There are two varieties of that species of nicotiana which is cultivated for common use, and which are distinguished by the names of *Oronokoe*, and *sweet-scented tobacco*. They differ from each other only in the figure of their leaves; those of the former being longer and narrower than the latter. They are tall herbaceous plants, growing erect with fine foliage, and rising with a strong stem from six to nine feet high. The stalk near the root is upward of an inch diameter, and surrounded with a kind of hairy or velvet clammy substance, of a yellowish green colour. The leaves are rather of a deeper green, and grow alternately at the distance of two or three inches from each other. They are oblong, of a spear-shaped oval, and simple; the largest about 20 inches long, but decreasing in size as they ascend, till they come to be only 10 inches long, and about half as broad. The face of the leaves is much corrugated, like those of spinage when full ripe. Before they come to maturity, when they are about five or six inches long, the leaves are generally of a full green, and rather smooth; but as they increase in size, they become rougher, and acquire a yellowish cast. The stem and branches are terminated by large bunches of flowers collected into clusters, of a delicate red; the edges, when full blown, inclining to a pale purple. They continue in succession till the end of the summer; when they are succeeded by seeds of a brown colour, and kidney-shaped. These are very small, each capsule containing about 1000; and the whole produce of a single plant is reckoned at about 350,000. The seeds ripen in the month of September.

Mr Carver informs us, that the Oronokoe, or, as it is called, the *long Virginian tobacco*, is the kind best suited for bearing the rigour of a northern climate, the strength as well as the scent of the leaves being greater than that of the other. The *sweet-scented* sort flourishes most in a sandy soil, and in a warm climate, where

Nicotiana. where it greatly exceeds the former in the celerity of its growth; and is likewise, as its name intimates, much more mild and pleasant.

Culture.—Tobacco thrives best in a warm, kindly, rich soil, that is not subject to be overrun by weeds. In Virginia, the soil in which it thrives best is warm, light, and inclining to be sandy; and therefore, if the plant is to be cultivated in Britain, it ought to be planted in a soil as nearly of the same kind as possible. Other kinds of soil might probably be brought to suit it, by a mixture of proper manure; but we must remember, that whatever manure is made use of, must be thoroughly incorporated with the soil. The best situation for a tobacco plantation is the southern declivity of a hill, rather gradual than abrupt, or a spot that is sheltered from the north winds: but at the same time it is necessary that the plants enjoy a free air; for without that they will not prosper.

As tobacco is an annual plant, those who intend to cultivate it ought to be as careful as possible in the choice of the seeds; in which, however, with all their care, they may be sometimes deceived. The seeds are to be sown about the middle of April, or rather sooner in a forward season, in a bed prepared for this purpose of such soil as has been already described, mixed with some warm rich manure. In a cold spring, hot beds are most eligible for this purpose, and gardeners imagine that they are always necessary: but Mr Carver tells us, that he is convinced, when the weather is not very severe, the tobacco seeds may be raised without doors; and for this purpose gives us the following directions.

Treatise on the Culture of Tobacco.

"Having sown the seed in the manner above directed, on the least apprehension of a frost after the plants appear, it will be necessary to spread mats over the beds, a little elevated from the ground by poles laid across, that they may not be crushed. These, however, must be removed in the morning, soon after the sun appears, that they may receive as much benefit as possible from its warmth and from the air. In this manner proceed till the leaves have attained about two inches in length and one in breadth; which they will do in about a month after they are sown, or near the middle of May, when the frosts are usually at an end. One invariable rule for their being able to bear removal is, when the fourth leaf is sprouted, and the fifth just appears. Then take the opportunity of the first rains or gentle showers to transplant them into such a soil and situation as before described; which must be done in the following manner.—The land must be ploughed, or dug up with spades, and made as mellow and light as possible. When the plants are to be placed, raise with the hoe small hillocks at the distance of two feet or a little more from each other, taking care that no hard sods or lumps are in it; and then just indent the middle of each, without drilling holes, as for some other plants.

"When your ground is thus prepared, dig in a gentle manner from their native bed such plants as have attained the proper growth for transplanting above mentioned; and drop, as you pass, one on every hillock. Insert a plant gently into each centre, pressing the soil around gently with your fingers; and taking the greatest care, during the operation, that you do not break off any of the leaves, which are at this time exquisitely tender. If the weather proves dry after they are thus transplanted, they must be watered with soft water, in the same manner as is usually done to coleworts, or plants of a similar kind. But though you now seem to have a sufficient quantity of plants for the space you intend to cultivate, it is yet necessary that you continue to attend to your bed of seedlings, that you may have enough to supply any deficiencies which through accident may arise. From this time great care must be taken to keep the ground soft and free from weeds, by often stirring with your hoe the mould round the roots; and to prune off the dead leaves that sometimes are found near the bottom of the stalk.

"The difference of this climate from that in which I have been accustomed to observe the progress of this plant, will not permit me to direct with certainty the time which is most proper to take off the top of it, to prevent it from running to seed. This knowledge can only be acquired by experience. When it has risen to the height of more than two feet, it commonly begins to put forth the branches on which the flowers and seeds are produced; but as this expansion, if suffered to take place, would drain the nutriment from the leaves, which are the most valuable part, and thereby lessen their size and efficacy, it becomes needful at this stage to nip off the extremity of the stalk to prevent its growing higher. In some other climates, the top is commonly cut off when the plant has 15 leaves; but if the tobacco is intended to be a little stronger than usual, this is done when it has only 13; and sometimes, when it is designed to be remarkably powerful, 11 or 12 are only allowed to expand. On the contrary, if the planter is desirous of having his crop very mild, he suffers it to put forth 18 or 20: but in this calculation, the three or four lower leaves next the ground, which do not grow so large and fine as the others, are not to be reckoned.

"This operation, denominated *topping* the tobacco, is much better performed by the finger and thumb than with any instrument; because the grasp of the fingers closes the pores of the plant; whereas, when it is done by instruments, the juices are in some degree exhausted. Care must also be taken to nip off the sprouts that will be continually springing up at the junction of the leaves with the stalks. This is termed *succouring*, or *suckering*, the tobacco; and ought to be repeated as often as occasion requires.

"As it is impossible to ascertain the due time for topping the plant, so it is equally impossible, without experiment, to ascertain the time it will take to ripen in this country. The apparent signs of its maturity are these: The leaves, as they approach a state of ripeness, become more corrugated or rough; and when fully ripe, appear mottled with yellowish spots on the raised parts; whilst the cavities retain their usual green colour. They are at this time also thicker than they have been before; and are covered with a downy velvet, like that formerly mentioned, on the stalks. If heavy rains happen at this critical period, they will wash off this excrescent substance, and thereby damage the plants. In this case, if the frosty nights are not begun, it is proper to let them stand a few days longer; when, if the weather be moderate, they will recover this substance again. But if a frost unexpectedly happens during

Nicotiana.

ring the night, they must be carefully examined in the morning, before the sun has any influence upon them; and those which are found to be covered with frosty particles, whether thoroughly ripe or not, must be cut up; for though they may not all appear to be arrived at a state of maturity, yet they cannot be far from it, and will differ but little in goodness from those that are perfectly so."

Tobacco is subject to be destroyed by a worm; and without proper care to exterminate this enemy, a whole field of plants may soon be lost. This animal is of the horned species, and appears to be peculiar to the tobacco plant; so that in many parts of America it is distinguished by the name of the *tobacco worm*. In what manner it is first produced, or how propagated, is unknown: but it is not discernible till the plants have attained about half their height; and then appears to be nearly as large as a gnat. Soon after this it lengthens into a worm; and by degrees increases in magnitude to the bigness of a man's finger. In shape it is regular from its head to its tail, without any diminution at either extremity. It is indented or ribbed round at equal distances, nearly a quarter of an inch from each other; and having at every one of these divisions a pair of feet or claws, by which it fastens itself to the plant. Its mouth, like that of the caterpillar, is placed under the fore part of the head. On the top of the head, between the eyes, grows a horn about half an inch long, and greatly resembling a thorn; the extreme part of which is of a brown colour, a firm texture, and the extremity sharp pointed. It is easily crushed; being only, to appearance, a collection of green juice enclosed in a membranaceous covering, without the internal parts of an animated being. The colour of its skin is in general green, interspersed with several spots of a yellowish white; and the whole covered with a short hair scarcely to be discerned. These worms are found the most predominant during the latter end of July and the beginning of August; at which time the plants must be particularly attended to, and every leaf carefully searched. As soon as a wound is discovered, and it will not be long before it is perceptible, care must be taken to destroy the cause of it, which will be found near it, and from its unsubstantial texture may easily be crushed: but the best method is to pull it away by the horn, and then crush it.

When the tobacco is fit for being gathered, as will appear from an attention to the foregoing directions, on the first morning that promises a fair day, before the sun is risen, take an axe or a long knife, and holding the stalk near the top with one hand, sever it from its root with the other, as low as possible. Lay it gently on the ground, taking care not to break off the leaves, and there let it remain exposed to the rays of the sun throughout the day, or until the leaves, according to the American expression, are entirely *wilted:* that is, till they become limber, and will bend any way without breaking. But if the weather should prove rainy without any intervals of sunshine, and the plants appear to be fully ripe, they must be housed immediately. This must be done, however, with great care, that the leaves, which are in this state very brittle, may not be broken. They are next to be placed under proper shelter, either in a barn or covered hovel, where they cannot be affected by rain or too much air, thinly scattered on the floor; and if the sun does not appear for several days, they must be left to wilt in that manner; but in this case the quality of the tobacco will not be quite so good.

When the leaves have acquired the above-mentioned flexibility, the plants must be laid in heaps, or rather in one heap if the quantity is not too great, and in about 24 hours they will be found to sweat. But during this time, when they have lain for a little while, and begin to ferment, it will be necessary to turn them; bringing those which are in the middle to the surface, and placing those which are at the surface in the middle. The longer they lie in this situation, the darker coloured is the tobacco; and this is termed *sweating* the tobacco. After they have lain in this manner for three or four days, (for a longer continuance might make the plants turn mouldy), they may be fastened together in pairs with cords or wooden pegs, near the bottom of the stalk, and hung across a pole, with the leaves suspended in the same covered place, a proper interval being left between each pair. In about a month the leaves will be thoroughly dried, and of a proper temperature to be taken down. This state may be ascertained by their appearing of the same colour with those imported from America. But this can be done only in wet weather.—The tobacco is exceedingly apt to attract the humidity of the atmosphere, which gives it a pliability that is absolutely necessary for its preservation; for if the plants are removed in a very dry season, the external parts of the leaves will crumble into dust, and a considerable waste will ensue.

Cure.—As soon as the plants are taken down, they must again be laid in a heap, and pressed with heavy logs of wood for about a week; but this climate may possibly require a longer time. While they remain in this state, it will be necessary to introduce your hand frequently into the heap, to discover whether the heat be not too intense; for in large quantities this will sometimes be the case, and considerable damage will be occasioned by it. When they are found to heat too much, that is, when the heat exceeds a moderate glowing warmth, part of the weight by which they are pressed must be taken away; and the cause being removed, the effect will cease. This is called the *second* or *last sweating;* and, when completed, which it generally will be about the time just mentioned, the leaves must be stripped from the stalks for use. Many omit this last sweating; but Mr Carver thinks that it takes away any remaining harshness, and renders the tobacco more mellow. The strength of the stalk also is diffused by it through the leaves, and the whole mass becomes equally meliorated.—When the leaves are stripped from the stalks, they are to be tied up in bunches or *hands*, and kept in a cellar or other damp place; though if not handled in dry weather but only during a rainy season, it is of little consequence in what part of the house or barn they are laid up. At this period the tobacco is thoroughly cured, and as proper for manufacturing as that imported from the colonies.

Our author advises the tobacco planter, in his first trials, not to be too avaricious, but to top his plants before they have gained their utmost height: leaving only about the middle quantity of leaves directed before to give it a tolerable degree of strength. For though this

this, if excessive, might be abated during the cure by an increase of sweating, or be remedied the next season by suffering more leaves to grow, it can never be added; and, without a certain degree of strength, the tobacco will always be tasteless and of little value. On the contrary, though it be ever so much weakened by sweating, and thereby rendered mild, yet it will never lose the aromatic flavour which accompanied that strength, and which greatly adds to its value. A square yard of land, he tells us, will rear about 500 plants, and allow proper space for their nurture till they are fit for transplanting.

The following extract, which is copied from a manuscript of Dr Barham (A), for directing the raising, cultivating, and curing tobacco in Jamaica, is perhaps worthy of the attention of those who wish to be further acquainted with this subject.

"Let the ground or woodland wherein you intend planting tobacco be well burned, as the greater the quantity of wood ashes the better. The spot you intend raising your plants on must be well strewed with ashes, laid smooth and light: then blow the seed from the palm of your hand gently on the bed, and cover it over with palm or plantain leaves.

"When your plants are about four inches high, draw them and plant them out about three feet asunder; and when they become as high as your knee, cut or pluck off the top; and if there are more than 12 leaves on the plant, take off the overplus, and leave the rest entire.

"The plant should now be daily attended to, in order to destroy the caterpillars that are liable to infest it; as also to take off every sprout or sucker that puts out at the joints, in order to throw the whole vegetable nourishment into the large leaves.

"When the edges and points of the leaves begin to turn a little yellow, cut down the stalks about ten o'clock in the morning, taking the opportunity of a fine day, and be careful the dew is fully off the plant, and do not continue this work after two in the afternoon. As fast as it is cut let it be carried into your tobacco house, which must be so close as to shut out all air, (on this much depends), and hung up on lines tied across, for the purpose of drying.

"When the stalks begin to turn brownish, take them off the lines, and put them in a large binn, and lay on them heavy weights for 12 days; then take them out, and strip off the leaves, and put them again into the binn, and let them be well pressed, and so as no air gains admission for a month. Take them out; tie them in bundles about 60 leaves in each, which are called *monococs*; and are ready for sale. But observe to let them always be kept close till you have occasion to dispose of them.

"Let your curing house be well built, and very close and warm; if a boarded building, it will not be amiss, in a wet situation, to cover the whole outside with thatch and plantain trash, to keep off the damps; for by this care you preserve the fine volatile oil in the leaves. Observe, no smoke is to be made use of or admitted into your curing house."

For an account of the medical effects of tobacco, see MATERIA MEDICA *Index*.

The most common uses of this plant, are either as a sternutatory when taken by way of snuff, as a masticatory by chewing it in the mouth, or as effluvia by smoking it; and when taken in moderation, it is not an unhealthful amusement. Before pipes were invented, it was usually smoked in segars, and they are still in use among some of the southern nations. The method of preparing these is at once simple and expeditious. A leaf of tobacco being formed into a small twisted roll, somewhat larger than the stem of a pipe, and about eight inches long, the smoke is conveyed through the winding folds which prevent it from expanding, as through a tube; so that one end of it being lighted, and the other applied to the mouth, it is in this form used without much inconvenience. But, in process of time, pipes being invented, they were found more commodious vehicles for the smoke, and are now in general use.

Among all the productions of foreign climes introduced into these kingdoms, scarce any has been held in higher estimation by persons of every rank than tobacco. In the countries of which it is a native, it is considered by the Indians as the most valuable offering that can be made to the beings they worship. They use it in all their civil and religious ceremonies. When once the spiral wreaths of its smoke ascend from the feathered pipe of peace, the compact that has been just made is considered as sacred and inviolable. Likewise, when they address their great Father, or his guardian spirits, residing, as they believe, in every extraordinary production of nature, they make liberal offerings to them of this valuable plant, not doubting but that they are thus secured of protection.

Tobacco is made up into rolls by the inhabitants of the interior parts of America, by means of a machine called a *tobacco wheel*. With this machine they spin the leaves after they are cured, into a twist of any size they think fit: and having folded it into rolls of about 20 pounds each, they lay it by for use. In this state it will keep for several years, and be continually improving, as it always grows milder. The Illinois usually form it into carrots; which is done by laying a number of leaves, when cured, on each other after the ribs have been taken out, and rolling them round with packthread, till they become cemented together. These rolls commonly measure about 18 or 20 inches in length, and nine round in the middle part.

Tobacco forms a very considerable article in commerce; for an account of which, see the articles GLASGOW and VIRGINIA.

NICTITATING MEMBRANE, a thin membrane chiefly found in the bird and fish kind, which covers the eyes of these animals, sheltering them from the dust or too much light; yet is so thin and pellucid, that they can see pretty well through it.

NIDDUI,

(A) This gentleman was cotemporary with Sir Hans Sloane. He was a man of great probity, an able physician, and a skilful naturalist. He collected and arranged a number of the plants of Jamaica, which he presented to Dr Sloane, and made several communications to the Royal Society.

NIDDUI, in the Jewish customs, is used to signify "separated or excommunicated." This, according to some, was to be understood of the lesser sort of excommunication in use among the Hebrews. He that had incurred it was to withdraw himself from his relations, at least to the distance of four cubits: it commonly continued a month. If it was not taken off in that time, it might be prolonged for 60 or even 90 days: but if, within this term, the excommunicated person did not give satisfaction, he fell into the *cherem*, which was a second sort of excommunication; and thence into the third sort, called *shammata* or *shematta*, the most terrible of all. But Selden has proved that there were only two kinds of excommunication, viz. the greater and less; and that these three terms were used indifferently.

NIDUS, among naturalists, signifies a nest or proper repository for the eggs of birds, insects, &c. where the young of these animals are hatched and nursed.

NIDIFICATION, a term generally applied to the formation of a bird's nest, and its hatching or bringing forth its young. See ORNITHOLOGY.

NIECE, a brother's or sister's daughter, which in the civil law is reckoned the third degree of consanguinity.

NIEMEN, a large river of Poland, which rises in Lithuania, where it passes by Bielica, Grodno, and Konno: it afterwards runs through part of Samogitia and Ducal Prussia, where it falls into the lake called the *Curisch-haff*, by several mouths, of which the most northern is called the *Russ*. This lake communicates with the Baltic.

NIENBURGH, a rich and strong town of Germany, in the duchy of Brunswick-Lunenburg, with a strong castle. It carries on a considerable trade in corn and wool, and is seated in a fertile soil on the river Weser. E. Long. 9. 26. N. Lat. 52. 44.

NIEPER, or DNIEPER, a large river of Europe, and one of the most considerable of the north, formerly called the Boristhenes. Its source is in the middle of Muscovy, running west by Smolensko, as far as Orsa; and then turns south, passing by Mohilow, Bohaczo, Kiow, Czyrkassy, the fortress of Kudak, Dessau, and Oczakow, falling into the Black sea; as also in its course it divides Little Tartary from Budziac Tartary.

NIESS, a mountain in the environs of Berne in Switzerland. It is the last mountain in a high chain of calcareous hills, of which the Stockhorn, the Neuneren, and the Ganterish, have been illustrated by the botanical labours of the celebrated Haller. Niess stands on the borders of the lake Thun, and separates the valley of Frutingen from that of Simme. It is very interesting to the curious traveller, on account of the fine view from its top; and to naturalists, because it joins the Alps. Towards its foot, beds of slate have been discovered: it is of calcareous stone higher up; and near its top is found a species of pudding-stone, filled with small fragments of broken petrifactions.

NIESTER, a large river of Poland, which has its source in the lake Niester, in the palatinate of Lemburg, where it passes by Halicz. Then it separates Podolia and Oczakow Tartary from Moldavia and Budziac Tartary; and falls into the Black sea at Belgorod, between the mouths of the Nieper and the Danube.

NIGELLA, FENNEL-FLOWER, or *Devil in a Bush*, a genus of plants, belonging to the pentandria class. See BOTANY *Index*.

NIGER, C. PESCENNIUS JUSTUS, a celebrated governor in Syria, well known by his valour in the Roman armies while in a private station. At the death of Pertinax he was declared emperor of Rome; and his claims to that elevated station were supported by a sound understanding, prudence of mind, moderation, courage, and virtue. He proposed to imitate the actions of the venerable Antoninus, of Trajan, of Titus, and M. Aurelius. He was remarkable for his fondness of ancient discipline. He never suffered his soldiers to drink wine, but obliged them when thirsty to use water and vinegar. He forbade the use of silver or gold utensils in his camp. All the bakers and cooks were driven away, and the soldiers were ordered to live during the expedition they undertook merely upon biscuits. In his punishments Niger was inexorable: he condemned ten of his soldiers to be beheaded in the presence of the army because they had stolen and eaten a fowl. The sentence was heard with groans. The army interfered; and when Niger consented to diminish the punishment, for fear of kindling rebellion, he yet ordered the criminals to make each a restoration of ten fowls to the person whose property they had stolen. They were besides ordered not to light a fire the rest of the campaign, but to live upon cold aliments and to drink nothing but water. Such great qualifications in a general seemed to promise the restoration of ancient discipline in the Roman armies; but the death of Niger frustrated every hope of reform. Severus, who had also been invested with the imperial purple, marched against him: some battles were fought, and Niger was at last defeated, A. D. 195. His head was cut off and fixed to a long spear, and carried in triumph through the streets of Rome. He reigned about a year.

NIGER, a large river of Africa, of which many erroneous opinions have been entertained. According to Herodotus, Pliny, Ptolemy, and many of the ancients, this river runs from west to east, an opinion which was long forgotten, and in more modern times it was believed to flow from east to west; but from the recent discoveries of the indefatigable Mr Park, who himself saw this majestic river, the opinion of the ancients is now fully established, that its course is from west to east. The source of the Niger is supposed to be in that mountainous region in western Africa, which gives origin to the rivers Gambia and Senegal, which discharge their waters into the Western ocean, while the Niger rising from the opposite side of the mountains, takes an easterly direction. See AFRICA, p. 264. and 272. See also AFRICA, SUPPLEMENT, p. 101.

NIGHT, that part of the natural day during which the sun is underneath the horizon; or that space wherein it is dusky.

Night was originally divided by the Hebrews and other eastern nations into three parts or watches. The Romans, and after them the Jews, divided the night into four parts or watches; the first of which began at sunset, and lasted till nine at night, according to our way of reckoning; the second lasted till mid-

night;

night; the third till three in the morning; and the fourth ended at sunrise. The ancient Gauls and Germans divided their time not by days but by nights; and the people of Iceland and the Arabs do the same at this day. The like is observed of the Anglo-Saxons.—The length and shortness of night or of darkness is according to the season of the year and position of the place; and the causes of this variety are now well known. See ASTRONOMY, &c.

NIGHT, in scripture language, is used for the times of heathenish ignorance and profaneness (Rom. xiii. 12.); for adversity and affliction (Is. xxi. 12.); and lastly, for death (John ix. 4.).

NIGHT-Angling, a method of catching large and shy fish in the night-time. Trout, and many other of the better sorts of fish, are naturally shy and fearful; they therefore prey in the night as the securest time.—The method of taking them on this plan is as follows: The tackle must be strong, and need not be so fine as for day fishing, when every thing is seen; the hook must be baited with a large earth worm, or a black snail, and thrown out into the river; there must be no lead to the line, so that the bait may not sink, but be kept drawling along, upon or near the surface. Whatever trout is near the place will be brought thither by the motion of the water, and will seize the worm or snail. The angler will be alarmed by the noise which the fish makes in rising, and must give him line, and time to swallow the hook; then a slight touch secures him. The best and largest trouts are found to bite thus in the night; and they rise mostly in the still and clear deeps, not in the swift and shallow currents. Sometimes, though there are fish about the place, they will not rise at the bait: in this case the angler must put on some lead to his line, and sink it to the bottom.

NIGHT-Mare, or *Incubus*. See MEDICINE, N° 329.

NIGHT-Walkers. See MEDICINE, N° 329, and NOCTAMBULI.

NIGHT-Walkers, in *Law*, are such persons as sleep by day and walk by night, being oftentimes pilferers or disturbers of the public peace. Constables are authorized by the common law to arrest night-walkers and suspicious persons, &c. Watchmen may also arrest night-walkers, and hold them until the morning; and it is said, that a private person may arrest any suspicious night-walker, and detain him till he give a good account of himself. One may be bound to the good behaviour for being a night-walker; and common night-walkers, or haunters of bawdy-houses, are to be indicted before justices of peace, &c. But it is not held lawful for a constable, &c. to take up any woman as a night-walker on bare suspicion only of being of ill-fame, unless she be guilty of a breach of the peace, or some unlawful act, and ought to be found misdoing.

NIGHTINGALE, a species of motacilla. See ORNITHOLOGY *Index*.

NIGHTSHADE. See SOLANUM, BOTANY *Index*.

Deadly NIGHTSHADE. See ATROPA, BOTANY *Index*.—The berries of this plant are of a malignant poisonous nature; and, being of a sweet taste, have frequently proved destructive to children. It is said, that a large glass of warm vinegar, taken as soon as possible after eating the berries, will prevent their bad effects.

NIGHT-Watching, a practice of very remote antiquity, which belongs to the oldest regulations of police. So early as the time of Solomon we find mention made of it, and likewise in the Psalms of David *. Sentinels were stationed in different places in Athens and other cities of Greece, and they were kept to their duty by the visitations of the *Thesmothetæ*. There were also *triumviri nocturni* in the city of Rome, as appears from the commentaries of Heubach on the police of the Romans. It appears, however, that the design of these institutions was rather the prevention of fires, than the guarding against alarms or dangers by night, although attention was likewise paid to these in process of time. The apprehension of fires was the pretext of Augustus, when he wished to strengthen the night-watch for suppressing nocturnal commotions.

* *Song of Solomon*, chap. iii. ver. 3. *Psal.* cxxvii. 1.

It does not appear that calling out the hours became an established practice before the erection of city gates, and probably had its rise in Germany; yet it would have been attended with advantages in ancient Rome, where there were no public clocks, nor any thing in private houses to indicate the hours. The periods for soldiers to mount guard were determined by water-clocks; at the end of each hour they blew a horn, and by means of this signal each individual might ascertain the hour of the night. It seems evident, however, that these regulations were only attended to in time of war.

In the city of Paris, night-watching was established, as at Rome, in the very commencement of its monarchy; and De la Mare quotes the ordinances of Clothaire II. upon this subject, in the year 595. The citizens at first kept watch in rotation; but this practice was afterwards set aside, and, by the payment of a certain sum of money, a permanent watch was established. In the opinion of the learned and indefatigable Beckmann, the establishment of single watchmen, to call out the hours through the streets, is peculiar to Germany, and only copied by surrounding nations in more modern times. The elector, John George, in 1588, appointed watchmen at Berlin; and Mabillon describes it as a practice peculiar to that country. Horns are made use of by watchmen in some places, and rattles in others, the former being most proper for villages, and the latter for cities.

The Chinese, so early as the ninth century, had watchmen posted on their towers, who announced the hours both by day and night, by striking forcibly on a suspended board, which in that country is said to be in use to the present period; and at Petersburgh, in Russia, the watchmen employ a suspended plate of iron for a similar purpose. In this manner also Christians are assembled together in the Levant, for the purpose of attending divine service; and monks were thus awakened in monasteries at the most early periods, to attend to the proper hours of prayer.

We find mention made of steeple-watchmen in Germany in the 14th century. In the year 1563, a church-steeple was erected in Leisnig, and an apartment built in it for a permanent watchman, who was obliged to proclaim the hours every time the clock struck. Permanent watchmen were kept in many of the steeples at Ulm in the 15th century. The same thing was practised at Frankfort on the Mayne, at Oettingen, and many other places; and Montaigne was astonished at finding a man on the steeple of Constance, who kept watch

Night-Watching || Nile.

watch upon it continually, and who on no pretext whatever was permitted to come down. *Beckman's Hist. of Inventions*, iii. 425.

NIGIDIUS FIGULUS, PUBLIUS, one of the most learned men of ancient Rome, flourished at the same time with Cicero. He wrote on various subjects; but his pieces appeared so refined and difficult that they were not regarded. He assisted Cicero, with great prudence, in defeating Catiline's conspiracy, and did him many services in the time of his adversity. He adhered to Pompey in opposition to Cæsar; which occasioned his exile, he dying in banishment. Cicero, who had always entertained the highest esteem for him, wrote a beautiful consolatory letter to him (the 13th of lib. iv. *ad Familiares*).

NIGRINA, a genus of plants belonging to the pentandria class. See BOTANY *Index*.

NIGRINE, an ore of titanium. See MINERALOGY *Index*.

NIGRITIA. See NEGROLAND.

NIGUA. See CHEGOE.

NILE, a large and celebrated river of Africa, to which the country of Egypt owes its fertility; and the exploring the sources of which, has from the remotest ages, been accounted an impracticable undertaking. This problem has been solved by James Bruce, Esq. of Kinnaird, in Scotland; who spent several years at the court of Abyssinia, and by the favour of the emperor and great people of the country was enabled to accomplish the arduous task.

In the account of his travels, this gentleman has been at particular pains to show, that none of those who undertook this task ever succeeded in it but himself. The inquiry concerning its springs, he says, began either before history or tradition, and is by some supposed to be the origin of hieroglyphics. Though Egypt was the country which received the greatest benefit from this river, it was not there that the inquiries concerning its inundation began: it being probable that every thing relative to the extent and periodical time of that inundation would be accurately settled (which could not be done but by a long series of observations) before any person would venture to build houses within its reach.

The philosophers of Meroe, in our author's opinion, were the first who undertook to make a number of observations sufficient to determine these points; their country being so situated, that they could perceive every thing relative to the increase or decrease of the river without any danger from its overflowing. Being much addicted to astronomy, it could not long escape them, that the heliacal rising of the dog-star, was a signal for Egypt to prepare for the inundation; without which it was vain to expect any crop. The connection of this celestial sign with the annual rising of the river would undoubtedly soon become a matter of curiosity; and as this could not easily be discovered, it was natural for an ignorant and superstitious people to ascribe the whole to the action of the dog-star as a deity. Still, however, by those who were more enlightened, the phenomenon would be ascribed to natural causes; and a great step towards the discovery of these, undoubtedly was that of the sources of the river itself. In the early ages, when travelling into foreign countries was impracticable by private persons, the inquiry into the sources of the Nile became an object to the greatest monarchs. Sesostris is said to have preferred the honour of discovering them almost to all the victories he obtained. Alexander the Great is well known to have had a great curiosity to discover these fountains. On his arrival at the temple of Jupiter Ammon, he is said to have made inquiry concerning the fountains of the Nile, even before he asked about his own descent from Jupiter. The priests are said to have given him proper directions for finding them: and Alexander took the most ready means of accomplishing his purpose, by employing natives of Ethiopia to make the search. These discoverers, in the opinion of Mr Bruce, missed their aim, by reason of the turn which the Nile takes to the east in the latitude of 9° where it begins to surround the kingdom of Gojam; but which they might imagine to be only a winding of the river soon to be compensated by an equal turn to the west. "They therefore (says he) continued their journey south till near the line, and never saw it more; as they could have no possible notion it had turned back behind them, and that they had left it as far north as latitude 9°. They reported then to Alexander, what was truth, that they had ascended the Nile, as far south as latitude 9°; where it unexpectedly took its course to the east, and was seen no more. The river was not known, nor to be heard of near the line, or farther southward, nor was it diminished in size, nor had it given any symptom that they were near its source; they had found the Nile *calentem* (warm), while they expected its rise among melting snows.

Nile.

Mr Bruce is of opinion that this turn of the Nile to the eastward was the occasion of Alexander's extravagant mistake, in supposing that he had discovered the fountains of the Nile when he was near the source of the Indus; and which he wrote to his mother, though he afterwards caused it to be erased from his books.

Ptolemy Philadelphus succeeded Alexander in his attempts to discover the source of the Nile; but he likewise proving unsuccessful, the task was next undertaken by Ptolemy Euergetes, the most powerful of the Greek princes who sat on the throne of Egypt. "In this (says Mr Bruce) he had probably succeeded, had he not mistaken the river itself. He supposed the Siris, now the Tacazze, to be the Nile; and ascending in the direction of its stream, he came to Axum, the capital of Sire and of Ethiopia. But the story he tells of the snow which he found knee-deep on the mountains of Samen, makes me question whether he ever crossed the Siris, or was himself an ocular witness of what he says he observed there."

Cæsar had the same curiosity with other conquerors to visit the springs of the Nile, though his situation did not allow him to make any attempt for that purpose. Nero, however, was more active He sent two centurions into Ethiopia, with orders to explore the unknown fountains of this river; but they returned without having accomplished their errand. They reported, that, after having gone a long way, they came to a king of Ethiopia, who furnished them with necessaries, and recommendations to some other kingdoms adjacent; passing which, they came to immense lakes, of which nobody knew the end, nor could they ever hope to find it. Their story, however, is by Mr Bruce supposed to be a fiction;

Nile.

fiction; as the Nile forms no lakes throughout its course, excepting that of Tzana or Dembea, the limits of which are easily perceived.

No other attempt was made by the ancients to discover the sources of this celebrated river; and the matter was looked upon to be an impossibility, insomuch that *caput Nili quærere* became a proverb, denoting the impossibility of any undertaking. The first who, in more modern ages, made any attempt of this kind, was a monk sent into Abyssinia in the year 522, by Nonnosus, ambassador from the emperor Justin. This monk is called *Cosmas the Hermit*, and likewise *Indoplaustes*, from his supposed travels into India. He proceeded as far as the city of Axum, but did not visit that part of the country where the head of the Nile lies; nor, in Mr Bruce's opinion, would it have been practicable for him to do so. The discovery, however, is said to have been made at last by Peter Paez the missionary. But the truth of this account is denied by Mr Bruce, for the following reasons: 1. "No relation of this kind (says he) was to be found in three copies of Peter Paez's history, to which I had access when in Italy, on my return home. One of these copies I saw at Milan; and, by the interest of friends, had an opportunity of perusing it at my leisure. The other two were at Bologna and Rome. I ran through them rapidly; attending only to the place where the description ought to have been, and where I did not find it: but having copied the first and last page of the Milan manuscript, and comparing them with the two last mentioned, I found that all the three were word for word the same, and none of them contained one syllable of the discovery of the source. 2. Alphonso Mendez came into Abyssinia about a year after Paez's death. New and desirable as that discovery must have been to himself, to the pope, king of Spain, and all his great patrons in Portugal and Italy; though he wrote the history of the country, and of the particulars concerning the mission in great detail and with good judgment, yet he never mentions this journey of Peter Paez, though it probably must have been conveyed to Rome and Portugal after his inspection and under his authority. 3. Balthazar Tellez, a learned Jesuit, has wrote two volumes in folio, with great candour and impartiality, considering the spirit of those times; and he declares his work to be compiled from those of Alphonso Mendez the patriarch, from the two volumes of Peter Paez, as well as from the regular reports made by the individuals of the company in some places, and by the provincial letters in others; to all which he had complete access, as also to the annual reports of Peter Paez, among the rest from 1598 to 1622; yet Tellez makes no mention of such a discovery, though he is very particular as to the merit of each missionary during the long reign of Facilidas, which occupies more than half the two volumes."

The first, and indeed the only account of the fountains of the Nile, published before that of Mr Bruce, was Kircher's; who says that he took it from the writings of Peter Paez. The time when the discovery is said to have been made was the 21st of April 1618; at which season the rains are begun, and therefore very unwholesome; so that the Abyssinian armies are not without extreme necessity in the field; between September and February at farthest is the time they are abroad from the capital and in action.

"The river (says Kircher) at this day, by the Ethiopians is called *Abavy*; it rises in the kingdom of Gojam, in a territory called *Sabala*, whose inhabitants are called *Agows*. The source of the Nile is situated in the west part of Gojam, in the highest part of a valley, which resembles a great plain on every side surrounded by high mountains. On the 21st of April 1618, being here, together with the king and his army, I ascended the place, and observed every thing with great attention: I discovered first two round fountains each about four palms in diameter, and saw, with the greatest delight, what neither Cyrus the Persian, nor Cambyses, nor Alexander the Great, nor the famous Julius Cæsar, could ever discover. The two openings of these fountains have no issue in the plain on the top of the mountain, but flow from the root of it. The second fountain lies about a stone-cast west from the former: the inhabitants say that this whole mountain is full of water; and add, that the whole plain about the fountain is floating and unsteady, a certain mark that there is water concealed under it; for which reason the water does not overflow at the fountain, but forces itself with great violence out at the foot of the mountain. The inhabitants, together with the emperor, who was then present with his army, maintain that that year it trembled very little on account of the drought; but in other years, that it trembled and overflowed so that it could scarce be approached without danger. The breadth of the circumference may be about the cast of a sling: below the top of this mountain the people live about a league distant from the fountain to the west; and this place is called *Geesh*; and the fountain seems to be about a cannon-shot distant from Geesh; moreover the field where the fountain is, is on all sides difficult of access, except on the north side, where it may be ascended with ease."

On this relation Mr Bruce observes, that there is no such place as *Sabala*; it ought to have been named *Sacala*, signifying the highest ridge of land, where the water falls equally down on both sides, from east and west, or from north and south. So the sharp roofs of our houses, where the water runs down equally on the opposite sides, are called by the same name. Other objections are drawn from the situation of places, and from the number and situation of the fountains themselves, every one of which Mr Bruce found by actual mensuration to be different from Kircher's account. The following, however, he looks upon to be decisive that Paez never was on the spot. He says, "the field in which the fountains of the Nile are, is of very difficult access; the ascent to it being very steep, excepting on the north, where it is plain and easy. Now, if we look at the beginning of this description, we should think it would be the descent, not the ascent, that would be troublesome; for the fountains were placed in a valley, and people rather *descend* into valleys than *ascend* into them; but supposing it was a valley in which there was a field upon which there was a mountain, and on the mountain these fountains; still, I say, that these mountains are nearly inaccessible on the three sides; but that the most difficult of them all is the north, the way we ascend from the plain of Goutto. From the east, by Sacala, the ascent is made from the valley of Litechambara, and from the plain of Assoa to the south you have the almost perpendicular craggy cliff of Geesh, covered with thorny

Nile. thorny bushes, trees, and bamboos, which cover the mouths of the caverns; and on the north you have the mountains of Aformaska, thick set with all sorts of thorny trees and shrubs, especially with the kantuffa: these thickets are, moreover, filled with wild beasts, especially huge, long-haired baboons, which we frequently met walking upright. Through these high and difficult mountains we have only narrow paths, like those of sheep, made by the goats, or the wild beasts we are speaking of, which, after we had walked on them for a long space, landed us frequently at the edge of some valley or precipice, and forced us to go back again to seek a new road. From towards Zeegam to the westward, and from the plain where the river winds so much, is the only easy access to the fountains of the Nile: and they that ascend to them by this way will not even think that approach too easy."

Peter Heiling, a Protestant of Lubec, resided several years in the country of Gojam, and was even governor of it, but he never made any attempt to discover the source of the Nile; dedicating himself entirely to a studious and solitary life. The most extraordinary attempt, however, that ever was made to discover the source of this or any other river, was that of a German nobleman named *Peter Joseph de Roux*, comte de Desreval. He had been in the Danish navy from the year 1721; and, in 1739, was made rear-admiral. That same year he resigned his commission, and began his attempt to discover the source of the Nile in Egypt. To this country he took his wife along with him; and had no sooner reached Cairo, than he quarrelled with a Turkish mob on a point of etiquette; which instantly brought upon them the janizaries and guards of police, to take them into custody. The countess exerted herself in an extraordinary manner; and armed only with a pair of scissars, put all the janizaries to flight, and even wounded several of them; so that her husband was left at liberty to pursue his plan of discovery. To accomplish this, he provided a barge with small cannon, and furnished with all necessary provisions for himself and his wife, who was still to accompany him. Before he set out, however, it was suggested to him, that, supposing government might protect him so far as to allow his barge to pass the confines of Egypt safely, and to the first cataract; supposing also that she was arrived at Ibrim, or Deir, the last garrisons depending on Cairo; yet still some days journey above the garrisons of Deir and Ibrim began the dreadful deserts of Nubia; and farther south, at the great cataract of Jan Adel, the Nile falls 20 feet down a perpendicular rock—so that here his voyage must undoubtedly end. The count, however, flattered himself with being able to obtain such assistance from the garrisons of Ibrim and Deir as would enable him to take the vessel to pieces, and to carry it above the cataract, where it could be again launched into the river. To facilitate this scheme he had even entered into a treaty with some of the barbarians named *Kennouss*, who reside near the cataract, and employ themselves in gathering sena, which abounds in their country. These promised to assist him in this extraordinary adventure; but, luckily for the count, he suffered himself at last to be persuaded by some Venetian merchants at Cairo not to proceed in person on such a dangerous and unheard of navigation, but rather to depute Mr Norden, his lieutenant, who was likewise to serve as his draughtsman, to reconnoitre the forts of Ibrim and Deir, as well as the cataract of Jan Adel, and renew his treaty with the Kennouss. This gentleman accordingly embarked upon one of the vessels common on the Nile, but met with a great many difficulties and disasters before he could reach Syene and the first cataract; after which having with still greater difficulty reached Ibrim, instead of meeting with any encouragement for the count to proceed on his voyage, he was robbed of all he had by the governor of the fort, and narrowly escaped with his life; it having been for some time determined by him and his soldiers that Mr Norden should be put to death. By these difficulties the count was so much disheartened, that he determined to make no more attempts on the Nubian side. He now resolved to enter Abyssinia by the island of Masuah. With this view he undertook a voyage round the Cape of Good Hope, in order to reach the Red sea by the straits of Babelmandel: but having begun to use his Spanish commission, and taken two English ships, he was met by Commodore Barnet, who made prizes of all the vessels he had with him, and sent home the count himself passenger in a Portuguese ship to Lisbon.

Thus Mr Bruce considers himself as the first European who reached the sources of this river. He informs us that they are in the country of the Agows, as Kircher had said; so that the latter must either have visited them himself, or have had very good information concerning them. The name of the place through which is the passage to the territory of the Agows, is *Abala*; a plain, or rather valley, generally about half a mile, and never exceeding a whole mile, in breadth. The mountains which surround it are at first of an inconsiderable height, covered to the very top with herbage and acacia trees; but as they proceed to the southward they become more rugged and woody.—On the top of these mountains are delightful plains producing excellent pasture. Those to the west join a mountain called *Aformaska*, where, from a direction nearly south-east, they turn south and enclose the villages and territory of Sacala, which lie at the foot of them; and still lower, that is, more to the westward, is the small village of Geesh, where the fountains of the Nile are situated. Here the mountains are in the form of a crescent; and along these the river takes its course. Those which enclose the east side of the plain run parallel to the former in their whole course, making part of the mountains of Lechtambara, or at least joining with them, and these two, when behind Aformaska, turn to the south, and then to the south-west, taking the same form as they do; only making a greater curve, and enclosing them likewise in the form of a crescent, the extremity of which terminates immediately above a small lake named *Gooderoo* in the plain of Assoa, below Geesh, and directly at the fountains of the Nile.

Having passed several considerable streams, all of which empty themselves into the Nile, our traveller found himself at last obliged to ascend a very steep and rugged mountain, where no other path was to be found but a very narrow one made by the sheep or goats, and which in some places was broken, and full of holes; in others, he was obstructed with large stones, which seemed to have remained there since the creation. The whole was covered with thick wood; and he was everywhere stopped by the kantuffa, as well as by several other

Nile.

thorny plants almost as troublesome as that. Having at last, however, reached the top, he had a sight of the Nile immediately below him; but so diminished in size, that it now appeared only a brook scarcely sufficient to turn a mill. The village of Geesh is not within sight of the fountains of the river, though not more than 600 yards distant from them. The country about that place terminates in a cliff of about 300 yards high, which reaches down to the plain of Assoa, continuing in the same degree of elevation till it meets the Nile again about 17 miles to the southward, after having made the circuit of the provinces of Gojam and Damot. In the middle of this cliff is a vast cave running straight northward, with many bye paths forming a natural labyrinth, of sufficient bigness to contain the inhabitants of the whole village with their cattle. Into this Mr Bruce advanced about 100 yards; but he did not choose to go farther, as the candle he carried with him seemed ready to go out; and the people assured him that there was nothing remarkable to be seen at the end. The face of this cliff, fronting the south, affords a very picturesque view from the plain of Assoa below; parts of the houses appearing at every stage through the bushes and thickets of trees. The mouths of the cavern above mentioned, as well as of several others which Mr Bruce did not see, are hid by almost impenetrable fences of the worst kind of thorn; nor is there any other communication betwixt the upper part and the houses but by narrow winding sheep paths, very difficult to be discovered; all of them being allowed to be overgrown, as a part of the natural defence of the people. The edge of the cliff is covered with lofty and high trees, which seem to form a natural fence to prevent people from falling down; and the beauty of the flowers which the Abyssinian thorns bear, seems to make some amends for their bad qualities. From the edge of the cliff of Geesh, above where the village is situated, the ground slopes with a descent due north, till we come to a triangular marsh upwards of 86 yards broad, and 286 from the edge of the cliff, and from a priest's house where Bruce resided. On the east, the ground descends with a very gentle slope from the large village of Sacala, which gives its name to the territory, and is about six miles distant from the source, though to appearance not above two. About the middle of this marsh, and not quite 40 yards from the foot of the mountain of Geesh, rises a circular hillock about three feet from the surface of the marsh itself, though founded apparently much deeper in it. The diameter of this hillock is not quite 12 feet, and it is surrounded by a shallow trench which collects the water, and sends it off to the eastward. This is firmly built of sod brought from the sides, and kept constantly in repair by the Agows, who worship the river, and perform their religious ceremonies upon this as an altar. In the midst of it is a circular hole, in the formation or enlargement of which the work of art is evidently discernible. It is always kept clear of grass and aquatic plants, and the water in it is perfectly pure and limpid, but without any ebullition or motion discernible on its surface. The mouth is some parts of an inch less than three feet diameter, and at the time our author first visited it (Nov. 5. 1770), the water stood about two inches from the brim, nor did it either increase or diminish during all the time of his residence at Geesh. On putting down the shaft of a lance, he found a very feeble resistance at six feet four inches, as if from weak rushes and grass; and, about six inches deeper, he found his lance had entered into soft earth, but met with no obstruction from stones or gravel; and the same was confirmed by using a heavy plummet, with a line besmeared with soap.—This is the first fountain of the Nile.

Nile.

The second fountain is situated at about ten feet distant from the former, a little to the west of south; and is only 11 inches in diameter, but eight feet three inches deep. The third is about 20 feet SSW from the first; the mouth being somewhat more than two feet in diameter, and five feet eight inches in depth. These fountains are made use of as altars, and from the foot of each issues a brisk running rill, which, uniting with the water of the first trench, goes off at the east side in a stream which, our author conjectures, would fill a pipe about two inches diameter. The water of these fountains is extremely light and good, and intensely cold, though exposed to the scorching heat of the sun, without any shelter; there being no trees nearer than the cliff of Geesh. The longitude of the principal fountain was found by Mr Bruce to be 36° 55′ 30″ E. from Greenwich. The elevation of the ground, according to his account, must be very great, as the barometer stood only at 22 English inches. "Neither (says he) did it vary sensibly from that height any of the following days I staid at Geesh; and thence I inferred, that at the sources of the Nile I was then more than two miles above the level of the sea; a prodigious height, to enjoy a sky perpetually clear, as also a hot sun never overcast for a moment with clouds from rising to setting." In the morning of Nov. 6. the thermometer stood at 44°, at noon 96°, and at sunset 46°. It was sensibly cold at night, and still more so about an hour before sunrise.

The Nile thus formed by the union of streams from these three fountains, runs eastward through the marsh for about 30 yards, with very little increase of its water, but still distinctly visible, till it is met by the grassy brink of the land descending from Sacala. By this it is turned gradually NE, and then due north; and in the two miles in which it flows in that direction it receives many small streams from springs on each side; so that about this distance from the fountains it becomes a stream capable of turning a common mill. Our traveller was much taken with the beauty of this spot. "The small rising hills about us (says he) were all thick covered with verdure, especially with clover the largest and finest I ever saw; the tops of the heights covered with trees of a prodigious size: the stream, at the banks of which we were sitting, was limpid, and pure as the finest crystal; the sod covered thick with a kind of bushy tree, that seemed to affect to grow to no height, but, thick with foliage and young branches, rather to assist the surface of the water; whilst it bore, in prodigious quantities, a beautiful yellow flower, not unlike a single rose of that colour, but without thorns; and indeed, upon examination, we found that it was not a species of the rose, but of the hypericum."

Here Mr Bruce exults greatly in his success; as having not only seen the fountains of the Nile, but the river itself running in a small stream; so that the ancient saying of the poet,

Nec licuit populis parvum te Nile videre,

could not be applied to him. Here he *stepped* over it, he says, more than 50 times, though he had told us, in the preceding page, that it was *three yards* over. From this ford, however, the Nile turns to the westward; and, after

Nile. after running over loose stones occasionally in that direction about four miles farther, there is a small cataract of about six feet in height; after which it leaves the mountainous country, and takes its course through the plains of Goutto. Here it flows so gently that its motion is scarcely to be perceived, but turns and winds in its direction more than any river he ever saw; forming more than 20 sharp angular peninsulas in the space of five miles. Here the soil is composed of a marshy clay, quite destitute of trees, and very difficult to travel through; and where its stream receives no considerable addition. Issuing out from thence, however, it is joined by several rivulets which fall from the mountains on each side, so that it becomes a considerable stream, with high and broken banks covered with old timber trees for three miles. In its course it inclines to the north-east, and winds very much, till it receives first a small river named *Diwa*, and then another named *Dee-obha*, or the river Dee. Turning then sharply to the east, it falls down another cataract, and about three miles below receives the Jemma, a pure and limpid stream, not inferior in size to itself. Proceeding still to the northward, it receives a number of other streams, and at last crosses the southern part of the lake Tzana or Dembea, preserving the colour of its stream during its passage, and issuing out at the west side of it in the territory of Dara.

There is a ford, though very deep and dangerous, at the place where the Nile first assumes the name of a river, after emerging from the lake Dembea; but the stream in other places is exceedingly rapid: the banks in the course of a few miles become very high, and are covered with the most beautiful and variegated verdure that can be conceived. It is now confined by the mountains of Begemder, till it reaches Alata, where is the third cataract. This, we are informed by Mr Bruce, is the most magnificent sight he ever beheld; but he thinks that the height has rather been exaggerated by the missionaries, who make it 50 feet; and after many attempts to measure it, he is of opinion that it is nearly 40 feet high. At the time he visited it, the river had been pretty much swelled by rains, and fell in one sheet of water, without any interval, for the space of half an English mile in breadth, with such a noise as stunned and made him giddy for some time. The river, for some space both above and below the fall, was covered with a thick mist, owing to the small particles of the water dashed up into the air by the violence of the shock. The river, though swelled beyond its usual size, retained its clearness, and fell into a natural bason of rock; the stream appearing to run back against the foot of the precipice over which it falls with great violence; forming innumerable eddies, waves, and being in excessive commotion, as may easily be imagined. Jerome Lobo pretends that he was able to reach the foot of the rock, and sit under the prodigious arch of water spouting over it; but Mr Bruce does not hesitate to pronounce this to be an absolute falsehood. The noise of the cataract, which, he says, is like the loudest thunder, could not but confound and destroy his sense of hearing; while the rapid motion of the water before his eyes would dazzle the sight, make him giddy, and utterly deprive him of all his intellectual powers. "It was a most magnificent sight, (says Mr Bruce), that ages, added to the greatest length of human life, would not deface or eradicate from my memory: it struck me with a kind of stupor, and a total oblivion of where I was, and of every other sublunary concern."

About half a mile below the cataract, the Nile is confined between two rocks, where it runs in a narrow channel with impetuous velocity and a great noise. At the village of Alata there is a bridge over it, consisting of one arch, and that no more than 25 feet wide. This bridge is strongly fixed into the solid rock on both sides, and some part of the parapet still remains. No crocodiles ever come to Alata, nor are any ever seen beyond the cataract.

Below this tremendous water-fall the Nile takes a south-east direction, along the western side of Begemder and Amhara on the right, enclosing the province of Gojam. It receives a great number of streams from both sides, and after several turns takes at last a direction almost due north, and approaches within 62 miles of its source. Notwithstanding the vast increase of its waters, however, it is still fordable at some seasons of the year; and the Galla cross it at all times without any difficulty, either by swimming, or on goats skins blown up like bladders. It is likewise crossed on small rafts, placed on two skins filled with wind: or by twisting their hands round the tails of the horses who swim over; a method always used by the women who follow the Abyssinian armies, and are obliged to cross unfordable rivers. In this part of the river crocodiles are met with in great numbers: but the superstitious people pretend they have charms sufficiently powerful to defend themselves against their voracity.—The Nile now seems to have forced its passage through a gap in some very high mountains which bound the country of the Gongas, and falls down a cataract of 280 feet high; and immediately below this are two others, both of very considerable height. These mountains run a great way to the westward, where they are called *Dyre* or *Tegla*, the eastern end of them joining the mountains of Kuara, where they have the name of *Fazuclo*. These mountains, our author informs us, are all inhabited by Pagan nations; but the country is less known than any other on the African continent. There is plenty of gold washed down from the mountains by the torrents in the rainy season; which is the fine gold of Sennaar named *Tibbar*.

The Nile, now running close by Sennaar in a direction nearly north and south, makes afterwards a sharp turn to the east; affording a pleasant view in the fair season, when it is brim-full, and indeed the only ornament of that bare and inhospitable country. Leaving Senaar, it passes by many large towns inhabited by Arabs, all of them of a white complexion; then passing Gerri, and turning to the north-east, it joins the Tacazze, passing, during its course through this country, a large and populous town named *Chendi*, probably the Candace of the ancients. Here Mr Bruce supposes the ancient island or peninsula of Meroe to have been situated. Having at length received the great river Atbara, the Astaboras of the ancients, it turns directly north for about two degrees; then making a very unexpected turn west by south for more than two degrees in longitude, and winding very little, it arrives at Korti, the first town in Barabra, or kingdom of Dongola. From Korti it runs almost south-west till it passes Dongola, called also *Beja*, the capital of Barabra; after which it comes to Moscho, a considerable town and place of refreshment to the caravans when they were allowed to pass from Egypt to Ethiopia. From thence turning to the north-east it meets with a chain of mountains in about 22° 15′ of N. latitude, where is the seventh cataract named *Jan Adel*. This is likewise very tremendous, though not above half as high as that of Alata. This course is now continued till it falls into the Mediterranean; there being only one other cataract in the whole space, which is much inferior to any of those already described.

This very particular and elaborate account of the sources of the Nile and of the course of the river given by Mr Bruce, hath not escaped criticism. We find him accused by the reviewers, not only of having brought nothing to light that was not previously known to the learned, but even of having revealed nothing which was not previously published in Guthrie's Geographical Grammar. This, however, seems by no means a fair and candid criticism. If the sources of the Nile, as described by Mr Bruce, were known to the author of Guthrie's Grammar, they must likewise have been so to every retailer of geography since the time of the missionaries; which, as the reviewers have particularized that book, would not seem to have been the case. If any thing new was published there previous to the appearance of Mr Bruce's work, it must probably have been derived indirectly from himself; of which clandestine method of proceeding that gentleman has had frequent occasion to complain in other cases. It is alleged, however, that he has given the name of *Nile* to a stream which does not deserve it. This, like all other large rivers, is composed of innumerable branches; to visit the top of every one of which would be indeed an Herculean task. The source of the largest branch, therefore, and that which has the longest course, is undoubtedly to be accounted the source of the river; but here it is denied that Mr Bruce had sufficient information. "Of the innumerable streams (say they) that feed the lake of Tzana, there is one that ends in a bog, to which Mr Bruce was conducted by Woldo, a lying guide, who told him it was the source of the Nile. Mr Bruce, in a matter of far less importance, would not have taken Woldo's word; but he is persuaded, that in this case he spoke truth; because the credulous barbarians of the neighbouring district paid something like worship to this brook, which, at the distance of 14 miles from its source, is not 20 feet broad, and nowhere one foot deep. Now it is almost unnecessary to observe, that the natives of that country being, according to Mr Bruce's report, pagans, might be expected to worship the pure and salutary stream, to which, with other extraordinary qualities, their superstition ascribed the power of curing the bite of a mad dog. Had he traced to its source any of the other rivulets which run into the lake Tzana, it is not unlikely that he might have met with similar instances of credulity among the ignorant inhabitants of its banks. Yet this would not prove any one of them in particular to be the head of the Nile. It would be trifling with the patience of our readers to say one word more on the question, whether the Portuguese Jesuits or Mr Bruce discovered what they erroneously call the head of the Nile. Before either they or he had indulged themselves in a vain triumph over the labours of antiquity, they ought to have been sure that they had effected what antiquity was unable to accomplish. Now the river described by the Jesuit Kircher, who collected the information of his brethren, as well as by Mr Bruce, is not the Nile of which the ancients were in quest. This is amply proved by the prince of modern geographers, the incomparable D'Anville (at least till our own Rennel appeared), in a copious memoir published in the 26th volume of the Memoirs of the Academy of Belles Lettres, p. 45.— To this learned dissertation we refer our readers; adding only what seems probable from the writings of Diodorus Siculus and Herodotus, that the ancients had two meanings when they spoke of the head or source of the Nile: First, Literally, the head or source of that great western stream now called the *White River*, which contains a much greater weight of waters, and has a much longer course than the river described by the Jesuits and by Mr Bruce: and, 2dly, Metaphorically, the cause of the Nile's inundation.— This cause they had discovered to be the tropical rains, which fall in the extent of 16 degrees on each side of the line; which made the sacristan of Minerva's temple of Saïs in Egypt tell that inquisitive traveller Herodotus, that the waters of the Nile run in two opposite directions from its source; the one north into Egypt, the other south into Ethiopia; and the reports of all travellers into Africa serve to explain and confirm this observation. The tropical rains, they acknowledge, give rise to the Nile and all its tributary streams which flow northward into the kingdom of Sennaar, as well as to the Zebee, and so many large rivers which flow south into Ethiopia; and then, according to the inclination of the ground, fall into the Indian or Atlantic ocean. Such then, according to the Egyptian priests, is the true and philosophical source of the Nile; a source discovered above 3000 years ago, and not, as Mr Bruce and the Jesuits have supposed, the head of a paltry rivulet, one of the innumerable streams that feed the lake Tzana."

See Rennel's Map of Herodotus, p. 441.

On this severe criticism, however, it is obvious to remark, that if the source of the Nile has been discovered so many years ago, there is not the least probability that the finding of it should have been deemed an impossible undertaking, which it most certainly was, by the ancients.—That the finding out the fountains of the river itself was an object of their inquiry, cannot be doubted; and from the accounts given by Mr Bruce, it appears very evident that none of the ancients had equal success with himself; though indeed the Jesuits, as has already been observed, seem to have a right to dispute it with him. From the correspondence of his accounts with that of the Jesuits, it appears certain that the most considerable stream which flows into the lake Tzana takes its rise from the fountains at Geesh already described; and that it is the most considerable plainly appears from its stream being visible through the whole breadth of the lake, which is not the case with any of the rest. The preference given to this stream by the Agows, who worship it, seems also an incontestable proof that they look upon it to be the great river which passes through Ethiopia and Egypt; nor will the argument of the reviewers hold good in *supposing* that other streams are worshipped, unless they could prove that they are so. As little can it be any objection or disparagement

disparagement to Mr Bruce's labours, that he did not discover the sources of the western branch of the Nile called the *White River*. Had he done so, it might next have been objected that he did not visit the springs of the Tacazze, or any other branch. That the origin of the White river was unknown to the ancients may readily be allowed; but so were the fountains of Geesh, as evidently appears from the erroneous position of the sources of the eastern branch of the Nile laid down by Ptolemy. Our traveller, therefore, certainly has the merit, if not of discovering the sources, at least of confirming the accounts which the Jesuits have given of the sources, of the river called the *Nile;* and of which the White river, whether greater or smaller, seems to be accounted only a branch. The superior veneration paid to the eastern branch of this celebrated river will also appear from the variety of names given to it, as well as from the import of these names; of which Mr Bruce gives the following account.

By the Agows it is named *Gzeir*, *Gcesu*, or *Seir;* the first of which terms signifies *a god*. It is likewise named *Ab*, father; and has many other names, all of them implying the most profound veneration. Having descended into Gojam it is named *Abay;* which, according to Mr Bruce, signifies the river that suddenly swells and overflows periodically with rain. By the Gongas on the south side of the mountains Dyre and Tegla, it is called *Dahli*, and by those on the north side *Kowass;* both of which names signify a *watching dog*, the *latrator anubis*, or *dog-star*. In the plain country between Fazuclo and Sennaar it is called *Nile*, which signifies *blue;* and the Arabs interpret this name by the word *Azergue;* which name it retains till it reaches Halfaia, where it receives the White river.

Formerly the Nile had the name of *Siris*, both before and after it enters Beja, which the Greeks imagined was given to it on account of its black colour during the inundation; but Mr Bruce assures us that the river has no such colour. He affirms, with great probability, that this name in the country of Beja imports the river of the *dog-star*, on whose vertical appearance this river overflows; "and this idolatrous worship (says he) was probably part of the reason of the question the prophet Jeremiah asks: And what hast thou to do in Egypt to drink the water of Seir, or the water profaned by idolatrous rites?" As for the first, it is only the translation of the word *bahar* applied to the Nile. The inhabitants of the Barabra to this day call it *Bahar el Nil*, or the sea of the Nile, in contradistinction to the Red sea, for which they have no other name than *Bahar el Molech*, or the Salt sea. The junction of the three great rivers, the Nile flowing on the west side of Meroe; the Tacazze, which washes the east side, and joins the Nile at Maggiran in N. Lat. 17°; and the Mareb, which falls into this last something above the junction, gives the name of *Triton* to the Nile.

The name *Ægyptus*, which it has in Homer, and which our author supposes to have been a very ancient name even in Ethiopia, is more difficult to account for. This has been almost universally supposed to be derived from the black colour of the inundation; but Mr Bruce, for the reasons already given, will not admit of this. "Egypt (says he) in the Ethiopic is called *y Gipt*, Agar; and an inhabitant of the country, *Gypt*, for precisely so it is pronounced; which means the country of ditches or canals, drawn from the Nile on both sides at right angles with the river: nothing surely is more obvious than to write *y Gipt*, so pronounced, *Egypt;* and, with its termination *us* or *os*, *Egyptus*. The Nile is also called *Kronides*, Jupiter; and has had several other appellations bestowed upon it by the poets; though these are rather of a transitory nature than to be ranked among the ancient names of the river. By some of the ancient fathers it has been named *Geon;* and by a strange train of miracles they would have it to be one of the rivers of the terrestrial paradise; the same which is said to have encompassed the whole land of Cush or Ethiopia. To effect this, they are obliged to bring the river a great number of miles, not only under the earth, but under the sea also; but such reveries need no refutation.

Under the article EGYPT we have so fully explained the cause of the annual inundation of the Nile, that, with regard to the phenomenon itself, nothing farther seems necessary to be added. We shall therefore only extract from Mr Bruce's work what he has said concerning the mode of natural operation by which the tropical rains are produced; which are now universally allowed to be the cause of the annual overflowing of this and other rivers.

According to this gentleman, the air is so much rarefied by the sun during the time that he remains almost stationary over the tropic of Capricorn, that the other winds loaded with vapours rush in upon the land from the Atlantic ocean on the west, the Indian ocean on the east, and the cold Southern ocean beyond the Cape. Thus a great quantity of vapour is gathered, as it were, into a focus; and as the same causes continue to operate during the progress of the sun northward, a vast train of clouds proceed from south to north, which, Mr Bruce informs us, are sometimes extended much farther than at other times. Thus he tells us, that for two years some white dappled clouds were seen at Gondar, on the 7th of January; the sun being then 34° distant from the zenith, and not the least cloudy speck having been seen for several months before. About the first of March, however, it begins to rain at Gondar, but only for a few minutes at a time, in large drops; the sun being then about 5° distant from the zenith. The rainy season commences with violence at every place when the sun comes directly over it; and before it commences at Gondar, green boughs and leaves appear floating in the Bahar el Abiad, or White river, which, according to the accounts given by the Galla, our author supposes to take its rise in about 5° north latitude.

The rains therefore precede the sun only about 5°; but they continue and increase after he has passed it. In April all the rivers in the southern parts of Abyssinia begin to swell, and greatly augment the Nile, which is now also farther augmented by the vast quantity of water poured into the lake Tzana. On the first days of May, the sun passes the village of Gerri, which is the limit of the tropical rains; and it is very remarkable, that, though the sun still continues to operate with unabated vigour, all his influence cannot bring the clouds farther northward than this village;

the

the reason of which Mr Bruce, with great reason, supposes, to be the want of mountains to the northward. In confirmation of this opinion, he observes, that the tropical rains stop at the latitude of 14° instead of 16° in the western part of the continent. All this time, however, they continue violent in Abyssinia; and in the beginning of June the rivers are all full, and continue so while the sun remains stationary in the tropic of Cancer.

This excessive rain, which would sweep off the whole soil of Egypt into the sea were it to continue without intermission, begins to abate as the sun turns southward; and on his arrival at the zenith of each place, on his passage towards that quarter, they cease entirely: the reason of which is no less difficult to be discovered than that of their coming on when he arrives at the zenith in his passage northward. Be the reason what it will, however, the fact is certain; and not only so, but the time of the rains ceasing is exact to a single day; insomuch, that on the 25th of September the Nile is generally found to be at its highest at Cairo, and begins to diminish every day after. Immediately after the sun has passed the line, he begins the rainy season to the southward; the rains constantly coming on with violence as he approaches the zenith of each place; but the inundation is now promoted in a different manner, according to the difference of circumstances in the situation of the places. From about 6° S. Lat. a chain of high mountains runs all the way along the middle of the continent towards the Cape of Good Hope, and intersects the southern part of the peninsula nearly in the same manner that the Nile does the northern. A strong wind from the south, stopping the progress of the condensed vapours, dashes them against the cold summits of this ridge of mountains, and forms many rivers, which escape in the direction either of east or west as the level presents itself. If this is towards the west, they fall down the sides of the mountains into the Atlantic, and if on the east into the Indian ocean.—"The clouds (says Mr Bruce), drawn by the violent action of the sun, are condensed, then broken, and fall as rain on the top of this high ridge, and swell every river; while a wind from the ocean on the east blows like a monsoon, up each of these streams, in a direction contrary to their current during the whole time of the inundation; and this enables boats to ascend into the western parts of Sofala, and the interior country, to the mountains where lies the gold. The same effect, from the same cause, is produced on the western side towards the Atlantic; the high ridge of mountains being placed between the different countries west and east, is at once the source of their riches, and of those rivers which conduct to the treasures, which would be otherwise inaccessible, in the eastern parts of the kingdoms of Benin, Congo, and Angola.

"There are three remarkable appearances attending the inundation of the Nile. Every morning in Abyssinia is clear, and the sun shines. About nine, a small cloud not above four feet broad, appears in the east, whirling violently round as if upon an axis; but arrived near the zenith, it first abates its motion, then loses its form, and extends itself greatly, and seems to call up vapours from all the opposite quarters. These clouds having attained nearly the same height, rush against each other with great violence, and put me always in mind of Elisha foretelling rain on Mount Carmel. The air, impelled before the heaviest mass, or swiftest mover, makes an impression of its form on the collection of clouds opposite; and the moment it has taken possession of the space made to receive it, the most violent thunder possible to be conceived instantly follows, with rain: after some hours the sky again clears, with a wind at north: and it is always disagreeably cold when the thermometer is below 63°.

"The second thing remarkable is the variation of the thermometer. When the sun is in the southern tropic, 36° distant from the zenith of Gondar, it is seldom lower than 72°; but it falls to 60°, and 63°, when the sun is immediately vertical; so happily does the approach of rain compensate the heat of a too scorching sun.

"The third is that remarkable stop in the extent of the rain northward, when the sun that has conducted the vapours from the line, and should seem now more than ever to be in the possession of them, is here overruled suddenly; till, on his return to Gerri, again it resumes the absolute command over the rain, and reconducts it to the line, to furnish distant deluges to the southward."

With regard to the Nile itself, it has been said that the quantity of earth brought down by it from Abyssinia is so great, that the whole land of Egypt is produced from it. This question, however, is discussed under the article EGYPT, where it is shown that this cannot possibly be the case.—Among other authorities there quoted was that of Mr Volney, who strenuously argues against the opinion of Mr Savary and others, who have maintained that Egypt is the gift of the Nile. Notwithstanding this, however, we find them asserting that the soil of Egypt has undoubtedly been augmented by the Nile, in which case it is not unreasonable to suppose that it has been produced by it altogether.—"The reader (says he) will conclude, doubtless, from what I have said, that writers have flattered themselves too much in supposing they could fix the precise limits of the enlargement and rise of the Delta. But, though I would reject all illusory circumstances, I am far from denying the fact to be well founded; it is plain from reason, and an examination of the country. The rise of the ground appears to be demonstrated by an observation on which little stress has been laid. In going from Rosetta and Cairo, when the waters are low, as in the month of March, we may remark, as we go up the river, that the shore rises gradually above the water; so that if overflowed two feet at Rosetta, it overflows from three to four at Faona, and upwards of twelve at Cairo (A). Now by reasoning from this fact, we may deduce the proof of an increase by sediment; for the layer of mud being in proportion to the thickness of the sheets of water by which it is deposited, must be more or less considerable

(A) "It would be curious to ascertain in what proportion it continues up to Asouan. Some Copts, whom I have interrogated on the subject, assured me that it was much higher through all the Said than at Cairo."

considerable as these are of a greater or less depth; and we have seen that the like gradation is observable from Asouan to the sea.

"On the other hand, the increase of the Delta manifests itself in a striking manner, by the form of Egypt along the Mediterranean. When we consider its figure on the map, we perceive that the country which is in the line of the river, and evidently formed of foreign materials, has assumed a semicircular shape, and that the shores of Arabia and Africa, on each side, have a direction towards the bottom of the Delta; which manifestly discovers that this country was formerly a gulf, that in time has been filled up.

"This accumulation is common to all rivers, and is accounted for in the same manner in all: the rain water and the snow descending from the mountains into the valleys, hurry incessantly along with them the earth they wash away in their descent. The heavier parts, such as pebbles and sands, soon stop, unless forced along by a rapid current. But when the waters meet only with a fine and light earth, they carry away large quantities with the greatest facility. The Nile, meeting with such a kind of earth in Abyssinia and the interior parts of Africa, its waters are loaded and its bed filled with it; nay, it is frequently so embarrassed with this sediment as to be straitened in its course. But when the inundation restores to it its natural energy, it drives the mud that has accumulated towards the sea, at the same time that it brings down more for the ensuing season; and this, arrived at its mouth, heaps up, and forms shoals, where the declivity does not allow sufficient action to the current, and where the sea produces an equilibrium of resistance. The stagnation which follows occasions the grosser particles, which till then had floated, to sink; and this takes place more particularly in those places where there is least motion, as towards the shores, till the sides become gradually enriched by the spoils of the upper country and of the Delta itself; for if the Nile takes from Abyssinia to give to the Thebais, it likewise takes from the Thebais to give to the Delta, and from the Delta to carry to the sea. Wherever its waters have a current, it despoils the same territory that it enriches. As we ascend towards Cairo, when the river is low, we may observe the banks worn steep on each side and crumbling in large flakes. The Nile, which undermines them, depriving their light earth of support, it falls into the bed of the river; for when the water is high, the earth imbibes it; and when the sun and drought return, it cracks and moulders away in great flakes, which are hurried along by the Nile."

Thus does Mr Volney argue for the increase of the Delta in the very same manner that others have argued for the production of the whole country of Egypt; an opinion which he is at great pains to refute. Under the article EGYPT, however, it is shown that the Nile does not bring down any quantity of mud sufficient for the purposes assigned; and with regard to the argument drawn from the shallowness of the inundation when near the sea, this does not prove any rise of the land; but as Mr Rennel has judiciously observed in his remarks on the inundation of the Ganges, arises from the nature of the fluid itself. The reason, in short, is this: The surface of the sea is the lowest point to which the waters of every inundation have a tendency; and when they arrive there, they spread themselves over it with more ease than any where else, because they meet with less resistance. Their motion, however, by reason of the small declivity, is less swift than that of the waters farther up the river, where the declivity is greater; and consequently the latter being somewhat impeded in their motion, are in some degree accumulated. The surface of the inundation, therefore, does not form a perfectly level plain, but one gradually sloping from the interior parts of the country towards the sea; so that at the greatest distance from the ocean the water will always be deepest, even if we should suppose the whole country to be perfectly smooth, and composed of the most solid materials.—This theory is easily understood from observing a quantity of water running along a wooden spout, which is always more shallow at the end of the spout where it runs off than at the others.—With regard to Mr Volney's other arguments, they are without doubt contradictory; for if, as he says, the river takes from Abyssinia to give to the Thebais, from Thebais to give to the Delta, and from Delta to the sea, it undoubtedly follows, that it gives nothing to any part of the land whatever, but that altogether is swept into the Mediterranean sea, which, indeed, some very trifling quantities excepted, is most probably the case.

It has been remarked by Mr Pococke, a very judicious traveller, that in the beginning of the inundation, the waters of the Nile run red, and sometimes green; and while they remain of that colour, they are unwholesome. He explains this phenomenon by supposing, that the inundation at first brings away that red or green filth which may be about the lakes where it takes its rise; or about the sources of the small rivers which flow into it, near its principal source; "for, says he, although there is so little water in the Nile when at lowest, that there is hardly any current in many parts of it, yet it cannot be supposed that the water should stagnate in the bed of the Nile so as to become green. Afterwards the water begins to be red and still more turbid, and then it begins to be wholesome." This circumstance is explained by Mr Bruce in the following manner: the country about Narea and Caffa, where the river Abiad takes its rise, is full of immense marshes, where, during the dry season, the water stagnates, and becomes impregnated with every kind of corrupted matter. These on the commencement of the rains, overflow into the river Abiad, which takes its rise there. The overflowing of these vast marshes first carries the discoloured water into Egypt; after which follows that of the great lake Tzana, through which the Nile passes; which having been stagnated, and without rain, under a scorching sun for six months, joins its putrid waters to the former. In Abyssinia also, there are very few rivers that run after November, but all of them stand in prodigious pools, which, by the heat of the sun, likewise turn putrid, and on the commencement of the rains throw off their stagnant water into the Nile; but at last, the rains becoming constant, all this putrid matter is carried off, and the sources of the inundation become sweet and wholesome. The river then passing through the kingdom of Sennaar, the soil of which is this red bole, becomes coloured with that earth; and a mixture, along with the moving sands of the deserts, of which it receives

Nile receives a great quantity when raised by the wind, precipitates all the viscous and putrid matters which float in the waters; whence Mr Pococke judiciously observes, that the Nile is not wholesome when the water is clear and green, but when so red and turbid that it stains the water of the Mediterranean.

The rains in Abyssinia, which cease about the 8th of September, generally leave a sickly season in the low country; but the diseases produced by these rains are removed by others which come on about the end of October, and cease about the 8th of November. On these rains depend the latter crops of the Abyssinians; and for these the Agows pray to the river, or the genius or spirit residing in it. In Egypt, however, the effect of them is seldom perceived; but in some years they prove excessive; and it has been observed that the Nile, after it has fallen, has again risen in such a manner as to alarm the whole country. This is said to have happened in the time of Cleopatra, when it was supposed to presage the extinction of the government of the Ptolemies; and in 1737 it was likewise imagined to portend some dreadful calamity.

The quantity of rain, by which all this inundation is occasioned, varies considerably in different years, at least at Gondar, where Mr Bruce had an opportunity of measuring it. In 1770 it amounted to $35\frac{1}{7}$ inches; but in 1771 it amounted to no less than 41,355 inches from the vernal equinox to the 8th of September. What our author adds concerning the variation of the rainy months seems totally irreconcilable with what he had before advanced concerning the extreme regularity of the natural causes by which the tropical rains are produced. "In 1770 (says he) August was the rainy month; in 1771, July. When July is the rainy month, the rains generally cease for some days in the beginning of August, and then a prodigious deal falls in the latter end of that month and first week of September. In other years July and August are the violent rainy months, while June is fair. And lastly, in others, May, June, July, August, and the first week of September." If this is the case, what becomes of the regular attraction of the clouds by the sun as he advances northwards; of the coming on of the rains when he arrives at the zenith of any place, in his passage to the tropic of Cancer; and of their ceasing when he comes to the same point in his return southward?

Under ABYSSINIA we have mentioned a threat of one of the Abyssinian monarchs, that he would direct the course of the Nile, and prevent it from fertilizing the land of Egypt; and it has likewise been related, that considerable progress was made in this undertaking by another emperor. Mr Bruce has bestowed an entire chapter on the subject; and is of opinion, that "there seems to be no doubt that it is possible to diminish or divert the course of the Nile, that it should be insufficient to fertilize the country of Egypt; because the Nile, and all the rivers that run into it, and all the rains that swell these rivers, fall in a country two miles above the level of the sea; therefore it cannot be denied, that there is level enough to divert many of the rivers into the Red sea, or perhaps still easier by turning the course of the river Abiad till it meets the level of the Niger, or pass through the desert into the Mediterranean." Alphonso Albuquerque is said to have written frequently to the king of Portugal to send him pioneers from Madeira, with people accustomed to level grounds, and prepare them for sugar canes; by whose assistance he meant to turn the Nile into the Red sea. This undertaking, however, if it really had been projected, was never accomplished; nor indeed is there any probability that ever such a mad attempt was proposed. Indeed, though we cannot deny that there is a possibility in nature of accomplishing it, yet the vast difficulty of turning the course of so many large rivers may justly stigmatize it as impracticable; not to mention the obstacles which must naturally be suggested from the apparent inutility of the undertaking, and those which would arise from the opposition of the Egyptians.

It has already been observed, in a quotation from the reviewers, that Herodotus was informed by the sacristan or secretary of the treasury of Minerva, that one half of the waters of the Nile run north and the other south. This is also taken notice of by Mr Bruce; who gives the following explanation of it. "The secretary was probably of that country himself, and seems by his observation to have known more of it than all the ancients together. In fact we have seen, that between 13° and 14° north latitude, the Nile, with all its tributary streams, which have their rise and course within the tropical rains, falls down into the flat country (the kingdom of Sennaar), which is more than a mile lower than the high country in Abyssinia; and thence, with a little inclination, it runs into Egypt. Again, In latitude 9°, in the kingdom of Gingiro, the Zebee runs south or south-east, into the Inner Ethiopia, as do also many other rivers, and, as I have heard from the natives of that country, empty themselves into a lake, as those on the north side of the line do into the lake Tzana, thence distributing their waters to the east and west. These become the heads of great rivers, that run through the interior countries of Ethiopia (corresponding to the sea coast of Melinda and Mombaza) into the Indian ocean; whilst, on the westward, they are the origin of the vast streams that fall into the Atlantic, passing through Benin and Congo, southward of the river Gambia and the Sierra Leona. In short, the periodical rains from the tropic of Capricorn to the line, being in equal quantity with those that fall between the line and the tropic of Cancer, it is plain, that if the land of Ethiopia sloped equally from the line southward and northward, the rains that fall would go the one half north and the other half south; but as the ground from 5° north declines all southward, it follows, that the rivers which run to the southward must be equal to those that run northward, *plus* the rain that falls in the 5° north latitude, where the ground begins to slope to the southward; and there can be little doubt that is at least one of the reasons why there are in the southern continent so many rivers larger than the Nile, that run both into the Indian and Atlantic oceans."

From this account given to Herodotus, it has been supposed, by some writers on geography, that the Nile divides itself into two branches, one of which runs northward into Egypt, and one through the country of the Negroes westward into the Atlantic ocean. This opinion was first broached by Pliny.—It has been adopted by the Nubian geographer, who urges

urges in support of it, that if the Nile carried down all the rains which fall into it from Abyssinia, the people of Egypt would not be safe in their houses. But to this Mr Bruce answers, that the waste of water in the burning deserts through which the Nile passes is so great, that unless it was supplied by another stream, the White River, equal in magnitude to itself, and which, rising in a country of perpetual rains, is thus always kept full, it never could reach Egypt at all, but would be lost in the sands, as is the case with many other very considerable rivers in Africa. "The rains (says he) are collected by the four great rivers in Abyssinia; the Mareb, the Bowiha, the Tacazze, and the Nile. All these principal, and their tributary streams, would, however, be absorbed, nor be able to pass the burning deserts, or find their way into Egypt, were it not for the White River, which having its source in a country of almost perpetual rains, joins to it a never-failing stream equal to the Nile itself."

We shall conclude this article with some account of the Agows who inhabit the country about the sources of the Nile. These, according to Mr Bruce, are one of the most considerable nations in Abyssinia, and can bring into the field about 4000 horse and a great number of foot; but were once much more powerful than they are now, having been greatly reduced by the invasions of the Galla. Their province is nowhere more than 60 miles in length, or than 30 in breadth; notwithstanding which they supply the capital and all the neighbouring country with cattle, honey, butter, wax, hides, and a number of other necessary articles; whence it has been customary for the Abyssinian princes to exact a tribute rather than military service from them. The butter is kept from putrefaction during the long carriage, by mixing it with a small quantity of root somewhat like a carrot, which they call *mormoco*. It is of a yellow colour, and answers the purpose perfectly well; which in that climate it is very doubtful if salt could do. The latter is besides used as money; being circulated instead of silver coin, and used as change for gold. Brides paint their feet, hands, and nails, with this root. A large quantity of the seed of the plant was brought into Europe by Mr Bruce.

The Agows carry on a considerable trade with the Shangalla and other black savages in the neighbourhood; exchanging the produce of their country for gold, ivory, horns of the rhinoceros, and some fine cotton. The barbarity and thievish disposition of both nations, however, render this trade much inferior to what it might be.

In their religion the Agows are gross idolaters, paying divine honours to the Nile, as has already been observed. Mr Bruce, who lodged in the house of the priest of the river, had an opportunity of becoming acquainted with many particulars of their devotion. He heard him address a prayer to the Nile, in which he styled it the "Most High God, the Saviour of the world." In this prayer he petitioned for seasonable rain, plenty of grass, and the preservation of a kind of serpents; deprecating thunder very pathetically. The most sublime and lofty titles are given by them to the spirit which they suppose to reside in the river Nile; calling it everlasting God, Light of the World, Eye of the World, God of Peace, their Saviour, and Father of the Universe.

The Agows are all clothed in hides, which they manufacture in a manner peculiar to themselves. These hides are made in the form of a shirt, reaching down to their feet, and tied about the middle with a kind of sash or girdle. The lower part of it resembles a large double petticoat, one fold of which they turn back over their shoulders, fastening it with a broach or skewer across their breast before, and the married women carry their children in it behind. The younger sort generally go naked. The women are marriageable at nine years of age, though they commonly do not marry till eleven; and they continue to bear children till 30, and sometimes longer. They are generally thin and below the middle size, as well as the men. Barrenness is quite unknown among them.

The country of the Agows has a very elevated situation, and is of course so temperate that the heat may easily be borne, though little more than 10° from the equator. The people, however, are but short lived; which may in part be owing to the oppression they labour under. "Though their country (says Mr Bruce) abound with all the necessaries of life, their taxes, tributes, and services, especially at present, are so multiplied upon them, whilst their distresses of late have been so great and frequent, that they are only the manufacturers of the commodities they sell, to satisfy these constant exorbitant demands, and cannot enjoy any part of their own produce themselves, but live in penury and misery scarcely to be conceived. We saw a number of women wrinkled and sun-burnt so as scarcely to appear human, wandering about under a burning sun, with one and sometimes two children upon their backs; gathering the seeds of bent grass to make a kind of bread." As to the opinions respecting the identity of the Nile and the Niger, see AFRICA, SUPPLEMENT, p. 106.

NILOMETER, or NILOSCOPE, an instrument used among the ancients to measure the height of the water of the river Nile in its overflowings. The word comes from Νειλος, Nile (and that from *νεα ιλυς*, "new mud," or as some others would have it, from *νεω*, "I flow," and *ιλυς*, "mud,") and *μετρον*, "measure." The Greeks more ordinarily call it, Νειλοσκοπειον.

The nilometer is said, by several Arabian writers, to have been first set up, for this purpose, by Joseph during his regency in Egypt: the measure of it was 16 cubits, this being the height of the increase of the Nile, which was necessary to the fruitfulness of Egypt.

From the measure of this column, Dr Cumberland * deduces an argument, in order to prove that the Jewish and Egyptian cubits were of the same length.

In the French king's library is an Arabic treatise on nilometers, entitled *Neil fi alnal al Nil;* wherein are described all the overflowings of the Nile, from the first year of the Hegira to the 875th.

Herodotus mentions a column erected in a point of the island Delta, to serve as a nilometer; and there is still one of the same kind in a mosque of the same place.

As all the riches of Egypt arise from the inundations of the Nile, the inhabitants used to supplicate them at the hands of their Serapis; and committed the most execrable crimes, as actions, forsooth, of religion, to obtain the favour. This occasioned Constantine expressly

* *Scripture Weights and Measures*, p. 18.

Nilometer ‖ Nimeguen.

to prohibit these sacrifices, &c. and to order the nilometer to be removed into the church; whereas, till that time, it had been in the temple of Serapis. Julian the Apostate had it replaced in the temple, where it continued till the time of Theodosius the Great.

† Bruce's Travels, vol. iii.

The following is Mr Bruce's account of the nilometer. "On the point † of the island Rhode, between Geeza and Cairo, near the middle of the river, is a round tower enclosing a neat well or cistern lined with marble. The bottom of this well is on the same level with the bottom of the Nile, which has free access to it through a large opening like an embrasure. In the middle of the well rises a thin column of eight faces of blue and white marble; of which the foot is on the same plane with the bottom of the river. This pillar is divided into 20 peeks, of 22 inches each. Of these peeks the two lowermost are left, without any division, to stand for the quantity of sludge which the water deposits there. Two peeks are then divided, on the right hand, into 24 digits each; then on the left, four peeks are divided into 24 digits; then on the right, four: and on the left another four: again, four on the right, which completes the number of 18 peeks from the first division marked on the pillar, each peek being 22 inches. Thus the whole marked and unmarked amounts to something more than 36 feet English."

On the night of St John, when, by the falling of the dew, they perceive the rain water from Ethiopia mixed with the Nile at Cairo, they begin to announce the elevation of the river, having then five peeks of water marked on the nilometer, and two unmarked for the sludge, of which they take no notice. Their first proclamation, supposing the Nile to have risen 12 digits, is 12 from 6, or it wants 12 digits to be 6 peeks. When it has risen three more, it is nine from six; and so on, till the whole 18 be filled, when all the land of Egypt is fit for cultivation. Several canals are then opened, which convey the water into the desert, and hinder any further stagnation on the fields. There is indeed a great deal of more water to come from Ethiopia; but were the inundation suffered to go on, it would not drain soon enough to fit the land for tillage: and to guard against this mischief is the principal use of the nilometer, though the Turkish government makes it an engine of taxation. From time immemorial the Egyptians paid, as tribute to the king, a certain proportion of the fruit of the ground; and this was anciently ascertained by the elevation of the water on the nilometer, and by the mensuration of the land actually overflowed. But the Saracen government, and afterwards the Turkish, has taxed the people by the elevation alone of the water, without attending to its course over the country, or the extent of the land actually overflowed; and this tax is sometimes cruelly oppressive.

NIMBUS, in antiquity, a circle observed on certain medals, or round the heads of some emperors; answering to the circles of light drawn round the images of saints.

NIMEGUEN, a large, handsome, and strong town of the Netherlands, and capital of Dutch Guelderland, with a citadel, an ancient palace, and several forts. It is noted for a congress of most of the powers of Europe, who concluded a peace here in 1678. It has a magnificent townhouse, and the inhabitants are greatly given to trade. It is seated on the Vahal or Wahal, between the Rhine and the Maese. It contains two Dutch churches, a French Calvinist and a Lutheran church, five Popish, and several hospitals. It was once a Hans town and an imperial city. It was once the seat of government, has a canal to Arnheim, and considerable trade to some parts of Germany: it trades also in fine beer brewing, fattening of cattle, and exporting of its butter, which is extremely good, into all the other provinces. It was taken by the French in 1794. It is in E. Long. 5. 45. N. Lat. 51. 55.

Nimeguen ‖ Nimrod.

NIMETULAHITES, a kind of Turkish monks, so called from their founder Nimetulahi, famous for his doctrines and the austerity of his life.

NIMPO, a city and seaport town of China, in the province of Chekiang. It is seated on the eastern sea of China, over against Japan. It is a city of the first rank, and stands at the confluence of two small rivers, which, after their union, form a channel that reaches to the sea, and is deep enough to bear vessels of 200 tons burden. The walls of Nimpo are 5000 paces in circumference, and are built with freestone. There are five gates, besides two water gates for the passage of barks into the city; a tower several stories high, built of bricks; and a long bridge of boats, fastened together with iron chains, over a very broad canal. The city is commanded by a citadel built on a very high rock, by the foot of which all vessels must necessarily pass. The Chinese merchants of Siam and Batavia go to this place yearly to buy silks, which are the finest in the empire. They have also a great trade with Japan, it being but two days sail from hence: thither they carry silks, stuffs, sugar, drugs, and wine; and bring back copper, gold, and silver. E. Long. 122. 0. N. Lat. 30. 0.

NIMROD, the sixth son of Cush, and in all appearance much younger than any of his brothers: for Moses mentions the sons of Raamah, his fourth brother, before he speaks of him. What the sacred historian says of him is short; and yet he says more of him than of any other of the posterity of Noah, till he comes to Abraham. He tells us, that "Nimrod began to be a mighty one in the earth;" that he was "a mighty hunter before the Lord," even to a proverb; and that "the beginning of his kingdom was Babel, and Erech, and Accad, and Calneh, in the land of Shinar."

From this account he is supposed to have been a man of extraordinary strength and valour. Some represent him as a giant; all consider him as a great warrior. It is generally thought that by the words *a mighty hunter*, is to be understood, that he was a great tyrant; but some of the rabbins interpret those words favourably, saying that Nimrod was qualified by a peculiar dexterity and strength for the chase, and that he offered to God the game which he took; and several of the moderns are of opinion, that this passage is not to be understood of his tyrannical oppressions, or of hunting of men, but of beasts. It must be owned that the phrase *before the Lord* may be taken in a favourable sense, and as a commendation of a person's good qualities; but in this place the generality of expositors understand it otherwise.

Hunting must have been one of the most useful employments in the times just after the dispersion, when all countries were overrun with wild beasts, of which it was necessary they should be cleared, in order to make them habitable; and therefore nothing seemed more proper to procure a man esteem and honour in those

ages

Nimrod.

ages than his being an expert hunter. By that exercise, we are told, the ancient Persians fitted their kings for war and government; and hunting is still, in many countries, considered as one part of a royal education.

There is nothing in the short history of Nimrod which carries the least air of reproach, except his name, which signifies a *rebel;* and that is the circumstance which seems to have occasioned the injurious opinions which have been entertained of him in all ages. Commentators, being prepossessed in general that the curse of Noah fell upon the posterity of Ham, and finding this prince stigmatized by his name, have interpreted every passage relating to him to his disadvantage. They represent him as a rebel against God, in persuading the descendants of Noah to disobey the divine command to disperse, and in setting them to build the tower of Babel, with an impious design of scaling heaven. They brand him as an ambitious usurper, and an insolent oppressor; and make him the author of the adoration of fire, of idolatrous worship given to men, and the first persecutor on the score of religion. On the other hand, some account him a virtuous prince, who, far from advising the building of Babel, left the country, and went into Assyria, because he would not give his consent to that project.

Nimrod is generally thought to have been the first king after the flood; though some authors, supposing a plantation or dispersion prior to that of Babel, have made kings in several countries before his time. Mizraim is thought, by many who contend for the antiquity of the Egyptian monarchy, to have begun his reign much earlier than Nimrod; and others, from the uniformity of the languages spoken in Assyria, Babylonia, Syria, and Canaan, affirm those countries to have been peopled before the confusion of tongues.

The four cities Moses gives to Nimrod constituted a large kingdom in those early times, when few kings had more than one; only it must be observed, that possessions might at first have been large, and afterwards divided into several parcels; and Nimrod being the leader of a nation, we may suppose his subjects settled within those limits: whether he became possessed of those cities by conquest or otherwise, does not appear; it is most probable he did not build Babel, all the posterity of Noah seeming to have been equally concerned in that affair; nor does it appear that he built the other three, though the founding of them, and many more, with other works, are attributed to him by some authors. It may seem also a little strange, that Nimrod should be preferred to the regal dignity, and enjoy the most cultivated part of the earth then known, rather than any other of the elder chiefs or heads of nations, even of the branch of Ham. Perhaps it was conferred on him for his dexterity in hunting; or, it may be, he did not assume the title of king till after his father Cush's death, who might have been settled there before him, and left him the sovereignty; but we incline to think, that he seized Shinar from the descendants of Shem, driving out Ashur, who from thence went and founded Nineveh, and other cities in Assyria.

The Scripture does not inform us when Nimrod began his reign: Some date it before the dispersion; but such a conjecture does not seem to suit with the Mosaical history; for before the dispersion we read of no city but Babel; nor could there well be more, while all mankind were yet in a body together; but when Nimrod assumed the regal title, there seem to have been other cities; a circumstance which shows it was a good while after the dispersion. The learned writers of the Universal History place the beginning of his reign 30 years from that event, and in all likelihood it should be placed rather later than earlier.

Nimrod
||
Nineveh.

Authors have taken a great deal of pains to find Nimrod in profane history: some have imagined him to be the same with Belus, the founder of the Babylonish empire; others take him to be Ninus, the first Assyrian monarch. Some believe him to have been Evechous, the first Chaldean king after the deluge; and others perceive a great resemblance between him and Bacchus, both in actions and name. Some of the Mohammedan writers suppose Nimrod to have been Zohak, a Persian king of the first dynasty: others contend for his being Cay Caus, the second king of the second race; and some of the Jews say he is the same with Amraphel the king of Shinar, mentioned by Moses. But there is no certainty in these conjectures, nor have we any knowledge of his immediate successors.

The Scripture mentions nothing as to the death of Nimrod; but authors have taken care that such an essential circumstance in his history should not be wanting. Some of the rabbins pretend he was slain by Esau, whom they make his contemporary. There is a tradition that he was killed by the fall of the tower of Babel, which was overthrown by tempestuous winds. Others say, that as he led an army against Abraham, God sent a squadron of gnats, which destroyed most of them, and particularly Nimrod, whose brain was pierced by one of those insects.

NINE, the last of the radical numbers or characters; from the combination of which any definite number, however large, may be produced. "It is observed by arithmeticians (says Hume), that the products of 9 compose always either 9 or some lesser products of 9, if you add together all the characters of which any of the former products is composed: thus of 18, 27, 36, which are products of 9, you make 9, by adding 1 to 8, 2 to 7, 3 to 6. Thus 369 is a product also of 9; and if you add 3, 6, and 9, you make 18, a lesser product of 9." See *Hume's Dialogues on Nat. Relig.* p. 167, 168, &c. 2d. edit.

NINEVEH, in *Ancient Geography*, the capital city of Assyria, founded by Ashur the son of Shem (Gen. x. 11.); or, as others read the text, by Nimrod the son of Cush.

However this be, yet it must be owned, that Nineveh was one of the most ancient, the most famous, the most potent, and largest cities of the world. It is very difficult exactly to assign the time of its foundation; but it cannot be long after the building of Babel. It was situated upon the banks of the Tigris; and in the time of the prophet Jonas, who was sent thither under Jeroboam II. king of Israel, and, as Calmet thinks, under the reign of Pul, father of Sardanapalus, king of Assyria, Nineveh was a very great city, its circuit being three days journey (Jonah iii. 3.). Diodorus Siculus, who has given us the dimensions of it, says it was 480 stadia in circumference, or 47 miles; and that it was surrounded with lofty walls and towers; the former being 200 feet in height, and so very broad that three chariots might drive on them abreast; and the latter 200 feet in height, and 1500 in number; and Strabo allows it to have been

much

much greater than Babylon. Diodorus Siculus was, however, certainly mistaken, or rather his transcribers, as the authors of the Universal History think, in placing Nineveh on the Euphrates, since all historians as well as geographers who speak of that city, tell us in express terms that it stood on the Tigris. At the time of Jonah's mission thither, it was so populous, that it was reckoned to contain more than six score thousand persons, who could not distinguish their right hand from their left (Jonah iv. 11.), which is generally explained of young children that had not yet attained to the use of reason; so that upon this principle it is computed that the inhabitants of Nineveh were then above 600,000 persons.

Nineveh was taken by Arbaces and Belesis, in the year of the world 3257, under the reign of Sardanapalus, in the time of Ahaz king of Judah, and about the time of the foundation of Rome. It was taken a second time by Astyages and Nabopolassar from Chynaladanus king of Assyria in the year 3378. After this time, Nineveh no more recovered its former splendour. It was so entirely ruined in the time of Lucianus Samosatensis, who lived under the emperor Adrian, that no footsteps of it could be found, nor so much as the place where it stood. However, it was rebuilt under the Persians, and destroyed again by the Saracens about the seventh age.

Modern travellers say (A), that the ruins of ancient Nineveh may still be seen on the eastern banks of the Tigris, opposite to the city of Mosul or Mousul: (See MOUSUL). Profane historians tell us, that Ninus first founded Nineveh; but the Scripture assures us, that it was Ashur or Nimrod.

The sacred authors make frequent mention of this city; and Nahum and Zephaniah foretold its ruin in a very particular and pathetic manner.

NINIA, or NINIAN, commonly called *St Ninian*, a holy man among the ancient Britons. He resided at or near a place called by Ptolemy *Leucopibia*, and by Bede *Candida Casa:* but the English and Scotch called it *Whithorne*. We mention him, because he is said to have been the first who converted the Scots and Picts to the Christian faith; which he did during the reign of Theodosius the Younger. Bede informs us, that he built a church dedicated to St Martin, in a style unknown to the Britons of that time; and adds, that during his time the Saxons held this province (*Gallovidia*, now *Galloway*), and that, as in consequence of the labours of this saint the converts to Christianity increased, an episcopal see was established there. Dr Henry, considering that "few or none of the writings of the most ancient fathers of the British church are now extant, and since little being said of them by their cotemporaries, we can know little of their personal history and of the extent of their erudition," gives a short account of some of them. Of St Ninian he says, "he was a Briton of noble birth and excellent genius. After he had received as good an education at home as his own country could afford, he travelled for his further improvement, and spent several years at Rome, which was then the chief seat of learning as well as of empire. From thence he returned into Britain, and spent his life in preaching the gospel in the most uncultivated parts of it, with equal zeal and success."

There is a small town called *St Ninian*, about a mile south of Stirling. Its church had been occupied by the rebels in 1745 as a powder magazine; who on their return blew it up in such haste, as to destroy some of their own people and about fifteen spectators.

NING-PO-FOU, called by the Europeans *Liampo*, is an excellent port, on the eastern coast of China, opposite to Japan. Eighteen or twenty leagues from this place is an island called *Tcheou-chan*, where the English first landed on their arrival at China.

The silks manufactured at Ning-po are much esteemed in foreign countries, especially in Japan, where the Chinese exchange them for copper, gold, and silver. This city has four others under its jurisdiction, besides a great number of fortresses.

NINON L'ENCLOS, a celebrated lady in the court of France, was of a noble family, and born at Paris in the year 1615; but rendered herself famous by her wit and gallantries. Her mother was a lady of exemplary piety; but her father early inspired her with the love of pleasure. Having lost her parents at 14 years of age, and finding herself mistress of her own actions, she resolved never to marry: she had an income of 10,000 livres a-year; and, according to the lessons she had received from her father, drew up a plan of life and gallantry, which she pursued till her death. Never delicate with respect to the number, but always in the choice, of her pleasures, she sacrificed nothing to interest; but loved only while her taste for it continued; and had among her admirers the greatest lords of the court. But notwithstanding the levity of her conduct, she had many virtues.—She was constant in her friendship, faithful to what are called the *laws of honour*, of strict veracity, disinterested, and more particularly remarkable for perfect probity. Women of the most respectable characters were proud of the honour of having her for their friend; at her house was an assemblage

(A) This assertion, however, is far from seeming probable; for every trace of it seems to have so totally disappeared, even so early as A. D. 627, that the vacant space afforded a spacious field for the celebrated battle between the emperor Heraclius and the Persians. There are few things in ancient history which have more puzzled the learned world, than to determine the spot where this city stood. Mr Ives informs us, that some have imagined it stood near Jonah's tomb; others, however, place it at another place, some hours journey up the Tigris. These different opinions, however, seem perfectly reconcileable; for it appears at least probable, that ancient Nineveh took in the whole of the ground which lies between these two ruined places. Mr Ives adds, that "what confirms this conjecture is, that much of this ground is now hilly, owing no doubt to the rubbish of the ancient buildings. There is one mount of 200 or 300 yards square, which stands some yards north-east of Jonah's tomb, whereon it is likely a fortification once stood. It seems to have been made by nature, or perhaps both by nature and art, for such an use."

semblage of every thing most agreeable in the city and the court; and mothers were extremely desirous of sending their sons to that school of politeness and good taste, that they might learn sentiments of honour and probity, and those other virtues, that render men amiable in society. But the illustrious Madame de Sevigné with great justice remarks in her letters, that this school was dangerous to religion and the Christian virtues; because Ninon L'Enclos made use of seducing maxims, capable of depriving the mind of those invaluable treasures. Ninon was esteemed beautiful even in old age; and is said to have inspired violent passions at 80. She died at Paris in 1705. This lady had several children; one of whom, named *Chevalier de Villiers*, excited much attention by the tragical manner in which he ended his life. He became in love with Ninon, without knowing that she was his mother; and when he discovered the secret of his birth, stabbed himself in a fit of despair. There have been published the pretended letters of Ninon L'Enclos to the Marquis de Sevigné.

NINTH, in *Music*. See INTERVAL.

NINUS, the first king of the Assyrians, was, it is said, the son of Belus. It is added, that he enlarged Nineveh and Babylon; conquered Zoroaster king of the Bactrians; married Semiramis of Ascalon; subdued almost all Asia; and died after a glorious reign of 52 years, about 1150 B. C.; but all these facts are uncertain. See SEMIRAMIS.

NIO, an island of the Archipelago, between Naxi to the north, Armago to the east, Santerino to the south, and Sikino to the west, and is about 35 miles in circumference. It is remarkable for nothing but Homer's tomb, which they pretend is in this island; for they affirm that he died here in his passage from Samos to Athens. The island is well cultivated, and not so steep as the other islands, and the wheat which it produces is excellent; but oil and wood are scarce. It is subject to the Turks. E. Long. 25. 35. N. Lat. 36. 43.

NIOBE, in fabulous history, according to the fictions of the poets, was the daughter of Tantalus, and wife of Amphion king of Thebes; by whom she had seven sons and as many daughters. Having become so proud of her fertility and high birth, as to prefer herself before Latona, and to slight the sacrifices offered up by the Theban matrons to that goddess, Apollo and Diana, the children of Latona, resented this contempt. The former slew the male children and the latter the female; upon which Niobe was struck dumb with grief, and remained without sensation. Cicero is of opinion, that on this account the poets feigned her to be turned into stone.

The story of Niobe is beautifully related in the sixth book of the Metamorphoses of Ovid. That poet thus describes her transformation into stone.

Widow'd and childless, lamentable state!
A doleful sight, among the dead she sat;
Harden'd with woes, a statue of despair,
To ev'ry breath of wind unmov'd her hair;
Her cheek still redd'ning, but its colour dead,
Fadded her eyes, and set within her head.
No more her pliant tongue its motion keeps,
But stands congeal'd within her frozen lips.
Stagnate and dull, within her purple veins,
Its current stopp'd, the lifeless blood remains.
Her feet the usual offices refuse,
Her arms and neck their graceful gestures lose:
Action and life from ev'ry part are gone,
And ev'n her entrails turn to solid stone.
Yet still she weeps; and whirl'd by stormy winds,
Borne thro' the air, her native country finds;
There fixed, she stands upon a bleaky hill;
There yet her marble cheeks eternal tears distil.

Niobe in this statue is represented as in an ecstacy of grief for the loss of her offspring, and about to be converted into stone herself. She appears as if deprived of all sensation by the excess of her sorrow, and incapable either of shedding tears or of uttering any lamentations, as has been remarked by Cicero in the third book of his Tusculan Questions. With her right hand she clasps one of her little daughters, who throws herself into her bosom; which attitude equally shows the ardent affection of the mother, and expresses that natural confidence which children have in the protection of a parent. The whole is executed in such a wonderful manner, that this with the other statues of her children, is reckoned by Pliny among the most beautiful works of antiquity: but he doubts to whom of the Grecian artists he ought to ascribe the honour of them (A). We have no certain information at what period this celebrated work was transported from Greece to Rome, nor do we know where it was first erected. Flaminius Vacca only says, that all these statues were found in his time not far from the gate of St John, and that they were afterwards placed by the grand duke Ferdinand in the gardens of the Villa de Medici near Rome.—An ingenious and entertaining traveller (Dr Moore), speaking of the statue of Niobe, says, "The author of Niobe has had the judgment not to exhibit all the distress which he might have placed in her countenance. This consumate artist was afraid of disturbing her features too much, knowing full well that the point where he was to expect most sympathy was there, where distress co-operated with beauty, and where *our pity met our love*. Had he sought it one step farther in *expression*, he had lost it."

In the following epigram this statue is ascribed to Praxiteles:

Εκ ζωης με Θεοι τευξαν λιθον. Εκ δε λιθοιο
Ζωην Πραξιτελης εμπαλιν ειργασατο.

While for my children's fate I vainly mourn'd,
The angry gods to massy stone me turn'd;
Praxiteles a nobler feat has done,
He made me live again from being stone.

The author of this epigram, which is to be found in the 4th book of the *Anthology*, is unknown. Scaliger the father, in his *Farrago Epigrammatum*, p. 172. ascribes it to Callimachus, but this appears to be only conjecture. Cœlius

(A) Par hæsitatio in templo Apollinis Sosiani, Nioben cum liberis morientem, Scopas an Praxiteles fecerit.

Cælius Calcagninus has made a happy translation of it into Latin.

Vivam olim in lapidem verterunt numina; sed me
Praxiteles vivam reddidit ex lapide.

And perhaps the following French version of it will appear no less happy:

De vive que j'étois, les Dieux
M'ont changée en pierre massive:
Praxitele a fait beaucoup mieux,
De pierre il m'a scû rendre vive.

NIPHON, the largest of the Japan islands, being 800 miles long and 100 broad. See JAPAN.

NIPPERS, in the manege, are four teeth in the fore part of a horse's mouth, two in the upper, and two in the lower jaw. A horse puts them forth between the second and third year.

NIPPLES, in *Anatomy*. See MAMMÆ, ANATOMY *Index*.

NIPPLE-WORT. See LAPSANA, BOTANY *Index*.

NISAN, a month of the Hebrews, answering to our March, and which sometimes takes from February or April, according to the course of the moon. It was the first month of the sacred year, at the coming out of Egypt (Exod. xii. 2), and it was the seventh month of the civil year. By Moses it is called Abib. The name Nisan is only since the time of Ezra, and the return from the captivity of Babylon.

On the first day of this month the Jews fasted for the death of the children of Aaron (Lev. x. 1, 2, 3.). On the tenth day was celebrated a fast for the death of Miriam the sister of Moses; and every one provided himself with a lamb for the passover. On this day the Israelites passed over Jordan under the conduct of Joshua (iv. 19.). On the fourteenth day in the evening they sacrificed the pascal lamb; and the day following, being the fifteenth, was held the solemn passover (Exod. xii. 18. &c.). The sixteenth they offered the sheaf of the ears of barley as the first fruits of the harvest of that year (Levit. xxiii. 9. &c.). The twenty-first was the octave of the passover, which was solemnized with particular ceremonies. The twenty-sixth the Jews fasted in memory of the death of Joshua. On this day they began their prayers to obtain the rains of the spring. On the twenty-ninth they called to mind the fall of the walls of Jericho.

NISI PRIUS, in *Law*, a judicial writ which lies in cases where the jury being impannelled and returned before the justices of the bank, one of the parties requests to have such a writ for the ease of the country, in order that the trial may come before the justices in the same county on their coming thither. The purport of a writ of *nisi prius* is, that the sheriff is thereby commanded to bring to Westminster the men impannelled, at a certain day, before the justices, "*nisi prius justiciarii domini regis ad assisas capiendas venerint.*"

NISIBIS, in *Ancient Geography*, a city both very ancient, very noble, and of very considerable strength, situated in a district called *Mygdonia*, in the north of Mesopotamia, towards the Tigris, from which it is distant two days journey. Some ascribe its origin to Nimrod, and suppose it to be the *Achad* of Moses. The Macedonians call it *Antiochia of Mygdonia* (Plutarch); situated at the foot of Mount Masius (Strabo). It was the Roman bulwark against the Parthians and Persians. It sustained three memorable sieges against the power of Sapor, A. D. 338, 346, and 350; but the emperor Jovianus, by an ignominious peace, delivered it up to the Persians, A. D. 363.——A colony called *Septimia Nisibitana.*——Another *Nisibis*, of Aria, (Ptolemy) near the lake Arias.

Mr Ives, who passed through this place in 1758, tells us, that "it looked pretty at a distance, being seated on a considerable eminence, at the foot of which runs a river, formerly called the *Mygdonius*, with a stone bridge of eleven arches built over it. Just by the river, at the foot of the hill, or hills (for the town is seated on two), begin the ruins of a once more flourishing place, which reach quite up to the present town. From every part of this place the most delightful prospects would appear, were the soil but properly cultivated and planted; but instead of those extensive woods of fruit trees, which Rawolf speaks of as growing near the town, not above thirty or forty straggling trees of any kind can be perceived; and instead of that great extent of arable land on which he dwells so much, a very inconsiderable number of acres are now remaining. The town itself is despicable, and streets extremely narrow, and the houses, even those which are of stone, are mean. It suffered grievously by the famine of 1757, losing almost all its inhabitants either by death or desertion. The streets presented many miserable objects, who greedily devoured rinds of cucumbers, and every other refuse article of food thrown out into the highway. Here the price of bread had risen near 4000 per cent. within the last 14 years.

NISMES, an ancient, large, and flourishing town of France, in the department of Garde, with a bishop's see, and an academy. The manufactures of cloth both of gold and silk, and of stuffs formerly known by the name of serge of Nismes, exceed that of all the rest of the province. There are several monuments of antiquity, of which the amphitheatre is the principal built by the Romans. The *maison quarrée*, or the square house, is a piece of architecture of the Corinthian order, and one of the finest in the world. The temple of Diana is in part gone to ruin. It was taken by the English in 1417. The inhabitants were chiefly Calvinists; but Louis XIV. demolished their church in 1685, and built a castle to keep them in awe. It is seated in a delightful plain, abounding in wine, oil, game and cattle. It contains a great number of venerable relicks of Roman antiquity and grandeur, which it is not our business to describe, though it is chiefly remarkable for these and its delightful situation. Its population in 1800 was 39,300, of whom about 10,000 are Protestants. After the second return of Louis XVIII. in 1815, Nismes was the scene of some disgraceful outrages. The Protestants had been friendly to the Revolution, though they took no part in its atrocities; but the Catholics made this a pretext for treating them as rebels. In the city alone nearly 300 of the Protestants were murdered, and in the neighbouring districts as many more as made a total of 2000: a great number were obliged to fly; 2000 ransomed their lives by sums of money, and 150 houses were pillaged or burnt within the town. Money was collected for the relief of the sufferers in London, Edinburgh, and other towns in Britain. E. Long. 4. 26. N. Lat. 43. 51.

NISROCH, a god of the Assyrians. Sennacherib was killed by two of his sons while he was paying his adoration to his god Nisroch in his temple (2 King xix. 37.). It is not known who this god Nisroch was. The Septuagint calls him Mesrach, Josephus calls him Araskes. The Hebrew of Tobit published by Munster calls him Dagon. The Jews have a strange notion concerning this deity, and fancy him to have been a plank of Noah's ark. Some think the word signifies a dove; and others understand by it an eagle, which has given occasion to an opinion, that Jupiter Belus, from whom the Assyrian kings pretended to be derived, was worshipped by them under the form of an eagle, and called Nisroch. Our poet Milton gives this name to one of the rebel angels.

——In the assembly next up stood
Nisroch, of principalities the prince.
Par. Lost, book vi. 447.

NISSOLIA, a genus of plants belonging to the diadelphia class, and in the natural method ranking under the 32d order, *Papilionaceæ*. See BOTANY *Index*.

NITHSDALE, NITHISDALE, or *Niddisdale*, a district of Dumfriesshire in Scotland, lying to the westward of Annandale. It is a large and mountainous tract, deriving its name from the river Nid, or Nith, which rises on the borders of Ayrshire, and running by Sanquhar and Dumfries, discharges itself into the Solway frith. This country was formerly shaded with noble forests, which are now almost destroyed; so that at present, nothing can be more naked, wild, and savage. Yet the bowels of the earth yield lead, and, as is said, silver and gold: the mountains are covered with sheep and black cattle; and here are still some considerable remains of the ancient woods, particularly that of Holywood, three miles from Dumfries, noted for a handsome church, built out of the ruins of an ancient abbey; and also for being the birthplace of the famous astrologer, hence called *Joannes de Sacro Bosco*. Mr Pennant calls it a beautiful vale, improved in appearance by the bold curvatures of the meandering stream, and for some space, he says, it is adorned with groves and gentlemen's seats.

NITOCRIS, the mother of Belshazzar (whose father was Evil Merodach and his grandfather Nebuchadnezzar), was a woman of extraordinary abilities; she took the burden of all public affairs upon herself; and, while her son followed his pleasures, did all that could be done by human prudence to sustain the tottering empire. She perfected the works which Nebuchadnezzar had begun for the defence of Babylon; raised strong fortifications on the side of the river, and caused a wonderful vault to be made under it, leading from the old palace to the new, 12 feet high and 15 wide. She likewise built a bridge across the Euphrates, and accomplished several other works, which were afterwards ascribed to Nebuchadnezzar. Philostrates, in describing this bridge, tells us, that it was built by a queen, who was a native of Media; whence we may conclude this illustrious queen to have been by birth a Mede. Nitocris is said to have placed her tomb over one of the most remarkable gates of the city, with an inscription to the following effect:

If any king of Babylon after me shall be in distress for money, he may open this sepulchre, and take out as much as may serve him; but if he be in no real necessity, let him forbear, or he shall have cause to repent of his presumption.

This monument and inscription are said to have remained untouched till the reign of Darius, who, considering the gate was useless, no man caring to pass under a dead body, and being invited by the hopes of an immense treasure, broke it open; but, instead of what he sought, is said to have found nothing but a corpse; and another inscription, to the following effect:

Hadst thou not been most insatiably avaricious and greedy of the most sordid gain, thou wouldst never have violated the abode of the dead.

NITHRARIA, a genus of plants belonging to the dodecandria class, and in the natural method ranking with those of which the order is doubtful. See BOTANY *Index*.

NITRE, SALTPETRE, or *Nitrate of Potash*. See CHEMISTRY, N° 938, *et seq*.

Calcareous NITRE. See LIME, *Nitrate of*, CHEMISTRY *Index*.

NITROUS, any thing impregnated with nitrous air.

Nitrous Air. See AZOTE, CHEMISTRY *Index*.

NIVELLE, a town in the Netherlands, in the province of Brabant, remarkable for its abbey of canonesses. Here is a manufacture of cambrics, and the town enjoys great privileges. The abbey just mentioned is inhabited by young ladies of the first quality, who are not confined therein as in nunneries, but may go out and marry whenever they see convenient, or a proper match offers. It contained 6537 inhabitants in 1800. E. Long. 4. 36. N. Lat. 50. 35.

NIVELLE *de la Chaussée* (Peter Claude), a comic poet, born in Paris; acquired great reputation by inventing a new kind of entertainment, which was called the *Weeping Comedy*. Instead of imitating Aristophanes, Terence, Moliere, and the other celebrated comic poets who had preceded him; and instead of exciting laughter by painting the different ridiculous characters, giving strokes of humour and absurdities in conduct; he applied himself to represent the weaknesses of the heart, and to touch and soften it. In this manner he wrote five comedies: 1. *La fausse Antipathie*. 2. *Le prejugé à la Mode*; this piece met with great success. 3. *Melanide*. 4. *Amour pour Amour*; and, 5. *L'Ecole des Meres*. He was received into the French academy in 1736; and died at Paris in 1754, at 63 years of age. He also wrote a tragedy, entitled, *Maximianus*; and an epistle to Clio, an ingenious didactic poem.

NIVERNOIS, an inland province of France, with the title of a *duchy*, lying on the west side of Burgundy, and between it, Bourbonnois, and Barri. It is pretty fertile in wine, fruit, and corn; except the part called *Morvant*, which is a mountainous country, and barren. There is a great deal of wood, and several iron mines; as also mines of pit coal, which serves to work their forges. This province is watered by a great number of rivers; of which the Allier, the Loire, and the Yonne, are navigable. It now forms the department of Nevers, which is also the name of the capital city.

Niwegal ‖ Noah.

NIWEGAL, a village lying on the coast in Pembrokeshire, South Wales, remarkably only for the discovery of an immense quantity of the stumps of trees appearing below low water mark, after and during a storm in the year 1590, notwithstanding the country all round is now entirely barren of wood.

NIXAPA, a rich and considerable town in New Spain, with a rich convent of Dominicans. The country about it abounds in cochineal, indigo, and sugar. E. Long. 97. 15. N. Lat. 16. 42.

NIZAM (says Gibbon, one of the most illustrious ministers of the east, was honoured by the caliph as an oracle of religion and science; he was trusted by the sultan as the faithful vicegerent of his power and justice. After an administration of 30 years, the fame of the vizier, his wealth, and even his services, were transformed into crimes. He was overthrown by the insidious arts of a woman and a rival; and his fall was hastened by a rash declaration, that his cap and ink horn, the badges of his office, were connected by the divine decree with the throne and diadem of the sultan. At the age of 93 years, the venerable statesman was dismissed by his master, accused by his enemies, and murdered by a fanatic: the last words of Nizam attested his innocence, and the remainder of Malek's life was short and inglorious.

NO, (Jeremiah, Ezekiel), NO-AMMON, (Nahum); a considerable city of Egypt, thought to be the name of an idol which agrees with Jupiter Ammon. The Septuagint translate the name in Ezekiel, *Diospolis*, "the city of Jupiter." Bochart takes it to be *Thebes* of Egypt; which, according to Strabo and Ptolemy, was called *Diospolis*. Jerome, after the Chaldee paraphrast Jonathan, supposes it to be Alexandria, named by way of anticipation; or an ancient city of that name is supposed to have stood on the spot where Alexandria was built.

No-Man's-Land, a space between the after part of the belfrey and the fore part of a ship's boat, when the said boat is stowed upon the booms, as in a deep waisted vessel. These booms are laid from the forecastle nearly to the quarter-deck, where their after ends are usually sustained by a frame called the *gallows*, which consists of two strong posts, about six feet high, with a cross piece reaching from one to the other, athwart ships, and serving to support the ends of those booms, masts, and yards, which lie in reserve to supply the place of others carried away, &c. The space called *No-Man's-Land* is used to contain any blocks, ropes, tackles, &c. which may be necessary on the forecastle. It probably derives this name from its situation, as being neither on the starboard nor larboard side of the ship, nor on the waste or forecastle; but, being situated in the middle, partakes equally of all those places.

NOAH, or NOE, the son of Lamech, was born in the year of the world 1056. Amidst the general corruption into which all mankind were fallen at this time, Noah alone was found to be just and perfect in his generation, walking with God (Gen. vi. 9.). This extraordinary person having therefore found favour in the eyes of the Lord, and God seeing that all flesh had corrupted their ways, told Noah, that he was resolved to destroy mankind from the face of the earth by a flood of waters; and not them alone, but all the beasts of the earth, and every creeping thing, as well as the fowls of the air (*Id. ib.* 7.). The Lord therefore directed Noah, as a means of preserving him and his family (for he had three sons, Shem, Ham, and Japheth, who were all married before the flood), to build an ark or vessel of a certain form and size fitted to that end, and which might besides accommodate such numbers of animals of all sorts, that were liable to perish in the flood, as would be sufficient to preserve the several species, and again replenish the earth; together with all necessary provisions for them; all which Noah performed, as may be seen more particularly under the article ARK.

Noah.

In the year of the world 1656, and the 600th year of his age, Noah, by God's appointment, entered the ark, together with his wife, his three sons, their wives, and all the animals which God caused to come to Noah; and being all entered, and the door of the ark being shut upon the outside, the waters of the deluge began to fall upon the earth, and increased in such a manner, that they were fifteen cubits above the tops of the highest mountains, and continued thus upon the earth for 150 days; so that whatever had life upon the earth, or in the air, was destroyed, except such as were with Noah in the ark. But the Lord remembering Noah, sent a wind upon the earth, which caused the waters to subside; so that upon the seventeenth day of the seventh month the ark rested on the mountains of Ararat; and Noah having uncovered the roof of the ark, and observing the earth was dry, he received orders from the Lord to come out of it, with all the animals that were therein; and this he did in the six hundred and first year of his age, on the 27th day of the second month. But the history of the deluge is more circumstantially related already under the article DELUGE.

Then he offered as a burnt sacrifice to the Lord one of all the pure animals that were in the ark; and the Lord accepted his sacrifice, and said to him that he would no more pour out his curse upon the whole earth, nor any more destroy all the animals as he had now done. He gave Noah power over all the brute creation, and permitted him to eat of them, as of the herbs and fruits of the earth: except only the blood, the use of which God did not allow them. He bid him increase and multiply, made a covenant with him, and God engaged himself to send no more an universal deluge upon the earth; and as a memorial of his promise, he set his bow in the clouds, to be as a pledge of the covenant he made with Noah (Gen. ix.).

Noah, being an husbandman, began now to cultivate the vine; and having made wine and drank thereof, he unwarily made himself drunk, and fell asleep in his tent, and happened to uncover himself in an indecent posture. Ham, the father of Canaan, having observed him in this condition, made himself sport with him, and acquainted his two brothers with it, who were without. But they, instead of making it a matter of sport, turned away from it, and going backwards they covered their father's nakedness, by throwing a mantle over him. Noah awaking, and knowing what Ham had done, said, that Canaan the son of Ham should be accursed, that he should be a slave of slaves in respect of his brethren. It is thought he had a mind to spare the person of his son Ham, for fear the curse might light

upon

Noah.

upon the other children of Ham, who had no part in this action. He cursed Canaan by a spirit of prophecy, because the Canaanites his descendants were after this to be rooted out by the Israelites. Noah added, Let the Lord, the God of Shem, be blessed, and let Canaan be the servant of Shem. And he was so in effect, in the person of the Canaanites subdued by the Hebrews. Lastly, Noah said, Let God extend the possession of Japheth; let Japheth dwell in the tents of Shem, and let Canaan be his servant. This prophecy had its accomplishment, when the Grecians, and afterwards the Romans, being descended from Japheth, made a conquest of Asia, which was the portion of Shem.

But Noah lived yet after the deluge three hundred and fifty years; and the whole time of his life having been nine hundred and fifty years, he died in the year of the world 2006. He left three sons, Shem, Ham, and Japheth, of whom mention is made under their several names; and, according to the common opinion, he divided the whole world amongst them, in order to repeople it. To Shem he gave Asia, to Ham Africa, and Europe to Japheth. Some will have it, that besides these three sons he had several others. The spurious Berosus gives him thirty, called Titans, from the name of their mother Titæa. They pretend that the Teutons or Germans are derived from a son of Noah called Thuiscon. The false Methodius also makes mention of Jonithus or Jonicus, a pretended son of Noah.

St Peter calls Noah a preacher of righteousness (2 Peter ii. 5.), because before the deluge he was incessantly preaching and declaring to men, not only by his discourses, but by his unblameable life, and by the building of the ark, in which he was employed six score years, that the wrath of God was ready to pour upon them. But his preaching had no effect, since when the deluge came, it found mankind plunged in their former enormities (Matt. xxiv. 37.).

Several learned men have observed, that the Heathens confounded Saturn, Deucalion, Ogyges, the god Cœlus or Uranus, Janus, Proteus, Prometheus, &c. with Noah. The wife of Noah is called Noriah by the Gnostics; and the fable of Deucalion and his wife Pyrrha is manifestly invented from the history of Noah.

The Rabbins pretend, that God gave Noah and his sons (all who are not of the chosen race of Abraham they call Noachidæ) certain general precepts, which contain, according to them, the natural right which is common to all men indifferently, and the observation of which alone will be sufficient to save them. After the law of Moses, the Hebrews would not suffer any stranger to dwell in their country, unless he would conform to the precepts of the Noachidæ. In war they put to death, without quarter, all that were ignorant of them. These precepts are seven in number.

The *first* directs, that obedience be paid to judges, magistrates, and princes.

By the *second*, the worship of false gods, superstition, and sacrilege, are absolutely forbidden.

The *third* forbids cursing the name of God, blasphemies, and false oaths.

The *fourth* forbids all incestuous and unlawful conjunctions, as sodomy, bestiality, and crimes against nature.

Noah ‖ Nobility.

The *fifth* forbids the effusion of blood of all sorts of animals, murder, wounds, and mutilations.

The *sixth* forbids thefts, cheats, lying, &c.

The *seventh* forbids to eat the parts of an animal still alive, as was practised by some Pagans.

To these the Rabbins have added some others; but what inclines us to doubt the antiquity of these precepts is, that no mention is made of them in Scripture, or in the writings of Josephus or Philo; and that none of the ancient fathers knew any thing of them.

NOB, a sacerdotal city of the tribe of Benjamin or Ephraim. St Jerome says, that in his time it was entirely destroyed, and that the ruins of it might be seen not far from Diospolis. When David was driven away by Saul, he went to Nob, and asking the high priest Ahimelech for some provisions and arms, the priest gave him the shew bread which had been lately taken off the holy table, and the sword of Goliath. Saul being informed of this by Doeg, caused all the priests of Nob to be slain, and the city to be destroyed, 1 Sam. xxi. xxii.

NOBAH, a city beyond Jordan. It took the name of Nobah from an Israelite of this name who had made a conquest of it, (Numb. xxxii. 42.). Gideon pursued the Midianites as far as this city, (Judg. viii. 2.) Eusebius says, that there is a desolate place of this name about eight miles from Heshbon towards the south. But this could not be the Nobah now mentioned, because it was much farther to the north.

NOBILIARY, in literary history, a book containing the history of the noble families of a nation or province: such are Choriere's Nobiliary of Dauphiné, and Caumartin's Nobiliary of Provence. The Germans are said to be particularly careful of their Nobiliaries, in order to keep up the dignity of their families.

NOBILITY, in general, signifies dignity, grandeur, or greatness; more particularly, it signifies antiquity of family, joined with riches: in the common acceptation of the word, it means that quality or dignity which raises a man above the rank of a peasant or a commoner.

At a time when the public mind is so much agitated on this subject, or subjects nearly allied to it, perhaps the less that is said on it the better. We should therefore (as far as concerns the question about its expediency in civil life, or the contrary) most cheerfully pass it over in silence, did we not esteem it our duty to give our readers at least some idea of it, and were it not our business to lay before them a few of those arguments which of late have been so copiously retailed both for and against this illustrious order of civil society: leaving them, however, that liberty which every man unquestionably ought to be allowed, of judging for themselves as they shall see most proper.

Whether that equality of rank and condition which has of late been so loudly contended for would be more agreeable to the order of nature, or more conducive to the happiness and prosperity of mankind, may indeed be made a question; but it is a question, we apprehend, which cannot receive different answers from men capable of reflecting without prejudice and partiality. A state of perfect equality can subsist only among

among beings possessing equal talents and equal virtues; but such beings are not men. Were all mankind under the constant influence of the laws of virtue, a distinction of ranks would be unnecessary; but in that case civil government itself would likewise be unnecessary, because men would have attained all that perfection to which it is the object of civil government as well as of religion to guide them: every man then would be a law unto himself. But whilst, in so many breasts, the selfish passions predominate over those which are social, violence must be restrained by authority; and there can be no authority without a distinction of ranks, such as may influence the public opinion.

It is well observed by Hume, that government is founded only on opinion; and that this opinion is of two kinds, opinion of interest, and opinion of right. When a people are persuaded that it is their interest to support the government under which they live, that government must be very stable. But among the worthless and unthinking part of the community, this persuasion has seldom place. All men, however, have a notion of rights—of a right to property and a right to power: and when the majority of a nation considers a certain order of men as having a right to that eminence in which they are placed, this opinion, call it prejudice or what we will, contributes much to the peace and happiness of civil society. There are many, however, who think otherwise, and imagine that "the society in which the greatest equality prevails must always be the most secure. These men conceive it to be the business of a good government to distribute as equally as possible those blessings which bounteous nature offers to all." It may readily be allowed that this reasoning is conclusive; but the great question returns, "How *far* can equality prevail in a society which is secure? and what is *possible* to be done in the equal distribution of the blessings of nature?" Till these questions be answered, we gain nothing by declaiming on the rights and equality of men; and the answers which have sometimes been given to them suppose a degree of perfection in human nature, which, if it were real, would make all civil institutions useless, as well as the reveries of those reformers. The conduct of the democratic states of Pagan antiquity, together with the oppressive anarchy and shameful violences which we have seen and still see in a neighbouring kingdom, will be considered by many as a full and satisfactory answer, deduced from experience, to all the schemes of the visionary theorist: such facts at least render the abolition of the order of nobility a matter of more importance, and of infinitely greater difficulty, than those who plead for it are disposed to allow.

It is an opinion not uncommon, and at least plausible, that the nobility of a well regulated state is the best security against monarchical despotism or lawless usurpation on the one hand, and the confusion of democratic insolence on the other. Self interest is the most powerful principle in the human breast; and it is obviously the interest of such men to preserve that balance of power in society upon which the very existence of their order depends. Corrupted as the present age confessedly is, a very recent instance could be given, in which the British House of Peers rescued at once the sovereign and the people from the threatened tyranny of a factious junto. As it is our business, however, to exhibit all opinions of any celebrity, we shall lay before our readers a short extract from Dulaure's Critical History of the French Nobility, which contains, in few but forcible words, some of the common arguments against this distinction of ranks.

"Nobility (says he), a distinction equally impolitic and immoral, and worthy of the times of ignorance and of rapine, which gave it birth, is a violation of the rights of that part of the nation that is deprived of it; and as equality becomes a *stimulus* towards distinction, so on the other hand this is the radical vice of a government and the source of a variety of evils. It is almost impossible that there should be any uncommon instances of virtue in a state, when recompenses belong exclusively to a certain class of society, and when it costs them no more to obtain these than the *trouble of being born*. Amongst this list of privileged persons, virtues, talents, and genius, must of course be much less frequent than in the other classes, since, without the possession of any of these qualities, they who belong to it are still honoured and rewarded. Those who profit by this absurd subversion of principles, and those who lose by this unjust distribution of favours, which seem to have grown into a right, cannot have any other than false, immoral, and pernicious ideas concerning *merit*."

A perfect equality, however, in rank and fortune has seldom been contended for, except by the most ignorant enthusiasts. It is indeed doubtful whether it could possibly exist. The more moderate and rational reformers have acknowledged, that as these differences have always existed in some way or other, so, from the infinite variety of talents and attainments in the world, we have reason to expect they will exist in every form of government and among every people. The question, therefore, is reduced to this: Whether the present mode of distinction, or any other which could be instituted in its stead, be upon the whole the best? That the present is not perfect, or wholly without faults, few will be sanguine enough to contradict: and a wise man in the sober hour of philosophical reflection will scarce presume to assert, that any other scheme which human ingenuity can plan would be wholly without imperfection, or altogether free from error. The case is, the errors of our own system are present, and on this account we see and feel them with peculiar force: the other plan we look forward to perhaps in too sanguine a manner, and we probably forget, in the delusive heat of imagination, that if distinction depended entirely on merit, we should scarce find a society of men so honest, or so able, as always to reward it according to its deserts; or if this were possible, as perhaps in the nature of things it is not, such is the self-partiality of the generality of men, that few would think he were dealt justly by if he were not promoted as well as his neighbour; and it is clearly impossible to promote every one. For such reasons then, and many more which our limits oblige us to omit, many think (and we are inclined to think with them), that it is safer to remain as we are, as we know the evils that attend our situation, and are still able to bear them, rather than to hazard a change, which, Nobility.

which, with some benefits, might also perhaps increase the troubles, and destroy many of the pleasures of social life.

Perhaps it may not be amiss to lay before our readers the following observations from that most judicious commentator on the laws of England, Mr Justice Blackstone, on this important subject.

Blackst. Comment.

"The distinction of rank and honours (says he) is necessary in every well-governed state, in order to reward such as are eminent for their services to the public, in a manner the most desirable to individuals, and yet without burden to the community; exciting thereby an ambitious, yet laudable ardour, and generous emulation, in others. And emulation, or virtuous ambition, is a spring of action which, however dangerous or invidious in a mere republic or under a despotic sway, will certainly be attended with good effects under a free monarchy; where, without destroying its existence, its excesses may be continually restrained by that superior power from which all honour is derived. Such a spirit, when nationally diffused, gives life and vigour to the community; it sets all the wheels of government in motion, which, under a wise regulator, may be directed to any beneficial purpose; and thereby every individual may be made subservient to the public good, while he principally means to promote his own particular views. A body of nobility is also more peculiarly necessary in our mixed and compounded constitution, in order to support the rights of both the crown and the people, by forming a barrier to withstand the encroachments of both. It creates and preserves that gradual scale of dignity, which proceeds from the peasant to the prince; rising like a pyramid from a broad foundation, and diminishing to a point as it rises. It is this ascending and contracting proportion that adds stability to any government; for when the departure is sudden from one extreme to another, we may pronounce that state to be precarious. The nobility, therefore, are the pillars, which are reared from among the people, more immediately to support the throne; and, if that falls, they must also be buried under its ruins. Accordingly, when in the 17th century the commons had determined to extirpate monarchy, they also voted the house of lords to be useless and dangerous. And since titles of nobility are thus expedient in the state, it is also expedient that their owners should form an independent and separate branch of the legislature. If they were confounded with the mass of the people, and like them had only a vote in electing representatives, their privileges would soon be borne down and overwhelmed by the popular torrent, which would effectually level all distinctions. It is therefore highly necessary that the body of nobles should have a distinct assembly, distinct deliberations, and distinct powers from the commons."—These remarks, at a time like the present, deserve our serious attention; nor do we suppose our readers will be displeased, if we add the following observations on the subject from a periodical publication of long standing and very considerable merit.

Gent. Mag. vol. xii.

"Birth and nobility are a stronger obligation to virtue than is laid upon meaner persons. A vicious or dishonourable nobleman is in effect perjured; for his honour is his oath.

"Under the patriarchal scheme, and at the first setting out of the tribes, the heads of families had their particular escutcheons, and their genealogies recorded with the utmost exactness: Even the Ancient of Days confirmed this,; he often put his people in mind of the glory and virtues of their forefathers; and hath set a precedent for attainders, by visiting the third and fourth generation.

Nobility.

"It is a vulgar error to suppose, that his blessed Son chose his followers out of the meanest of the people, because mechanics; for this was part of the education of every Jewish nobleman: Two of the number, being his kinsmen, were of the royal house of David; one was a Roman gentleman, and another of the royal family of Syria; and for the rest, he had the same right of creation as his Father and his vicegerents, of advancing the poor to honour, and of exalting the lowly and meek.

"The ancient Greeks and Romans paid great regard to nobility; but when the levelling principle obtained, and the people shared power and honour, those states soon dwindled and came to ruin. And in present Rome, great respect is paid to the renowned families of Colonna and Cæsarini. In Venice, the notion of nobility is carried so high as to become inconsistent with a republican scheme. The Spaniards pay more regard to their old nobles than to their old Christians; and the French are but little behind them. What was said of the duke of Montmorency by Henry IV. "That he was a better gentleman than himself," was, perhaps, the reason why the last heir of so illustrious a family was cut off, to make the house of Bourbon the first in France.—The Welsh, Irish, and Polanders, are remarkable for their attachment to blood and pedigree.

"It is for the sake of the meanest of our people, that the high value and regard for quality should be kept up; for they are best governed by those who seem formed for power: the robe of authority sits easy upon them, and submission is as much our choice as our duty; but upstarts prove the worst of tyrants.

"The ancient legislators, who studied human nature, thought it adviseable, for the better government of states, that the people should be divided into the noble and the common. They judged it for the universal good of mankind, that the valiant and the wise should be separated from the rest, and appointed for council and command.

"To this I take it that the institution of nobility is owing in all countries; even those nations which we are pleased to call *savage*, distinguish the wise and the valiant, obey them as counsellors and commanders, which is placing them in the rank of nobles.

"Some, I know, look upon the institution of nobility to be one of the grossest impositions upon the common sense of mankind; they confine it indeed to hereditary nobility; they allow, that those who have done the commonwealth any signal service should be distinguished with honours, but it seems an absurdity to them that a man should be born a legislator, as if wisdom or a knowledge of government ran in the blood. But if they would consider how strong the love of posterity is planted in human nature, they must allow that nothing can be a stronger motive to great and worthy actions, than the notion that a man's posterity will reap the honour and profit of his labours.

 Besides

Nobility.

Besides, we are to suppose that men born to honours and a high fortune may be bred up in generous sentiments, and formed for the station they are to fill; that they must be strangers to those vicious falsehoods and corruptions which necessity first, and then habit, puts men upon practising, whose lives are spent in pursuit of their fortunes. I will own, notwithstanding all these advantages, that many of them are like rocks whose heads are in the clouds, but are so barren that they are quite incapable of producing any thing; but in general, were their minds only upon a level with those of other men, we should expect better fruit from them.

"As authority is founded in opinion, all wise commonwealths have been extremely jealous in keeping up the honour of their nobility. Wherever they become base, effeminate, cowardly, or servile, their authority sinks, they fall into contempt; then the people begin to consider them as useless to government, and look upon their privileges as a grievance to society, and perhaps they think how to get rid of them, as happened in the commonwealth of Florence, where, after the expulsion of the duke of Athens, a petty tyrant of that city, many of the nobility having behaved servilely to him, and insolently to the people, were degraded from the senate and the magistracy, and rendered incapable of holding any employment in the commonwealth.

"Father Paul, the Venetian, says, that you must either keep your nobility free from taint, or have no nobility at all: That the high employments of the commonwealth should be bestowed amongst the most ancient families, unless where a person should distinguish himself by some signal service to the state. Such a man would think himself sufficiently rewarded by the honour of being out upon a footing with the ancient nobility; and the nobility would be pleased to find that no commoner, except some of great reputation and merit, was to hold any of the employments usually possessed by their body. If the person so preferred should not be rich enough to support the dignity of the office, the state may give him a pension, but by no means should employments be made lucrative; which not only exhaust and weaken the commonwealth, but wherever the high employments are sought for profit, the nobility lose their generous sentiments, and it is a means of introducing corruption amongst them."

The origin of nobility in Europe is by some referred to the Goths; who, after they had seized a part of Europe, rewarded their captains with titles of honour, to distinguish them from the common people. We shall only in this place further consider the manner in which in our own country they may be created, and the incidents attending them; referring for a fuller account of their origin in Europe to the articles REVOLUTION, and *Civil* SOCIETY.

1. The right of peerage seems to have been originally territorial; that is, annexed to lands, honours, castles, manors, and the like; the proprietors and possessors of which were (in right of those estates) allowed to be peers of the realm, and were summoned to parliament to do suit and service to their sovereign: and, when the land was alienated, the dignity passed with it as appendant. Thus in England the bishops still sit in the house of lords in right of succession to certain ancient baronies annexed, or supposed to be annexed, to their episcopal lands; and thus in 11. Henry VI. the possession of the castle of Arundel was adjudged to confer an earldom on its possessor. But afterwards, when ALIENATIONS grew to be frequent, the dignity of peerage was confined to the lineage of the party ennobled, and instead of territorial became personal. Actual proof of a tenure by barony became no longer necessary to constitute a lord of parliament; but the record of the writ of summons to him or his ancestors was admitted as a sufficient evidence of the tenure.

Blackst. Comment.

Peers of Great Britain are now created either by writ or by patent; for those who claim by prescription must suppose either a writ or patent made to their ancestors; though by length of time it is lost. The creation by writ or the king's letter is a summons to attend the house of peers, by the style and title of that barony which the king is pleased to confer: that by patent is a royal grant to a subject of any dignity and degree of peerage. The creation by writ is the more ancient way; but a man is not ennobled thereby, unless he actually take his seat in the house of lords; and some are of opinion that there must be at least two writs of summons, and a sitting in two distinct parliaments, to evidence a hereditary barony; and therefore the most usual, because the surest way, is to grant the dignity by patent, which endures to a man and his heirs according to the limitation thereof, though he never himself makes use of it. Yet it is frequent to call up the eldest son of a peer to the house of lords by writ of summons, in the name of his father's barony, because in that case there is no danger of his children's losing the nobility in case he never takes his seat; for they will succeed to their grandfather. Creation by writ has also one advantage over that by patent; for a person created by writ holds the dignity to him and his heirs, without any words to that purport in the writ; but in letters patent there must be words to direct the inheritance, else the dignity endures only to the grantee for life. For a man or woman may be created noble for their own lives, and the dignity not descend to their heirs at all, or descend only to some particular heirs: as where a peerage is limited to a man and the heirs male of his body by Elizabeth his present lady, and not to such heirs by any former or future wife.

2. Let us next take a view of a few of the principal incidents attending the nobility,—exclusive of their capacity as members of parliament, and as hereditary counsellors of the crown; for both which we refer to the articles LORDS and PARLIAMENT. And first we must observe, that in criminal cases a nobleman shall be tried by his peers. The great are always obnoxious to popular envy: were they to be judged by the people, they might be in danger from the prejudices of their judges; and would moreover be deprived of the privilege of the meanest subjects, that of being tried by their equals, which is secured to all the realm by magna charta, c. 29. It is said, that this does not extend to bishops, who, though they are lords of parliament, and sit there by virtue of their baronies which they hold *jure ecclesiæ*, yet are not ennobled in blood, and consequently not peers with the nobility. As to peeresses, no provision was made for their

Nobility. their trial when accused of treason or felony, till after Eleanor duchess of Gloucester, wife to the lord protector, had been accused of treason, and found guilty of witchcraft, in an ecclesiastical synod, through the intrigues of Cardinal Beaufort. This very extraordinary trial gave occasion to a special statute, 20 Hen. II. c. 9. which enacts, that peeresses, either in their own right or by marriage, shall be tried before the same judicators as peers of the realm. If a woman, noble in her own right, marries a commoner, she still remains noble, and shall be tried by her peers; but if she be only noble by marriage, then by a second marriage with a commoner she loses her dignity; for as by marriage it is gained, by marriage it is also lost. Yet if a duchess dowager marries a baron, she continues a duchess still: for all the nobility are *pares*, and therefore it is no degradation. A peer or peeress (either in her own right or by marriage) cannot be arrested in civil cases: and they have also many peculiar privileges annexed to their peerage in the course of judicial proceedings. A peer sitting in judgment, gives not his verdict upon oath, like an ordinary juryman, but upon his honour; he answers also to bills in chancery upon his honour, and not upon his oath: but when he is examined as a witness either in civil or criminal cases, he must be sworn; for the respect which the law shows to the honour of a peer does not extend so far as to overturn a settled maxim, that *in judicio non creditur nisi juratus*. The honour of peers is however so highly tendered by the law, that it is much more penal to spread false reports of them, and certain other great officers of the realm, than of other men: scandal against them being called by the peculiar name of *scandalum magnatum*, and subjected to peculiar punishment by divers ancient statutes.

A peer cannot lose his nobility but by death or attainder; though there was an instance, in the reign of Edward IV. of the degradation of George Neville duke of Bedford by act of parliament, on account of his poverty, which rendered him unable to support his dignity. But this is a singular instance, which serves at the same time, by having happened, to show the power of parliament; and, by having happened but once, to show how tender the parliament hath been in exerting so high a power. It hath been said indeed, that if a baron wastes his estate, so that he is not able to support the degree, the king may degrade him: but it is expressly held by later authorities, that a peer cannot be degraded but by act of parliament.

Anton. Matthæus observes, that nobility, among the Romans, was a quite different thing from what it is among us. The nobles, among the Romans, were either those raised to the magistrature, or descended from magistrates: there was no such thing as nobility by patent.

Bartoli says, that doctors, after they have held a professor's chair in an university for 20 years, become noble; and are entitled to all the rights of counts.

But this claim is not admitted at court, &c. though Bartoli's sentiments be backed with those of several other authors, particularly Chassanæus in his *Consuetudin. Burgundiæ; Boyer sur la Coutume de Berry; Faber C. de Dig. Def.* 9. &c. which last, however, restrains Bartoli's rule to doctors in law, and princes physicians.

By an edict of the French king in 1669, it is declared, that trade shall not derogate from nobility, provided the person do not sell by retail.

Nobility, Noble. In Bretagne, by ancient custom, a nobleman loses nothing by trading even in retail; but he reassumes all his rights as soon as he ceases traffic, his nobility having slept all the time.

In Germany, a woman, not noble by birth, doth not become, *v. gr.* a countess or baroness by marrying a count or baron: a lady of the higher degree indeed becomes a princess by marrying a prince; but this does not hold of a lady of the lower nobility.

On the coast of Malabar, children are only capable of being noble by the mother's side; it being allowed them to take as many husbands as they please, and to quit them whenever they think proper.

NOBLE, *Nobilis*, a person who has a privilege which raises him above a commoner or peasant, either by birth, by office, or by patent from his prince. The word comes from the Latin *nobilis;* formed from the ancient *noscibilis*, "distinguishable, remarkable."

In England, the word *noble* is of a narrower import than in other countries, being confined to persons above the degree of knights; whereas, abroad, it comprehends not only knights, but what we simply call *gentlemen*. The nobles of England are also called *pares regni*, as being *nobilitatis pares*, though *gradu impares*.

The Venetian *noblesse* is famous: it is in this that the sovereignty of the state resides. It is divided into three classes. The first only comprehends 24 families. The second includes the descendants of all those who were entered into the Golden Book, in 1289, and destined to govern the state, which then began to be aristocratic. The third consists of such as have bought the dignity of noble Venetians. This last class is only admitted to the inferior employs; the two former to all indifferently. The title of *noble Venetians* is sometimes also given to foreign kings, princes, &c.

NOBLES, among the Romans, were such as had the *jus imaginum*, or the right of using the pictures or statues of their ancestors; a right which was allowed only to those whose ancestors had borne some *curule* office, that is, had been *curule ædile, censor, prætor* or *consul*. For a long time, none but the *patricii* were the *nobiles*, because no person but of that superior rank could bear any *curule* office; hence in Livy, Sallust, &c. *nobilitas* is used to signify the patrician order, and so opposed to *plebs*. To make the true meaning of *nobiles* still more clear, let it be observed, that the Roman people were divided into *nobiles*, *novi*, and *ignobiles*. *Nobiles* were they who had the pictures, &c. of their ancestors; *novi* were such as had only their own; *ignobiles* were such as had neither. See *Jus Imaginis*.

The Roman nobility, by way of distinction, wore a half-moon upon their shoes, especially those of patrician rank.

The Grecian nobility were called Ευπατριδαι, as being descended from those old heroic ancestors so famous in history. Such were the *Praxiergidæ, Etrobutidæ, Alcmæonidæ*, &c. all which had many privileges annexed to their quality; amongst which was this, that they wore grashoppers in their hair as a badge of nobility.

NOBLE, a money of account containing six shillings and eight pence.

The noble was anciently a real coin struck in the reign of Edward III. and then called the *penny of gold;* but

Noble || Noctambuli.

but it was afterwards called a *rose-noble*, from its being stamped with a rose: it was current at 6s. 8d.

NOCERA, a town in Italy, in the dominions of the king of Naples and Sicily, or, as he is more commonly called, the king of the Two Sicilies. It is an episcopal city, but might with greater propriety be styled a cluster of villages; its several parts being extended along the foot of the mountains, from the Cittá Sotana, or low town; and the bishop's palace, together with some convents embowered in cypress groves, cover the peak of a single hill in a very picturesque manner, and compose the Cittá Soprana.

Nocera (A), it is reported, contains near 30,000 inhabitants; they are dispersed in forty patches of habitation. Their houses are constructed of two kinds of stone: the common walls are built with yellow tufa dug out of the hills that lie about a mile to the east of the town; which stone seems unquestionably to have been formed by a consolidation of substances thrown out of Vesuvius, because, on opening these quarries, the workmen have frequently discovered tombs, vases, and coins locked up in the body of the stony stratum. The cases of their doors and windows are made of a black stone drawn from the hill of Fiano, two miles to the north: it lies eight feet below the surface, in a bed or vein 140 feet thick, resting upon a base of sand. This seems evidently to be a stream of lava congealed.

Nocera is a place of very considerable antiquity: in the 13th century it was called de Pagani, to distinguish it from a city in Umbria of a similar name; this addition was in allusion to a colony of Saracens which Frederick of Suabia brought from Sicily, and settled here, that they might be out of the way of their dangerous connexions with Africa: hence Nocera has often been confounded with Lucera by the negligent or ignorant chroniclers of the succeeding ages. The most remarkable event that occurs in its history is the siege of its castle, A. D. 1384. E. Long. 12. 49. N. Lat. 43. 1.

Terra Noceriana, Earth of Nocera, in the *Materia Medica*, a species of bole, remarkably heavy, of a grayish-white colour, of an insipid taste, and generally with some particles in it which grit between the teeth. It is much esteemed by the Italians as a remedy for venomous bites, and in fevers; but, excepting as an absorbent and astringent, no dependence is to be had on it.

NOCTAMBULI, NOCTAMBULONES, or *Night-walkers*; a term of equal import with *somnambuli*, applied to persons who have a habit of rising and walking about in their sleep. The word is a compound of the Latin *nox*, "night," and *ambulo*, "I walk."

Schenkius, Horstius, Glauderus, and Hildanus, who have written of sleep, give us divers unhappy histories of such noctambuli. When the disease is moderate, the persons affected with it only repeat the actions of the day on getting out of bed, and go quietly to the places they frequented at other times; but those who have it in the most violent degree, go up to dangerous places, and do things which would terrify them to think of when they are awake. These are by some called *lunatic* night-walkers, because fits are observed to return with the most frequency and violence at the changes of the moon.—For the cure some recommend purging and a cooling regimen: others are of opinion that the best method is to place a vessel of water at the patient's bedside, in such a manner that he will naturally step into it when he gets out of bed; or if that should fail, a person should sit up to watch and beat him every time it happens. See SLEEP-WALKERS, or SOMNAMBULI.

Noctambuli || Nocturnal.

NOCTILUCA, a species of phosphorus, so called because it shines in the dark without any light being thrown upon it.

NOCTURNAL, something relating to the night, in contradistinction to diurnal.

NOCTURNAL, *Nocturlabium*, an instrument chiefly used at sea, to take the altitude or depression of some stars about the pole, in order to find the latitude and hour of the night.

Some nocturnals are hemispheres, or planispheres, on the plane of the equinoctial. Those commonly in use among seamen are two; the one adapted to the polar star, and the first of the guards of the Little Bear; the other to the pole star, and the pointers of the Great Bear.

This instrument consists of two circular plates, applied to each other. The greater, which has a handle to hold the instrument, is about 2½ inches diameter, and is divided into twelve parts, agreeing to the twelve months; and each month subdivided into every fifth day; and so as that the middle of the handle corresponds to that day of the year, wherein the star here regarded has the same right ascension with the sun. If the instrument be fitted for two stars, the handle is made moveable. The upper left circle is divided into twenty-four equal parts for the twenty-four hours of the day, and each hour subdivided into quarters. These twenty-four hours are noted by twenty-four teeth to be told in the night. Those at the hour 12 are distinguished by their length. In the centre of the two circular plates is adjusted a long index, moveable upon the upper plate; and the three pieces, viz. the two circles and index, are joined by a rivet which is pierced through the centre with a hole, through which the star is to be observed. Plate CCCLXX.

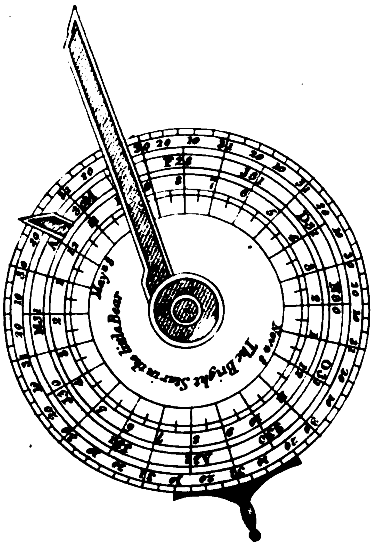
To use the nocturnal, turn the upper plate till the long tooth, marked 12, be against the day of the month on the under plate; then, bringing the instrument near the eye, suspend it by the handle with the plane nearly parallel to the equinoctial, and viewing the pole star through the hole of the centre, turn the index about, till, by the edge coming from the centre, you see the bright star or guard of the Little Bear, (if the instrument be fitted to that star): then that tooth of the upper circle, under the edge of the index, is at the hour of the night on the edge of the hour circle, which may be known without a light, by counting the teeth from the longest, which is for the hour 12.

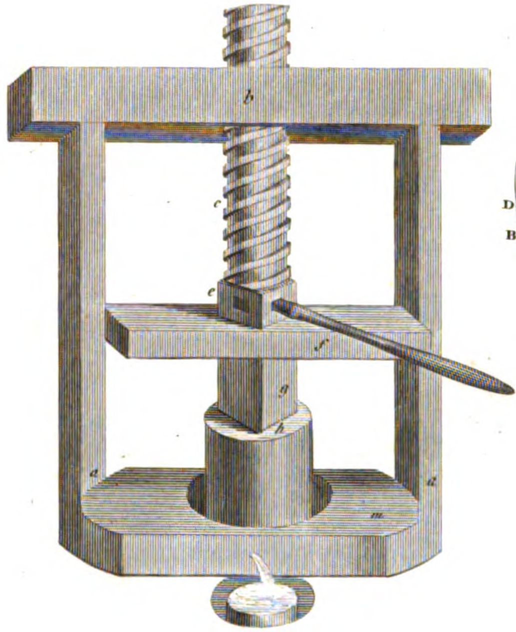
NOD,

(A) Anciently, Nuceria Alphaterna, a word of unknown etymology. It was a Roman colony, and had its mint. Num. Nucerin.

1. Caput virile imberbe. Equus stans capite reflexo inter crura. A . . IN . .

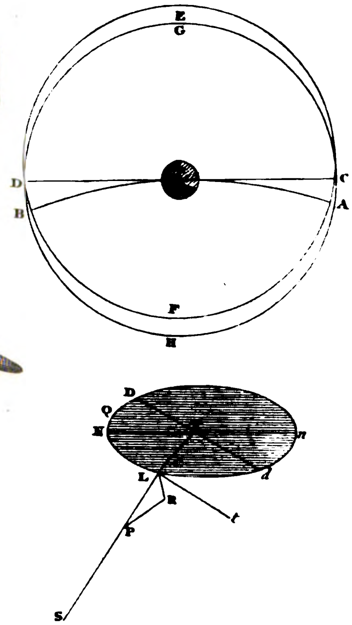
NOCTURNAL



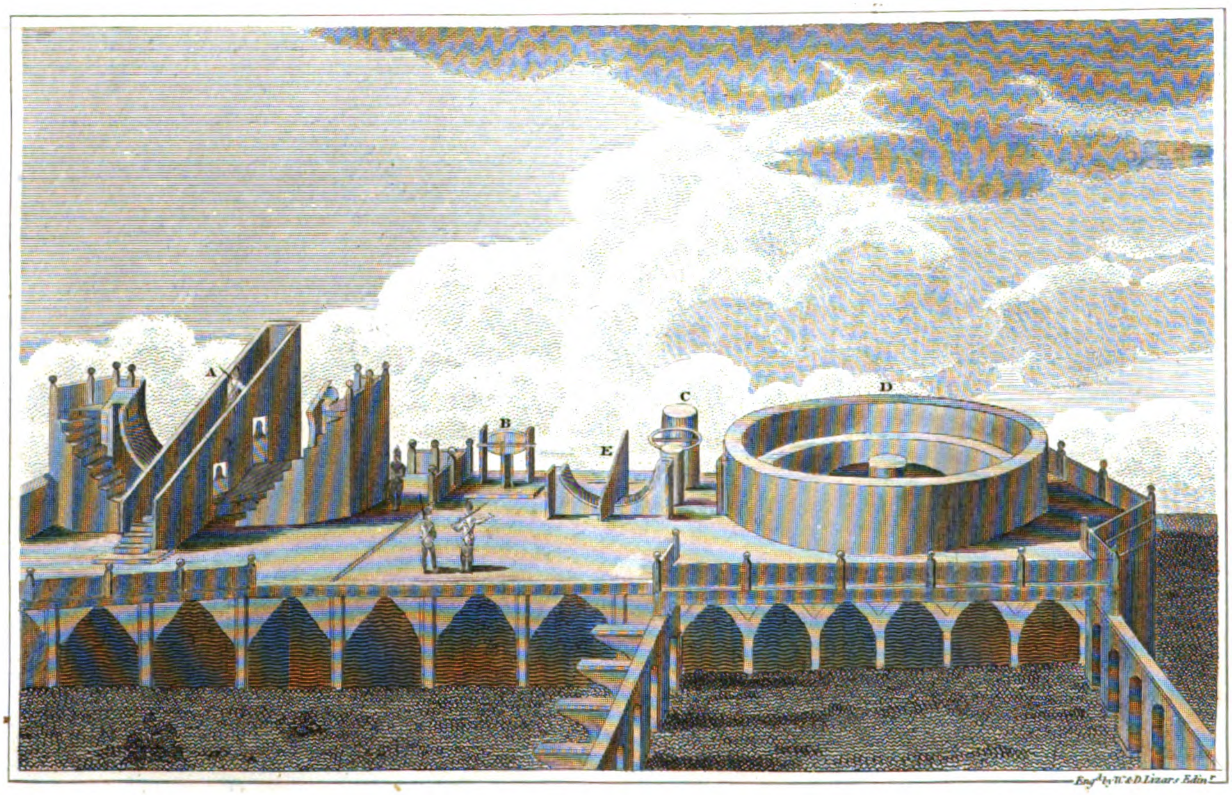


NODES

Fig. 1.



BRAMIN'S OBSERVATORY



Eng^d by W. & D. Lizars Edin^r.

NOD, or the *Land of Nod*. It was to this country that Cain withdrew after his fratricide, (Gen. iv. 16.). The Septuagint, as well as Josephus, read *Naid* instead of *Nod*, and have taken it for the name of a place. It is not easily known what country this was, unless perhaps it was the country of Nyse or Nysea, towards Hyrcania. St Jerome and the Chaldee interpreters have taken the word Nod in the sense of an appellative, for *vagabond* or *fugitive*; "He dwelt a fugitive in the land." But the Hebrew reads, "He dwelt in the land of Nod," (Gen. iv. 16.)

NODAB, a country bordering upon Iturea and Idumæa, but now unknown. We read in the Chronicles, that the tribe of Reuben, assisted by those of Gad and Manasseh, had a war against the Hagarites, the Jeturites, and the people of Nephish, and of Nodab, in which the Israelites had the advantage (1 Chr. v. 19.). But the time and the other particulars of this war are unknown.

NODATED HYPERBOLA, a name given by Sir Isaac Newton to a kind of hyperbola, which, by turning round, decussates or crosses itself.

NODDY. See STERNA, ORNITHOLOGY *Index*.

NODE, a tumor arising on the bones, and usually proceeding from some venereal cause; being much the same with what is otherwise called *exostosis*.

NODES, in *Astronomy*, the two points where the orbit of a planet intersects the ecliptic.

Plate CCCLXX. fig. 1.

Such are the two points C and D, fig. 1. of which the node C, where the planet ascends northward above the plane of the ecliptic, is called the *ascending node*, or the *dragon's head*, and is marked thus ☊. The other node D, where the planet descends to the south, is called the *descending node*, or the *dragon's tail*, marked thus ☋.

The line CD, wherein the two circles CEDF and CGDH intersect, is called the *line of nodes*. It appears from observation, that the line of the nodes of all the planets constantly changes its place, and shifts its situation from east to west, contrary to the order of the signs; and that the line of the moon's nodes, by a retrograde motion, finishes its circulation in the compass of 19 years; after which time, either of the nodes having receded from any point of the ecliptic, returns to the same again; and when the moon is in the node, she is also seen in the ecliptic. If the line of nodes were immoveable, that is, if it had no other motion than that whereby it is carried round the sun, it would always look to the same point of the ecliptic, or would keep parallel to itself, as the axis of the earth does.

From what hath been said, it is evident, that the moon can never be observed precisely in the ecliptic, but twice in every period; that is, when she enters the nodes. When she is at her greatest distance from the nodes, viz. in the points E, F, she is said to be in her limits.

The moon must be in or near one of the nodes, when there is an eclipse of the sun or moon.

To make the foregoing account of the motion of the moon's nodes still clearer, let the plane of fig. 2. represent that of the ecliptic, S the sun, T the centre of the earth, L the moon in her orbit DN*dn*. N*n* is the line of the nodes passing between the quadrature Q and the moon's place L, in her last quarter. Let now LP, or any part LS, represent the excess of the sun's action at T; and this being resolved into the force LR, perpendicular to the plane of the moon's orbit, and PR parallel to it, it is the former only that has any effect to alter the position of the orbit, and in this it is wholly exerted. Its effect is twofold: 1. It diminishes its inclination by a motion which we may conceive as performed round the diameter D*d*, to which LT is perpendicular. 2. Being compounded with the moon's tangential motion at L, it gives it an intermediate direction L*t*, through which and the centre a plane being drawn, must meet the ecliptic nearer the conjunction C than before.

NODUS, or NODE, in *Dialling*, a certain point or pole in the gnomon of a dial, by the shadow or light whereof either the hour of the day in dials without furniture, or the parallels of the sun's declination, and his place in the ecliptic, &c. in dials with furniture are shown. See DIALLING.

NOEOMAGUS LEXUVIORUM, (Ptol.); thought to be the *Civitas Lexoviorum* of the lower age. Now *Lisieux*, a city in Normandy.—Another of the *Tricastini*; a town of Gallia Narbonensis; thought to be *S. Pol. de Trois Chateaux*, six miles to the west of Nyons in Dauphiné.

NOETIANS, in church history, Christian heretics in the third century, followers of Noetius, a philosopher of Ephesus, who pretended that he was another Moses sent by God, and that his brother was a new Aaron. His heresy consisted in affirming that there was but one person in the Godhead; and that the Word and the Holy Spirit were but external denominations given to God in consequence of different operations: that, as Creator, he is called *Father*; as Incarnate, *Son*; and as descending on the apostles, *Holy Ghost*.

NOLA, a very ancient city, formerly populous and strong, situated in a plain to the north-east of Vesuvius, in Campania, said to be built by the Chalcidians; (Justin, Silius Italicus); according to others by the Tuscans. At this place Hannibal met with the first check by Marcellus. Vespasian added the appellation *Augusta Colonia*, (Frontinus). At this place, or in its neighbourhood, Augustus is said to have expired. It is also said that bells were first invented there in the beginning of the 5th century; hence their Latin names *Nolæ* or *Campanæ*. It retains its old name to this day, but has greatly declined from its ancient splendour. A town of the kingdom of Naples. E. Long. 15. N. Lat. 41. 5.

NOLANA, a genus of plants belonging to the pentandria class; and in the natural method ranking under the 41st order, *Asperifoliæ*. See BOTANY *Index*.

NOLLE PROSEQUI, is where a plaintiff in an action does not declare in a reasonable time; in which case it is usual for the defendant's attorney to enter a rule for the plaintiff to declare, after which a *non pros.* may be entered. A *nolle prosequi* is esteemed a voluntary confession, that the plaintiff has no cause of action; and therefore if a plaintiff enters his *nolle prosequi*, he shall be amerced; and if an informer cause the same to be entered, the defendant shall have costs.

NOLLET, JEAN ANTOINE, a deacon, licentiate in theology, preceptor to the *Enfans de France* for physics and natural history, regius professor of physics in the college of Navarre, member of the Academy of Sciences

Nollet. Sciences at Paris, of the Royal Society of London, of the Institution of Bologna, and of the Academy of Sciences of Erfort; was born at Pimbré, in the diocese of Noyon, on the 17th of November 1700, of respectable but not wealthy parents. To make up the want of riches, they determined to give their son a good education. They sent him to the college of Clermont in Beauvoisis, and afterwards to Beauvais, there to finish his introductory studies. The progress which he made in the different classes, determined them to send him to study philosophy at Paris. Thenceforward they intended him for the clerical order; and they considered the strictness and purity of his morals, together with his unwearied application to study, as sufficient proofs of his vocation. The young Nollet yielded without reluctance to the wishes of his parents. As soon as he was capable of showing an inclination for any thing, he had discovered a taste for physics; but this was not become his ruling passion; he therefore sacrificed it to the study of scholastic divinity, to which he wholly dedicated himself during his time of probation in 1728. No sooner had he been invested with the deaconship, than he solicited and obtained a licence to preach. This new occupation, however, did not make him entirely lose sight of those studies which had first engaged his attention. They insensibly began to occupy a greater portion of his time, which was now more equally divided between theology and the sciences. The latter, however, prevailed; and thenceforth he entered into the study of physics with an ardour which was only increased by that kind of privation to which he had been long subject. He was received into the Society of Arts, established at Paris under the patronage of the late count de Clermont. In 1730, the abbé Nollet was engaged in a work conjunctly with Reaumur and du Fay of the Academy of Sciences. In 1734, he went to London in company with M. M. du Fay, du Hamel, and de Jussieu. His merit procured him a place in the Royal Society without any solicitation. Two years after, he went to Holland, where he formed an intimate connection with Desaguliers, Gravesande, and Muschenbroeck. On his return to Paris, he resumed the course of experimental physics which he had begun in 1735, and which he continued till 1760. These courses of physics first suggested the idea of particular courses in other branches of science, such as in chemistry, anatomy, natural history, &c. In 1738, the count de Maurepas prevailed on the cardinal Fleury to establish a public class for experimental physics; and the abbé Nollet was appointed the first professor. In the beginning of the year 1739, he was admitted a member of the Royal Academy of Sciences; and in the month of April following, the king of Sardinia intending to establish a professorship of physics at Turin, invited the abbé Nollet into his dominions. From thence he travelled into Italy. In 1744, he was honoured with an invitation to Versailles, to instruct the dauphin in experimental philosophy; the king and royal family were often present at his lectures. The qualities as well of his understanding as of his heart gained him the esteem and confidence of his pupil. Going one day in state to Paris, he caused intimation to be made that he was to dine at the Thuilleries. M. Nollet having gone thither to pay his court, the dauphin no sooner perceived him, than he had the goodness to say, "Binet has the advantage of me, he has been at your house." Till the period of his death, this prince showed marks of the strongest attachment and favour for this ingenious philosopher. He would have wished that he had been a little more attentive to the improvement of his fortune. He prevailed upon him to go and pay court to a man in power, whose patronage might have been of service to him. The abbé Nollet accordingly waited upon the placeman, and made him a present of his works. "I never read any works of that kind," said the patron coldly, and casting a look at the volumes before him. "Sir (replied the abbé), will you allow them to remain in your antichamber? There perhaps there may be found men of genius who will read them with pleasure." In the month of April 1749, he made a grand tour into Italy, being sent thither for the purpose of making observations. At Turin, Venice, and Bologna, the abbé Nollet appeared as a deputy from the philosophers of the rest of Europe. During his short stay in Italy, the wonders of electricity were not the only object of his researches; every part of physics, the arts, agriculture, &c. came equally under his notice. Upon his return through Turin, the king of Sardinia, always truly sensible of his merit, offered him the order of Saint Maurice, which he did not think proper to accept without his sovereign's permission. In 1753 the king instituted a class of experimental philosophy in the royal college of Navarre, and appointed the abbé Nollet professor. In 1757, he received from the king a brevet appointing him preceptor in physics and natural history to the *Enfans de France*. In the month of August, the same year, he was appointed professor of experimental philosophy in the school of artillery, at that time established at la Fere. In the month of November following, he was admitted as a pensionary of the Royal Academy of Sciences. M. de Cremillo, director general of artillery and fortification, having founded a class of experimental philosophy at Mezieres in 1761, the abbé Nollet was appointed professor. This celebrated and laborious philosopher, who has rendered the most important services to physics by the discoveries with which he has enriched every branch of this science, but particularly electricity, died at Paris on the 25th of April 1770, aged 70; much regretted by the literary world, and by his friends, of whom his gentle character and beneficent heart had procured him a great number. He often retired from the gay and splendid societies of Paris, to give assistance to his relations, who were by no means in affluent circumstances. His works are 1. Several papers inserted in the memoirs of the Academy of Sciences; among which one on the Hearing of Fishes is particularly valuable. 2. *Leçons de Physique Experimentale*, 6 vols 12mo; a book well composed, and uniting pleasure with instruction. 3. *Recueil de Lettres sur l'Electricité*, 3 vols 12mo, 1753. 4. *Essai sur l'Electricité des corps*, 1 vol. 12mo. 5. *Recherches sur les causes particulieres des Phenoménes Electriques*, 1 vol. 12mo. 6. *L'Andes experiences*, 3 vols 12mo, with figures, 1770.

Nollet, Nomades.

NOMADES, a name given in antiquity, to several nations, whose whole occupation was to feed and tend their flocks; and who had no fixed place of abode, but were constantly shifting, according to the conveniences of pasturage.—The word comes from the Greek νεμω, *pasco*, "I feed."

The

The most celebrated among the Nomades were those of Africa, who inhabited between Africa properly so called, to the east, and Mauritania to the west. They are also called *Numidæ* or *Numidians*.—Sallust says, they were a colony of Persians brought into Africa with Hercules.

The Nomades of Asia inhabited the coasts of the Caspian sea. The Nomades of Scythia were the inhabitants of Little Tartary; who still retain the ancient manner of living.

NOMARCHA, in antiquity, the governor or commander of a nome or nomos.—Egypt was anciently divided into several regions or quarters, called *nomes*, from the Greek νομος, taken in the sense of a division; and the officer who had the administration of each *nome* or *nomos*, from the king, was called *nomarcha*, from νομος and αρχη, "command."

NOMBRE-DE-DIOS, a town of Mexico, in the province of Darien, a little to the eastward of Porto-Bello. It was formerly a famous place; but it is now abandoned, on account of its unhealthy situation. W. Long. 78. 35. N. Lat. 9. 43.

NOMBRIL POINT, in *Heraldry*, is the next below the fess point, or the very centre of the escutcheon.

Supposing the escutcheon divided into two equal parts below the fess, the first of these divisions is the nombril, and the lower the base.

NOME, or NAME, in *Algebra*, denotes any quantity with a sign prefixed or added to it, whereby it is connected with some other quantity, upon which the whole becomes a binomial, trinomial, or the like. See ALGEBRA.

NOMENCLATOR, in Roman antiquity, was usually a slave who attended upon persons that stood candidates for offices, and prompted or suggested to them the names of all the citizens they met, that they might court them and call them by their names, which among that people was the highest piece of civility.

NOMENCLATORS, among botanical authors, are those who have employed their labours about settling and adjusting the right names, synonymes, and etymologies of names, in regard to the whole vegetable world.

NOMENCLATURE, NOMENCLATURA, a catalogue of several of the more usual words in any language, with their significations, compiled in order to facilitate the use of such words to those who are to learn the tongue: such are our Latin, Greek, French, &c. nomenclatures: Or a system of technical language by which the objects of any science are denoted, as, for instance, the present language of chemical science, usually called the *new chemical nomenclature*, from its recent construction.

NOMENEY, a town in France, in the department of Meurthe, situated on the river Seille, 15 miles north of Nancy.

NOMINALS, or NOMINALISTS, a sect of school philosophers, the disciples and followers of Occam, or Ocham, an English Cordelier, in the 14th century. They were great dealers in words, whence they were vulgarly denominated *Word-sellers*; but had the denomination of *Nominalists*, because, in opposition to the *Realists*, they maintained, that words, and not things, were the object of dialectics.

This sect had its first rise towards the end of the 11th century, and pretended to follow Porphyry and Aristotle; but it was not till Ocham's time that they bore the name. The chief of this sect, in the 11th century, was a person called *John*, who, on account of his logical subtility, was called the *sophist*; and his principal disciples were Robert of Paris, Roscelin of Compiegne, and Arnoul of Laon. At the beginning, the Nominals had the upper hand: but the Realists, though greatly divided among themselves, were supported by men of great abilities; such as Albertus Magnus, T. Aquinas, and Duns Scotus. The Nominal sect came hereby into disrepute; till William Occam, in the 14th century, again revived it, and filled France and Germany with the flame of disputation. Having joined the party of the Franciscan monks, who strenuously opposed John XXII. that pope himself, and his successors after him, left no means untried to extirpate the philosophy of the Nominalists, which was deemed highly prejudicial to the interests of the church: and hence it was, that in the year 1339, the university of Paris, by a public edict, solemnly condemned and prohibited the philosophy of Occam, which was that of the Nominalists. The consequence was, that the Nominalists flourished more than ever. In the 15th century, the controversy was continued with more vigour and animosity than before; and the disputants were not content with using merely the force of eloquence, but had frequently recourse to more hostile and dangerous weapons; and battles were the consequence of a philosophical question, which neither side understood. In most places, however, the Realists maintained a manifest superiority over the Nominalists. While the famous Gerson and the most eminent of his disciples were living, the Nominalists were in high esteem and credit in the university of Paris. But upon the death of these patrons, the face of things was much changed to their disadvantage. In the year 1473, Louis XI. by the instigation of his confessor, the bishop of Avranches, issued out a severe edict against the doctrines of the Nominalists, and ordered all their writings to be seized and secured, that they might not be read by the people; but the same monarch mitigated this edict the year following, and permitted some of the books of that sect to be delivered from their confinement. In the year 1481, he not only granted a full liberty to the Nominalists and their writings, but also restored that philosophical sect to its former authority and lustre in the university.

The Nominalists were the founders of the university of Leipsic: and there are many yet abroad who pique themselves on being Nominals.

The Nominals, with the Stoics, admit the formal conceptions or ideas of things, as the subject and foundation of universality: but to this they add names, which represent and signify, after the same univocal manner, and without any distinction, a great variety of single things alike in genus and species.

Whence it is that they are called *Nominals*; as pretending, that to become learned, it is not enough to have just ideas of things, but it is likewise required to know the proper names of the genera and species of things, and to be able to express them clearly and precisely, without confusion or ambiguity.

NOMINATIVE, in *Grammar*, the first CASE of NOUNS which are declinable.

The simple position, or laying down of a noun, or name,

name, is called the *nominative case;* yet it is not so properly a case, as the matter or ground whence the other cases are to be formed, by the several changes and inflections given to this first termination. Its chief use is to be placed in discourse before all verbs, as the subject of the proposition or affirmation.

NONA, a city of Dalmatia, remarkable at present only for its ruins, which might furnish abundant materials to gratify the curiosity of antiquaries; but indeed they are so buried by repeated devastations, to which that unhappy city has been exposed, that rarely any vestige of them appears above ground. "I went thither (says Fortis in his Travels), in hopes of finding something worthy of notice, but was disappointed. Nothing is to be seen that indicates the grandeur of the Roman times; neither are there any remains of barbarous magnificence, to put one in mind of the ages in which the kings of the Croat Slavi had their residence there. It lies on a small island, surrounded by a harbour, which in former times was capable of receiving large ships; but is now become a fetid pool, by means of a little muddy river that falls into it, after a course of about six miles through the rich abandoned fields of that district. The ancient inhabitants turned this water into another channel, and made it run through the valley of Drasnich into the sea; and the remains of the bank raised by them for that purpose are still to be seen. Notwithstanding, however, the depopulation of this district, and the dreary situation of Nona in particular, the new inhabitants have not lost courage; and animated by the privileges granted to them by the most serene republic, are endeavouring to bring the population and agriculture once more into a flourishing state. Proper drains for the water would not only render that rich territory habitable, but moreover very fertile; and the brackish marsh that surrounds the walls of Nona is well calculated to supply a considerable quantity of fish, especially eels. The government generously granted the investiture to private persons, who already draw no inconsiderable advantage from the fishing; and did they but adopt better methods, they might every year salt many thousands of eels, which would greatly answer our internal commerce, and save at least a part of the money that goes out of the country for foreign salt fish. To the left of the city of Nona, the walls of some ancient ruinous buildings appear; which probably in ancient times were situated on the main land, though now surrounded by water. The sea forms a narrow channel in this place, which is easily fordable, and, at low water, the smallest boat can scarcely pass."

NONAGE, in *Law*, generally signifies all the time a person continues under the age of 21; but in a special sense, it is all the time that a person is under the age of 14.

NONAGESIMAL, or *Nonagesimal Degree*, called also the *Mid Heaven*, is the highest point, or 90th degree of the ecliptic, reckoned from its intersection with the horizon at any time; and its altitude is equal to the angle which the ecliptic makes with the horizon at their intersection, or equal to the distance of the zenith from the pole of the ecliptic. It is much used in the calculation of solar eclipses.

NONAGON, a figure having nine sides and angles. In a regular nonagon, or that whose angles and sides are all equal, if each side be 1, its area will be $6.1818242 = \frac{9}{4}$ of the tangent of 70°, to the radius 1.

NON, Cape, a promontory on the west coast of Africa, opposite to the Canary islands. W. Long. 12. 0. N. Lat. 44. 28.

NONCONFORMISTS, those who refuse to join the established worship.

Nonconformists, in England, are of two sorts. First, Such as absent themselves from divine worship in the established church through total irreligion, and attend the service of no other persuasion. These, by the statute 1 Eliz. c. 2. 23 Eliz. c. 1. and 3 Jac. I. c. 4. forfeit one shilling to the poor every Lord's day they so absent themselves, and 20l. to the king if they continue such default for a month together. And if they keep any inmate thus irreligiously disposed in their houses, they forfeit 10l. per month.

The second species of nonconformists are those who offend through a mistaken or perverse zeal. Such were esteemed, by the English laws enacted since the time of the Reformation, to be Papists and Protestant dissenters: both of which were supposed to be equally schismatics, in not communicating with the national church; with this difference, that the Papists divided from it upon material, though erroneous, reasons; but many of the dissenters upon matters of indifference, or, in other words, for no reason at all. "Yet certainly (says Sir William Blackstone) our ancestors were mistaken in their plans of compulsion and intolerance. The sin of schism, as such, is by no means the object of temporal coercion and punishment. If, through weakness of intellect, through misdirected piety, through perverseness and acerbity of temper, or (which is often the case) through a prospect of secular advantage in herding with a party, men quarrel with the ecclesiastical establishment, the civil magistrate has nothing to do with it; unless their tenets and practice are such as threaten ruin or disturbance to the state. He is bound indeed to protect the established church: and if this can be better effected by admitting none but its genuine members to offices of trust and emolument, he is certainly at liberty so to do; the disposal of offices being matter of favour and discretion. But this point being once secured, all persecution for diversity of opinions, however ridiculous or absurd they may be, is contrary to every principle of sound policy and civil freedom. The names and subordination of the clergy, the posture of devotion, the materials and colour of the minister's garment, the joining in a known or unknown form of prayer, and other matters of the same kind, must be left to the option of every man's private judgment.

Blackst. Comment.

"With regard therefore to *Protestant dissenters*, although the experience of their turbulent disposition in former times occasioned several disabilities and restrictions (which I shall not undertake to justify) to be laid upon them by abundance of statutes; yet at length the legislature, with a true spirit of magnanimity, extended that indulgence to these sectaries, which they themselves, when in power, had held to be countenancing schism, and denied to the church of England. The penalties are conditionally suspended by the statute 1 W. & M. st. 1. c. 18. "for exempting their majesties Protestant subjects, dissenting from the church of England, from the penalties of certain laws," commonly called

Noncon-formists. Blackst. Comment. called the *toleration act;* which declares, that neither the laws above mentioned, nor the statutes 1 Eliz. c. 2. § 14. 3 Jac. I. c. 4. and 5. nor any other penal laws made against Popish recusants (except the test acts), shall extend to any dissenters, other than Papists and such as deny the Trinity: provided, 1. That they take the oaths of allegiance and supremacy, (or make a similar affirmation, being Quakers), and subscribe the declaration against Popery. 2. That they repair to some congregation certified to and registered in the court of the bishop or archdeacon, or at the county sessions. 3. That the doors of such meeting-house shall be unlocked, unbarred, and unbolted; in default of which, the persons meeting there are still liable to all the penalties of the former acts. Dissenting teachers, in order to be exempted from the penalties of the statutes 13 and 14 Car. II. c. 4. 17 Car. II. c. 2. and 22 Car. II. c. 1. are also to subscribe the articles of religion mentioned in the statute 13 Eliz. c. 12. (viz. those which only concern the confession of the true Christain faith, and the doctrine of the sacraments), with an express exception of those relating to the government and powers of the church, and to infant baptism. And by stat. 10 Ann. c. 2. this toleration is ratified and confirmed; and it is declared, that the said act shall at all times be inviolably observed for the exempting such Protestant dissenters as are thereby intended from the pains and penalties therein mentioned. Thus, though the offence of non-conformity is by no means universally abrogated, it is suspended, and ceases to exist with regard to these Protestant dissenters, during their compliance with the conditions imposed by the act of toleration: and, under these conditions, all persons, who will approve themselves no Papists or oppugners of the Trinity, are left at full liberty to act as their consciences shall direct them in the matter of religious worship. And if any person shall wilfully, maliciously, or contemptuously disturb any congregation, assembled in any church or permitted meeting-house, or shall misuse any preacher or teacher there, he shall (by virtue of the same statute) be bound over to the sessions of the peace, and forfeit 20l. But by statute 5 Geo. I. c. 4. no mayor or principal magistrate must appear at any dissenting meeting with the ensigns of his office, on pain of disability to hold that or any other office: the legislature judging it a matter of propriety, that a mode of worship, set up in opposition to the nation, when allowed to be exercised in peace, should be exercised also with decency, gratitude, and humility. Neither doth the act of toleration extend to enervate those clauses of the statutes 13 & 14 Car. II. c. 4. and 17 Car. II. c. 2. which prohibit (upon pain of fine and imprisonment) all persons from teaching school, unless they be licensed by the ordinary, and subscribe a declaration of conformity to the liturgy of the church, and reverently frequent divine service *established* by the laws of this kingdom.

"As to *Papists* what has been said of the Protestant dissenters would hold equally strong for a general toleration of them; provided their separation was founded only upon difference of opinion in religion, and their principles did not also extend to a subversion of the civil government. If once they could be brought to renounce the supremacy of the Pope, they might quietly enjoy their seven sacraments; their purgatory and auricular confession; their worship of relicks and images; nay, even their transubstantiation. But while they acknowledge a foreign power, superior to the sovereignty of the kingdom, they cannot complain, if the laws of that kingdom will not treat them upon the footing of good subjects.

Noncon-formists.

"The following are the laws that have been enacted against the Papists; who may be divided into three classes, persons professing Popery, Popish recusants convict, and Popish priests. 1. Persons professing the Popish religion, besides the former penalties for not frequenting their parish church, are disabled from taking any lands either by descent or purchase, after 18 years of age, until they renounce their errors; they must at the age of 21 register their estates before acquired, and all future conveyances and wills relating to them; they are incapable of presenting to any advowson, or granting to any other person any avoidance of the same; they may not keep or teach any school, under pain of perpetual imprisonment; and, if they willingly say or hear mass, they forfeit the one 200, the other 100 merks, and each shall suffer a year's imprisonment. Thus much for persons, who, from the misfortune of family prejudices, or otherwise, have conceived an unhappy attachment to the Romish church from they infancy, and publicly profess its errors. But if any evil industry is used to rivet these errors upon them; if any person sends another abroad to be educated in the Popish religion, or to reside in any religious house abroad for that purpose, or contributes to their maintenance when there; both the sender, the sent, and the contributor, are disabled to sue in law or equity, to be executor or administrator to any person, to take any legacy or deed of gift, and to bear any office in the realm; and shall forfeit all their goods and chattels, and likewise all their real estate for life. And where these errors are also aggravated by apostasy or perversion; where a person is reconciled to the see of Rome, or procures others to be reconciled, the offence amounts to high treason. 2. Popish recusants, convicted in a court of law of not attending the service of the church of England, are subject to the following disabilities, penalties, and forfeitures, over and above those before mentioned. They are considered as persons excommunicated; they can hold no office or employment: they must not keep arms in their houses, but the same may be seized by the justices of the peace; they may not come within 10 miles of London, on pain of 100l.; they can bring no action at law or suit in equity; they are not permitted to travel above five miles from home, unless by license, upon pain of forfeiting all their goods; and they may not come to court, under pain of 100l. No marriage or burial of such recusant, or baptism of his child, shall be had otherwise than by the ministers of the church of England, under other severe penalties. A married woman, when recusant, shall forfeit two-thirds of her dower or jointure, may not be executrix or administratrix to her husband, or have any part of his goods; and during the coverture may be kept in prison, unless her husband redeems her, at the rate of 10l. a month, or the third part of all his lands. And lastly, as a feme-covert recusant may be imprisoned, so all others must, within three months after conviction, either submit and renounce their errors, or if required so to do by four justices, must abjure and renounce the realm: and if they do not depart, or if they re-

Nonconformists. *Blackst. Comment.*

turn without the king's licence, they shall be guilty of felony, and suffer death as felons, without benefit of clergy. There is also an inferior species of recusancy, (refusing to make the declaration against Popery enjoined by statute 30 Car. II. st. 2. when tendered by the proper magistrate); which, if the party resides within ten miles of London, makes him an absolute recusant convict; or, if at a greater distance, suspends him from having any seat in parliament, keeping arms in his house, or any horse above the value of 5l. 3. Popish priests are still in a more dangerous condition. By statute 11 & 12 W. III. c. 4. Popish priests, or bishops, celebrating mass or exercising any part of their functions in England, except in the houses of ambassadors, are liable to perpetual imprisonment. And by the statute 27 Eliz. c. 2. any Popish priest, born in the dominions of the crown of England, who shall come over hither from beyond sea (unless driven by stress of weather and tarrying only a reasonable time), or shall be in England three days without conforming and taking the oaths, is guilty of high treason: and all persons harbouring him are guilty of felony without the benefit of clergy.

"This is a short summary of the laws against the Papists; of which the president Montesquieu observes, that they are so rigorous, though not professedly of the sanguinary kind, that they do all the hurt that can possibly be done in cold blood. But in answer to this, it may be observed (what foreigners who only judge from our statute book are not fully apprized of); that these laws are seldom exerted to their utmost rigour: and indeed, if they were, it would be very difficult to excuse them. For they are rather to be accounted for from their history, and the urgency of the times which produced them, than to be approved (upon a cool review) as a standing system of law. The restless machinations of the Jesuits during the reign of Elizabeth, the turbulence and uneasiness of the Papists under the new religious establishment, and the boldness of their hopes and wishes for the succession of the queen of Scots, obliged the parliament to counteract so dangerous a spirit by laws of a great, and then perhaps necessary, severity. The powder-treason, in the succeeding reign, struck a panic into James I. which operated in different ways: it occasioned the enacting of new laws against the Papists; but deterred him from putting them in execution. The intrigues of Queen Henrietta in the reign of Charles I. the prospect of a Popish successor in that of Charles II. the assassination-plot in the reign of King William, and the avowed claim of a Popish pretender to the crown in subsequent reigns, will account for the extension of these penalties at those several periods of our history."

But now that all just fears of a pretender may be said to have vanished, and the power and influence of the pope has become feeble, ridiculous, and despicable, not only in Britain, but in almost every kingdom of Europe: and as in fact the British Catholics solemnly disclaim the dangerous principles ascribed to them *; the British legislature, giving way to that liberality of sentiment becoming Protestants, have lately repealed the most rigorous of the above edicts, viz. The punishment of Popish priests or Jesuits who should be found to teach or officiate in the services of that church; which acts were felony in foreigners, and high treason in the natives of this kingdom:—The forfeitures of Popish heirs, who had received their education abroad, and whose estates went to the next Protestant heir:—The power given to the son, or other relation, being a Protestant, to take possession of the father's or other relation's estate, during the life of the real proprietor:—And the debarring Papists from the power of acquiring any legal property by purchase.—In proposing the repeal of these penalties, it was observed, That, besides that some of them had now ceased to be necessary, others were at all times a disgrace to humanity. The imprisonment of a Popish priest for life, only for officiating in the services of his religion, was horrible in its nature: And although the mildness of government had hitherto softened the rigour of the law in the practice, it was to be remembered that the Roman Catholic priests constantly lay at the mercy of the basest and most abandoned of mankind—of common informers; for on the evidence of any of these wretches, the magisterial and judicial powers were of necessity bound to enforce all the shameful penalties of the act. Others of these penalties held out the most powerful temptations for the commission of acts of depravity, at the very thought of which our nature recoils with horror: They seemed calculated to loosen all the bands of society; to dissolve all civil, moral, and religious obligations and duties, to poison the sources of domestic felicity, and to annihilate every principle of honour. The encouragement given to children to lay their hands upon the estates of their parents, and the restriction which debars any man from the honest acquisition of property, need only to be mentioned to excite indignation in an enlightened age.

* See their loyal Address to the throne, May 1. 1778. as inserted in the Magazines or Annual Register for that year.

Nonconformists.

In order the better to secure the English established church against perils from nonconformists of all denominations, Infidels, Turks, Jews, Heretics, Papists, and Sectaries, there are, however, two bulwarks erected; called the *corporation* and *test acts*: By the former of which, no person can be legally elected to any office relating to the government of any city or corporation, unless, within a twelvemonth before, he has received the sacrament of the Lord's supper according to the rites of the church of England; and he is also enjoined to take the oaths of allegiance and supremacy at the same time that he takes the oath of office: or, in default of either of these requisites, such election shall be void. The other, called the *test act*, directs all officers civil and military to take the oaths and make the declaration against transubstantiation, in any of the king's courts at Westminster, or at the quarter sessions, within six calendar months after their admission; and also within the same time to receive the sacrament of the Lord's supper, according to the usage of the church of England, in some public church immediately after divine service and sermon, and to deliver into court a certificate thereof signed by the minister and church warden, and also to prove the same by two credible witnesses; upon forfeiture of 500l. and disability to hold the said office. And of much the same nature with these is the statute 7 Jac. I. c. 2. which permits no persons to be naturalized or restored in blood, but such as undergo a like test; which test having been removed in 1753, in favour of the Jews, was the next session of parliament restored again with some precipitation.

Non-

Non-Naturals, in *Medicine*, so called, because by their abuse they become the causes of diseases.

Physicians have divided the non-naturals into six classes, viz. the air, meats and drinks, sleep and watching, motion and rest, the passions of the mind, the retentions and excretions. See Medicine, *passim*.

Non-Obstante (*notwithstanding*) a clause frequent n statutes and letters patent, importing a license from the king to do a thing, which at common law might be lawfully done, but being restrained by act of parliament cannot be done without such license.

Non-Pros. See Nolle *Prosequi.*

Non-Suit, signifies the dropping of a suit or action, or a renouncing thereof by the plaintiff or defendant; which happens most commonly upon the discovery of some error in the plaintiff's proceedings when the cause is so far proceeded in, that the jury is ready at the bar to deliver in their verdict.

NONES, (nonæ), in the Roman kalendar, the fifth day of the months January, February, April, June, August, September, November, and December; and the seventh of March, May, July, and October. March, May, July, and October, had six days in their nones; because these alone, in the ancient constitution of the year by Numa, had 31 days a-piece, the rest having only 29, and February 30: but when Cæsar reformed the year, and made other months contain 31 days, he did not allot them six days of nones.

NONJURORS, those who refused to take the oaths to government, and who were in consequence under certain incapacities, and liable to certain severe penalties. It can scarcely be said that there are any nonjurors now in the kingdom; and it is well known that all penalties have been removed both from Papists and Protestants, formerly of that denomination, as well in Scotland as in England. The members of the Episcopal church of Scotland have long been denominated Nonjurors; but perhaps they are now called so improperly, as the ground of their difference from the establishment is more on account of ecclesiastical than political principles.

NONIUS, Peter, in Spanish *Nunez*, a learned Portuguese, and one of the ablest mathematicians of the 16th century, was born at Alcacer. He was preceptor to Don Henry, King Emmanuel's son, and taught mathematics in the university of Coimbra. He published the following works, by which he gained great reputation: 1. *De arte Navigandi*. 2. *Annotationes in theorias planetarum Purbachii;* which are greatly esteemed. 3. A treatise *De Crepusculis*. 4. A treatise on Algebra. It is observed in Furetiere's dictionary, that Peter Nonius in 1530, first invented the angles of 45 degrees made in every meridian, and that he called them *rhumbs* in his language, and calculated them by spherical triangles. Nonius died in 1577, aged 80.

Nonius, the name which was not many years ago given to the common device for subdividing the arcs of quadrants and other astronomical instruments, from the persuasion that it was invented by *Nonius* or *Nunez*, of whom some account has been given in the preceding article. The generality of astronomers of the present age, transferring the honour of the invention from *Nunez* to *Peter Vernier*, a native of Franche Comte, have called this method of division by his name. (See Vernier). Mr Adams, however, in his *Geometrical and Geographical Essays*, has lately shown that Clevius the Jesuit may dispute the invention with them both. The truth seems to be, that Nunez started the idea, Clevius improved it, and Vernier carried it to its present state of perfection. The method of Nunez, described in his treatise *De Crepusculis*, printed at Lisbon 1542, consists in describing within the same quadrant 45 concentric circles, dividing the outermost into 90 equal parts, the next within into 89, the next into 88, &c. till the innermost was divided into 46 only. On a quadrant thus divided the plumb line or index must cross one or other of the circles very near a point of division; whence, by computation, the degrees and minutes of the arch might be easily ascertained. This method is also described by Nunez in his treatise *De arte atque ratione Navigandi*, where he would fain persuade himself, that it was not unknown to Ptolemy. But as the degrees are thus divided very unequally, and as it is very difficult to attain exactness in the division, especially when the numbers into which the arches are to be divided are incomposite (of which there are no less than nine), the method of diagonals, first published by Thomas Digges, Esq. in a treatise entitled *Alæ seu scalæ mathematicæ*, printed at London in 1573, and said to be invented by one Richard Chenseler, was substituted in its room. Nonius's method was, however, improved at different times and by different persons; and it must be acknowledged, that if Vernier saw either the original or any of the improvements (and there can be little doubt of his having seen them all), his merit is only that of having applied to an useful practical purpose the speculative invention of another person.

NONNUS, a Greek poet of the 5th century, and native of Panopilis in Egypt, was the author of an heroic poem in 48 books, entitled *Dionysiacorum*, and a paraphrase in verse of St John's Gospel, which may serve as a commentary upon it.

NONUPLA, in the Italian music, denotes a quick time, peculiar to jigs. This species of time is otherwise called *the measure of nine times*, which requires two falls of the hand, and one rise. There are three sorts of nonupla. 1. *Nonupla di semi minime*, or *dupla sesquiquarta*, thus marked $\frac{9}{4}$, where nine crotchets are to be in the bar, of which four make a semibreve in common time, i. e. in the down stroke six, and but three up: it is usually beat *adagio*. 2. *Nonupla di crome*, or *sesqui ottava*, marked thus $\frac{9}{8}$, wherein nine quavers make a bar instead of eight in common time, i. e. six down and three up: it is beat *presto*. 3. *Nonupla di semicrome* or *super setti partiente nona*, thus distinguished $\frac{9}{16}$, in which nine semiquavers are contained in a bar, whereof sixteen are required in common time, six down, and three up: it is ordinarily beat *prestissimo*. Besides these, there are two other species of nonupla, for which see Triple.

NOOTKA sound, or, as it was called by Captain Cook, *King George's Sound*, lies in N. Lat. 49. 33. W. Long. 127. 12. It is an entrance or strait to a vast inland sea on the west coast of North America, and is said to resemble the Baltic or Mediterranean in Europe. Upon the sea-coast the land is tolerably high and level; but within the sound it rises into steep hills, which have an uniform appearance. The trees of which the woods are composed, are the Canadian pine, white cypress, Nootka Sound.

cypress, and two or three other sorts of pine. In general, the trees grow here with great vigour, and are of a large size. About the rocks and borders of the woods were seen some strawberry plants, and raspberry, currant, and gooseberry bushes, all in a flourishing state. The principal animals seen here were racoons, martens, and squirrels. Birds are far from being numerous, and those that are to be seen are remarkably shy, owing perhaps to their being continually harassed by the natives, either to eat them, or to become possessed of their feathers to be worn as ornaments. The quebrantahuessos, shags, and gulls, were seen off the coast; and the two last were also frequent in the sound. Though the variety of fish is not very great, yet they are in greater quantities than birds. The principal sorts are the common herring, a silver coloured bream, and another of a brown colour. Captain Cook and Mr King, who visited this place, consider it as an excellent shelter for ships: and in the account of *A Voyage to the Pacific Ocean*, they give some directions for sailing into it. These and other matters of that kind we shall not trouble our readers with; and perhaps the generality of them will be better pleased with the following extract from Meares's Voyages to the Northwest Coast of America.

"The people of the Nootka nation are, in general, robust and well-proportioned:—their faces are large and full, their cheeks high and prominent, with small black eyes:—their noses are broad and flat, their lips thick, and they have generally very fine teeth, and of the most brilliant whiteness.

"The manner in which the children of Nootka are treated, when young, is not more extraordinary from its strange, and, as it should appear, total inutility, than from its agreement with the customs of the Chinese and Tartars, to whom this practice gives these people a considerable resemblance. The head of the infant is bound by the mother with a kind of fillet of several folds, as low down as the eyes, in order to give it a certain form, which, at this tender age, it is capable of receiving. It might be supposed, that such a tight drawn ligature must cause considerable pain to the child; but we never observed that any of the infants, in such a state of preparation for sugar-loaf heads, suffered any visible pain or inconvenience.

"Though the custom of compressing the head in this manner gives them an unpleasant appearance, by drawing up the eyebrows, and sometimes producing the disagreeable effect of squinting, as well as of flattening the nose and distending the nostrils, they are by no means an ill-looking race of people. They have also the custom, which is known to prevail in so many Indian nations, of plucking out the beard by the roots, on its first appearance; and, as it continues to sprout, to keep it down by the same practice. It is one of the domestic employments assigned to their wives, to watch this appearance of manhood, and to eradicate the hairs as they come forth; which they do in a very dexterous manner with their fingers, and without giving the least pain in the operation.—Soon of them, however, though we saw but very few of this disposition, when they advance in years and become infirm, suffer their beards to grow without interruption. But, notwithstanding they have so great an aversion to the hair of their chin, that of the head is an object of their attentive vanity: it is strong, black, and glossy; grows to a considerable length; and is either tied in a kind of knot on the top of their heads, or suffered to hang down their backs in flowing negligence.

"In their exterior form they have not the symmetry or elegance which is found in many other Indian nations.—Their limbs, though stout and athletic, are crooked and ill-shaped; their skin, when cleansed of filth and ochre, is white; and we have seen some of the women, when in a state of cleanliness (which, however, was by no means a common sight, and obtained with difficulty), who not only possessed the fair complexion of Europe, but features that would have attracted notice, for their delicacy and beauty, in those parts of the world where the qualities of the human form are best understood. But these examples of beauty are by no means numerous among the women of Nootka, who are calculated rather to disgust than to charm an European beholder. Their hair, like that of the men, is black; their eyes are of the same colour; and, in exterior appearance, they are not to be immediately distinguished from the men. In their characters they are reserved and chaste; and examples of loose and immodest conduct were very rare among them. There were women in St George's Sound, whom no offers could tempt to meretricious submissions."

All reports concerning Nootka Sound agree in characterizing the inhabitants as "a very inoffensive race of people."—Inoffensive, however, as they are, a custom of a very unnatural, and we should imagine cruel, kind prevails among them; for, together with many other articles which they exposed to sale to Captain Cook's ships, they brought human skulls and hands (part of the flesh still remaining on them), which they acknowledged they had been feeding on; and some of them, we are told, had evident marks of the fire.

From hence it is too apparent, that the horrid practice of devouring their enemies exists here as well as at New Zealand and other South sea islands: and hence, too, appears what men of even the best natural dispositions will be, if left entirely to the freedom of their own will, without law to controul or religion to instruct them. As there are but two villages of the Sound inhabited, the number of people cannot be many; perhaps they are about 2000 in all. Our limits prevent us from being so minute as we could wish to be, respecting the form of their houses and their manner of building them; of their furniture, decorations, and other things of that kind: we can therefore only refer those who wish for further information on this subject to Cook, and other voyagers and travellers, &c.

The employment of the men is chiefly fishing, &c. whilst the women manufacture their garments. Their ingenuity in this and in the mechanic arts is far from being inconsiderable; and in the imitative arts their skill is very great. On these subjects, however, we cannot enlarge: we have in general made it our business, and it certainly is our duty, to dwell, where it can be done, on the manners or religion of the inhabitants of the several places which come under our notice; and they who know the utility of this in developing the philosophy of the human mind, the most important of all sciences, will not blame our intentions, even if they should not approve of the execution. In Cook's

Nootka Sound

Cook's Voyages before referred to, we find the following observations on the religion and language of the inhabitants of Nootka Sound.

"Little knowledge we can be supposed to have acquired of the political and religious institutions established among these people. We discovered, however, that there were such men as chiefs, distinguished by the title of *Acweek*, to whom the others are, in some degree, subordinate. But the authority of each of these great men seems to extend no farther than to his own family, who acknowledge him as their head. As they were not all elderly men, it is possible this title may be hereditary.

"Nothing that we saw could give us any insight into their notions of religion, except the figures already mentioned, called *Klumma*. These, perhaps, were idols; but as the word *acweek* was frequently mentioned when they spoke of them, we may suppose them to be the images of some of their ancestors, whose memories they venerate. This, however, is all conjecture; for we could receive no information concerning them; knowing little more of their language than to enable us to ask the names of things, and being incapable of holding any conversation with the natives relative to their traditions or their institutions.

"Their language is neither harsh nor disagreeable, farther than proceeds from their pronouncing the *k* and *h* with less softness than we do. As to the composition of their language, we are enabled to say but little. It may, however, be inferred from their slow and distinct method of speaking, that it has few prepositions or conjunctions, and is destitute of even a single interjection to express surprise or admiration. The affinity it may bear to other languages, we have not been able sufficiently to trace, not having proper specimens to compare it with; but from the few Mexican words we have procured, there is an obvious agreement throughout the language, in the frequent terminations of the words in *l*, *tl* or *z*.

"The word *wakash* was frequently in the mouths of the people of Nootka. It seemed to express approbation, applause, and friendship. Whenever they appeared to be pleased or satisfied at any sight or occurrence, they would call out *wakash! wakash!*—It is worthy of remark, that as these people do essentially differ from the natives of the islands in the Pacific ocean, in their persons, customs, and language, we cannot suppose their respective progenitors to have belonged to the same tribe, when they emigrated into those places where we now find their descendants."

We cannot finish this article without taking notice of a circumstance, which at the time made a great noise in Europe, and which it is probable will find a place in the future histories of the contending countries.

A small association of British merchants resident in the East Indies had, early in the year 1786, formed the project of opening a trade to this part of the world, for the purpose of supplying the Chinese market with furs. The principal point towards which these expeditions were directed, was Port Nootka, or King George's Sound; and the adventurers, being in some degree satisfied with their traffic, took measures, in the year 1788, to secure to themselves a permanent settlement; at the same time that the shipping employed in this expedition was generally two, and never exceeded the amount of four, small vessels. The Spaniards conceived some jealousy of the intrusion of the English into a part of the world which they had long been desirous to regard as their exclusive property; and accordingly a Spanish frigate of 26 guns was despatched from the province of Mexico, for the purpose of putting an end to this commerce. The Spanish frigate arrived in May 1789, and captured two English vessels in the following July, at the same time taking possession of the little settlement which had been formed upon the coast. Such, in short, is the circumstance which was likely to involve us in an expensive war. Happily, however, for both countries, and perhaps for Europe, the matter was at length, after great altercation, amicably settled; and it must still be so fresh in the memories of our readers, that we trust they will excuse us from enlarging further upon it—the whole article having extended perhaps to more than a sufficient length.

Nootka Sound || Nordheim.

NOPAL, RAQUETTE, or *Indian fig;* plants so named by the Indians, on which the cochineal insect breeds in Mexico. See COCHINEAL, DYEING *Index*.

NOPALXOCHQUETZALLI, or NOPALCOCHQUETZALLI, the prickly pear of Mexico, which is common over all the West Indies. See CACTUS, BOTANY *Index*.

NOPH. See MEMPHIS.

NORBURY, a town of Staffordshire, in England, on the south-west side of Eccleshall. Here is a surprising echo, which, taken 440 yards north-east from the manor house, near a little bank under a wood side, repeats in a still day 10 or 11 syllables very distinctly, or 12 or 13, if spoke very quick. It is remarked that the banks of the Black Meer, in this parish, grow forward every year over the surface of the water at the rate of three or four yards every seven years.

NORDEN, FREDERIC LEWIS, an ingenious traveller and naval officer in the Danish service, was born at Gluckstadt in Holstein in the year 1708. He was well skilled in mathematics, ship-building, and especially in architecture; and in 1732 obtained a pension to enable him to travel for the purpose of studying the construction of ships, particularly the galleys and other rowing vessels used in the Mediterranean. He spent near three years in Italy: and Christian VI. being desirous of obtaining a circumstantial account of Egypt, Mr Norden while at Florence received an order to extend his travels to that country. How he acquitted himself in this commission, appears from his Travels into Egypt and Nubia, printed at Copenhagen in folio, 1756; and which were soon after translated into English by Dr Peter Templeman. In the war between England and Spain, Mr Norden, then a captain in the Danish navy, attended Count Ulric Adolphus, a sea captain, to England; and they went out volunteers under Sir John Norris, and afterwards under Sir Chaloner Ogle. During his stay in London, Mr Norden was made a fellow of the Royal Scoiety, and gave the public drawings of some ruins and colossal statues at Thebes in Egypt, with an account of the same in a letter to the Royal Society, 1741. His health at this time was declining; and taking a tour to France, he died at Paris in 1742.

NORDHEIM, a town in Germany, in the Hanover quarter. Of the four larger towns of this principality, it is the third in order. It is situated on the Ruhme,

Ruhme, which runs into the Leine. It contains 500 houses, and, besides a secularized Lutheran abbey, has one parish church, some charitable foundations, and also some manufactures. E. Long. 9. 58. N. Lat. 51. 40.

NORES, JASON DE, a scholar, poet, and philosopher, was born at Nicosia in Cyprus. He lost his fortune when the Turks made themselves masters of that island in 1570. He retired to Padua; where he acquired great reputation by teaching moral philosophy. His character had that cast of severity which is often the consequence of scholastic habits. He was one of those men who discuss every thing without being capable of feeling any thing. The *Pastor Fido* of Guarini made its appearance; and pastorals became a fashionable species of reading throughout all Italy. Nores, who did not relish works of this kind, attacked the production of Guarini; who entirely confuted him in a little piece printed at Ferrara in 1588. Nores made a reply two years after; and the poet was preparing an answer still more severe than the former, when his antagonist died of grief, occasioned by the banishment of his only son for having killed a Venetian in a duel. He left behind him a great many works, some in Italian, and others in Latin. The chief of his Italian works, are, 1. The Poeticks, Padua, 1588, 4to; this edition is rare. 2. A Treatise on Republics, 1578, 4to; which he forms on the model of that of the Venetians, his masters. 3. A Treatise on the World and its Parts, Venice, 1571, 8vo. 4. Introduction to three books of Aristotle's Rhetoric, Venice, 1548, 4to, valuable. 5. A Treatise on what Comedy, Tragedy, and Epic Poetry, may receive from Moral Philosophy. His Latin works are, 1. *Institutio in Philosophiam Ciceronis*, Padua, 1576, 8vo. 2. *Brevis et distincta summa præceptorum de arte discendi, ex libris Ciceronis collecta*, Venice, 1553, 8vo; a good work. 3. *De Constitutione partium humanæ et civilis philosophiæ*, 4to. 4. *Interpretatio in artem poeticam Horatii*, &c. In all his works we remark great perspicuity and accuracy, profound erudition, happy expressions, an elevated and sometimes forcible style.—His son Peter Nores, successively secretary to several cardinals, at once a man of letters and a man of business, left behind him different manuscripts; among others, the life of Paul IV. in Italian.

NORFOLK, a county of England, so called from its northern situation in respect of Suffolk, is bounded on the east and north by the German ocean; on the south by Suffolk, from which it is parted by the rivers Waveney and the Lesser Ouse; and on the west it is separated from Cambridgeshire by the Greater Ouse, and from a small part of Lincolnshire by the Washes. According to Templeman, it extends in length 57 miles, in breadth 35, and 140 in circumference. It contains an area of 1426 square miles, one city, 32 market towns, 711 villages. In 1811 it contained 52,807 houses, and 291,999 inhabitants, of whom 100,410 were in towns, and 191,589 in the country. It is divided into 31 hundreds, 164 vicarages, and 660 parishes.

The air differs in different parts of the county according to the soil, which in some places is marshy, especially on the sea coast, and there the air is foggy and unwholesome; in others it is clayey and chalky, poor, lean, and sandy, and there the air is good. The county is almost all champaign, except in some places, where rise gentle hills. The marsh lands yield rich pasture for cattle; the clay grounds pease, rye, and barley; and the sandy heaths feed vast flocks of large sheep, of which some villages are said to keep 4000 or 5000. These heaths abound also in rabbits of a silver gray colour. Walsingham is noted for producing the best saffron. Great quantities of mackarel and herring are caught upon the coasts of this county, the former in the spring, and the latter in September; especially at Yarmouth, where they are cured in a particular manner, and to great perfection. Wood and honey are also very plentiful in this county; and on the coasts jet and ambergrease are sometimes found. The inhabitants are generally strong and active, sagacious and acute. That they are so robust, is the more to be wondered at, because the common people live much on puddings, *Norfolk dumplings*. They are for the most part in easy circumstances, and were formerly very quarrelsome and litigious. In consequence of this disposition, lawyers swarmed among them to such a degree, that a statute was made so early as the reign of Henry VI. to restrain their number. The manufactures of the county, which is exceedingly populous, are chiefly woollen and worsted stuffs and stockings, for which they are well supplied with wool from the vast flocks of sheep bred in it. It gives title of duke to the elder branch of the family of Howard, lies in the diocese of Norwich, and sends twelve members to parliament, viz. two knights for the shire, two citizens for Norwich, and two burgesses for each of the boroughs of Lynn Regis, Great Yarmouth, Thetford, and Castle-rising.

The county is well watered, and supplied with fish by the rivers Yare, Thyrn, Waveney, the Greater and Lesser Ouse, and the Bure, besides rivulets. The Bure abounds in excellent perch, and the Yare has a fish peculiar to it called the *ruffe*. The latter rises about the middle of the county; and after being joined by the Waveney and Bure, falls into the sea at Yarmouth. At the equinoxes, especially the autumnal, the Ouse is subject to great inundations, being forced back by the sea, that enters it with great fury. See NORFOLK, SUPPLEMENT.

NORFOLK, the most considerable seaport in the state of Virginia in North America. It is situated on the east side of Elizabeth river, which flows into the Chesapeake, and has an excellent harbour. It is well built, with wide paved streets, running in right lines, and contained in 1817 about 10,000 inhabitants, of whom one third were slaves. W. Long. 76. 10. N. Lat. 36. 5.

NORFOLK Island, a small island of the South sea, lying in 29° 12′ 30″ south latitude, and 168° 16′ east longitude. A colony was lately settled on it; and the following account of it is given in *Governor Philips's Voyage to Botany Bay*, &c.

"Norfolk island is about seven leagues in circumference; and if not originally formed, like many other small islands, by the eruption of volcanic matter from the bed of the sea, must doubtless have contained a volcano. This conclusion is formed from the vast quantity of pumice stone which is scattered in all parts of it, and mixed with the soil. The crater, or at least some traces of its former existence, will probably be found at the summit of a small mountain, which rises

Norfolk Island.

rises near the middle of the island. To this mountain the commandant has given the name of *Mount Pitt*. The island is exceedingly well watered. At or near Mount Pitt rises a strong and copious stream, which flowing through a very fine valley, divides itself into several branches, each of which retains sufficient force to be used in turning mills; and in various parts of the island springs have been discovered.

"The climate is pure, salubrious, and delightful; preserved from oppressive heats by constant breezes from the sea, and of so mild a temperature throughout the winter, that vegetation continues there without interruption, one crop succeeding another. Refreshing showers from time to time maintain perpetual verdure: not indeed of grass, for none has yet been seen upon the island; but of the trees, shrubs, and other vegetables, which in all parts grow abundantly. On the leaves of these, and of some kinds in particular, the sheep, hogs, and goats, not only live, but thrive and fatten very much. To the salubrity of the air every individual in this little colony can bear ample testimony, from the uninterrupted state of good health which has been in general enjoyed.

"When our settlers landed, there was not a single acre clear of wood in the island, and the trees were so bound together by that kind of creeping shrub called *supple jack*, interwoven in all directions, as to render it very difficult to penetrate far among them. The commandant, small as his numbers were at first, by indefatigable activity, soon caused a space to be cleared sufficient for the requisite accommodations, and for the production of esculent vegetables of all kinds in the greatest abundance. When the last accounts arrived, three acres of barley were in a very thriving state, and ground was prepared to receive rice and Indian corn. In the wheat there had been a disappointment, the grain that was sown having been so much injured by the weevil as to be unfit for vegetation. But the people were all at that time in commodious houses; and, according to the declarations of Mr King himself, in his letters to Governor Philip, there was not a doubt that this colony would be in a situation to support itself entirely without assistance in less than four years; and with very little in the intermediate time. Even two years would be more than sufficient for this purpose, could a proper supply of black cattle be sent.

"Fish are caught in great plenty, and in the proper season very fine turtle. The woods are inhabited by innumerable tribes of birds, many of them very gay in plumage. The most useful are pigeons, which are very numerous; and a bird not unlike the Guinea fowl, except in colour (being chiefly white), both of which were at first so tame as to suffer themselves to be taken by hand. Of plants that afford vegetables for the table, the chief are cabbage palm, the wild plantain, the fern tree, a kind of wild spinage, and a tree which produces a diminutive fruit, bearing some resemblance to a currant. This, it is hoped, by transplanting and care, will be much improved in size and flavour.

"But the productions which give the greatest importance to Norfolk Island are the pines and the flax plant; the former rising to a size and perfection unknown in other places, and promising the most valuable supply of masts and spars for our navy in the East Indies; the latter not less estimable for the purposes of making sailcloth, cordage, and even the finest manufactures, growing in great plenty, and with such luxuriance as to attain the height of eight feet. The pines measure frequently 160, or even 180 feet in height, and are sometimes 9 or 10 feet in diameter at the bottom of the trunk. They rise to about 80 feet without a branch; the wood is said to be of the best quality, almost as light as that of the best Norway masts; and the turpentine obtained from it is remarkable for purity and whiteness. The fern tree is found also of a great height for its species, measuring from 70 to 80 feet, and affords excellent food for the sheep and other small cattle. A plant producing pepper, and supposed to be the true oriental pepper, has been discovered lately in the island, growing in great plenty; and specimens have been sent to England in order to ascertain this important point."

Norfolk Island ‖ Noria.

Norfolk Sound, according to the account of Captain George Dixon, is situated in 57° 3′ north latitude, and 135° 36′ west longitude. It is a very extensive place, but how far it stretches to the northward is not known. There may possibly be a passage through to the Bay of Islands, but neither is this certain. The shore, in common with the rest of the coast, abounds with pines; there are also great quantities of the witch hazel. There are various kinds of flowering trees and shrubs, wild goosberries, currants, and raspberries; and parsley is found here in great plenty, and it eats excellently either as a salad or boiled amongst soup. The saranne, or wild lily root, grows also in great plenty and perfection. There are a very few wild geese or ducks seen here, but they are shy and difficult of approach.

NORHAM, a town in England, in the county of Northumberland, on the river Tweed, near the mouth of the Till, under the castle, which was anciently erected on a steep rock moated round, for the better security against the incursions of the Scotch moss troopers. It is of great antiquity; and its old church has lately received repairs, and been made a decent place of worship. Antiquities have been discovered here. The church had the privilege of a sanctuary. The castle has been frequently honoured with the presence of sovereigns, particularly Edward I. here received the oath of treaty from John Baliol of Scotland. It has been a formidable structure, a great part of which is in ruins; the site of which, with its demesnes, consisted of 1030 acres.

NORIA, a hydraulic machine much used in Spain. It consists of a vertical wheel of 20 feet diameter, on the circumference of which are fixed a number of little boxes or square buckets, for the purpose of raising the water out of the well, communicating with the canal below, and to empty it into a reservoir above, placed by the side of the wheel. The buckets have a lateral orifice to receive and to discharge the water. The axis of this wheel is embraced by four small beams, crossing each other at right angles tapering at the extremities, and forming eight little arms. This wheel is near the centre of the horse walk contiguous to the vertical axis, into the top of which the horse beam is fixed: but near the bottom it is embraced by four little beams, forming eight arms similar to those above described, on the axis of the water wheel. As the mule which they use goes round,

round, these horizontal arms, supplying the place of cogs, take hold, each in succession, of those arms which are fixed on the axis of the water wheel, and keep it in rotation.

This machine, than which nothing can be cheaper, throws up a great quantity of water; yet undoubtedly it has two defects: the first is, that part of the water runs out of the buckets and falls back into the well after it has been raised nearly to the level of the reservoir: the second is, that a considerable proportion of the water to be discharged is raised higher than the reservoir, and falls into it only at the moment when the bucket is at the highest point of the circle, and ready to descend.

Both these defects might be remedied with ease, by leaving these square buckets open at one end, making them swing on a pivot fixed a little above their centre of gravity, and placing the trough of the reservoir in such a position as to stop their progress whilst perpendicular; make them turn upon their pivot, and so discharge their contents.

From the reservoir the water is conveyed by channels to every part of the garden; these have divisions and subdivisions on beds, lome large, others very small, separated from each other by little channels, into which a boy with his shovel or his hoe directs the water, first into the most distant trenches, and successively to all the rest, till all the beds and trenches have been either covered or filled with water.

Mr Townsend, from whom we have taken the above account, thinks, that on account of the extreme simplicity of this machine, it is an invention of the most remote antiquity. By means of it the inhabitants every morning draw as much water from the well as will serve through the day, and in the evening distribute it to every quarter according to the nature of their crops. The reservoirs into which they raise the water are about 20, 30, or even 40 feet square, and three feet high above the surface of the ground, with a stone cope on the wall, declining to the water, for the women to wash and beat their clothes upon.

Our limits preclude us from following Mr Townsend farther in the description of a particular noria used at Barcelona; which he conceives to be the original chain pump, or at least its patent. He compares it with similar instruments, and shows its advantages and disadvantages.

NORICUM (Ptolemy, Tacitus); a Roman province, situated between the Danube on the north, and thus separated from ancient Germany; the Alpes Noricæ on the south; the river Ænus on the west, which separates it from Vindelicia; and Mons Cetius on the east, which divides it from Pannonia. Now containing a great part of Austria, all Saltzburg, Stiria, and Carinthia. It was anciently a kingdom under its own kings (Cæsar, Velleius, Suetonius). *Norici* the people, subdued by Tiberius under Augustus, as allies of the Pannonii (Dio, Velleius). Tacitus reckons Noricum among those provinces which were governed by procurators, officers sent by the emperors to receive and dispose of the public revenue according to order. It was divided into two provinces, but at what time uncertain; supposed as low down as Dioclesian and Constantine: *viz.* the *Noricum Ripense*, running along the south side of the Danube; and the *Noricum Mediterraneum*, extending towards the Alps. How far each of these extended in breadth does not appear: all the account we have of the matter being from Sextus Rufus, and the *Notitia Imperii Occidentalis*. Anciently a country famous for its iron and steel (Horace); as is Stiria at this day, a part of Noricum. A climate cold and more sparingly fruitful (Solinus).

NORIN, a river which rises in a corner of the Venetian confines, that runs between the rugged marble hills, and is left entirely to itself from its very source; hence a vast tract of land is overflowed by it, and encumbered with reeds, willows, and wild alders. A small space of ground only remains dry between the roots of the hills and the marsh at a place called *Prud*, and that is all covered with pieces of ancient hewn stones, fragments of inscriptions, columns, and capitals, and bass reliefs of the best age, worn and deformed by time, and the barbarism of the northern people, who begun on that side to destroy Narona. The inhabitants, who go often to cut reeds in the marsh, assert, that the vestiges of that large city may still be seen under water. It appears to have been extended over the plain a great way, and undoubtedly it was three miles in length at the foot of the hills. The ancient road is now under water; and it is necessary to ascend a very steep road, in order to pass the point of a craggy hill, on which, probably before the Roman times, those fortifications were erected that coast Vetinius so much labour.

NORIS, Henry, cardinal, a great ornament of the order of the monks of St Augustine, was descended from the president Jason, or James de Noris, and was born at Verona 1631. He was carefully educated by his father Alexander Noris, originally of Ireland, and well known by his history of Germany. He discovered from his infancy an excellent understanding, great vivacity, and a quick apprehension. His father instructed him in the rudiments of grammar, and procured an able professor of Verona, called *Massoleim*, to be his preceptor. At 15 he was admitted a pensioner in the Jesuits college at Rimini, where he studied philosophy; after which he applied himself to the writings of the fathers of the church, particularly those of St Augustine: and taking the habit in the convent of the Augustine monks of Rimini, he distinguished himself among that fraternity in a short time by his erudition: insomuch, that as soon as he was out of his noviciate or time of probation, the general of the order sent for him to Rome, in order to give him an opportunity of improving himself in the more solid branches of learning. He did not disappoint his superior's expectations. He gave himself up entirely to his study, and spent whole days, and even nights, in the library of the Angeliques of St Augustine. His constant course was to stick to his books 14 hours a day; and this course he continued till he became a cardinal. By this means he became qualified to instruct others; and on this errand he was first sent to Pezaro, and thence to Perousa, where he took his degree of doctor of divinity; after which, proceeding to Padua, he applied himself to finish his History of Pelagianism. He had begun it at Rome at the age of 26; and, having completed his design, the book was printed at Florence, and published in 1673. The great duke of Tuscany invited him the following year

to

Noris, Norkoping

to that city, made him his chaplain, and professor of ecclesiastical history in the university of Pisa, which his highness had founded with that view.

In his history he set forth and defended the condemnation pronounced, in the eighth general council, against Origen and Mopsuesta, the first authors of the Pelagian errors: he also added an account of the Schism of Aquileia, and a Vindication of the Books written by St Augustine against the Pelagians and Semi-Pelagians. The work had procured him a great reputation, but met with several antagonists, to whom he published proper answers: the dispute grew warm, and was carried before the sovereign tribunal of the inquisition. There the history was examined with the utmost rigour, and the author dismissed without the least censure. It was reprinted twice afterwards, and Mr Noris honoured by Pope Clement X. with the title of Qualificator of the Holy Office. Notwithstanding this, the charge was renewed against the Pelagian History, and it was dilated afresh before the inquisition in 1676; but it came out again with the same success as at first. Mr Noris was now suffered to remain in peace for sixteen years, and taught ecclesiastical history at Pisa, without any molestation, till he was called to Rome by Innocent XII. who made him under-librarian of the Vatican in 1692. This post was the way to a cardinal's hat; his accusers, therefore, took fresh fire, and published several new pieces against him. Hence the Pope appointed some learned divines, who had the character of having taken neither side, to re-examine Father Noris's books, and make their report of them. Their testimony was so advantageous to the author, that his holiness made him counsellor of the inquisition. Yet neither did this hinder one of his adversaries, the most formidable on account of his erudition, to rise up against him, and attack him warmly, under the assumed title of a *Scrupulous Doctor of the Sorbonne.* Noris tried to remove these scruples in a work which appeared in 1695, under the title of An Historical Dissertation concerning one of the Trinity that suffered in the Flesh; wherein, having justified the monks of Scythia, who made use of that expression, he vindicated himself also from the imputation of having attainted the Pope's infallibility, of having abused Vincentius Lirinensis, and other bishops of Gaul, as favourers of Semi-Pelagianism, and of having himself gone into the errors of the bishop of Ypres.

His answers to all these accusations were so much to the satisfaction of the pope, that at length his holiness honoured him with the purple in 1695. After this, he was in all the congregations, and employed in the most important affairs; so that he had little time to spend in his study, a thing of which he frequently complained to his friends. Upon the death of Cardinal Casanati, he was made chief library keeper of the Vatican in 1700; and two years afterwards nominated, among others, to reform the kalendar: but he died at Rome in 1704 of a dropsy. He was one of the most learned men in the last century; his writings abound with erudition, and are very elegantly finished. He was a member of the Academy; whence he assumed the name of Eucrates Agoretico. His works are numerous, and were published at Verona, in 1729 and 1730, in five volumes folio.

NORKOPING, a town of Sweden, in the province of East Gothland, in east longitude 15° 30′, latitude 58° 20.′ Its name signifies "the northern market," in the Swedish language. It stands on the banks of a large river called *Motala*, which coming from the lake *Vetter*, falls a little lower into a gulf called *Brawicken*. It is the largest and most populous town in Sweden, next to Stockholm, conveniently situated near the sea on a navigable river, which brings large vsssels up to the middle of the town. There are some handsome streets, and the houses in general are neatly built. Some of the churches are worth seeing; but the greatest curiosity are the famous copper mines, where there is a vast number of people constantly at work. In this article the town carries on a very good trade; as also in several other manufactures, as leather, steel, and guns, which they make the best in Sweden.

Norkoping, Normandy

It covers a large space of ground, being ten miles in circumference; but the houses are small and scattered, and the inhabitants do not exceed 10,000. The river Motala flows through the town, forms a series of cataracts, and is divided into four principal streams, which encircle several rocky islands, covered with houses and manufactories. At the extremity of the town it is navigable for small vessels. Several manufactories are established in the town; 55 fabrics of cloth, which employ 1500 men; 3 sugar-houses; 1 of snuff; 50 mills for grinding corn, which is exported in large quantities; and a brass foundery. A salmon fishery gives employment and riches to many of the inhabitants.

NORMANDY, a province of France, bounded on the north by the English channel; on the east by Picardy and the Isle of France; on the south by Perche and Maine, and one part of Bretagne; and on the west by the ocean. It is about 155 miles in length, 85 in breadth, and 600 in circumference. It includes nearly the whole of the departments of Lamanche, Calvados, Orne, Eure, and Seine Inferior. It abounds in all things except wine, but they supply that defect by cyder and perry. There are vast meadows, fat pastures, and the sea yields plenty of fish. It contains iron, copper, and a great number of rivers and harbours. It carries on a great trade, is very populous, and comprehends a vast number of towns and villages. It is divided into the Upper and Lower; the Upper borders upon Picardy, and the Lower upon Bretagne. It contains seven dioceses or bishoprics, Rouen, Bayeux, Avranches, Evreux, Sées, Lisieux, and Coutances, in which they compute 4189 parishes, and 80 abbeys. The inhabitants are ingenious, and capable of understanding any arts and sciences, but they are chiefly fond of law. The Normans, a people of Denmark and Norway, having entered France under Rollo, Charles the Simple ceded this country to them in 912, which from that time was called *Normandy*, and contains about 8200 square miles. Its chief city is Rouen. Rollo was the first duke, and held it as a fief of the crown of France, and several of his successors after him, till William, the seventh duke, conquered England in 1066: from which time it became a province of England, till it was lost in the reign of King John, and reunited to the crown of France; but the English still keep the islands on the coast.

The principal rivers are the Seine, the Eure, the Aure, the Iton, the Dive, the Andelle, the Rille, the Touque, the Drômec, and the Orne: among the sea ports, the principal are those of Dieppe, Havre, Honfleur, Cherburg, and Granville. Rouen is the principal city.

NORMANS, a fierce warlike people of Norway, Denmark, and other parts of Scandinavia. They at different times overran and ravaged most countries in Europe: to the respective histories of those countries we therefore refer for a fuller account of them, as it is impossible to enlarge upon particulars in this place without repeating what has been already said, or may be said, in different parts of this work.

Norman Characters, a species of writing introduced into England by William I. From some old manuscripts the Norman writing appears to have been composed of letters nearly Lombardic. In regal grants, charters, public instruments, and law proceedings, this character was used with very little variation from the reign of the Conqueror to that of Edward III. See Writing.

NORRIS, or Noris. See Noris.

NORTH, one of the four cardinal points of the world; being that point of the horizon which is directly opposite to the sun in meridian. The north wind is generally accompanied with a considerable degree of cold. It sometimes blows with almost irresistible fury. It is often mentioned by the classic authors under the name of *Boreas*, which is of Greek original. See Boreas.

North Pole. See Pole.

North, *Dudley*, *Lord*, the third baron of that accomplished family, was one of the finest gentlemen in the court of King James; but in supporting that character, dissipated and gamed away the greatest part of his fortune. In 1645, he appears to have acted with the parliament; and was nominated by them to be administrator of the admiralty, in conjunction with the great earls of Northumberland, Essex, Warwick, and others. He lived to the age of 85, the latter part of which he passed in retirement; and wrote a small folio of miscellanies, in prose and verse, under this title, A Forest promiscuous of several Seasons Productions, in four parts, 1659.

North, *Dudley*, *Lord*, son of the former, was made knight of the Bath in 1616, at the creation of Charles prince of Wales; and sat in many parliaments, till excluded by the prevailing party in that which condemned the king. From that period Lord North lived privately in the country, and towards the end of his life entertained himself with books, and, as his numerous issue required, with economy; on which he wrote a little tract, called *Observations and advices economical*, 12mo. His other works are, Passages relating to the long parliament; the history of the life of Lord Edward North, the first baron of the family, addressed to his eldest son; and a volume of Essays.

North, *Francis*, *Lord Guildford*, lord-keeper of the great seal in the reigns of Charles II. and James II. was a third son of the second Dudley lord North, baron of Kertling; and studied at St John's college in Cambridge, from whence he removed to the Middle Temple. He acquired French, Italian, Spanish, and Dutch; and became not only a good lawyer, but was well versed in history, mathematics, philosophy, and music. He was afterwards made the king's solicitor-general, and was chosen to represent the borough of Lynn in parliament. He succeeded Sir Heneage Finch in the post of attorney-general; and Lord Chief-Justice Vaughan, in the place of lord chief-justice of the common pleas. He was afterwards made keeper of the great seal; and in 1683 was created a baron by the title of *Lord Guildford*. He died at his house at Wroxton in 1685. He wrote a philosophical essay on music; a paper on the gravitation of fluids, considered in the bladders of fishes, printed in Lowthorp's abridgement of the Philosophical Transactions; and some other pieces.

North, Right Honourable *Frederick*, earl of Guildford, Lord North, lord warden and admiral of the Cinque Ports, governor of Dover castle, lord lieutenant and custos rotulorum of Somersetshire, chancellor of the university of Oxford, recorder of Gloucester and Taunton, an elder brother of the Trinity house, president of the Foundling hospital and of the Asylum, a governor of the Turkey Company and of the Charter house, K.G. and LL. D. was born April 13. 1732; and married, May 20. 1756, Miss Ann Speke, an heiress of the ancient family of Dillington in Somersetshire, by whom he has left two sons and three daughters: the eldest son George Augustus, born September 11. 1759, and married, September 30. 1785, to Miss Hobart, succeeds to the earldom and estates. The late earl succeeded his father August 4. 1790. His lordship succeeded the celebrated Mr Charles Townsend as manager of the house of commons and chancellor of the exchequer; and in 1770, on the resignation of the duke of Grafton, was made first lord of the treasury; in which office he continued until the close of the American war, or rather until the formation of the Rockingham ministry, which began the business of peace with the colonies. He was a man of strong mental faculties; and as an orator, at once commanded attention and enforced conviction: but taking the helm at a time when the king's party were unpopular, and when it was supposed that the late earl of Bute was the great machine by which the cabinet was moved, he continued in that state of unpopularity until he resigned the seals. During the whole of his premiership (and to conduct the helm at that time required uncommonly great abilities) he studiously avoided imposing any taxes that should materially affect the lower class of people. The luxuries, and not the necessaries, of life were repeated objects of his budget. As a financier, he stood high, even in the opinion of opposition; and they were a combination of all the great talents in the kingdom: but, fatally wedded to the destructive plan of subduing the republican spirit of the Americans, his administration will not only stand marked in the page of history with an immense waste of public treasure, but it will appear besprinkled with the kindred blood of thousands of British subjects. To the very last moment he spoke in the senate, however, he defended that war; and said, he was then, as he was formerly, prepared to meet the minutest investigation as to his conduct in that business; which nothing but the unforeseen intervention of France could have prevented from being crowned with success. His lordship was one of the firmest and most strenuous supporters of the constitution in church and state. He died on the 5th of August 1792. His recollection he retained to his last moments: his family, except Lord North, who came within a few minutes afterwards, were assembled round his bed, and he took leave of them individually. Their grief did not suffer them to leave the room for some time after the event;

event; and Lady Caroline Douglas was at last forced from it. Even Dr Warren, who must be strengthened as far as habit can operate against nature to endure such scenes, ran from this, convulsed with sorrow. If any extent of sympathy can lessen affliction, this family may find such relief; for perhaps no man was ever more generally beloved by all who had access to him than the earl of Guildford.

We may form an opinion of the estimation the celebrated university of Oxford entertained of their chancellor while living, by the very great honour they paid to his remains. About five o'clock in the afternoon of the 15th, the great bell at St Mary's church at Oxford rang out, which was a signal that the funeral procession had arrived in the environs of that city. The officers of the university, and the whole body of resident students, were previously assembled in Magdalen College, in order to pay some tribute to the memory of their deceased chancellor. They joined the procession at Magdalen Bridge, and paraded on foot before the herse up the high street to Carfax; from thence down the corn market to St Giles's church at the town's end, in a most solemn manner. Here they halted, and opening to the right and left, the herse and other carriages passed through, the whole university being uncovered. The herse and attendants then proceeded to Banbury, where his lordship's remains were deposited in the family vault.

North Cape, the most northerly promontory in Europe, on the coast of Norway. E. Long. 21. 0. N. Lat. 78. 0.

North Ferry, a small village, on the north side of the frith of Forth, at the Queen's Ferry passage. There was here formerly a chapel, served by the monks of Dunfermline, and endowed by Robert I. Near it are large whinstone quarries, which partly supply London with paving stones, and employ many vessels for the conveyance. "The granite (whinstone) (Mr Pennant says) lies in perpendicular strata, and above is a reddish earth, filled with micaceous friable nodules."

North Foreland, a cape or promontory of Kent, in the isle of Thanet, four miles east of Margate. Between this and the South Foreland are the Downs, through which all ships pass that are bound to or from the west. E. Long. 1. 25. N. Lat. 51. 25.

North-West Passage, a passage to the Pacific ocean through Hudson's bay or Davis's straits, and which hath been frequently attempted without success; notwithstanding which, many people are still of opinion that it is practicable.

The idea of a passage to the East Indies by the north pole, or through some opening near to it, was suggested as early as the year 1527. The person who had the honour to conceive this idea was Robert Thorne, a merchant of Bristol, who addressed two papers on the subject, the one to King Henry VIII. the other to Dr Ley, ambassador from that monarch to the emperor Charles V. To remove any objection to the undertaking, which might be drawn from the supposed danger, he insists, in his address to the king, upon the great advantages of constant daylight in the polar seas, and the probability of the climate being in those regions temperate during the summer months. In the paper addressed to Dr Ley, he observes that cosmographers may as probably be mistaken in the opinion which they entertain of the polar regions being impassable from extreme cold, as it has been found they were in supposing the countries under the line to be uninhabitable from excessive heat.

The possibility of the passage was, in consequence of these addresses, very generally supposed; and in 1557, Sir Martin Forbisher sailed to 62° north latitude, where he discovered the straits which have since borne his name. In 1577, Barne, in a book entitled the *Regiment of the Sea*, mentions a north-west passage as one of the five ways to Cathay; and dwells on the mildness of the climate, which, from the constant presence of the sun during summer, he imagines must be found near the pole. In 1578, George Best, a gentleman who had been with Sir Martin Forbisher in his voyages of discovery, wrote a very ingenious discourse to prove all parts of the world habitable. It does not, however, appear that any voyage was undertaken, for the express purpose of attempting to sail to India in a north-west direction, till the year 1607; when Henry Hudson was sent, at the expence of some merchants in London to discover a passage by the north pole to Japan and China. He sailed from Gravesend on the 1st of May, and on the 21st of June fell in with the land to the westward, in latitude 73°, which he named *Hold-with-hope*. On the 27th he discovered Spitsbergen, and met with much ice. The highest latitude in which he made an observation was 80° 27′. See Hudson.

In March 1609, Jones Poole was sent by Sir Thomas Smith, and the rest of the Muscovy Company, to make further discoveries towards the north pole. After great severity of weather, and much difficulty from ice, he made the south part of Spitsbergen on the 16th of May; and sailing along and sounding the coast, he made many accurate discoveries; but was not in that voyage able to proceed beyond 79° 50′. He was again employed (1611), in a small vessel called the *Elizabeth*, to attempt the north-west passage; but after surmounting numberless difficulties, and penetrating to 80° of latitude, he lost his ship at Spitsbergen. Two voyages, equally unsuccessful, were made in 1614 and 1615, by Baffin and Fotherby; the latter of whom concludes the account of his discoveries and dangers, with exhorting the company which employed him not to adventure more than 150l. or 200l. at most on yearly voyages to these seas.

Hitherto nothing had been done in this great undertaking but by private adventurers, fitted out for the double purpose of discovery and present advantage; and the polar regions were suffered to remain unexplored in that direction, from the year 1615 till 1773, when the earl of Sandwich, in consequence of an application which had been made to him by the Royal Society, laid before his majesty a proposal for an expedition to try how far navigation is practicable towards the north pole. Upon receiving this proposal, his majesty was pleased to direct that the voyage should be immediately undertaken, with every assistance that could contribute to its success. Accordingly, the Racehorse and Carcass bombs were fitted out for the purpose, and the command of the expedition given to Captain Phipps, now Lord Mulgrave. His Lordship's instructions were to proceed up to the pole, or as far towards it as possible, and as nearly upon a meridian as the ice or other obstructions should admit; and during the course of the voyage, to make such observa-

North-west Passage.

tions of every kind as might be useful to navigation, or tend to the promotion of natural knowledge. A very accurate account of this voyage was published by his Lordship in 1774. He had, by exerting all the powers of a skilful and intrepid seaman, forced his way, on the 1st of August, to 80° 37′; but could proceed no farther, as he was there opposed by one continued plain of smooth unbroken ice, bounded only by the horizon.

Many other attempts have been made to discover this passage, by sailing along the western coast of America; but hitherto none of them has been crowned with success. So early as 1579, Sir Francis Drake assured Queen Elizabeth that he had sailed some leagues up the straits of Anian (see ANIAN), and discovered New Albion, to the north of California; but the strait is now known to have no existence; and Drake's real discoveries were not improved. In 1638, King Charles I. sent Captain Luke Fox in one of his pinnaces to attempt the passage; but of his proceedings we know nothing, but that he reached Port Nelson in Hudson's bay, where he found some remains of former navigators. Next year Captain James was fitted out by the merchants of Bristol for the same purpose. James was one of the ablest navigators that ever sailed from England or any other country; and his voyages to the north were printed in 1633. After all the experiments he had made, he concluded that there was no such passage; or if there be, he affirmed that the discovery of it would not be attended with those advantages which are commonly expected. His reasons, however, for these opinions have been answered, and many subsequent attempts have been made to perform what he thought impossible. The arguments for a north-west passage were so plausible, that in 1744, an act of parliament was passed to encourage the discovery of it. Among many others, Captain Cook attempted the discovery in vain, and thence adopted James's opinion. (See *COOKE's Discoveries*, N° 103.). This celebrated navigator, after having proceeded northwards to the western extremity of America, and ascertained the proximity of the two great continents of Asia and America, returned to the Sandwich islands, firmly persuaded of the impracticability of a passage in that hemisphere from the Atlantic into the Pacific ocean, either by an eastern or a western course.

An attempt was made by Vancouver between the years 1790 and 1795; but the result of this voyage renders the existence of such a passage still more doubtful.

The last attempt to discover this passage was made in 1818. The two ships employed, the Isabella, Captain Ross, and the Alexander, Lieutenant Parry, sailed from the Thames on the 18th April. They reached Cape Dudley Diggs on the 17th August, and afterwards passed Smith's sound and Whale sound, but found the coast in many parts unapproachable from ice. Jones's sound was explored, but no appearance of a passage found. From this they followed the line of the coast southward till they came, on the 30th August, to Lancaster sound, which at first presented appearances favourable to their hopes, but on examination land was found to extend across its bottom. Several other inlets were observed, but all blocked up with ice. The sea was generally of great depth, and the coast mountainous; and where bays occurred they were still backed by high land. On the 1st October they reached Cumberland strait, which, from the current at its entrance, afforded, in Captain Ross's opinion, a better chance of a passage than any other place; but their instructions and the lateness of the season would not allow them to explore it. The expedition arrived at Shetland on the 30th October, having coasted the whole of Baffin's bay, but generally at a considerable distance from the shore, without discovering the passage sought. It appears also, from Captain Ross's journal, that the supposed current setting southward from the bay, which was one chief reason for inferring the reality of the passage, does not exist. Since Captain Ross's return, however, strong objections have been raised to the accuracy of his survey in some points; and for this and other reasons, a new expedition is preparing, with the view of exploring the coast more minutely at those points where a passage is conceived to be most probable. A party is also to proceed by land from the north-western lakes of Canada, to ascertain the position of the coast towards the bay. It is highly probable, therefore, that the question will soon be set at rest. But what is known already shows that, were the passage discovered, the navigation can scarcely be at any time practicable, and the subject is no farther of importance than as it would settle a point in geography.

North-west Passage, North-east Passage.

NORTH-East Passage, a passage to the East Indies along the northern coasts of Asia, which, like the former, hath frequently been attempted, but hitherto without success. The first attempt was made in 1553, by Sir Hugh Willoughby, who commanded three ships. He departed from the Thames, and sailed to the North Cape, where one of his ships left him, and returned home. The other two ships being separated, Sir Hugh proceeded farther northward, and discovered that part of Greenland which the Dutch have since called *Spitzberg*: but the severity of the cold obliging him to return to the southward, he was forced, by bad weather, into the river Arzina, in Muscovite Lapland, where, not being able to come out, he was found the next spring frozen to death, with all his ship's company; having the notes of his voyage and his last will lying before him, whereby it appeared that he lived till January. But Richard Chancellor, in the third ship, with better success, in the meanwhile entered Wardhuys, where he waited some time for his companions to no purpose; uncertain whether they were lost, or driven farther by stress of weather. He held a council on what he should do; whether to return, or pursue his voyage. Whatever danger might be in the last, every one agreed to it, that they might not seem to have less courage than their captain. They therefore set sail, and in a few days found themselves in a sea where they could no longer perceive any night. This ship, wandering about, entered soon after into a large bay or gulf. Here they cast anchor, in sight of land; and while they were examining the coast, they discovered a fishing boat. Chancellor getting into his sloop, went towards it; but the fishermen took to flight. He followed, and, overtaking them, showed them such civilities as conciliated their affections to him; and they carried him to the place where now is the famous port of St Michael the Archangel. These people immediately spread through all the coasts an account of the arrival of those strangers; and people came from several parts to see them, and ask them questions. They, in their turn, examined the others, and found

found that the country they were in was Russia, governed by the mighty emperor John Basilowitz. Chancellor from Archangel travelled on sledges to the Czar at Moscow; from whom, overjoyed at the prospect of opening a maritime commerce with Europe, he obtained privileges for the English merchants, and letters to King Edward VI. who was not, however, alive to receive them.

In 1585, Mr John Davis in two barks discovered Cape Desolation, which is supposed to be part of Greenland; and two years after advanced as far as Lat. 72°, where he discovered the strait which still bears his name. To enumerate all the attempts which have been made to discover a north-east passage, would swell the article to very little purpose. The English, Dutch, and Danes, have all attempted it without success. The last voyage from England for this purpose was made in 1676, under the patronage of the duke of York. That unfortunate prince, who was on all occasions earnest for the promotion of commerce, and the Lord Berkeley, &c. fitted out a ship, commanded by Captain Wood, for an attempt once more to find a north-east passage to India, accompanied with a ship of the king's. They were encouraged to this attempt, after it had been so long despaired of, by several new reports and reasonings: some of which seem not to have been very well grounded—As,

"1. On the coast of Corea, near Japan, whales had been found with English and Dutch harpoons sticking in them. This is no infallible proof that ships could get thither by a north-east passage, although whales might.

"2. That, 20 years before, some Dutchmen had sailed within one degree of the north pole, and found it temperate weather there: and that therefore William Barents, the Dutch navigator who wintered at Nova Zembla in the year 1596, should have sailed further to the north before turning eastward; in which case, said they, he would not have found so much obstruction from the ice.

"3. That two Dutch ships had lately sailed 300 leagues to the eastward of Nova Zembla; but their East India Company had stifled that design, as against their interest:—and such like other airy reports. But this attempt proved very unfortunate. They doubled the North Cape, and came among much ice and drift wood, in 76° of north latitude, steering to the coast of Nova Zembla, where the king's ship struck upon the rocks, and was soon beat to pieces; and Captain Wood returned home with an opinion, "that such a passage was utterly impracticable, and that Nova Zembla is a part of the continent of Greenland."

These passages, however, are not yet deemed impracticable by all. The count de Buffon holds it for certain, that there is such a passage; and he thinks, that if any farther attempts be made to discover a passage to China by the north, it will be necessary to steer directly towards the pole; and to explore the most open seas, where unquestionably, says he, there is little or no ice. This opinion has been revived by the honourable Daines Barrington. See *North Pole*.

NORTHALLERTON, a borough town of England, though not incorporated, in the north riding of Yorkshire. It sends two members to parliament. The population in 1811 was 2234. In 1138, the Scots army under King David was defeated by the English near this town. It is 34 miles S. from Durham, and 223 N. from London.

NORTHAMPTON, a town in England, capital of a county of the same name, situated in W. Long. 0. 55. N. Lat. 52. 15. According to Camden, it was formerly called *North-afandon*, from its situation to the north of the river Nen, called anciently *Aufona*, by which and another lesser river it is almost enclosed. Dr Gibson says, that the ancient Saxon annals called both it and Southampton simply *Hampton;* and afterwards, to distinguish them, called the one, from its situation, *Southampton*, and the other *Northampton;* but never *North-afandon*. Though it does not appear to be a place of very great antiquity, nor to have emerged from obscurity till after the Conquest, it has sent members to parliament since the reign of Edward I. and being in the heart of the kingdom, several parliaments have been held at it. There was also a castle, and a church dedicated to St Andrew, built by Simon de Sancto Licio, commonly called *Senlez*, the first earl of Northampton of that name. It is said to have been burnt down during the Danish depredations; but in the reign of St Edward it appears to have been a considerable place. It was besieged by the barons in their war with King John; at which time that military work called *Hunshill*, is supposed to have been raised. In the time of Henry III. it sided with the barons, when it was besieged and taken by the king. Here the bloody battle was fought in which Henry VI. was taken prisoner. It was entirely consumed by a most dreadful fire in 1675; yet, by the help of liberal contributions from all parts of the country, it hath so recovered itself, that it is now one of the neatest and best built towns of the kingdom. Among the public buildings, which are all lofty, the most remarkable are the church called *All-hallows* (which stands at the meeting of four spacious streets), the sessions and assize house, and the George inn, which belongs to the poor of the town. A county hospital or infirmary has been lately built here, after the manner of those of Bath, London, Bristol, &c. It has a considerable manufacture of shoes and stockings; and its fairs are noted for horses both for draught and saddle; besides, it is a great thoroughfare for the north and west roads. It was formerly walled, and had seven churches within and two without. The horse market is reckoned to exceed all others in the kingdom, it being deemed the centre of all its horse markets and horse fairs, both for saddle and harness, and the chief rendezvous of the jockies both from York and London. Its principal manufacture is shoes, of which great numbers are sent beyond sea; and the next to that, stockings and lace, as we have hinted at above. It is the richer and more populous, by being a thoroughfare both in the north and west roads; but, being 80 miles from the sea, it can have no commerce by navigation. The walls of this town were above two miles in compass. The number of inhabitants in 1811 was 8427. It had formerly a nunnery in the neighbouring meadows, with several other monasteries; and of its very old castle on the west side of the town, a small part of the ruins is still to be seen. Some discontented scholars came hither from Oxford and Cambridge, about the end of the reign of Henry III. and, with the king's leave, prosecuted their studies here academically for three years; during which there was the face of an university, till it was put a stop to by express prohibition, because it was a damage to both universities. The public horse races are on a neighbouring down, called *Pey-Leys*. In and about the town are abundance of cherry gardens. Within half a mile of the town is one of the crosses erected by King Edward I. in memory of his queen Eleanor, whose corpse was rested there in its way to Westminster. On the north side of the river, near that cross, many Roman coins have been ploughed up. At Guilesborough, north-west of Northampton, are to be seen the vestiges of a Roman camp, the situation of which is the more remarkable, as lying between the Nen and the Avon, the only pass from the north to the south parts of England not intercepted by any river. This camp was secured only by a single intrenchment, which was, however, very broad and deep.

NORTHAMPTONSHIRE, a county of England, is situated in the very heart of the kingdom: bounded on the east by the counties of Bedford and Huntingdon; on the south by those of Buckingham and Oxford; on the west by Warwickshire; and on the north by the counties of Leicester, Rutland, and Lincoln, which are separated from it by the Lesser Avon, and the Welland. Its greatest length is about 50 miles, its greatest breadth about 20, and its circumference about 130. It includes 336 parishes, one city, eleven market towns; and in 1811 contained 28,857 houses, and 141,353 inhabitants, of whom 34,741 live in towns, and 106,612 in the country. Nine members are returned to parliament for this county, viz. two knights for the shire, two for the city of Peterborough, two for each of the towns of Northampton and Brockly, and one for Higham Ferrers. It lies in the midland circuit, and in the diocese of Peterborough. As this county is dry, well cultivated, free from marshes, except the fens about Peterborough, in the centre of the kingdom, and of course at a distance from the sea, it enjoys a very pure and wholesome air. In consequence of this, it is very populous, and so full of towns and churches, that 30 spires or steeples may be seen in many places at one view; and even in the fens the inhabitants seem to enjoy a good state of health, and to be little affected by the water which frequently overflows their grounds, especially in winter, but is never suffered to remain long upon it. Its soil is exceeding fertile both in corn and pasturage; but it labours under a scarcity of fuel, as it doth not produce much wood, and by lying at a distance from the sea, cannot be easily supplied with coal. Its commodities, besides corn, are sheep, wool, black cattle, and saltpetre; and its manufactures are serges, tammies, shalloons, boots, and shoes. Besides many lesser brooks and streams, it is well watered by the rivers Nen, Welland, Ouse, and Lerm; the three first of which are large, and for the most part navigable. See NORTHAMPTONSHIRE, SUPPLEMENT.

NORTH ROCKS (otherwise called *St Patrick's rocks*, from a seat of stone amongst them called *St Patrick's chair*, whence the rocks have taken this second name); situated in the harbour of Donaghadee, in the county of Down, and province of Ulster, in Ireland. From north to south they are about two-thirds of a league, between which is clean good ground. But care must be taken of the south rock, on which many ships have perished: for it is overflowed by every tide, and no crew can save their lives if the wind blows high. This rock stands a full mile from the shore.

NORTH SEA. See *North Sea*.

NORTHERN LIGHTS, the same with AURORA BOREALIS, under which article we have given a copious account of this phenomenon, and of the supposed causes of it. Natural science, however, does not arrive at perfection at once, and it is well if it does so after trials repeated for years with care and accuracy. How far the causes that have been assigned for this appearance will account for it, or whether they will be able to remove all difficulties, it is not for us to determine; but it is the part of philosophers to hear all sides, and to attend with patient assiduity to every hypothesis, rejecting or receiving, as reason, after the strictest investigation, shall seem to favour the one side or the other. We shall here notice a hypothesis which Doctor Stearns, an American, formed, about the year 1788, to account for the appearances called *aurora borealis*, and *aurora australis*.

Doctor Stearns supposes that these phenomena originate from aqueous, nitrous, sulphureous, bituminous, and other exhalations, from the fumes of various kinds of earths or other minerals, vegetables, animals, fires, volcanoes, &c. These, he thinks, become rarefied, and being charged with electrical fluid, become specifically lighter than the circumambient air; hence, of course, they ascend; and being elevated to the upper regions of the air, and driven by the winds from warmer to colder climates, the cold makes them combine and stiffen. When they are afterwards agitated by different currents of air, they sparkle and crackle like the hairs of cats and other animals when stiffened with cold. This coruscation in quite cold atmospheres, and in those which are more temperate, appears in different positions in the horizon, zenith, or otherwise, according to the situation of the spectator, and the position of the elevated exhalations. The difference of colours the doctor supposes to arise from the different qualities of the articles combined, those of the most inflammable nature shining with the greatest lustre.

The doctor likewise tries to account for these lights not appearing, or but seldom appearing, in ancient times. The atmosphere, he thinks, was not impregnated with materials proper to produce them. He imagines that the increased consumption of fuel, in America in particular, the burning of volcanoes, and the approach of blazing stars, whose atmospheres have been so expanded by the sun's heat that part of them have fallen into the earth's atmosphere, and communicated to it new matter, have so changed and prepared our air, that whenever its consistence is proper, then, if the light of the sun and moon is not too powerful, the aurora borealis will appear.

NORTHUMBERLAND, the most northerly county of England, and formerly a distinct kingdom, is bounded on the north and west by the river Tweed, which divides it from Scotland, the Cheviot hills, and part of Cumberland; washed on the east by the German ocean; and separated from Durham on the south by the rivers Tyne and Derwent. This county, which gives

Northumberland. gives the title of *duke* to a nobleman, who married the daughter of Algernon duke of Somerset, whose mother was heiress of the Percy family, extends about 66 miles in length from north to south, and about 47 in breadth from east to west. It is remarkably populous, containing 12 market towns, 280 villages, and 460 parishes. The face of the country, especially towards the west, is roughened with huge mountains, the most remarkable of which are the Cheviot hills, and the high ridge called *Redesdale;* but the lands are level towards the sea side and the borders of Durham. The climate, like that of every other mountainous country in the neighbourhood of the sea, is moist and disagreeable: the air, however, is pure and healthy, as being well ventilated by breezes and strong gales of wind; and in winter mitigated by the warm vapours from the two seas, the Irish and the German ocean, between which it is situated. The soil varies in different parts of the county. Among the hills it is barren; though it affords good pasture for sheep, which cover those mountains. The low country, when properly cultivated, produces plenty of wheat, and all sorts of grain; and great part of it is laid out in meadow lands and rich enclosures. Northumberland is well watered with many rivers, rivulets, and fountains: its greatest rivers are the Tweed and the Tyne. The Tyne is composed of two streams called *South* and *North Tyne:* the first rises on the verge of Cumberland, near Alston moor; enters Northumberland, running north to Haltwhistle; then bends easterly, and receiving the two small rivers East and West Alon, unites above Hexham with the other branch, taking its rise at a mountain called *Fane-head* in the western part of the county, thence called *Tynedale;* is swelled in its course by the little river Shele; joins the Read near Billingham; and running in a direct line to the south-east, is united with the southern Tyne, forming a large river that washes Newcastle, and falls into the German ocean near Tynemouth.

In all probability the mountains of Northumberland contain lead ore and other mineralized metals in their bowels, as they in all respects resemble those parts of Wales and Scotland where lead mines have been found and prosecuted. Perhaps the inhabitants are diverted from inquiries of this nature, by the certain profits and constant employment they enjoy in working the coal pits, with which this county abounds. The city of London, and the greatest part of England, are supplied with fuel from these stores of Northumberland, which are inexhaustible, enrich the proprietors, and employ an incredible number of hands and shipping. About 658,858 chaldrons are annually shipped for London.

There are no natural woods of any consequence in this county; but many plantations belonging to the seats of noblemen and gentlemen, of which here is a great number. As for pot herbs, roots, salading, and every article of the kitchen garden and orchard, they are here raised in great plenty by the usual means of cultivation; as are also the fruits of more delicate flavour, such as the apricot, peach, and nectarine. The spontaneous fruits it produces in common with other parts of Great Britain, are the crab-apple, the sloe or bullace, the hazel nut, the acorn, hips, and haws, with the berries of the bramble, the juniper, wood strawberries, cranberries, and bilberries.

Northumberland raises a good number of excellent horses and black cattle, and affords pasture for numerous flocks of sheep; both the cattle and sheep are of a large breed, but the wool is coarser than that which the more southern counties produce. The hills and mountains abound with a variety of game, such as red deer, foxes, hares, rabbits, heathcock, grouse, partridge, quail, plover, teal, and woodcock: indeed, this is counted one of the best sporting counties in Great Britain. The sea and rivers are well stocked with fish; especially the Tweed, in which a vast number of salmon is caught and carried to Tynemouth, where being pickled, they are conveyed by sea to London, and sold under the name of *Newcastle salmon*.

The Northumbrians were anciently stigmatized as a savage, barbarous people, addicted to cruelty, and inured to rapine. The truth is, before the union of the two crowns of England and Scotland, the borders on each side were extremely licentious and ungovernable, trained up to war from their infancy, and habituated to plunder by the mutual incursions made into each kingdom; incursions which neither truce nor treaty could totally prevent. People of a pacific disposition, who proposed to earn their livelihood by agriculture, would not on any terms remain in a country exposed to the first violence of a bold and desperate enemy; therefore the lands lay uncultivated, and in a great measure deserted by every body but lawless adventurers, who subsisted by theft and rapine. There was a tract 50 miles in length and six in breadth, between Berwick and Carlisle, known by the name of the *debateable land*, to which both nations laid claim, though it belonged to neither; and this was occupied by a set of banditti who plundered on each side, and what they stole in one kingdom, they sold openly in the other: nay, they were so dexterous in their occupation, that by means of hot bread applied to the horns of the cattle which they stole, they twisted them in such a manner, that, when the right owners saw them in the market, they did not know their own property. Wardens were appointed to guard the marches or borders in each kingdom; and these offices were always conferred on noblemen of the first character for influence, valour, and integrity. The English border was divided into three marches, called the *east*, *west*, and *middle marches;* the gentlemen of the county were constituted deputy wardens, who held march courts, regulated the watches, disciplined the militia, and took measures for assembling them in arms at the first alarm: but in the time of peace between the two nations, they were chiefly employed in suppressing the insolence and rapine of the borderers. Since the union of the crowns, however, Northumberland is totally changed, both with respect to the improvement of the lands, and the reformation of the inhabitants. The grounds, being now secure from incursion and insult, are settled by creditable farmers, and cultivated like other parts of the kingdom. As hostilities have long ceased, the people have forgotten the use of arms; and exercise themselves in the more eligible avocations of peace, in breeding sheep and cattle, manuring the grounds, working at the coal pits, and in different branches of commerce and manufacture. In their persons they are generally tall, strong, bold, hardy, and fresh coloured; and though less unpolished than their ancestors, not quite so civilized as their southern

southern neighbours. The commonalty are well fed, lodged, and clothed; and all of them remarkably distinguished by a kind of *shibboleth* or *whurle*, being a particular way of pronouncing the letter R as if they hawked it up from the windpipe, like the cawing of rooks. In other respects, the language they speak is an uncouth mixture of the English and Scottish dialects. There is no material distinction between the fashionable people of Northumberland and those of the same rank in other parts of the kingdom; the same form of education will produce the same effects in all countries. The gentlemen of Northumberland, however, are distinguished for their industry, knowledge of rural affairs, and hospitality. The number of inhabitants in 1801 was reckoned at 157,101, and in 1811, 172,161.

A great number of Roman monuments have been found in this county; but the most remarkable are the remains of Hadrian's vallum and the wall of Severus. See *Adrian*, note (A), and *Severus's Wall*.

The most noted towns in Northumberland, are Newcastle, Morpeth, Alnwick, Berwick, Hexham, and North Shields. It sends two members to parliament. See Northumberland, Supplement.

NORTHWICK, a small town of Cheshire, long celebrated for its rock salt and brine pits. The stratum of salt lies about 40 yards deep; and some of the pits are hollowed into the form of a temple. The descent is through a dome, the roof supported by rows of pillars about two yards thick, and several in height; and when illuminated with a sufficient number of candles, they make a most magnificent appearance. Above the salt is a bed of whitish clay, (*Argilla cærula-cinerea*), used in making the Liverpool earthen ware; and in the same place is also dug a good deal of the gypsum, or plaster stone. The fossil salt is generally yellow and semipellucid, sometimes debased with a dull greenish earth; and is often found, but in small quantities, quite clear and colourless. The town is situated near the river Dane, and is tolerably handsome: it has a market on Fridays. Population in 1811, 1382. It is 20 miles north-east of Chester, and 173 north-west of London. W. Long. 2. 36. N. Lat. 53. 16.

NORTON, in Cheshire, a good modern alms-house, founded by P—y Brooke, Esq. on the site of a priory of canons regular of St Augustine, founded by William, son of Nigellus, A. D. 1135, who did not live to complete his design; for Eustace de Burgaville granted to Hugh de Catherine pasture for 100 sheep, in case he finished the church in all respects conformable to the intent of the founders. It was granted afterwards to R. Brooke, Esq.

NORTON'S SOUND, on the north-west coast of America, was discovered in Captain Cook's last voyage, and was so named in honour of Sir Fletcher Norton (Lord Grantley), a near relation of Mr afterwards Dr King. It extends as far as N. Lat. 64° 55′. There is no good station for ships, nor even a tolerable harbour in all the sound. Mr King, on his landing here, discerned many spacious valleys, with rivers flowing through them, well wooded, and bounded with hills of a moderate height. One of the rivers towards the north-west seemed to be considerable; and he was inclined to suppose, from its direction, that it discharged itself into the sea from the head of the bay. Some of his people, penetrating beyond this into the country, found the trees to be of a larger size the further they proceeded. E. Long. 197. 13. N. Lat. 64. 31.

NORWAY, a country of Europe (for the map see Denmark), lying between the 57th and 72d degrees of north latitude, and between the 5th and 31st degrees of longitude east from London; extending in length about 1000 miles, in a direct line from Lindefnaes, in the diocese of Christiansand, to the North Cape, at the extremity of Finmark. Its breadth, from the frontiers of Sweden westward to Cape Statt, may amount to about 300 miles; but from thence the country becomes gradually narrower towards the north. On the south it is bounded by the Schagen rock, or Categate, the entrance into the Baltic; on the east it is divided from Sweden by a long ridge of high mountains; and on the west and north it is washed by the northern ocean. In the southern part of Norway, the country is craggy, abrupt, and mountainous, diversified sometimes with fertile and even delightful spots. In these respects it resembles Switzerland: the prospects and the meteorological phenomena seem to be very similar. The range of the thermometer is of great extent; in the summer having risen to 88°, and in the winter fallen to —40°: in general it is between 80° and —22°.

Respecting the population of Norway it is difficult to attain to certainty. An author of some note (Coxe) seems to think it amounts to 750,000; but he appears to have over-rated it considerably.

The Norwegian peasants are free, well clothed, well lodged, spirited, active, frank, open, and undaunted. They are said to have a very considerable resemblance to the peasants of Switzerland. The soil is too thin for the plough: corn is therefore obtained from the neighbouring states; and the chief employment of the peasants of Norway is grazing. The following extract from Mr Coxe, being a description of the scene near Christiana, is not beside our purpose, and may not perhaps be disagreeable to our readers.

Coxe's Travels.

"As we approached Christiana, the country was more wild and hilly, but still very fertile and agreeable; and about two miles from the town we came to the top of a mountain, and burst upon as fine a view as ever I beheld. From the point on which we stood in raptures, the grounds laid out in rich enclosures, gradually sloped to the sea: below us appeared Christiana, situated at the extremity of an extensive and fertile valley, forming a semicircular bend along the shore of a most beautiful bay, which, being enclosed by hills, uplands, and forests, had the appearance of a large lake. Behind, before, and around, the inland mountains of Norway rose on mountains covered with dark forests of pines and fir, the inexhaustible riches of the north. The most distant summits were caped with eternal snow. From the glow of the atmosphere, the warmth of the weather, the variety of the productions, and the mild beauties of the adjacent scenery, I could scarcely believe that I was nearly in the 60th degree of northern latitude."

The coast of Norway, extending above 300 leagues, is studded with a multitude of small islands, affording habitation to fishermen and pilots, and pasture to a few cattle. They form an infinite number of narrow channels, and a natural barrier of rocks, which renders Norway inaccessible to the naval power of its enemies.

mies. Attempts of this kind are the more dangerous, as the shore is generally bold, steep, and impending; so that close to the rocks the depth of the sea amounts to 100, 200, or 300 fathoms. The perils of the north sea are moreover increased by sudden storms, sunk rocks, violent currents, and dreadful whirlpools. The most remarkable vortex on this coast is called *Moskoestrom*, from the small island Moskoe, belonging to the district of Lofoden in the province of Nordland. In time of flood, the stream runs up between Lofoden and Moskoe with the most boisterous rapidity; but in its ebb to the sea, it roars like a thousand cataracts, so as to be heard at the distance of many leagues. The surface exhibits different vortices; and if in one of these any ship or vessel is absorbed, it is whirled down to the bottom, and dashed in pieces against the rocks. These violent whirlpools continue without intervals, except for a quarter of an hour, at high and low water, in calm weather; for the boiling gradually returns as the flood or ebb advances. When its fury is heightened by a storm, no vessel ought to venture within a league of it. Whales have been frequently absorbed within the vortex, and howled and bellowed hideously in their fruitless endeavours to disengage themselves. A bear, in attempting to swim from Lofoden to Moskoe, was once hurried into this whirlpool, from whence he struggled in vain for deliverance, roaring so loud as to be heard on shore; but notwithstanding all his efforts, he was borne down and destroyed. Large trees being absorbed by the current are sucked down, and rise again all shattered into splinters. There are three vortices of the same kind near the islands of Ferroe.

Norway under the Danish government was divided into the four governments of Aggerhus, Bergen, Drontheim, and Wardhus, besides that of Bahus, which belonged to Sweden. The province of Aggerhus comprehends the south-east part of Norway, extending in length about 300 miles. Its chief towns are Christiana, the see of a bishop, suffragan to the metropolitan see of Drontheim, where the sovereign court of justice is held, in presence of the viceroy and the governor of the province; Aggerhus, about 15 miles to the south-west of Christiana; Frederickshall or Frederickstadt, in the siege of which Charles XII. of Sweden lost his life; Saltzberg, Tonsberg, Alleen, Hammar, and Hollen.

The government of Bergen lies in the most southerly and westerly part of Norway, including the city of the same name, which is an episcopal see, and a place of considerable trade; and Staffhanger, situated in the bay of Buckenfior, about 80 miles to the southward of Bergen. The third province, called *Drontheim* or *Trontheim*, extends about 500 miles along the coast; and is but thinly peopled. The chief town, Drontheim, seated on a little gulf at the mouth of the river Nider, is the only metropolitan see in Norway; and carries on a considerable trade in masts, deals, tar, copper, and iron. Leetstrand, Stronden, Scoerdale, Opdal, Romsdael, and Solendael, are likewise places of some traffic. The northern division of Drontheim, called the *sub-government of Salten*, comprehends the towns Melanger and Scheen. The province of Wardhus, extending to the North Cape, and including the islands, is divided into two parts; namely, Finmark and Norwegian Lapland. The chief town, which is very inconsiderable, stands upon an island called *Ward*, from whence the place and the government derive their name. The province of Bahus, though now yielded to the Swedes, is reckoned part of Norway, being a narrow tract of land, about 90 miles in length, lying on coast of the Categate.

The great chain of Norway mountains, running from north to south, called indifferently *Rudfield*, *Sudefield*, *Skarsfield*, and *Scoreberg*, is known in different parts by other appellations; such as *Dofrefield*, *Lamsfield*, *Sagnifield*, *Filefield*, *Halnefield*, *Hardangerfield*, *Joklefield*, *Byglefield*, *Hicklefield*, and *Hangfield*. The height and breadth of this extensive chain likewise vary in different parts. To pass the mountain Hardanger, a man must travel about 70 English miles, wheras Filefield may be about 50 over. This last rises about two miles and a half in perpendicular height; but Dofrefield is counted the highest mountain of Norway, if not of Europe. The river Drivane winds along the side of it in a serpentine course so as to be met nine times by those who travel the winter road to the other side of the chain. The bridges are thrown over roaring cataracts, and but indifferently fastened to the steep rocks on either side; so that the whole exhibits a very dreadful appearance, sufficient to deter the traveller from hazarding such a dangerous passage; for which reason, people generally choose the road over Filefield, which is much more tedious. This, however, is the post road used by the king's carriages. The way is distinguished by posts fixed at the distance of 200 paces from each other, that, in snowy or dark weather, the traveller may not be bewildered. For the convenience of resting and refreshing, there are two mountain stoves or houses maintained on Filefield, as well as upon other mountains, at the expence of the public, and furnished with fire, light, and kitchen utensils. Nothing can be more dismal and dreary than those mountains covered with eternal snow, where neither house, tree, nor living creature is to be seen, but here and there a solitary rein deer, and perchance a few wandering Laplanders.

In travelling from Sweden to Nordenfields, there is only one way of avoiding this chain of mountains; and that is, where it is interrupted by a long deep valley, extending from Romsdale to Guldbrandsdale. In the year 1612, a body of 1000 Scots, commanded by Sinclair, and sent over as auxiliaries to the Swedes, were put to the sword in this defile, by the peasants of Guldbrand, who never give quarter.

Besides this chain, there is a great number of detached mountains over all the country, that form valleys and ridges, inhabited by the peasants. Some of these are of incredible height, and others exhibit very remarkable appearances. In sailing up Joering Creek on the left hand, the sight is astonished with a group of mountains, resembling the prospect of a city, with old Gothic towers and edifices. In the parish of Oerskong is the high mountain Skopshorn, the top of which represents the figure of a fortification, with regular walls and bastions. In the district of Hilgeland appears a very high range of mountains, with seven pinnacles or crests, known by the appellation of the *Seven Sisters*, discernible a great way off at sea. To the southward of this range, though in the same district, rises the famous mountain *Torghatten*, so called because the summit resembles a man's head with a hat on, under which appears a single eye, formed by an aperture through the mountain, Norway. mountain, 150 ells high, and 3000 ells in length. The sun may be seen through this surprising cavity, which is passable by the foot of travellers. On the top of the mountain we find a reservoir of water, as large as a moderate fish pond: in the lower part is a cavern, through which a line 400 fathoms in length, being let down, did not reach the bottom. At Herroe in Sundmoer is another cavern called *Dolsteen*, supposed to reach under the sea to Scotland; which, however, is no more than an idle tradition. In the year 1750, two clergymen entered this subterranean cavity, and proceeded a considerable way, until they heard the sea dashing over their heads: the passage is as wide and high as an ordinary church, the sides perpendicular, and the roof vaulted. They descended one flight of natural stairs; but arriving at another, they were afraid to penetrate farther: they had gone so far, however, that two candles were consumed in their progress and return. A cavern of a very curious nature, serving as a conduit to a stream of water, penetrates through the sides of the mountain Limur. In the district of Rake, in the neighbourhood of Fredrickshall, are three cavities in a rock; one of which is so deep, that a small stone dropped down does not reach the bottom in less than two minutes; and then the sound it produces is pleasant and melodious, not unlike the sound of a bell.

The vast mountains and rugged rocks that deform the face of this country are productive of numberless inconveniences. They admit of little arable ground: they render the country in some parts impassable, and everywhere difficult to travellers: they afford shelter to wild beasts, which come from their lurking holes, and make terrible havock among the flocks of cattle: they expose the sheep and goats, as well as the peasants, to daily accidents of falling over precipices: they occasion sudden torrents, and falls of snow, which descend with incredible impetuosity, and often sweep away the labours of the husbandman; and they are subject to dreadful disruptions, by which huge rocks are rent from their sides, and, hurling down, overwhelm the plains below with inevitable ruin. The peasants frequently build their houses on the edge of a steep precipice, to which they must climb by ladders, at the hazard of their lives; and when a person dies, the corpse must be let down with ropes, before it can be laid in the coffin. In winter the mail is often drawn up the sides of steep mountains. Even in the king's road, travellers are exposed to the frequent risks of falling over those dreadful rocks; for they are obliged to pass over narrow pathways, without rails or rising on the sides, either shored up with rotten posts, or suspended by iron bolts fastened in the mountains. In the narrow pass of Naeroe is a remarkable way of this kind, which, above 600 years ago, the famous King Surre caused to be made for the passage of his cavalry; and even this would have been found impassable by any other horses than those of Norway, which are used to climb the rocks like goats. Another very difficult and dangerous road is that between Shogstadt and Vang-in-Volders, along the side of a steep mountain, in some places so narrow, that if two travellers on horseback should meet in the night, they would find it impracticable either to pass each other, or turn back. In such a case their lives could not be saved, unless one of them should alight, and throw his horse headlong into the lake below, and then cling to the rock, until the other could pass. When a sheep or goat makes a false step to the projection of a rock, from whence it can neither ascend nor descend, the owner hazards his own life to preserve that of the animal. He directs himself to be lowered down from the top of the mountain, sitting on a cross stick, tied to the end of a long rope; and when he arrives at the place where the creature stands, he fastens it to the same cord, and it is drawn up with himself. Perhaps the other end of the rope is held by one person only; and there are some instances in which the assistant has been dragged down by the weight of his friend, so that both have perished. When either man or beast has had the misfortune to fall over very high precipices, they have not only been suffocated by the repercussion of the air, but their bodies have been always burst before they reached the ground. Sometimes entire crests of rocks, many fathoms in length and breadth, have fallen down at once, creating such a violent agitation of the air, as seemed a prelude to the world's dissolution. At Steenbroe in Laerdale, a stupendous mass, larger than any castle in the universe, appears to have been severed and tumbled from the mountain in large, sharp, and ragged fragments, through which the river roars with hideous bellowing. In the year 1731, a promontory on Sundmoer, called *Rammersfield*, that hung over Nordal Creek, suddenly gave way, and plunged into the water; which swelled to such a degree, that the church of Strand, though half a league on the other side of the bank, was overflowed: the creek however was not filled up; on the contrary, the fishermen declare they find no difference in the depth, which is said to exceed 900 fathoms.

The remarkable rivers of Norway are these: The Nied, issuing from Tydalen, on the borders of Sweden, runs westward into the lake Selboe; and afterwards, turning to the northward, passes by the city of Drontheim, to which it anciently gave the name of *Nidcros* and *Nidrosia:* Sule Ely, that descending from Sulefield, runs with a rapid course through Nordale into the sea: Gulen, which rises near Sffarsfield in the north; and running 20 leagues westward, through Aalen, Hlotaalen, Storen, and Melhuus, discharges itself into the sea about a league to the west of Drontheim. In the year 1344, this river buried itself under ground: from whence it again burst forth with such violence, that the earth and stones thrown up by the eruption filled the valley, and formed a dam; which, however, was soon broken and washed away by the force of the water. Divers churches, 48 farm houses, with 250 persons, were destroyed on this occasion.—Otteroen, a large river, taking its rise from the mountain Agde, runs about 30 leagues through Seeterdale and Efie, and disembogues itself into the cataract of Wiland. The river Syre rises near the mountain Lang, and winds its course through the vale of Syre into the lake of Lunde in the diocese of Christiansand; thence it continues its way to the sea, into which it discharges itself through a narrow strait formed by two rocks. This contraction augments its impetuosity, so that it shoots like an arrow into the sea, in which it produces a very great agitation. Nid and Sheen are two considerable rivers, issuing out of Tillemark. Their water-falls have been diverted, with infinite labour, by canals and passages cut through the rocks, for the convenience of floating down the timber. Tyrefiord or Dramme, is in the neighbourhood of Honifosse,

nifosse, joined by two rivers from Oedale and Hadeland, and disembogues itself into the sea near Bragness. Loven rises in the highest part of Nummedal, and runs through Konsberg to the sea near Laurwig. Glaamen is the largest river of Norway, distinguished by the name of *Stor Elvin*, or the *great river*. It derives its origin from the mountain Dofre, from whence it winds all along the plains of Oesterdale and Soloe; then joins the Vorme, another considerable river rising out of Mioes and Guldbrandsdale. These being joined, traverse the lake Oeyern; and thence issuing, run on to Sarp near Frederickstadt.

Norway abounds with fresh-water lakes; the principal of which are Rysvand in Nordland, Snaasen, Selboe, the Greater and Lesser Mioes, Slirevand, Sperdille, Rand, Vestn, Saren, Modum, Lund, Norsoe, Huidsoe, Farisvand, and Oeyevand; all these are well stocked with fish, and navigable for large vessels. Wars have been formerly carried on upon these inland seas; in some of which are small floating islands, or parcels of earth, with trees on them, separated from the main land, and probably preserved in compact masses by the roots of trees, shrubs, and grass, interwoven in the soil. In the year 1702, the family seat of Borge, near Frederickstadt, being a noble edifice, with lofty towers and battlements, suddenly sunk into an abyss 100 fathoms deep, which was instantaneously filled by a piece of water 300 ells in length and about half as broad. Fourteen persons, with 200 head of cattle, perished in this catastrophe, which was occasioned by the river Glaamen precipitating itself down a water-fall near Sarp, and undermining the foundation. Of all the water-falls in Norway this of Sarp is the most dangerous for its height and rapidity. The current drives 17 mills; and roars with such violence, that the water, being dashed and comminuted among the rocks, rises in the form of rain, where a beautiful rainbow may be always seen when the sun shines. In ancient times this cataract was made use of for the execution of traitors and other malefactors: they were thrown down alive, that they might be dashed in pieces on the points of rocks, and die in a dreadful commotion, analogous to those they had endeavoured to excite in the community.

Great part of Norway is covered with forests of wood, which constitute the principal article of commerce in this country. They chiefly consist of fir and pine, for which great sums are received from foreigners, who export an immense number of masts, beams, planks, and boards. Besides, an incredible quantity is consumed at home in building houses, ships, bridges, piles, moles, and fences; over and above the vast demand for charcoal to the founderies, and fuel for domestic uses.—Nay, in some places, the trees are felled for no other purpose but to clear the ground, and to be burned into ashes for manure. A good quantity of timber is yearly exported from all parts of Norway; but the chief exports are from Drammen, Frederickshall or Frederickstadt, Christiana, Skeen, Arendal, Christiansand, Christian's Bay, and Drontheim. The masts and large beams are floated down the rivers, and the rest is divided into boards at the saw mills. These works supply a vast number of families with a comfortable subsistence.—A tenth part of all sawed timber belongs to his Danish majesty, and makes a considerable branch of his revenue. The forests in Norway are so vast and thick, that the people seem to think there can never be a scarcity of wood, especially as the soil is peculiarly adapted for the production of timber: they therefore destroy it with a wasteful hand; insomuch that more wood rots in Norway than is burned in the whole kingdom of Denmark. The best timber grows in the provinces of Saltan, Helleland, Romsdale, Guldbrandsdale, Oesterdale, Soloe, Valders, Hallingdale, Sognifiord, Tellemark, and the lordship of Nedenes.

The climate of Norway is very different in different parts of the kingdom. At Bergen the winter is so moderate, that the seas are always open and practicable both to mariners and fishermen, except in creeks and bays, that reach far up into the country towards Filefield, when the keen north-east wind blows from the land. On the east side of Norway, from the frontiers of Sweden to Filefield, the cold generally sets in about the middle of October with great severity, and lasts till the middle of April; during which interval the waters are frozen to a very considerable thickness, and the face of the country is covered with snow. In the year 1719, 7500 Swedes, who intended to attack Drontheim, perished in the snow on the mountain of Ruden or Tydel, which separates Jempteland in Sweden from the diocese of Drontheim. A company of 200 Norwegian sledgemen under Major Emahus, found them all frozen to death on the ridge of the mountain, where they had been overtaken by a storm accompanied with snow, hail, and extreme cold. Some of these unhappy victims appeared sitting, some lying, and others kneeling in a posture of praying. They had cut in pieces their muskets, and burned the little wood they afforded.—The generals Labarre and Zoega lost their lives; and of the whole corps, consisting originally of 10,000, no more than 2500 survived this dreadful catastrophe.

The cold is still more intense in that part of Norway called *Finmark*, situated in the frigid zone near the polar circle. But if the winter is generally cold, the summer is often excessively hot in Norway. The rays of the sun are reverberated from the sides of the mountains so as to render the weather close and sultry in the valleys; besides, the sun's absence below the horizon is so short, that the atmosphere and mountains have not time to cool. The heat is so great, that vegetation is remarkably quick. Barley is sown, grows, ripens, and is reaped, in the space of six weeks or two months. The longest day at Bergen consists of 19 hours; the sun rising at half an hour after two, and setting at half an hour after nine. The shortest day does not exceed six hours; for the sun rises at nine in the morning, and sets at three in the afternoon.—In the beginning of the year the daylight increases with remarkable celerity; and, at the approach of winter, decreases in the same proportion. In summer one may read and write at midnight by the light of the sky. Christian V. while he resided at Drontheim, used to sup at midnight without candles. In the district of Tromsen, at the extremity of Norway, the sun is continually in view at midsummer. It is seen to circulate day and night round the north pole, contracting its orbit, and then gradually enlarging it, until at length it leaves the horizon. In the depth of winter, therefore, it is for some weeks invisible; and all the light perceived at noon is a faint glimmering for about an hour and a half, proceeding from the reflection of the sun's rays from the highest mountains.

mountains. But the inhabitants of these provinces are supplied with other lights that enable them to follow their employments in the open air. The sky being generally serene, the moonshine is remarkably bright, and, being reflected from the mountains, illuminates the valleys. They are also assisted by the aurora borealis, which is very frequent in the northern parts of Europe.

The air of Norway is generally pure and salubrious. On the sea coasts, indeed, it is rendered moist by vapours and exhalations: but in the midland parts of the country, towards the mountains, the climate is so dry, that meal may be kept for many years without being worm-eaten or damaged in the least. The inhabitants have no idea of sickness, except what is occasioned by excesses. It is said, that in the vale of Guldbrand the inhabitants live to such extreme old age, that they become weary of life, and cause themselves to be removed to a less salubrious climate, whereby they may have a chance of dying the sooner. In consumptions, however, the moist air on the sea side is found to be most agreeable to the lungs in respiration. Norway, being a mountainous country intersected by creeks, abounding with lakes, rivers, and snow, must be subject to frequent rains; and from sudden thaws the inhabitants are sometimes exposed to terrible disasters. Vast masses of snow falling from precipices overwhelm men, cattle, boats, houses, nay even whole villages. About two centuries ago, a whole parish was covered and destroyed by an immense mass of snow; and several domestic utensils, as scissars, knives, and basons, have been at different times brought to light by a rivulet that runs under the snow, which has been gradually hardened and increased by repeated frosts and annual accessions.

The winds that chiefly prevail on the western coast are those that blow from the south; whereas, on the other side of Filefield, the winds that produce and continue the hard frosts are always northerly. In the summer, there is a kind of regular trade-wind on the coast of Bergen. In the forenoon the sea begins to be cooled with a westerly breeze, which continues till midnight. Then the land breeze begins from the east, and blows till about ten in the morning. The coast is likewise subject to sudden squalls and storms. Hurricanes sometimes rise at sea; and in these latitudes the phenomenon called a *water-spout* is not uncommon. One of these in the neighbourhood of Ferro is said to have sucked up with the water some lasts of herrings, which were afterwards dropped on Kolter, a mountain 1200 feet high.

The fresh water of Norway is not very light or pure; but on the contrary is generally turbid, and deposites a sediment of adventitious matter, being sometimes impregnated with ochre and particles of iron.—Nevertheless it is agreeable to the taste, and remarkably salubrious; as appears from the good health of the common people, who drink little or no other liquor.

The soil of Norway varies in different places according to the situation of rock or valley. The mountains, here, as in every other country, are bare and barren; but the earth washed down from them by the rains enriches and fertilizes the valleys. In these the soil generally consists of black mould, sand, loam, chalk, and gravel, lying over one another in unequal strata, and sometimes in three or four successions: the mould that lies uppermost is very fine and mellow, and fit to nourish all sorts of vegetables. There is also clay found in different parts of this kingdom, of which the inhabitants begin to make earthen ware; but bricks and tiles are not used in building. The face of the country is in many places deformed by large swamps and marshes, very dangerous to the traveller. Near Leessoe in the diocese of Christiansand, a wooden causeway is extended near a mile over a morass; and if a horse or any other animal should make a false step, he will sink at once into the abyss, never to rise again.

In a cold country like Norway, roughened with rocks and mountains, interspersed with bogs, and covered with forests, we cannot expect to find agriculture in perfection. The ploughed lands, in respect to mountains, woods, meadows, and wastes, do not exceed the proportion of 1 to 80; so that the whole country does not produce corn to maintain above half the number of its inhabitants. The peasants are discouraged from the practice of husbandry by the frequency of accidents that seem peculiar to the climate. Even in the fruitful provinces of Guldbrandsdale, Oesterdale, and Soloer, as well as in the other places, when the corn appears in the most flourishing condition, the whole hope of the harvest is sometimes destroyed in one night by a sudden frost that nips the blade and extinguishes the vegetation. The kingdom is moreover visited by some unfavourable years, in which the sun seems to have lost his genial power; the vegetables are stunted; the trees bud and bloom, yet bear no fruit; and the grain, though it rises, will yet produce nothing but empty ears and straw. This calamity, however, rarely occurs; and in general the cultivated parts of Norway yield plentiful crops of excellent rye, barley, and oats. The most fruitful provinces are Nordland, Inderbarre, and Numedale, in the diocese of Drontheim; Sognifiord and Vaas, in that of Bergen; Jedderen, Ryefylsk, Raabygdelag, and the lordship of Nedenes, in the diocese of Christiansand; Hedemark in the diocese of Aggerhus; Hadeland, Toten, Romerige, Ringerige, and Guldbrandsdale: these territories not only produce grain enough for their own consumption, but likewise support their neighbours, and even supply part of Sweden.—Pease are likewise propagated in this country, together with wheat, buckwheat, hops, hemp, and flax, but not to any considerable advantage. The meadows are well stored with pasturage for sheep and cattle, and the fields are productive of those vegetables which are common in other northern countries. Within these 50 years the people of Norway have bestowed some attention on the culture of gardens, which in former times was so neglected, that the cities and towns were supplied with leeks, cabbage, and roots, from England and Holland. At present, however, the Norwegians raise their own culinary and garden roots and vegetables, which thrive there as well as in any other country. The scurvy being a disease that prevails along the sea coast, Nature has scattered upon it a variety of herbs efficacious in the cure of that distemper; such as angelica, rose-wort, gentian, cresses, trefoil, sorrel, scurvy-grass, and a plant called *erich's grass*, that grows in great plenty on the islands of Nordland: from whence the people of the continent fetch away boat loads of it, to be preserved in barrels as a succedaneum for cabbage. There are also a few noxious vegetables little known in any country but Norway. In

Norway.

In Guldbrandsdale is a species of grass called *selfnape*; the root of which is so poisonous, that any beast which eats of it dies immediately, the belly bursting; nay, the carnivorous fowls that prey upon the carcass of the beast meet with the same fate: children have been more than once poisoned by this root, which nevertheless is sometimes used externally as an amulet for arthritic disorders. Another vegetable pernicious to the cattle is the *Gramen ossifragum Norwegiense*, which is said to mollify the bones of the cattle which feed upon it. Among the noxious plants of Norway we may also reckon the igle-grass, fatal to the sheep and goats; the tourgrass, which affects horses and cows with a sort of lethargy; and the plant torboe, or histe-spring, which produces nearly the same effect on horses, but is not at all prejudicial to cows, sheep, or any ruminating animals. The herb turte, not unlike angelica, operates nearly in the same manner: yet the bears are said to feed upon it with peculiar relish; and when their hair begins to fall off by feeding upon this plant, they cure themselves by eating the flesh of animals.

The common fruit trees thrive tolerably well in Norway, the inhabitants of which have plenty of cherries, apples, and pears. Some kinds of plums attain maturity; which is seldom the case with grapes, apricots, and peaches. But even the apples and pears that ripen here are summer fruit; that which grows till the winter seldom coming to perfection. Great variety of agreeable berries is produced in different parts of this kingdom; such as the hagebar, a kind of sloes; an infusion of which in wine makes a pleasant cooling liquor; juniper berries, corinths red and white, soelbar or sunberries, raspberries, gooseberries, blackberries, strawberries, &c. with many other species that seem to be natives of Norway and Sweden. Among those are the tranæbar, the produce of the myrtillus repens, red and austere, found in the spring in perfection under the snow, and much relished by the reindeer; crakebeer, resembling bilberries, deemed a powerful antiscorbutic; agerbeer, larger and blacker than bilberries, of a pleasant acid, ripened by cold, and used as cherries for an infusion in wine; and finally tyltebeer, a red pleasant berry growing on a short stem, with leaves like those of box; they are plucked off by handfuls, and sent to Denmark to be preserved for the table, where they are eaten by way of dessert.

Of the trees that grow wild in Norway, the principal are the fir and the pine. The first yield an annual revenue of 1,000,000 of rixdollars, if we include the advantages resulting from the saw mills and the masts; one of which last has been known to sell for 200 rixdollars. The red fir tree, which grows on the mountains, is so rich in turpentine as to be almost incorruptible. Some of the houses belonging to the Norway peasants, built of this timber, are supposed to be above 400 years standing. In Guldbrandsdale the house is still to be seen standing in which King Olaf lodged five nights, above 700 years ago, when he travelled round the kingdom to convert the people to the Christian faith. Even 100 years after the trunk of the fir tree has been cut down, the peasants burn the roots for tar, which is a very profitable commodity. In the fens, the resin of the fir tree is by nature transformed into a substance which may be called *Norway frankincense*. The buds or pine apples of this tree, boiled in stale beer, make an excellent medicine for the scurvy; less unpleasant to the taste, though as efficacious, as tar-water. The pine tree is more tall and beautiful than the fir, though inferior to it in strength and quality; for which reason the planks of it are sold at an inferior price, and the peasants waste it without remorse. Norway likewise produces some forests of oak, which is found to be excellent for ship-building. Here also grow plenty of elm trees; the bark of which, being powdered, is boiled up with other food to fatten hogs, and even mixed by the poor among their meal; also the ash, from which the peasants distil a balsam used in certain disorders, and which is used both externally and internally. Many other trees flourish in this country, an enumeration of which would prove too tedious. Hazels grow here in such abundance, that 100 tons of the nuts are annually exported from Bergen alone.

A great diversity of stones is found in Norway, some of which are of a surprising figure. Several mountains consist chiefly of a brown pebble, which decays with age; nay, it sometimes dissolves, and drops into the sea, and the cement being thus loosened, a terrible disruption ensues. In some places the gray and black pebbles are intermixed with iron, copper, lead, silver, and gold. The ground in certain districts is covered with the fragments of rocks that have been precipitated from the summits of mountains, and broken by their fall into innumerable shivers. Between 20 and 30 years ago, in the neighbourhood of Bergen, a man was suddenly overwhelmed with such a mass, which formed a kind of vault around him. In this dreadful tomb he remained alive for several weeks. By his loud cries the place of his confinement was discovered: but it was found impossible to remove the huge stones by which he was inclosed. All that his friends could do for him was, to lower down meat and drink through some crevices; but at length the stones fell in, and crushed him to death.

In Norway are inexhaustible quarries of excellent marble, black, white, blue, gray, and variegated; together with some detached pieces of alabaster, several kinds of spar, chalk-stone, gypsum, sand-stone, millstone, baking-stone, slate, talc, magnets, and swine-stone, a production natural to Norway and Sweden, of a brown colour, fetid smell, in texture resembling crystal, and deriving its name from a supposed efficacy in curing a distemper incident to swine. Here also is found the amianthus or stone-flax, of which incombustible cloth may be made. Norway, however, affords no flints, but plenty of pyrites, beautiful rock crystals, granites, amethysts, agate, thunder-stones, and eagle-stones. Gold has formerly been found in small quantity in the diocese of Christiansand, and coined into ducats. There is at present a very considerable silver mine wrought at Kongsberg on account and at the risk of his Danish majesty: the ore is surprisingly rich, but interrupted in such a manner, that the vein is often lost. Many masses of pure silver have been found; and, among the rest, one piece weighing 560 pounds, preserved in the royal museum at Copenhagen. Such is the richness of these mines, that the annual produce amounts in value to a ton and a half in gold. About 5000 people are daily employed, and earn their subsistence, in those stupendous works.

Norway.

works (A). Other silver mines are prosecuted at Jarlsberg, but not to the same advantage; and here the ore is mixed with lead and copper. In many parts of this country copper mines have been discovered; but the principal, and perhaps the richest in all Europe, is at Roraas, about 100 English miles from Drontheim. This work yields annually about 1100 ship pounds of pure copper: the founderies belonging to it consume yearly about 14,000 lasts of coal, and 500 fathoms of wood. The next in importance is the copper work at Lykken, about 20 miles from Drontheim. A third mine is carried on at Indset or Quickne, at the distance of 30 miles from the same place; and here they precipitate the copper from its menstruum, by means of iron. There is a fourth copper work at Silboe, about 30 miles distant from Drontheim, though the least considerable of the four. Other copper mines of less note are worked in different parts of the kingdom. Iron is still in greater plenty, and was the first metal wrought in this country. Many hundred thousand quintals are annually exported, chiefly in bars, and part of it in stoves, pots, kettles, and cannon: the national profit arising from this metal is estimated at 300,000 rixdollars. There is a species called *moor-iron*, found in large lumps among the morasses: of this the peasants make their own domestic tools and utensils, such as knives, scythes, and axes. The lead found mixed in the silver ore is an article of small importance in Norway; yet some mines of this metal have been lately opened in the district of Soloer by the proprietors of the copper work at Oudal. A vitriol work has been begun near Kongsberg: the mines yield great plenty of sulphur; which, however, the Norwegians will not take the trouble to melt and depurate, because immense quantities are found at a cheaper rate in the island of Iceland. Alum is found between the slate flakes near Christiana in such plenty, that works have been set up for refining this mineral, though they have not yet brought it to any degree of transparency. His Danish majesty has established salt works in the peninsula of Valoe, about six English miles from Tonsberg, where this mineral is extracted in large quantities from the sea water.

Besides the animals common to other countries, Norway is said to contain many of the uncommon and dubious kind; such as the kraken, mermaid, sea serpent, &c. See these articles.

Many Danish, English, Scotch, Dutch, and German families have now settled in Norway; and indeed form no inconsiderable part of the trading people: but the original inhabitants are the descendants of those ferocious Normanni, who harassed almost all the coasts of Europe with piratical armaments in the 8th, 9th, and 10th centuries.

"Our first certain knowledge of the inhabitants of this country (says Pennant *) was from the desolation they brought on the southern nations by their piratical invasions. Their country had before that period the name of *Nortmanland*, and the inhabitants *Nortmans*, a title which included other adjacent people. Great Britain and Ireland were ravaged by them in 845; and they continued their invasion till they effected the conquest of England, under their leader Canute the Great. They went up the Seine as far as Paris, burnt the town, and forced its weak monarch to purchase their absence at the price of fourteen thousand marks. They plundered Spain, and at length carried their excursions through the Mediterranean to Italy, and even into Sicily. They used narrow vessels, like their ancestors the Sitones; and, besides oars, added the improvement of two sails; and victualled them with salted provisions, biscuit, cheese, and beer. Their ships were at first small; but in after times they were large enough to hold 100 or 120 men. But the multitude of vessels was amazing. The fleet of Harold Blaatand consisted of 700. A hundred thousand of these savages have at once sailed from Scandinavia, so justly styled *Officina gentium, aut certè velut vagina nationum*. Probably necessity, more than ambition, caused them to discharge their country of its exuberant numbers. Multitudes were destroyed; but multitudes remained, and peopled more favourable climates.

"Their king, Olaus, was a convert to Christianity in 994; Bernard an Englishman had the honour of baptizing him, when Olaus happened to touch at one of the Scilly islands. He plundered with great spirit during several years; and in 1006 received the crown of martyrdom from his pagan subjects. But religious zeal first gave the rest of Europe a knowledge of their country and the sweets of its commerce. The Hanse towns poured in their missionaries, and reaped a temporal harvest. By the year 1204, the merchants obtained from the wise prince Suer every encouragement to commerce; and by that means introduced wealth and civilization into his barren kingdom. England by every method cherished the advantages resulting from an intercourse with Norway, and Bergen was the emporium. Henry III. in 1217, entered into a league with its monarch Haquin; by which both princes stipulated for free access for their subjects into their respective kingdoms, free trade, and security to their persons. In 1269, Henry entered into another treaty with Magnus; in which it was agreed, that no goods should be exported from either kingdom except they had been paid for; and there is, besides, a humane provision on both sides, for the security of the persons and effects of the subjects, who should suffer shipwreck on their several coasts."

The inhabitants now speak the same language that is used in Denmark, though their original tongue is the dialect now spoken in Iceland. They profess the Lutheran religion, under an archbishop established at Drontheim,

* Arct. Zool.

(A) Mr Coxe tells us, that he visited those mines. They formerly, he says, produced annually 70,000l. but at present yield little more than 50,000l. The expences generally exceed the profits; and government gains only by the number of miners employed. The mines of cobalt, and the preparation of Prussian blue, are much more productive. The latter goes through 270 hands, and the number of men employed is 365. It is supposed, that, at this period (1793), it may produce to government a profit of 16,000l. a-year.

Norway. Drontheim, with four suffragans; namely, of Bergen, Staffanger, Hammer, and Christiana. By the union of Calmar, the two kingdoms of Norway and Denmark were united under one monarch; and then the people of both nations enjoyed considerable privileges: but the Danish government soon became absolute; and Norway was ruled despotically by a viceroy, who resided in the capital, and presided in the supreme court, to which appeals were made from the subordinate courts of judicature. The rigour of the government was however greatly mitigated, during the reign of the present king of Denmark.

The Norwegians are generally well formed, tall, sturdy, and robust, brave, hardy, honest, hospitable, and ingenious; yet savage, rash, quarrelsome, and litigious. The same character will nearly suit the inhabitants of every mountainous country in the northern climates. Their women are well shaped, tall, comely, remarkably fair, and obliging. The nobility of Norway have been chiefly removed by the kings of Denmark, in order to prevent faction and opposition to the court; or are long ago degenerated into the rank of peasants; some families, however, have been lately raised to that dignity. Every freeholder in Norway enjoys the right of primogeniture and power of redemption; and it is very usual to see a peasant inhabiting the same house which has been possessed 400 years by his ancestors. The *odels-gads*, or freehold, cannot be alienated by sale or otherwise from the right heir, called *odels-mand*: if he is not able to redeem the estate, he declares his incapacity every 10th year at the sessions; and if he, or his heirs to the third generation, should acquire wealth enough for that purpose, the possessor *pro tempore* must resign his possession.

The mountaineers acquire surprising strength and dexterity by hard living, cold, laborious exercise, climbing rocks, skating on the snow, and handling arms, which they carry from their youth to defend themselves against the wild beasts of the forest. Those who dwell in the maritime parts of Norway exercise the employments of fishing and navigation, and become very expert mariners.

The peasants of Norway never employ any handicraftsmen for necessaries to themselves and families: they are their own hatters, shoemakers, taylors, tanners, weavers, carpenters, smiths, and joiners: they are even expert at ship-building; and some of them make excellent violins. But their general turn is for carving in wood, which they execute in a surprising manner with a common knife of their own forging. They are taught in their youth to wrestle, ride, swim, skate, climb, shoot, and forge iron. Their amusements consist in making verses, blowing the horn, or playing upon a kind of guitar, and the violin: this last kind of music they perform even at funerals. The Norwegians have evinced their valour and fidelity in a thousand different instances. The country was always distracted by intestine quarrels, which raged from generation to generation. Even the farmers stand upon their punctilio, and challenge one another to single combat with their knives. On such occasions they hook themselves together by their belts, and fight until one of them is killed or mortally wounded. At weddings and public feasts they drink to intoxication, quarrel, fight, and murder generally ensues. The very common people are likewise passionate, ambitious of glory and independence, and vain of their pedigree. The nobility and merchants of Norway fare sumptuously; but the peasant lives with the utmost temperance and frugality, except at festivals: his common bread is made of oatmeal, rolled into broad thin cakes, like those used in Scotland. In time of scarcity, they boil, dry, and grind the bark of the fir tree into a kind of flour which they mix with oat meal: the bark of the elm tree is used in the same manner. In those parts where a fishery is carried on, they knead the roes of cod with their oat meal. Of these last, mixed with barley meal, they make hasty pudding and soup, enriched with a pickled herring or salted mackerel. Fresh fish they have in plenty on the sea coast. They hunt and eat grouse, partridge, hare, red deer, and reindeer. They kill cows, sheep, and goats, for their winter stock: these they pickle, or smoke, or dry for use. They make cheese of their milk, and a liquor called *syre* of their sour whey: this they commonly drink mixed with water; but they provide a store of strong ale for Christmas, weddings, christenings, and other entertainments. From their temperance and exercise, joined to the purity and elasticity of their air, they enjoy good health, and often attain to a surprising degree of longevity. Nothing is more common than to see a hearty Norwegian turned of 100. In the year 1733, four couples danced before his Danish majesty at Frederickshall: their ages, when joined, exceeded 800 years. Nevertheless the Norwegians are subject to various diseases; such as the scab, the leprosy, the scurvy, the catarrh, the rheumatism, gout, and epilepsy. The dress of the Norway peasants consists of a wide loose jacket made of coarse cloth, with waistcoat and breeches of the same. Their heads are covered with flapped hats, or caps ornamented with ribbons. They wear shoes without outer soles, and in the winter leathern buskins. They have likewise snow shoes and long skates, with which they travel at a great pace, either on the land or ice. There is a corps of soldiers thus accoutred, who can outmarch the swiftest horses. The Norwegian peasant never wears a neckcloth, except on extraordinary occasions: he opens his neck and breast to the weather, and lets the snow beat into his bosom. His body is girt round with a broad leathern belt, adorned with brass plates, from which depends a brass chain that sustains a large knife, gimlet, and other tackle. The women are dressed in close laced jackets, having leathern girdles decorated with ornaments of silver. They likewise wear silver chains round their necks, to the ends of which are fixed gilt medals. Their caps and handkerchiefs are almost covered with small plates of silver, brass, and tin, large rings, and buttons. A maiden bride appears with her hair plaited, and, together with her clothes, hung full of such jingling trinkets.

The churches, public edifices, and many private houses in Norway, are built of stone; but the people in general live in wooden houses, made of the trunks of fir and pine tree laid upon each other, and joined by mortises at the corners. These are counted more dry, warm, and healthy, than stone or brick buildings. In the whole diocese of Bergen, one hardly sees a farm house with a chimney or window: they are generally lighted by a square hole in the top of the house, which lets in the light, and lets out the smoke. In summer this hole is left quite open: in the winter, it is covered with what they call a *siau*; that is, the membrane of some animal, stretched upon a wooden frame that fits the hole, and transmits the rays of light. It is fixed or removed with a long pole occasionally. Every person that

that enters the house, upon business or courtship, takes hold of this pole, according to ancient custom. The ceiling is about eight feet high in the middle; and, being arched like a cupola, the smoke of the fire underneath rolls about, until it finds a vent at the hole, which is called *liur*. Under this opening stands a thick table with benches, and a high seat at the upper end for the master of the family: he has likewise a small cupboard for his own use, in which he locks up his most valuable effects. The boards of the roof are coated with the bark of the birch trees, which is counted incorruptible: this again is covered with turf, which yields a good crop of grass for goats and sheep, and is often mowed as hay by the farmer.

The Norwegians carry on a considerable trade with foreign nations. The duty on the produce of their own country exported, amounts annually to 100,000 rixdollars. These commodities are, copper wrought and unwrought; iron cast into cannon, stoves, and pots, or forged into bars; lead, in small quantity; masts, timber, deal boards, planks, marble, millstones, herring, cod, ling, salmon, lobsters, flounders, cow hides, goat skins, seal skins, the furs of bears, wolves, foxes, beavers, ermines, martens, &c. down, feathers, butter, tallow, train oil, tar, juniper, and other sorts of berries, and nuts; salt, alum, glass, vitriol, and pot ashes. All other commodities and articles of luxury the Norwegians import from different nations. The nature of the ground does not admit of much improvement in agriculture: nevertheless, the farmers are not deficient in industry and skill to drain marshes, and render the ground arable and fit for pasture. Many are employed in grazing and breeding cattle: but a much greater number is engaged in felling wood, floating timber, burning charcoal, and extracting tar from the roots of the trees which have been cut down; in the silver, copper, and iron mines; in the navigation and fishery. A considerable number of people earn a comfortable livelihood by hunting, shooting, and bird-catching. Every individual is at liberty to pursue the game, especially in the mountains and commons: therefore every peasant is expert in the use of fire arms; and there are excellent marksmen among the mountains, who make use of the bow to kill those animals, whose skins, being valuable, would be damaged by the shot of fire arms.

Norway can produce above 14,000 excellent seamen. The army of this country amounts to 30,000 effective men; and the annual revenue exceeds 800,000 rixdollars.

In consequence of an agreement between Russia, Sweden, and Great Britain in 1812, the king of Denmark was compelled to cede this country to Sweden, and a treaty to that effect was made at Kiel in January 1814. The Norwegians, indignant at having their liberties bartered away, invited Prince Christian, a younger son of the Danish monarch, to accept of the regency, and declared themselves independent. A representative constitution was framed, and the people took up arms to resist the Swedes. But their resistance was vain; the crown prince (Bernadotte) entered the country with a strong army, and the British fleet at the same time blockading the coast, the Norwegians were forced to submit in August 1814. Norway was united to the Swedish crown, but retained its separate legislature as organized a short time before.

Norway Rat. See Mus, Mammalia *Index*.

NORWICH, the capital of the county of Norfolk in England, situated in E. Long. 1. 26. N. Lat. 52. 40. It is supposed to have had its name, which signifies "a castle to the north," from its situation in respect of Caster, the ancient Venta Icenorum, three or four miles to the south of it, out of whose ruins it seems to have risen. In its infancy, in the reign of Etheldred, it was plundered and burnt by Sueno the Dane, when he invaded England with a great army. Afterwards it recovered; and in the reign of Edward the Confessor was a considerable place, having 1320 burghers. But it suffered again much in the reign of William I. by being the seat of a civil war, which Ralph earl of the East Angles raised against that king. So much was it impaired by the siege it then underwent, that there were scarce 560 burghers left in it, as appears from Doomsday book. From that time forward it began by little and little to recover, especially after Bishop Herbert translated the episcopal see hither from Thetford in the reign of William Rufus in 1096; and built a beautiful cathedral. In the time of Edward I. it was walled round by the citizens, who had presented a petition to parliament for liberty to do it. Henry IV. allowed them, instead of bailiffs, which they had before, to elect a mayor yearly, and made the city a county of itself. In the year 1348, near 58,000 persons were carried off by the plague; and in 1505 the city was almost consumed by fire. For the flourishing state to which the city is now arrived, they are much indebted to the Flemings, who fled hither from the tyranny of the duke of Alva and the inquisition, and taught them the manufacture of those striped and flowered damasks, camblets, druggets, black and white crape, for which the place is now so noted, and which have been computed to yield sometimes 200,000l. a-year. In the year 1583, the citizens, by the help of an engine, conveyed water through pipes to the highest parts of the city, which is pleasantly seated along the side of a hill, extending a mile and a half in length from north to south; but the breadth is much less, and it contracts itself by degrees towards the south. It is now one of the most considerable cities in Britain for wealth, populousness, neat buildings, beautiful churches, (of which it had once 58, but now only 36), and the industry and civility of the inhabitants. The cathedral is a very venerable structure, with a curious roof, adorned with the history of the Bible in little images, carved to the life, and a lofty steeple 105 yards high. The wall of flint stone, beautified with 40 towers and 12 gates, finished in 1309, is now much decayed. The city, though there is a great deal of waste ground within the walls, was computed, about 60 years ago, to contain 8000 houses and 50,000 inhabitants. In 1811 the inhabitants amounted to 37,256. Besides the cathedral already mentioned, the most remarkable buildings are, the duke of Norfolk's house, one of the largest in England; the castle, which is now the county gaol, and stands in the heart of the city, with a deep moat round it, over which is a bridge of one very large arch; the town hall; the guild hall, formerly the church belonging to the monastery of Black Friars; the house of correction; the shire house, where the assizes are held; a lofty market cross, built after the manner of a piazza; the bishop's palace; the king's school, founded by Edward VI. the boys of which are nominated by the mayor for the time being, with the consent

Norwich. consent of the majority of aldermen. There having been formerly many thatched houses, an order was made, that all houses that should hereafter be built should be covered with tiles. The city is interspersed with gardens, orchards, and trees, which make it both pleasant and healthful. It has four hospitals, in which a great number of old men and women, boys and girls, are maintained; and a dozen charity schools. Here are two churches for the Dutch and French Flemings; who have particular privileges, and are very numerous. Some of the churches are thatched, and all of them crusted with flint stone curiously cut; which is the more wonderful, as Norwich stands in a clay country, and has no flint within 20 miles of it. It is now governed by a mayor, recorder, steward, two sheriffs, 24 aldermen, 60 common council, with a town clerk, sword-bearer, and other inferior officers. The mayor is chosen on May-day by the freemen, and sworn in on the Tuesday before Midsummer-eve. The sheriffs are also chosen annually, on the first Tuesday in August, one by the freemen, the other by the aldermen, and sworn in on Michaelmas day. The freemen of the several wards choose each their alderman. The common council is chosen in Midlent. The mayor is a justice of the peace and quorum, during his year (as are also the recorder and steward) within the city and liberties; and after his mayoralty, he is a justice during life. The trade and manufactures of the city are very considerable. At Yarmouth they export large quantities of their manufactures, most of which are sent to London; and import a great deal of wine, coal, fish, oil, &c. All the city and country round are employed in the worsted manufacture, brought hither, as already observed, by the Flemings, in which they not only consume the wool of their own county, in spinning, weaving, &c. but use many thousand packs of yarn which they receive from other parts of England, as far as Yorkshire and Westmoreland. There are eight wardens of the weavers chosen annually, and sworn to take care that there be no frauds committed in spinning, weaving or dyeing the stuffs. It is computed that there are not less than 120,000 people employed in the city and neighbourhood in the silk and woollen manufactures. Their markets are thought to be the greatest in England, and furnished with a surprising plenty and variety of goods and provisions. At a small village to the north of the city, called *St Faith's*, not less than 40,000 head of Scotch cattle are said to be yearly bought up by the Norfolk graziers, and fattened in their meadows and marshes. Its markets are on Wednesday, Friday, and Saturday. It has a great number of fairs, sends two members to parliament, and gives the title of earl to the duke of Gordon.

Few cities or towns seem to have suffered more than Norwich has done at various periods, and few seem to have felt it less; for though quite burnt down by Sueno as above, it was of considerable consequence in Edward the Confessor's time; nor did it long feel the evils of the insurrection and siege in William the Conqueror's time, for it was rebuilt in Stephen's reign, and made a corporation.

The city of Norwich has long been famous for its manufactures; which are not, in the opinion of some, at present in so flourishing a state as formerly. In addition to the manufacture of camblets, druggets, and crapes, it is also remarkable for baize, serges, shalloons, stockings, and woollen cloths. Norwich, Nose.

The inhabitants of Norwich are generally so employed in their manufactures within doors, that the city has the appearance of being deserted, except on Sundays and holidays, when the streets swarm with people.

Caster, near Norwich, was the Venta Icenorum, or capital city of the Iceni, the broken walls of which contain a square of about thirty acres. In those walls may still be perceived the remains of four gates and a tower. Several Roman urns, coins, and other relicks of antiquity, have been found in this place.

NOSE, the organ of smell. See ANATOMY. The uses of the nose are, its giving us the sense of smelling; its serving in the great office of respiration, and in modelling the voice; in receiving the abundant humours from the eyes, and in adding to the beauty of the face.

The nose was by the augurs particularly attended to in forming conjectures concerning future good or ill success. The tingling of the right or left side of it, for instance, was thought to have different significations as it happened to different sexes, or persons in different conditions.

In Tartary, the greatest beauties are those who have the least noses. Ruybrock mentions the wife of the great Jenghiz Khan as a celebrated beauty, because she had only two holes for a nose. The Crim Tartars break the noses of their children while young, as thinking it a great piece of folly to have their noses stand before their eyes. In most other countries, China excepted, great noses are an honour.

In what the beauty of the nose consists, different nations have different opinions: and the following reflections of Sir Joshua Reynolds on this subject are perhaps the most philosophical account of the beauty of form that is to be found in any language. "I *Idler*, vol. ii. suppose (says Sir Joshua) it will be easily granted, that no man can judge whether any animal be beautiful in its kind, or deformed, who has seen only one of that species: that is as conclusive in regard to the human figure; so that if a man born blind was to recover his sight, and the most beautiful woman was brought before him, he could not determine whether she was handsome or not; nor, if the most beautiful and most deformed were produced, could he any better determine to which he should give the preference, having seen only those two. To distinguish beauty, then, implies the having seen many individuals of that species. If it is asked, how is more skill required by the observation of greater numbers? I answer, that, in consequence of having seen many, the power is acquired, even without seeking after it, of distinguishing between accidental blemishes and excrescences, which are continually varying the surface of Nature's works, and the invariable general form which Nature most frequently produces, and always seems to intend in her productions.

"Thus amongst the blades of grass or leaves of the same tree, though no two can be found exactly alike, yet the general form is invariable: a naturalist, before he chose one as a sample, would examine many, since, if he took the first that occurred, it might have, by accident or otherwise, such a form as that it would scarce be known to belong to that species; he selects as the painter does, the most beautiful, that is, the most general form of nature.

"Every species of the animal as well as the vegetable creation may be said to have a fixed or determinate form, towards which nature is continually inclining, like various lines terminating in the centre; or it may be compared to pendulums vibrating in different directions over one central point; and as they all cross the centre, though only one passes through any other point, so it will be found that perfect beauty is oftener produced by nature than deformity: I do not mean than deformity in general, but than any one kind of deformity. To instance in a particular part of a feature: the line that forms the ridge of the nose is beautiful when it is straight; this then is the central form, which is oftener found than either concave, convex, or any other irregular form that shall be proposed. As we are then more accustomed to beauty than deformity, we may conclude that to be the reason why we approve and admire it, as we approve and admire customs and fashions of dress for no other reason than that we are used to them; so that though habit and custom cannot be said to be the cause of beauty, it is certainly the cause of our liking it: and I have no doubt, but that if we were more used to deformity than beauty, deformity would then lose the idea now annexed to it, and take that of beauty; as if the whole world should agree that *yes* and *no* should change their meanings, *yes* would then deny, and *no* would affirm.

"Whoever undertakes to proceed further in this argument, and endeavours to fix a general criterion of beauty respecting different species, or to show why one species is more beautiful than another, it will be required from him first to prove that one species is really more beautiful than another. That we prefer one to the other, and with very good reason, will be readily granted; but it does not follow from thence that we think it a more beautiful form; for we have no criterion of form by which to determine our judgment. He who says a swan is more beautiful than a dove, means little more than that he has more pleasure in seeing a swan than a dove, either from the stateliness of its motions, or its being a more rare bird; and he who gives the preference to the dove, does it from some association of ideas of innocence that he always annexes to the dove; but if he pretends to defend the preference he gives to one or the other, by endeavouring to prove that this more beautiful form proceeds from a particular gradation of magnitude, undulation of a curve, or direction of a line, or whatever other conceit of his imagination he shall fix on as a criterion of form, he will be continually contradicting himself, and find at last that the great mother Nature will not be subjected to such narrow rules. Among the various reasons why we prefer one part of her works to another, the most general, I believe, is habit and custom: custom makes, in a certain sense, white black, and black white; it is custom alone determines our preference of the colour of the Europeans to the Æthiopians; and they, for the same reason, prefer their own colour to ours. I suppose nobody will doubt, if one of their painters was to paint the goddess of beauty, but that he would represent her black, with thick lips, flat nose, and woolly hair; and it seems to me he would act very unnaturally if he did not; for by what criterion will any one dispute the propriety of his idea? We indeed say, that the form and colour of the European is preferable to that of the Ethiopian: but I know of no other reason we have for it, but that we are more accustomed to it. It is absurd to say, that beauty is possessed of attractive powers, which irresistibly seize the corresponding mind with love and admiration, since that argument is equally conclusive in favour of the white and the black philosopher.

"The black and white nations must, in respect of beauty, be considered as of different kinds, at least a different species of the same kind; from one of which to the other, as I observed, no inference can be drawn.

"Novelty is said to be one of the causes of beauty: that novelty is a very sufficient reason why we should admire, is not denied; but because it is uncommon, is it therefore beautiful? The beauty that is produced by colour, as when we prefer one bird to another, though of the same form, on account of its colour, has nothing to do with this argument, which reaches only to form, I have here considered the word beauty as being properly applied to form alone. There is a necessity of fixing this confined sense; for there can be no argument, if the sense of the word is extended to every thing that is approved. A rose may as well be said to be beautiful, because it has a fine smell, as a bird because of its colour. When we apply the word *beauty*, we do not mean always by it a more beautiful form, but something valuable on account of its rarity, usefulness, colour, or any other property. A horse is said to be a beautiful animal; but had a horse as few good qualities as a tortoise, I do not imagine that he would be then esteemed beautiful.

"A fitness to the end proposed is said to be another cause of beauty; but supposing we were proper judges of what form is the most proper in an animal to constitute strength or swiftness, we always determine concerning its beauty before we exert our understanding to judge of its fitness.

"From what has been said, it may be inferred, that the works of nature, if we compare one species with another, are all equally beautiful; and that preference is given from custom, or some association of ideas; and that in creatures of the same species, beauty is the medium or centre of all various forms. See the article Beauty, towards the end.

NOSOLOGY, is a Greek word signifying a discourse or treatise of diseases; otherwise called *pathology*.

The importance of a comprehensive and accurate nosology has been long and generally allowed. Baglivi, Boerhaave, Gorter, Gaubius, and Sydenham, have expressed their desire of a work of this kind, the great object of which is to fix pathognomonics to every disease; or in which all diseases are disposed into certain classes, orders, and genera, founded on distinctions taken from the symptoms only, without regard to remote or proximate causes. See Medicine.

NOSTOCH, Shot Stars; *tremella nostoc*, (Lin. Spec. Plant. Dillenius de Muscis, tab. 10. fig. 14. Flor. Danica, tab. 885. fig. 1); *tremella intestinalis vel mesenterica*, Nostoch. *mesenterica*, (Lin. Spec. Plant. Dillen. de Mus. tab. 10. fig. 16. Flor. Danic. tab. 885. fig. 2.).

A writer in the Gentleman's Magazine gives this account of it: "The substance in question is not unfrequent in England, nor in all other parts of Europe, after rains, both in spring and autumn. Very large spots of it are seen in gravelly soils, and particularly on the tops of hills, and on open downs, and often it is found on gravel walks.

"It is met with in some of the old authors, under the name of *nostoch*, as in Paracelsus and others; and the alchemists fancied there was something wonderful in it, and that it would afford a menstruum for gold. Nostoch is said to be a word synonymous to *Jaculum alicujus stellæ, vel potius ejus repurgatione dejectum quid in terram*; *flos aëris*; *fragmentum nimbi*; as this substance was believed to fall from the sky with the meteors that we often see, and call *falling-stars*. Hence the country people in Sweden have called it *sky-fall*; and in England it is known by the name of *witches butter*, in common with some of the gelatinous liverworts.

"Paracelsus, Helmont, and others, ranked it with the *terniabin*, or manna, and thought it dropped, as that did, from heaven. It is described, and the chemical analysis thereof given, by M. Geoffroy, in the Paris Memoirs for 1708, and is there said to yield, besides an acid phlegm, a portion of concrete volatile salt and some fixed salt. The distilled water from it was believed by some to possess singular virtues, in allaying pains of the joints; but there is certainly no room to attribute any extraordinary qualities to it.

"Since the days of Paracelsus it has been considered as a vegetable production; but the botanists have had difficulty to assign its place or genus in their several systems. Our own countryman, Dr Merret, seems to have been among the first authors who ranked it among vegetables, and he calls it *Lichen humiditate intumescens, siccitate evanescens* (Pin. page 71.). Others have retained it among the plants of that genus to this day; as does the celebrated Dr Haller, in his *Historia Stirp. Helvetiæ*, who calls it *Lichen gelatinosus, plicatus, undulatus; laciniis crispatis, granulosis*, N° 2041, as there are several of the liverworts that have a gelatinous texture and appearance; though they differ much from the nostoch, in not being so instantly dried up. It was put into Ray's Synopsis, by Dr Dillenius, under the name of *Ulva terrestris pinguis et fugax*, p. 64.; but he afterwards changed that name for *tremella*, in his *Historia Muscorum*, whence he calls it *tremella terrestris sinuosa pinguis et fugax*, p. 52. tab. 10. f. 14, and reduces the lavers to the same genus. Micheli, an Italian botanist, famous for his attention to the Cryptogamia class of plants, makes it a *fungus*, as Magnol and Dr Morison had done before him, and describes and figures it, in his *Nova Plantarum Genera*, under the name of *Linkia terrestris gelatinosa, membranacea, vulgatissima*, p. 126. t. 67. f. 1. He describes the seeds as lying in the form of little strings of beads, coiled up within the plant, or rather in the folds thereof, and only to be discovered by the microscope. Linnæus mentions it, first under the name of *Byssus gelatinosa fugax terrestris*, in his *Flora Lapponica*, N° 530; but he afterwards adopted Dillenius's term, though he does not make it a laver. Linnæus has called it, in all his subsequent works, *tremella (nostoc) plicata, undulata*, under which name it stands in his *Species Plantarum*, p. 1157, and in Hudson's *Flora Anglica*, p. 463, as also in a numerous set of other authors who follow his system." Nostoch.

Another writer in the same work gives this account of it. "This substance is very rarely seen between the middle of April and the month of October. It is most frequently to be found in the high pasture lands, where the ground is inclined to wet, and on the moors and commons in the north of England. The time we always meet with it is after a very wet night, when the air in the morning suddenly clears up, and a sharp frost ensues. The frogs that then happen to be out are immediately seized by the frost, and turned into this jelly-like substance. For as I have had occasion sometimes to go out very early, I have found several parts of the frog not yet dissolved among the jelly, such as feet, legs, and thighs, yet in a little time afterwards the change was fully completed. The quantity of jelly produced from one single frog is almost beyond belief, even to five or six times its bulk when in its natural state.

"I communicated this discovery to an acquaintance, who has since had frequent opportunities of observing and examining this production; and we are fully assured, that, whatever opinion the learned may have of it, it certainly proceeds from the above-mentioned cause wherever found.

"Most people that I have conversed with on the subject, are of opinion that this jelly falls from the stars, or out of the higher regions of the air; which notion, however absurd, many are credulous enough to believe."

Naturalists had for some years begun to doubt whether these gelatinous substances were of a vegetable or animal nature, when at length Mr J. Platt of Oxford, in a letter printed in the Gentleman's Magazine for 1776, page 402, threw such light on the subject as to us, at least, is perfectly satisfactory.

"From a child I remember seeing the meteors shooting in the air, which appearance, by my comrades, was called *star-shooting*, believing the stars no larger than their apparent magnitude. This jelly-like substance mentioned in your magazine, was believed to be the dross of these meteors, and took the name of *star-shot*, which passed for certain with me till I had arrived at the age of 24, when I was engaged in business that required my frequently passing over both meadows and pasture-grounds, where in spring and autumn I saw many portions of this supposed alga or nostoch, but never more than one or two contiguous, mostly near the water, when the meadows were or had been just before flooded. My conjectures were various, until I saw a crow pecking of something in a field, which I heard to cry; when turning my horse to the place, I found a frog of the common size, which the crow (of the carrion kind) would soon have killed and gorged, had I not disturbed her, and chased her away.

"About this time I found in a meadow the bowels of a frog indigested, and compact as the chitterlings of a calf or pig; but white as the paper I write upon, though not translucid. I took it up and placed it in a paper exposed to the air; leaving it in some grass where I found it, till my return that way in three days time, Nostoch, Nostradamus.

time, when I saw it changed to that tremulous jelly-like substance, the alga or star-shot. I was much pleased with this discovery, and took it home in my pocket wrapped in a paper, where I showed it to a society of young persons of which I was a member, who agreed with my sentiments of its being the indigestible part of a frog disgorged by some bird of prey.

"To corroborate my sentiments of this alga being the bowels of a frog, I luckily saw some of it lying by the side of a brook, where I lighted and took it up, and to my great surprise found attached to the jelly the head, heart, liver, and one leg of the frog, which had been (I presume) disgorged by some carrion crow, who frequented the flooded grounds to pick up worms and other vermine. There was also some of it found on an apple tree at Wyston Magna, near Leicester, where I then lived, which, no doubt, was disgorged by some owl."

Dr Darwin, in his Poem on the Loves of the Plants, is of the same opinion with Mr Platt, that these gelatinous substances are of an animal nature, and that the different appearances they put on are owing to various circumstances, viz. the different birds who feed on frogs, the quantity they devour at a time, and the state of digestion before they are voided.

NOSTRADAMUS, Michel, an able physician and a celebrated astrologer, was a Provençal, and descended of a noble family, and born Dec. 14. 1503, at St Remy, in the diocese of Avignon. By his grandfather he was initiated in the study of the mathematics. He afterwards completed his courses of humanity and philosophy at Avignon; and, going thence to Montpelier, he there applied himself to physic, till being forced away by the plague in 1525, he took his route towards Thoulouse, and passed on till he came to Bourdeaux. This course held him five years, during which he undertook the cure of all such patients as were willing to put themselves under his care. After this he returned to Montpelier, and was created doctor of his faculty in 1529, and then revisited the same places where he had practised physic before. At Agen he contracted an acquaintance with Julius Cæsar Scaliger, which induced him to make some stay in that town, and there he entered into matrimony; but having buried his wife, and two children which she brought him, he quitted Agen after a residence of about four years. He returned into Provence, and fixed himself first at Marseilles; but his friends having provided an advantageous match for him at Salon, he transported himself thither in 1544. In 1546, Aix being afflicted with the plague, he went thither at the solicitation of the inhabitants, and was of great service; particularly by a powder of his own invention: so that the town in gratitude gave him a considerable pension for several years after the contagion ceased. Returning afterwards to Salon, he became a recluse, and made use of his leisure to apply himself to his studies. He had a long time followed the trade of a conjurer occasionally; and now he began to think himself inspired, and miraculously illuminated with a prospect into futurity. As fast as these illuminations had discovered to him any future event, he entered it in writing, in simple prose, but by enigmatical sentences, as he declared himself; but revising them afterwards, he thought the sentences would appear more respectable, and would savour more of a prophetic spirit, if they were expressed in verse. This opinion determined him to throw them all into quatrains, and he afterwards ranged them into centuries. When this was done, he hesitated about making them public, till reflecting that the time of many events which he had foretold was very near at hand, he determined to print them. This he did with a dedication addressed to his son Cæsar, an infant only some months old, in the form of a letter or preface, dated March 1. 1555. This first edition, which is included in seven centuries, was printed by Rigault at Lyons. He prefixed his name in Latin, but gave to his son Cæsar the name as it is pronounced, *Notradame*.

The public were divided in their sentiments of this work: many looked upon the author as a simple visionary or a fool; while he was accused of the black art, or black magic, by others, and treated as an impious person, who held a commerce with the devil: at the same time there were not wanting such, and those in great numbers, who believed him to be really and truly endued with the supernatural gift of prophecy. Lastly, Some were found who remained in suspense, and refrained from giving any judgment at all upon the point. However, Henry II. and Queen Catherine of Medicis his mother, were resolved to see our prophet; and, receiving orders to that effect, he presently repaired to Paris. He was very graciously received at court; and, besides the extraordinary respect that was paid to him, received a present of 200 crowns. He was sent afterwards to Blois, to make a visit to his majesty's children there, and report what he should be able to discover concerning their destinies. No doubt he exerted himself to the utmost on the occasion; but what his sentence was is not known; however, it is certain, he returned to Salon loaded with honour and presents. Animated with his success, he augmented his work from 300 quatrains to the number of a complete milliade, and published it with a dedication to the king in 1558. That prince dying the next year of a wound which he received, as is well known, at a tournament, the book of our prophet was immediately consulted; and in the 35th quatrain of the first century this unfortunate event was found predicted in the following verse:

Le lion jeune le vieux surmontera,
En champ bellique par singulier duel,
Dans cage d'or les yeux lui crevera,
Deux classes une puis mourir, mort cruelle.

So remarkable a prediction added new wings to his fame; and he was honoured shortly after with a visit from Emanuel duke of Savoy and the princess Margaret of France his consort. From this time Nostradamus found himself even overburdened with visitors, and his fame made every day new acquisitions. Charles IX. coming to Salon, was eager above all things to have a sight of him. Nostradamus, who then was in waiting as one of the retinue of the magistrates, being instantly presented to his majesty, complained of the little esteem his countrymen had for him; whereupon the monarch publicly declared, that he should hold the enemies of Nostradamus to be his enemies, and desired to see his children. Nor did that prince's favour stop here; in passing, not long after, through the city of Arles, he sent for Nostradamus, presented him with a purse of 200 crowns,

crowns, together with a brevet, constituting him his physician in ordinary, with the same appointment as the rest. But our prophet enjoyed these honours only for the space of sixteen months, for he died July 2. 1566, at Salon. Besides his "Centuries," we have the following compositions of his: A Treatise *de Fardemens et de Senteurs*, 1552.—A Book of singular Receipts, *pour Entretenir la Santé du Corps*, 1556.—A piece *des Confitures*, 1557.—A French Translation of the Latin of Galen's Paraphrase, exhorting Menedolas to Study, especially to that of Physic, 1552. Some years before his death, he published a small instruction for husbandmen, showing the best seasons for their several labours, which he entitled, The Almanack of Nostradamus. Lastly, After his death there came out The eleventh and twelfth Centuries of his Quatrains, added to the former ten, which had been printed three times in two separate parts. It is only in these first editions that our author's Centuries are found without alterations, additions, &c. It is to this work that the following distich of Stephen Jodelle alludes.

Nostra damus cum falsa damus, nam fallere nostrum est,
Et cum falsa damus, nil nisi Nostra damus.

NOSTRE, Andrew le, comptroller of the buildings of the French king, and designer of his gardens, distinguished himself by carrying the art of laying out gardens to great perfection. He was born at Paris in 1631; and was near 40 years of age when M. Fouquet, superintendant of the finances, gave him an opportunity of becoming known by the fine gardens of Vaux le-Vicomte. He was afterwards employed by Louis XIV. at Versailles, Trianon, St Germains, &c. and discovered an admirable taste in all his works. In 1678 he went to Rome, with the permission of the French king, to improve his skill; but he found nothing there comparable to what he himself had done. Pope Innocent XI. resolved to see Le Nostre, and gave him a pretty long audience; at the conclusion of which Le Nostre said, "I have seen the two greatest men in the world, your holiness, and the king my master." "There is a great difference," answered the pope: "The king is a great victorious prince; and I am a poor priest, the servant of the servants of God." Le Nostre, charmed with this answer, and forgetting who he was with, clapped the pope on the shoulder, saying, "Reverend father, you look extremely well, and will live to bury all the sacred college." The pope laughed at his prediction. Le Nostre, charmed more and more at the goodness of the sovereign pontiff and the singular esteem he showed for the king, threw his arms about the pope's neck and kissed him. It was his custom to behave in the same manner to all who spoke in praise of Louis XIV. and he even embraced the king himself whenever that prince returned from the country. Le Nostre had also a talent for painting. He preserved his good sense and vivacity of mind to the end of his life; and died at Paris, in 1700, aged 87.

NOTÆ, signs used in writing, which have the force of many letters. This contrivance for expedition is of great antiquity. It was known to the Greeks, and from them derived to the Romans. By whom the invention was brought into Rome is not precisely ascertained; but the most general opinion † is, that in matters of importance Tully first made use of notes or short-hand writing, when Cato made an oration in order to oppose Julius Cæsar relative to the conspiracy of Catiline. Cicero, who was at that time consul, placed *notarii*, or expert short-hand writers, in different parts of the senate house, to take down the speech; and this was the first public occasion which we find recorded of employing short-hand writers among the Romans. It is unnecessary to observe, that hence proceeded the name of *notary* still in use.

† Astle's Origin and Progress of Writing.

There were three kinds of notes for short-hand writing used by the ancients, either for despatch or secrecy. The first and most ancient was that of hieroglyphics, which are rather images or representations of things than of words. (See Hieroglyphics). The Chinese characters are of this kind, and may with greater propriety be called *notæ* than *literæ*, as appears from what hath been already advanced.

The second species of notes were called *singulariæ*, from their expressing words by single letters. Sertorius Ursatus has compiled a very copious collection of such abbreviations, of which work there are several editions.

The third kind of notes were called *notæ Tironianæ*, from Tiro the freed man of Cicero, who was excellently skilled in this art; and it is to him that we are indebted for the preservation of Cicero's letters, of which a great part still remain, and one entire book of them written to Tiro himself.

From books it appears, that notes were very frequent among the Romans, and continued in use to the 10th and 11th centuries. We have indeed but few books remaining that are written in short-hand; but this is not surprising, when such was the unhappy situation of early ages, that either superstition condemned them to the flames as the works of impious magicians or necromancers, or they were left to be devoured by vermine, through ignorance and stupidity, which was so very great, that some people, as Trithemius affirms, looked upon notes in those days as the elements of the Armenian language. It is probable, however, that there are writings of this sort still extant, which might contribute to enrich the republic of letters.

There are several MSS. and instruments written in these kind of notæ, in the royal library at Paris. In the year 1747, the learned and ingenious Mons. Charpentier, engraved and published at Paris a capitulary, and 54 charters of Louis the Pious, emperor and king of France, written in these notæ Tironianæ. To this work the learned editor hath prefixed an Alphabetum Tironianum, together with a great number and variety of notes or marks for the different parts of speech, and rules for acquiring the art of writing in these kind of notes. Valerius Probus, in his book *De Literis Antiquis*, explains many of the characters used by the short-hand writers; and there is a dictionary of them set forth by Janus Gruterus. See Stenography.

NOTARII, persons employed by the Romans to take, by *notæ*, trials and pleadings in their courts of judicature, or to write as amanuenses from the mouth of an author. These notarii were of servile condition. Under the reign of Justinian, they were formed into a college or corporate body. Notarii were also appointed to attend the prefects, to transcribe for them. There were likewise *notarii domestici*, who were employed in keeping

keeping the accounts of the Roman nobility; and when the empire became Christian, there were notaries for ecclesiastical affairs, who attested the acts of archbishops, bishops, and other spiritual dignitaries. We find ecclesiastical notaries at Rome, under Pope Julius IV. and in the church of Antioch, about the year 370. From these notaries is derived the office of chancellor to the bishops; afterwards almost every advocate was admitted a notary.

NOTARY (NOTARIUS), signifies a person, usually some scrivener, who takes notes, or frames short draughts, of contracts, obligations, charter parties, or other writings. At present we call him a *notary public*, who publicly attests deeds or writings, in order to make them authentic in another nation: but he is principally employed in business concerning merchants; as making protests of bills of exchange, &c. And noting a bill, is where he goes to take notice of a merchant's refusal to accept or pay the same.

NOTATION, in *Arithmetic* and *Algebra*, the method of expressing numbers or quantities by signs or characters appropriated for that purpose. See ARITHMETIC and ALGEBRA.

NOTES, in *Music*, characters which mark the sounds, i. e. the elevations and fallings of the voice, and the swiftnes and slowness of its motions.

NOTE is likewise used for a mark made in a book or writing, where there occurs something remarkable and worthy of particular notice: as also for an observation or explication of some passage in an author added in the margin, at the bottom of the page, or elsewhere; in which sense it stands contradistinguished to *text*.

NOTE, is also a minute, or short writing, containing some article of business; in which sense we say, promissory note, note of hand, bank note, &c.

NOTHUS, signifies *spurious* or *bastard;* whence it is figuratively applied by physicians to such diseases as, though in respect of a similitude of symptoms, &c. they have the same denomination as some others, yet are of a different origin, seat, or the like, from the same.

NOTHUS a Persian prince, and grandfather to Darius Codomannus. He is worthy of being mentioned only as he was progenitor to that sovereign whose overthrow conferred upon Alexander the title of *Great*.

NOTION, a word which in common language is considered as of the same import with idea. This, however, is improper. Notion comprehends the meaning of idea, but it denotes much more. We have a notion of spirit, of power, of solidity; but of these things we can have no ideas. Ideas are relicks of sensation; but there are objects of knowledge which fall under the cognizance of no sense; of these objects, however, we may have very distinct notions either direct or relative. See METAPHYSICS, N° 11.

NOTITIA, in literary history, a book that gives an account of a particular country, city, or other place: such is the *Notitia Imperii Romani, Notitia Romæ Antiquæ*, &c.

NOTO, an ancient, large, and handsome town of Sicily, and capital of the Val-di-Noto. It was entirely ruined by an earthquake in 1693; but the inhabitants built another town at some distance from it, which they call *Noto Nuovo*. E. Long. 14. 0. N. Lat. 36. 50.

NOTO, *Val di*, one of the three valleys or provinces into which Sicily is divided; and it lies between the sea, Val-di-Demona, and Val-di-Mazara. Noto is the capital town.

NOTONECTA, the boat fly, a genus of insects belonging to the order of hemiptera. See ENTOMOLOGY *Index*.

NOTTEBURG, a town of Russia, in the province of Ingria, seated on an island in the lake Ladoga, at the place where the river Neva proceeds from this lake. It is strong, has a good citadel, and was capital of the province before Petersburg was built. E. Long. 31. 40. N. Lat. 60. 0.

NOTTINGHAMSHIRE, a county of England, bounded on the east by Lincolnshire, on the south-east and south by Leicestershire, on the west by Derbyshire, and on the north and north-west by Yorkshire. It extends in length 48 miles, 25 in breadth, and 110 in compass; containing 560,000 acres, 8 hundreds, 9 market towns, 168 parishes, 450 villages, and in 1811 32,298 houses, and 162,900 inhabitants. No county in England enjoys a pleasanter and healthier air. As for the soil, it differs widely in different parts of the county. Towards the west, where lies the forest of Sherwood, it is sandy; and therefore that part of the county is called by the inhabitants the *Sand:* but the south and east parts, watered by the Trent and the rivulets that fall into it, are clayey; and for that reason are called by the inhabitants the *Clay*. The latter is fruitful both in corn and pasture; but the former produces little besides wood, coal, and some lead. The county has a variety of commodities and manufactures, as wool, leather, tallow, butter, cheese, coal, marl, cattle, malt, liquorice, stockings, glass, earthen wares, and strong ale. The principal rivers are the Trent and Idle. The Trent, whose name is supposed to be derived from the French or Latin word signifying *thirty*, either because it receives thirty smaller rivers, or has thirty different sorts of fish in it, is inferior to no river in England, but the Severn, Thames, and Humber. It enters the county on the south-west, and passes through it to the north-east, where it enters Lincolnshire, and after a long course falls at last into the Humber. The Idle rises in Sherwood forest; and after traversing the northern part of the county, falls into the Trent upon the borders of Yorkshire and Lincolnshire.

The spacious forest of Sherwood lies in the west part of the county, and indeed takes up the greatest part of it. It was formerly so thick, that it was hardly passable; but now it is much thinner. It feeds an infinite number of deer and stags; and has some towns in it, of which Mansfield is the chief. It abounds in coal, and a road lies through it for thirty miles together. Since the reign of King Edward I. the nobility and gentry have had grants of it. It was governed by a great number of officers under the late earl of Chesterfield, chief forester; whose ancestor, Sir John Stanhope, had a grant of it, with liberty to destroy and kill at pleasure, reserving only a hundred deer in the whole walk. The duke of Newcastle is now steward and keeper. See NOTTINGHAMSHIRE, SUPPLEMENT.

NOTTINGHAM, chief town of the above county. It is a handsome town, and a county of itself by charter. The name is derived from the Saxon word *Snottengham*, which signifies *caves*, from the caves and apartments anciently dug in the rocks on which the town stands. These, being soft, easily yield to the spade and pickaxe; whence

Nottingham. whence the townsmen have excellent cellars for the vast quantities of malt liquors made here, and sent, as well as their malt, to most parts of England. The situation of the town is very pleasant, having meadows on one hand, and hills of a gentle easy ascent, on the other, It is well supplied with fuel, both wood and coal, from the forest; and with fish by the Trent, which runs about a mile to the south of it, and has been made navigable for barges: so that they receive by it not only great quantities of cheese from Warwickshire and Staffordshire; but all the heavy goods from the Humber, and even from Hull. Over the Trent is a stately stone bridge of 19 arches, where the river is very large and deep, having received the addition of the Dove, the Derwent, the Irwash, and the Soar, three of them great rivers of themselves, which fall into it after its passing by Burton in Staffordshire.

The town is of great antiquity, and it had formerly a strong castle, in which the Danes, in the time of the heptarchy, held out a siege against Buthred king of Mercia, Alfred, and Ethelred his brother king of the West Saxons.

Soon after the Conquest, William either repaired this fortress, or built a new one on the same spot, in the second year of his reign, probably to secure a retreat on his expedition against Edwin earl of Chester and Morcar earl of Northumberland, who had revolted. He committed the custody of it to William Peverell, his natural son, who has by some been considered as the founder. It stands on a steep rock, at the foot of which runs the river Leen.

Deering, in his history of Nottingham, seems very justly to explode the story of the place called Mortimer's Hole, having been made as a hiding place for him; and from his description of it, shows that it was meant as a private passage to the castle, to relieve it with men or provisions in a siege. He says that it is one continued staircase, without any room, or even a place to sit down on. It was by this passage that Edward III. got into the castle and surprised Mortimer and the queen; and from hence, and his being carried away through it, it has its name.

Edward IV. greatly enlarged the castle, but did not live to complete the buildings he began. Richard III. finished them.

It was granted by James I. to Francis earl of Rutland, who pulled down many of the buildings; but it was still of so much strength, that Charles I. in 1642, pitched on it as the place for beginning his operations of war. He set up his standard, first on the walls of the castle, but in two or three days removed it to a close on the north side of the castle, without the wall, on a round spot; after which it was for many years called Standard close, and since from the name of one who rented it, Nevil's close. Where the standard was fixed, there stood a post for a considerable time. It is a common error that it was erected on a place called Derrymount, a little further north than the close just mentioned; this is an artificial hill, raised on purpose for a wind-mill which formerly stood there. The castle was afterwards sequestered by the parliament, and the trees in the park cut down.

This castle was so strong that it was never taken by storm. After the civil war, Cromwell ordered it to be demolished. On the Restoration, the duke of Buckingham, whose mother was daughter and heir of this Francis earl of Rutland, had it restored to him, and sold it to William Cavendish, marquis and afterwards duke of Newcastle. In 1674 he began the present building, but died in 1676, when the work was not far advanced. However, he had the building of it so much at heart, that he left the revenue of a considerable estate to be applied to that purpose, and it was finished by Henry his son. The expence was about 14,000l. It is one of the seats of the present duke of Newcastle.

In the park, west of the castle, and facing the river Leen, are some remains of an ancient building (if it may be so called) cut and framed in the rock. Dr Stukeley gives it, as he does most things, to the Britons. Many other ancient excavations have been found in other parts of the rocks.

The frames for knitting stockings were invented by one William Lea of this county, about the beginning of the 17th century; but not meeting with the encouragement he expected, he went with several of his workmen to France on the invitation of Henry IV. The death of that king, and the troubles which ensued, prevented attention being given to the work. Lea died there, and most of his men returned to England. Other attempts were made to steal the trade, without better success, and it has flourished here ever since, and is now carried on to a very considerable extent. It is noted for its horse-races on a fine course on the north side of the town. The corporation is governed by a mayor, recorder, six aldermen, two coroners, two sheriffs, two chamberlains, and twenty-four common-council men, eighteen of the senior council, and six of the junior, and a bell-bearer. The population, which in 1801 was 28,861, in 1811 had increased to 34,253. The town being within the jurisdiction of the forest, the former of these pinders is town-woodward, and attends the forest courts. It has three neat churches, the chief of which is St Mary's; and an alms-house, endowed with 100l. a-year, for twelve poor people; with a noble townhouse, surrounded with piazzas. A considerable trade is carried on in glass and earthen wares, and frame stockings, besides the malt, and malt liquors, mentioned above: Marshal Tallard, when a prisoner in England, was confined to this town and county. In the duke of Newcastle's park there is a ledge of rocks hewn into a church, houses, chambers, dove-houses, &c. The altar of the church is natural rock; and between that and the castle there is a hermitage of the like workmanship. Upon the side of a hill there is a very extraordinary sort of a house, where you enter at the garret, and ascend to the cellar, which is at the top of the house. Here is a noted hospital founded by John Plumtree, Esq. in the reign of Richard II. for thirteen poor old widows. There are four handsome bridges over the Trent and Lind. To keep these in repair, and for other public purposes, the corporation has good estates. This town and Winchelsea both give title of earl to the noble family of Finch. Here David king of Scots, when a prisoner in England, resided; and under ground is a vault, called *Mortimer's hole*, because Roger Mortimer, earl of March, is said to have concealed himself in it, when he was taken and hanged by order of Edward III. W. Long. 1. 5. N. Lat. 53. 0.

NOVA SCOTIA. See *Nova SCOTIA*.

NOVA *Zembla*. See *Nova ZEMBLA*.

NOVALLE, a small, rich, and populous town of Italy, between Padua and Treviso. E. Long. 12. 5. N. Lat. 45. 35.

NOVARA, an ancient and strong city of Italy, in that part of the duchy of Milan which belongs to Sardinia. Some pretend that this city was built by the Trojans, and so called *quasi Nova Ara*, because they had erected there a temple to Venus. Tacitus mentions its being made a municipal city by the Romans, and there are many inscriptions still extant, which sufficiently prove its ancient splendour. It is now a small, but well-built town, situated on a little eminence, in a fine country, betwixt two rivers, very well fortified, and is the see of a bishop, suffragan of Milan. It is remarkable for the several sieges sustained in past times, and for being the birthplace of Peter Lombard, master of the sentences. E. Long. 8. 35. N. Lat. 45. 25.

NOVATIAN, who made so much noise and so greatly disturbed the peace of the church, was, we are told, first a Pagan philosopher. He was baptized in bed when dangerously ill: recovering, however, he was afterwards ordained priest of the church of Rome, his bishop having obtained this favour for him, which the clergy and the people were far from being disposed to grant. He does not appear to have had the good of the church much at heart; for with his wit, knowledge, and eloquence, he might have been peculiarly serviceable to her, had he not with cowardice shrunk from his duty when he dreaded persecution. His ambition to be made a bishop likewise misled him; and what occasioned the apostasy of most of the first heresiarchs, also occasioned his. On the death of Fabian bishop of Rome, after writing a letter to St Cyprian, he remained quiet whilst the see was vacant; but the promotion of Cornelius to that dignity excited his envy and jealousy to no common pitch. The consequence was a separation from the new bishop, and from those who professed to believe, what Novatian strenuously denied, that the church could receive those again who had been guilty of idolatry. He soon got a number of followers among the laity, and some even among the clergy. Novatus, a priest of Carthage, was one of his party, and having been a party-man himself against St Cyprian, brought his adherents with him. He got himself consecrated bishop of Rome in a most infamous and clandestine manner, by three weak men, whom he had most grossly imposed upon, and one of whom did penance for having been concerned in what was so contrary to order, decency, and the rules of the church.

His designs, however, in this disgraceful affair did not succeed, for he was not acknowledged as bishop of that diocese; Cornelius being confirmed in it, whilst he was condemned and excommunicated. He still, however, taught his doctrine, and at length became the head of the party which bears his name. Besides the letter mentioned above, St Jerome says he wrote on the *Passover*, on the *Sabbath*, on *Circumcision*, on the *High Priests*, on *Prayer*, on *Jewish meals*, and on *Firmness of mind*, &c. with a large treatise *on the Trinity*. None of them appear under his own name, and some are thought not to be his.

NOVATIANS, *Novatiani*, a sect of ancient heretics, that arose towards the close of the third century, so called from Novatian, a priest of Rome, (see the preceding article). They were called also *Cathari*, from καθαρος, *pure*, q. d. Puritans.

Novatian first separated from the communion of Pope Cornelius, on pretence of his being too easy in admitting to repentance those who had fallen off in times of persecution.

Novatus coming to Rome, joined himself to the faction of Novatian; and both maintained, that there was no other admission into the church but by the repentance in baptism; grounding their opinion on that of St Paul: "It is impossible for those once "enlightened, and who have tasted the heavenly gift, "if they fall away, to renew themselves by repent-"ance."

Not that they denied but a person fallen into any sin, how grievous soever, might obtain pardon by repentance; for they themselves recommend repentance in the strongest terms: but their doctrine was, that the church had it not in its power to receive sinners into its communion, as having no way of remitting sins but by baptism; which once received could not be repeated.

In process of time the *Novatians* softened and moderated the rigour of their master's doctrine, and only refused absolution to very great sinners.

The two leaders were proscribed, and declared heretics, not for excluding penitents from communion, but for denying that the church had a power of remitting sins. See NOVATUS.

NOVATION, or INNOVATION, in the *Civil Law*, denotes the change of one kind of obligation for another; as when a promise is accepted instead of a written obligation.

NOVATUS, a priest of Carthage, in the third century, who, to avoid being punished for a crime, joined with the deacon, named *Felicissimus*, against St Cyprian. He went to Rome in 251; and there found Novatian, who had acquired great reputation by his eloquence, but who murmured at his not being raised to the see of Rome in preference to Cornelius. Novatus contracted a friendship with him; and afterwards promoted the detestable consecration of Novatian to the see of Rome. This irregular consecration produced a very great schism. Novatus also maintained, that the church had not the power to receive those to communion who were fallen into idolatry.

NOVEL, a fictitious narrative in prose, which professes to exhibit the natural workings of the human heart, the happiness and misery of private life, and, above all, the nature of the affection called *Love*, and the consequence of indulging it in certain circumstances.

The novel sprung out of the old romance, and has been censured for insipidity, as its parent was for extravagance. (See ROMANCE). That the greater part of those absurd things, which, under this title, are daily issuing from the press, deserve all the contempt with which they can be treated, is a position which we feel not ourselves inclined to controvert; but we cannot admit that any species of writing is in itself insipid, merely because numbers have attempted it without success. The heroic poems of Blackmore are universally

Novel.

versally known to be contemptible performances; and if we had before us all the heroic poetry that has ever been written, how many thousands of volumes should we have as mean as either *Prince Arthur*, *King Arthur*, *Elize*, or *Alfred?* Yet no critic has hitherto dared to maintain, that heroic poetry is an insipid species of writing.

But to the novel objections have been urged of more importance than its insipidity. It has been often affirmed, with learned solemnity, that the perusal of novels tends to corrupt the youth of both sexes; to produce effeminacy in men and extravagant notions of the happiness of love in women; that it diverts the minds of the former from more serious and useful studies, and exposes the latter to the arts of seduction. That there are too many novels to which this objection is applicable in its full force, is a fact which we are afraid cannot be denied: but when it is admitted, let not these performances be again accused of insipidity: for were they insipid, they could have no such consequences. It is by laying fast hold of the heart that they lead it astray. That a novel might be written so as to interest the heart in behalf of virtue, as much as any one has ever warped it to the side of vice, is a truth which no man will ever venture to call in question who has any knowledge of human nature; and therefore we are decidedly of opinion, that there may be novels worthy at once of the perusal of inexperienced youth and hoary wisdom. A critic *, by no means too indulgent to works of fancy, and among whose failings laxity of morals has never been numbered, thus expresses himself on the subject of novel-writing:—"These familiar histories may perhaps be made of greater use than the solemnities of professed morality, and convey the knowledge of vice and virtue with more efficacy than axioms and definitions. But if the power of example is so great, as to take possession of the memory by a kind of violence, and produce effects almost without the intervention of the will, care ought to be taken, that, when the choice is unrestrained, the best examples only should be exhibited; and that what is likely to operate so strongly, should not be mischievous or uncertain in its effects."

* *Johnson.*

We have said, that the novel professes above all things to exhibit the nature of love and its consequences. Whether this be essential to such performances may perhaps be reasonably questioned: but it has been made an important part of the drama in most novels, and, we think, with great propriety. It is the object of the novelist to give a true picture of life, diversified only by accidents that daily happen in the world, and influenced by passions and qualities which are really to be found in conversing with mankind. To accomplish this object, he conceives a hero or heroine, whom he places in a certain rank of life, endues with certain qualities of body and mind, and conducts, through many vicissitudes of fortune, either to the summit of happiness or to the abyss of misery, according to the passion which he wishes to excite in his readers. In the modern novel, this hero or heroine is never placed on a throne, or buried in a cottage; because to the monarch and the cottager no difficulties occur which can deeply interest the majority of readers. But among the virtuous part of the intermediate orders of society, that affection which we call *love* seldom fails, at some period of life, to take possession of the hearts of both sexes; and wherever it has place, it must be productive of happiness or of misery. In the proper management of this passion consists much of the difficulty of the novel writer. He must exhibit his hero as feeling all the pangs and pleasures of love, as sometimes animated with hope, and sometimes ready to sink into despair, but always exerting himself to obtain the gratification of his wishes. In doing this, care should be taken, either that he never transgress the laws of virtue, or at least that he never transgress them with impunity.

"It is justly considered as the greatest excellency of art to imitate nature; but it is necessary to distinguish those parts of nature which are most proper for imitation: greater care is still required in representing life, which is so often discoloured by passion or deformed by wickedness. If the world be promiscuously described, I cannot perceive (says the great critic already quoted) of what use it can be to read the account; or why it may not be as safe to turn the eye immediately upon mankind, as upon a mirror which shows all that presents itself without discrimination. It is therefore not a sufficient vindication of a character, that it is drawn as it appears; for many characters ought never to be drawn: nor of a narrative, that the train of events is agreeable to observation; for that observation which is called knowledge of the world will be found much more frequently to make men cunning than good. The purpose of these writings is surely not only to show mankind, but to provide that they may be seen hereafter with less hazard; to teach the means of avoiding the snares which are laid by TREACHERY for INNOCENCE, without ensuring any wish for that superiority with which the betrayer flatters his vanity; to give the power of counteracting fraud, without the temptation to practise it; to initiate youth by mock encounters in the art of necessary defence; and to increase prudence, without impairing virtue.

"Many writers, for the sake of following nature, so mingle good and bad qualities in their principal personages, that they are both equally conspicuous; and as we accompany them through their adventures with delight, and are led by degrees to interest ourselves in their favour, we lose the abhorrence of their faults, because they do not hinder our pleasures, or perhaps regard them with some kindness for being united with so much merit.—There have been men indeed splendidly wicked, whose endowments threw a brightness on their crimes, and whom scarce any villany made perfectly detestable, because they never could be wholly divested of their excellencies: but such have been in all ages the great corrupters of the world; and their resemblance ought no more to be preserved than the art of murdering without pain.

"In narratives, where historical veracity has no place, there should be exhibited the most perfect idea of virtue; of virtue not angelical, nor above probability (for what we cannot credit we shall never imitate), but the highest and purest that humanity can reach, which, exercised in such trials as the various revolutions of things shall bring upon it, may, by conquering some calamities and enduring others, teach us what we may hope, and what we can perform. Vice (for vice is necessary to be shown) should always disgust; nor should the graces of gaiety, or the dignity of courage, be so united with it, as to reconcile it to the mind. Wherever it appears, it should raise hatred by the malignity of its practices, and contempt by the meanness of its stratagems; for while it is supported by either parts or spirit, it will seldom be heartily abhorred."

If these observations be just, and to us they appear unanswerable, Richardson's *Lovelace* is a character which ought never to have been drawn. In the graces of gaiety and the dignity of courage, in liberality without profusion, in perseverance and address, he everywhere appears as the first of men; and that honour with which he protects the virtue of his *Rosebud*, if any instruction is to be drawn from it, can only lead the admirers of Richardson to believe that another Clarissa might be in perfect safety were she to throw herself upon the honour of another Lovelace. Yet in the composition of this splendid character there is not one principle upon which confidence can securely rest; and Lovelace, whilst he is admired by the youth of both sexes, and escapes the contempt of all mankind, must excite in the breast of the cool moralist sentiments of abhorrence and detestation. A French critic †, speaking of this character, says, "By turns I could embrace and fight with Lovelace. His pride, his gaiety, his drollery, charm and amuse me: his genius confounds me and makes me smile; his wickedness astonishes and enrages me; but at the same time I admire as much as I detest him." Surely this is not the character which ought to be presented to the inexperienced and ardent mind.

† The author of *La jolie femme*, or *La femme du jour.*

The most perfect characters which we at present recollect in any novel are Richardson's Grandison and Fielding's Allworthy. The virtues of the former are perhaps tinctured with moral pedantry, if we may use the expression: and the latter suffered himself to be long imposed upon by the arts of the hypocrite and the philosophical coxcomb; but without some defects they would not be human virtues, and therefore no objects of human imitation. Clarissa is an excellent character: she has as much perfection as can be expected in woman, whilst she exhibits, at the same time, some obvious defects.

As it is the object of the novelist to interest the heart, and to communicate instruction through the medium of pleasure, his work, like a tragedy or comedy, should be one, exhibiting a hero or heroine, whose success every incident should contribute to forward or to retard. In this respect no work of fancy has ever surpassed the Tom Jones of Fielding. It is constructed upon principles of the soundest criticism, and contains not a single event which does not in some way contribute towards the winding up of the piece. A living author, deeply read in Grecian literature, and far from being prejudiced in behalf of any modern, has been heard to say, that had Aristotle seen Tom Jones, he would have pronounced it a poem perfect in its kind.

Against this sentence another critic of name has entered his protest, and strenuously maintained that nothing can be a poem which is not written in verse. We shall judge of the truth of this conclusion by comparing it with the principles from which it is deduced. Having laid down as a maxim incontrovertible, that "the end of poetry is pleasure, to which use itself must be subservient," he very justly infers from this IDEA, that "poetry should neglect no advantage that fairly offers itself, of appearing in such a dress or mode of language as is most taking and agreeable to us. It follows (he says), from the same idea of the *end* which poetry would accomplish, that not only rhythm, but NUMBERS properly so called, is essential to it, and that it cannot obtain its own purpose unless it be clothed in VERSE." He then proceeds to ask, "What, from this conclusion, are we to think of those *novels* or *romances*, as they are called, which have been so current of late through all Europe? As they propose pleasure for their end, and prosecute it, besides, in the way of *fiction*, though without metrical numbers, and generally indeed in harsh and rugged prose, one easily sees what their pretensions are, and under what idea they are ambitious to be received. Yet as they are wholly destitute of measured sounds (to say nothing of their other numberless defects), they can at most be considered but as hasty, imperfect, and abortive poems: whether spawned from the dramatic or narrative species, it may be hard to say.

Unfinish'd things one knows not what to call,
Their generation's so equivocal.

However, such as they are, those *novelties* have been generally well received: *Some* for the real merit of their execution; *others*, for their amusing subjects; all of them for the gratification they afford, or at least promise, to a vitiated, pallid, and sickly imagination, that last disease of learned minds, and sure prognostic of expiring letters. But whatever may be the temporary success of these things (for they vanish as fast as they are produced), good sense will acknowledge no work of art but such as is composed according to the law of its kind."

Of this severe criticism the author himself has given us, what amounts to a complete confutation. He tells us, that the ancients looked for so much force and spirit of expression in whatever they dignified with the name of *poem*, as sometimes to make a question "whether comedy were rightly referred to this class, because it differed only in measure from mere prose? Their doubt (he justly adds) might have been spared or at least resolved, if they had considered that comedy adopts as much of this force and spirit of words as is consistent with the nature and dignity of that pleasure which it pretends to give: For the name of *poem* will belong to every composition whose *primary* end is to please, provided it be so constructed as to afford *all* the pleasure which its kind or sort will permit."

If this decision be just, and we readily admit it, a well composed novel is entitled to the appellation of a *poem*, though it be written in prose and in a style not remarkable for elevation. The business of the novelist is to interest the heart by a display of the incidents of common life. In doing this, he must exhibit scenes that are probable, and record speeches that are natural. He is not at liberty to invent, but only to select, objects, and to cull from the mass of mankind those individuals upon which the attention ought most to be employed. The more closely he adheres to this rule, the more deeply does he interest us in his narrative; because every reader sees at once that it is possible he may at some time or other be in circumstances nearly resembling those of the hero of the tale. But the business of life

Novel, Novelty.

life is not transacted in pompous language, nor the speeches of real lovers made in verse either rhymed or blank. Were *Tom Jones* or *Clarissa Harlowe* to be translated into verse, we shall venture to assert that they would quickly lose their hold of the public mind: because the hero and heroine would then appear in a light which every heart must feel to be unnatural.

It is well observed by Johnson, that the task of the novel writer "requires, together with that learning which is to be gained from books, that experience which can never be attained by solitary diligence, but must arise from general converse and accurate observation of the living world. Their performances have, as Horace expresses it, *plus oneris quantum variæ minus*, little indulgence, and therefore more difficulty. They are engaged in portraits of which every one knows the original, and can detect any deviation from exactness of resemblance. Other writings are safe, except from the malice of learning, but these are in danger from every common reader; as the slipper ill executed was censured by a shoemaker who happened to stop in his way at the Venus of Apelles." It is in thus faithfully copying nature that the excellence of Fielding consists. No man was ever better acquainted with the shades which diversify characters, and none ever made his personages act and speak more like real men and women in the particular circumstances which he describes.

"But the fear of not being approved as a just copier of human manners, is not the most important concern that an author of this class ought to have before him. Novels are written chiefly to the young, the ignorant, and the idle, to whom they serve as lectures of conduct and introduction into life. In every such work, it should therefore be carefully inculcated, that virtue is the highest proof of understanding, and the only solid basis of greatness; and that vice is the natural consequence of narrow thoughts; that it begins in mistake and ends in ignominy: and since love must be introduced, it should be represented as leading to wretchedness, whenever it is separated from duty or from prudence."

Novel, in the civil law, a term used for the constitutions of several emperors, more particularly those of Justinian. They were called *novels*, either from their producing a great alteration in the face of the ancient law, or because they were made on new cases, and after the revisal of the ancient code.

NOVELTY, or Newness. Of all the circumstances that raise emotions, not excepting beauty, nor even greatness, says Lord Kames *, novelty hath the most powerful influence. A new object produces instantaneously an emotion termed *wonder*, which totally occupies the mind, and for a time excludes all other objects. Conversation among the vulgar never is more interesting than when it turns upon strange objects and extraordinary events. Men tear themselves from their native country in search of things rare and new; and novelty converts into a pleasure the fatigues and even perils of travelling. To what cause shall we ascribe these singular appearances? To curiosity undoubtedly: a principle implanted in human nature for a purpose extremely beneficial, that of acquiring knowledge; and the emotion of wonder raised by new and strange objects, inflames our curiosity to know more of such objects. This emotion is different from *admiration*: novelty, wherever found, whether in a quality or action, is the cause of wonder; admiration is directed to the person who performs any thing wonderful.

* *Elements of Criticism.*

Novelty.

During infancy, every new object is probably the occasion of wonder, in some degree; because, during infancy, every object at first sight is strange as well as new: but as objects are rendered familiar by custom, we cease by degrees to wonder at new appearances, if they have any resemblance to what we are acquainted with; for a thing must be singular as well as new, to raise our wonder. To save multiplying words, we would be understood to comprehend both circumstances when we hereafter talk of novelty.

In an ordinary train of perceptions, where one thing introduces another, not a single object makes its appearance unexpectedly: the mind thus prepared for the reception of its objects, admits them one after another without perturbation. But when a thing breaks in unexpectedly, and without the preparation of any connection, it raises an emotion, known by the name of *surprise*. That emotion may be produced by the most familiar object, as when one unexpectedly meets a friend who was reported to be dead; or a man in high life, lately a beggar. On the other hand, a new object, however strange, will not produce the emotion, if the spectator be prepared for the sight: an elephant in India will not surprise a traveller who goes to see one; and yet its novelty will raise his wonder: an Indian in Britain would be much surprised to stumble upon an elephant feeding at large in the open fields; but the creature itself, to which he was accustomed, would not raise his wonder.

Surprise thus in several respects differs from wonder: unexpectedness is the cause of the former emotion; novelty is the cause of the latter. Nor differ they less in their nature and circumstances, as will be explained by and by. With relation to one circumstance they perfectly agree; which is, the shortness of their duration: the instantaneous production of these emotions in perfection, may contribute to that effect, in conformity to a general law, That things soon decay which soon come to perfection: the violence of the emotions may also contribute; for an ardent emotion, which is not susceptible of increase, cannot have a long course. But their short duration is occasioned chiefly by that of their causes: we are soon reconciled to an object, however unexpected; and novelty soon degenerates into familiarity.

Whether these emotions be pleasant or painful, is not a clear point. It may appear strange, that our own feelings and their capital qualities should afford any matter for a doubt: but when we are engrossed by any emotion, there is no place for speculation; and when sufficiently calm for speculation, it is not easy to recal the emotion with accuracy. New objects are sometimes terrible, sometimes delightful: the terror which a tyger inspires is greatest at first, and wears off gradually by familiarity: on the other hand, even women will acknowledge that it is novelty which pleases the most in a new fashion. It would be rash, however, to conclude, that wonder is in itself neither pleasant nor painful, but that it assumes either quality according to circumstances. An object, it is true, that hath a threatening appearance, adds to our terror by its novelty: but from that experiment it doth not follow, that novelty is in itself disagreeable;

disagreeable; for it is perfectly consistent, that we be delighted with an object in one view, and terrified with it in another. A river in flood swelling over its banks, is a grand and delightful object; and yet it may produce no small degree of fear when we attempt to cross it: courage and magnanimity are agreeable; and yet, when we view these qualities in an enemy, they serve to increase our terror. In the same manner, novelty may produce two effects clearly distinguishable from each other: it may, directly and in itself, be agreeable; and it may have an opposite effect indirectly, which is, to inspire terror; for when a new object appears in any degree dangerous, our ignorance of its powers and faculties affords ample scope for the imagination to dress it in the most frightful colours. The first sight of a lion, for example, may at the same instant produce two opposite feelings, the pleasant emotion of wonder, and the painful passion of terror: the novelty of the object produces the former directly, and contributes to the latter indirectly. Thus, when the subject is analyzed, we find that the power which novelty hath indirectly to inflame terror, is perfectly inconsistent with its being in every circumstance agreeable. The matter may be put in the clearest light, by adding the following circumstance. If a lion be first seen from a place of safety, the spectacle is altogether agreeable without the least mixture of terror. If, again, the first sight puts us within reach of that dangerous animal, our terror may be so great as quite to exclude any sense of novelty. But this fact proves not that wonder is painful: it proves only, that wonder may be excluded by a more powerful passion. Every man may be made certain from his own experience, that wonder raised by a new object that is inoffensive, is always pleasant; and with respect to offensive objects, it appears from the foregoing deduction, that the same must hold as long as the spectator can attend to the novelty.

Whether surprise be in itself pleasant or painful, is a question not less intricate than the former. It is certain that surprise inflames our joy when unexpectedly we meet with an old friend; and not less our terror when we stumble upon any thing noxious. To clear that question, the first thing to be remarked is, that in some instances an unexpected object overpowers the mind, so as to produce a momentary stupefaction: where the object is dangerous, or appears so, the sudden alarm it gives, without preparation, is apt totally to unhinge the mind, and for a moment to suspend all its faculties, even thought itself; in which state a man is quite helpless: and if he move at all, is as like to run upon the danger as from it. Surprise carried to such a height, cannot be either pleasant or painful; because the mind, during such momentary stupefaction, is in a good measure, if not totally, insensible.

If we then inquire for the character of this emotion, it must be where the unexpected object or event produceth less violent effects. And while the mind remains sensible of pleasure and pain, is it not natural to suppose, that surprise, like wonder, should have an invariable character? It would appear, however, that surprise has no invariable character, but assumes that of the object which raises it. Wonder being an emotion invariably raised by novelty, and being distinguishable from all other emotions, ought naturally to possess one constant character. The unexpected appearance of an object, seems not equally entitled to produce an emotion distinguishable from the emotion, pleasant or painful, that is produced by the object in its ordinary appearance: the effect it ought naturally to have, is only to swell that emotion, by making it more pleasant or more painful than it commonly is. And that conjecture is confirmed by experience, as well as by language which is built upon experience: when a man meets a friend unexpectedly, he is said to be agreeably surprised; and when he meets an enemy unexpectedly, he is said to be disagreeably surprised. It appears, then, that the sole effect of surprise is to swell the emotion raised by the object. And that effect can be clearly explained: a tide of connected perceptions glide gently into the mind, and produce no perturbation; but an object breaking in unexpectedly, sounds an alarm, rouses the mind out of its calm state, and directs its whole attention to the object, which, if agreeable, becomes doubly so. Several circumstances concur to produce that effect: on the one hand, the agitation of the mind and its keen attention prepare it in the most effectual manner for receiving a deep impression: on the other hand, the object, by its sudden and unforeseen appearance, makes an impression, not gradually, as expected objects do, but as at one stroke with its whole force. The circumstances are precisely similar where the object is in itself disagreeable (A).

The pleasure of novelty is easily distinguished from that of variety: to produce the latter, a plurality of objects is necessary; the former arises from a circumstance found in a single object. Again, Where objects, whether co-existent or in succession, are sufficiently diversified, the pleasure of variety is complete, though every single object of the train be familiar; but the pleasure of novelty, directly opposite to familiarity, requires no diversification.

There are different degrees of novelty, and its effects are

(A) What Mareschal Saxe terms *le cœur humain*, is no other than fear occasioned by surprise. It is owing to that cause that an ambush is generally so destructive: intelligence of it beforehand renders it perfectly harmless. The Mareschal gives from Cæsar's Commentaries two examples of what he calls *le cœur humain*. At the siege of Amiens by the Gauls, Cæsar came up with his army, which did not exceed 7000 men; and began to entrench himself in such hurry, that the barbarians judging him to be afraid, attacked his entrenchments with great spirit. During the time they were filling up the ditch, he issued out with his cohorts, and by attacking them unexpectedly struck a panic that made them fly with precipitation, not a single man offered to make a stand. At the siege of Alesia, the Gauls, infinitely superior in number, attacked the Roman lines of circumvallation, in order to raise the siege. Cæsar ordered a body of his men to march out silently, and to attack them on the one flank, while he with another body did the same on the other flank. The surprise of being attacked when they expected a defence only, put the Gauls into disorder, and gave an easy victory to Cæsar.

A

are in proportion. The lowest degree is found in objects surveyed a second time after a long interval; and that in this case an object takes on some appearance of novelty, is certain from experience: a large building of many parts variously adorned, or an extensive field embellished with trees, lakes, temples, statues, and other ornaments, will appear new oftener than once: the memory of an object so complex is soon lost, of its parts at least, or of their arrangement. But experience teaches, that, even without any decay of remembrance, absence alone will give an air of novelty to a once familar object; which is not surprising, because familiarity wears off gradually by absence: thus a person with whom we have been intimate, returning after a long interval, appears like a new acquaintance. And distance of place contributes to this appearance, not less than distance of time: a friend, for example, after a short absence in a remote country, has the same air of novelty as if he had returned after a longer interval from a place nearer home: the mind forms a connexion between him and the remote country, and bestows upon him the singularity of the objects he has seen. For the same reason, when two things equally new and singular are presented, the spectator balances between them; but when told that one of them is the product of a distant quarter of the world, he no longer hesitates, but clings to it as the more singular: hence the preference given to foreign luxuries, and to foreign curiosities, which appear rare in proportion to their original distance.

The next degree of novelty, mounting upward, is found in objects of which we have some information at second hand; for description, though it contribute to familiarity, cannot altogether remove the appearance of novelty when the object itself is presented: the first sight of a lion occasions some wonder, after a thorough acquaintance with the correctest pictures and statues of that animal.

A new object that bears some distant resemblance to a known species, is an instance of a third degree of novelty: a strong resemblance among individuals of the same species, prevents almost entirely the effect of novelty, unless distance of place or some other circumstance concur; but where the resemblance is faint, some degree of wonder is felt, and the emotion rises in proportion to the faintness of the resemblanee.

The highest degree of wonder ariseth from unknown objects that have no analogy to any species we are acquainted with. Shakespeare in a simile introduces that species of novelty:

> As glorious to the sight
> As is a winged messenger from heaven
> Unto the white up-turned wond'ring eye
> Of mortals, that fall back to gaze on him,
> When he bestrides the lazy pacing clouds,
> And sails upon the bosom of the air.
>
> *Romeo and Juliet.*

One example of that species of novelty deserves peculiar attention; and that is, when an object altogether new is seen by one person only, and but once. These circumstances heighten remarkably the emotion: the singularity of the spectator concurs with the singularity of the object, to inflame wonder to its highest pitch.

In explaining the effects of novelty, the place a being occupies in the scale of existence, is a circumstance that must not be omitted. Novelty in the individuals of a low class is perceived with indifference, or with a very slight emotion: thus a pebble, however singular in its appearance, scarcely moves our wonder. The emotion rises with the rank of the object; and, other circumstances being equal, is strongest in the highest order of existence; a strange insect affects us more than a strange vegetable; and a strange quadruped more than a strange insect.

However natural novelty may be, it is a matter of experience, that those who relish it the most are careful to conceal its influence. Love of novelty, it is true, prevails in children, in idlers, and in men of shallow understanding: and yet, after all, why should one be ashamed of indulging a natural propensity? A distinction will afford a satisfactory answer. No man is ashamed of curiosity when it is indulged to acquire knowledge. But to prefer any thing merely because it is new, shows a mean taste which one ought to be ashamed of: vanity is commonly at the bottom, which leads those who are deficient in taste to prefer things odd, rare, or singular, in order to distinguish themselves from others. And in fact, that appetite, as above mentioned, reigns chiefly among persons of a mean taste, who are ignorant of refined and elegant pleasures.

Of this taste we have some memorable instances in men of the highest and the best education. Lucian tells the following story of Ptolemy I. which is as disgraceful to him, as honourable to his subjects. This prince had ransacked the world for two curiosities; one was a camel from Bactria all over black; the other a man, half black half white. These he presented to the people in a public theatre, thinking they would give them as much satisfaction as they did him; but the black monster instead of delighting them, affrighted them; and the party-coloured man raised the contempt of some and the abhorrence of others. Ptolemy, finding the Egyptians preferred symmetry and beauty to

A third may be added not less memorable. In the year 846, an obstinate battle was fought between Xamire king of Leon, and Abdoulrahman the Moorish king of Spain. After a very long conflict the night only prevented the Arabians from obtaining a complete victory. The king of Leon, taking advantage of the darkness, retreated to a neighbouring hill, leaving the Arabians masters of the field of battle. Next morning, perceiving that he could not maintain his place for want of provisions, nor be able to draw off his men in the face of a victorious army, he ranged his men in order of battle, and, without losing a moment, marched to attack the enemy, resolving to conquer or die. The Arabians, astonished to be attacked by those who were conquered the night before, lost all heart: fear succeeded to astonishment, the panic was universal, and they all turned their backs without almost drawing a sword.

to the most astonishing productions of art or nature without them, wisely removed his two enormous trifles out of sight; the neglected camel died in a little time, and the man he gave for a song to the musician Thespis.

One final cause of wonder, hinted above, is, that this emotion is intended to stimulate our curiosity. Another, somewhat different, is, to prepare the mind for receiving deep impressions of new objects. An acquaintance with the various things that may affect us, and with their properties, is essential to our well-being: nor will a slight or superficial acquaintance be sufficient; they ought to be so deeply engraved on the mind, as to be ready for use upon every occasion. Now, in order to a deep impression, it is wisely contrived, that things should be introduced to our acquaintance with a certain pomp and solemnity productive of a vivid emotion. When the impression is once fairly made, the emotion of novelty being no longer necessary, vanisheth almost instantaneously; never to return, unless where the impression happens to be obliterated by length of time or other means; in which case the second introduction hath nearly the same solemnity with the first.

Designing wisdom is nowhere more legible than in this part of the human frame. If new objects did not affect us in a very peculiar manner, their impressions would be so slight as scarce to be of any use in life: on the other hand, did objects continue to affect us as deeply as at first, the mind would be totally engrossed with them, and have no room left either for action or reflection.

The final cause of surprise is still more evident than of novelty. Self-love makes us vigilantly attentive to self-preservation; but self-love, which operates by means of reason and reflection, and impels not the mind to any particular object or from it, is a principle too cool for a sudden emergency; an object breaking in unexpectedly, affords no time for deliberation; and in that case, the agitation of surprise comes in seasonably to rouse self-love into action: surprise gives the alarm; and if there be any appearance of danger, our whole force is instantly summoned to shun or to prevent it.

NOVELLARA, a handsome town of Italy, and capital of a small district of the same name, with a handsome castle, where the sovereign resides. E. Long. 10. 37. N. Lat. 45. 50.

NOVEMVIRI, nine magistrates of Athens, whose government lasted but for one year. The first of whom was called *archon*, or prince; the second *basilius*, or king; the third *polemarchus*, or general of the army: the other six were called *thesmothetæ*, or lawgivers. They took an oath to observe the laws; and in case of failure, obliged themselves to bestow upon the commonwealth a statue of gold as big as themselves. Those who discharged their office with honour, were received into the number of the senators of Areopagus.

NOVI, a town of Italy, in the territory of Genoa, on the confines of the Milanese. It was taken by the Piedmontese in 1746. E. Long. 8. 48. N. Lat. 44. 45.

Novi Bazar, a considerable town of Turkey in Europe, and in Servia, near the river Oresco. E. Long. 20. 24. N. Lat. 43. 25.

NOVICE, a person not yet skilled or experienced in an art or profession.

In the ancient Roman militia, *novicii* or *novitii*, were the young raw soldiers, distinguished by this appellation from the veterans.

In the ancient orders of knighthood, there were novices or clerks in arms, who went through a kind of apprenticeship ere they were admitted knights.—See KNIGHT.

NOVICE is more particularly used in monasteries for a religious yet in his, or her, year of probation, and who has not made the vows.

In some convents, the sub-prior has the direction of the novices. In nunneries, the novices wear a white veil; the rest a black one.

NOVICIATE, a year of probation appointed for the trial of religious, whether or no they have a vocation, and the necessary qualities for living up to the rule; the observation whereof they are to bind themselves to by vow. The noviciate lasts a year at least; in some houses more. It is esteemed the bed of the civil death of a novice, who expires to the world by profession.

NOVIGRAD, a small but strong town of Upper Hungary, capital of a county of the same name, with a good castle, seated on a mountain near the Danube. E. Long. 18. 10. N. Lat. 40. 50.

NOVIGRAD, a small but strong town of Dalmatia, with a castle, and subject to the Turks; seated on a lake of the same name, near the gulf of Venice. E. Long. 16. 45. N. Lat. 44. 30.

NOVIGRAD, a very strong place of Servia, subject to the Turks; seated near the Danube. E. Long. 26. 5. N. Lat. 45. 5.

NOVIODUNUM (Cæsar,), a town of the Ædui, commodiously seated on the Liguris: the *Nivernum* of Antonine. Now *Nevers* in the Orleannois, on the Loire.—A second *Noviodunum* of the Aulerci Diablintes, in Gallia Celtica, (Antonine); called *Noviodunum* (Ptolemy), and *Noningentum Rotrudum* by the moderns: *Nogente le Rotrou*, capital of the duchy of Perche.—A third of the Bituriges, (Cæsar): Now *Nueve sur Baranion*; a village 15 miles to the north of Bourges, towards Orleans.—A fourth, of Mœsia Inferior, (Ptolemy), situated on the Ister; now *Nivorz*, in Bessarabia.—A fifth, of Pannonia Superior, (Antonine); now *Gurkfeld* in Carinthia.—A sixth, *Noviodunum Suessionum*, the same with *Augusta Suessionum*.—A seventh, *Noviodunum* of the Veromandui in Gallia Belgica, (Cæsar): now *Noyon* in the Isle of France, on the borders of Picardy.

NOUN, see GRAMMAR, N° 7.; and Chapter I. *in toto*.

NOVOGOROD WELICKI, *Great Novogorod*, according to Mr Coxe, is one of the most ancient cities in Russia. It was formerly called *Great Novogorod*, to distinguish it from other Russian towns of a similar appellation; and now presents to the attentive and intelligent traveller a striking instance of fallen grandeur, According to Nestor, the earliest of the Russian historians, it was built at the same time with Kiof, namely, in the middle of the 5th century, by a Sclavonian horde, who, according to Procopius, issued from the banks of the Volga. Its antiquity is clearly proved

proved by a passage in the Gothic historian Jornandes, in which it is called *Civitas Nova*, or new town. We have little insight into its history before the 9th century, when Ruric the first great duke of Russia reduced it, and made it the metropolis of his vast dominion. The year subsequent to his death, which happened in 879, the seat of government was removed, under his son Igor, then an infant, to Kiof; and Novogorod continued, for above a century, under the jurisdiction of governors nominated by the great dukes, until 970, when Svatoslaf, the son of Igor, created his third son Vladimir duke of Novogorod: the latter, succeeding his father in the throne of Russia, ceded the town to his son Yaroslaf, who in 1036 granted to the inhabitants very considerable privileges, that laid the foundation of that extraordinary degree of liberty which they afterwards gradually obtained. From this period Novogorod was for a long time governed by its own dukes: these sovereigns were at first subordinate to the great dukes, who resided at Kiof and Volodimir; but afterwards, as the town increased in population and wealth, they gradually usurped an absolute independency. Its independency, however, was not perpetual. It continued, indeed, in a flourishing state until the middle of the 15th century: but the great dukes of Russia, whose ancestors had reigned over this town, and who still retained the title of dukes of Novogorod, having transferred their residence from Kiof to Volodimir, and afterwards to Moscow, laid claim to its feudal sovereignty; a demand which the inhabitants sometimes put off by composition, sometimes by resistance, but were sometimes compelled to acknowledge. At length, however, the great duke became absolute sovereign of Novogorod, though the ostensible forms of government were still preserved. It even then, however, continued to be the largest and most commercial city of Russia; a proof of which we have as late as the year 1554, from the following description of Richard Chancellor, who passed through it in 1554 on his way to Moscow. "Next unto Moscow, the city of Novogorod is reputed the chiefest of Russia; for although it be in majesty inferior to it, yet in greatness it goeth beyond it. It is the chiefest and greatest mart town of all Muscovy; and albeit the emperor's seat is not there, but at Moscow, yet the commodiousness of the river, falling into that gulf which is called Sinus Finnicus, whereby it is well frequented by merchants, makes it more famous than Moscow itself." An idea of its population during this period, when compared with its present declined state, is manifest from the fact, that in 1508 above 15,000 persons died of an epidemical disorder; more than double the number of its present inhabitants. In its most flourishing condition it contained at least 400,000 souls. Its ruin was brought on by Ivan Vasilievitch II. and completed by the foundation of Petersburgh, from which it lies about 90 miles south. The present town is surrounded by a rampart of earth, with a range of old towers at regular distances, forming a circumference of scarcely a mile and a half; and even this inconsiderable circle includes much open space, and many houses which are not inhabited. As Novogorod was built after the manner of the ancient towns in this country, in the Asiatic style, this rampart, like that of the Semlainogorod at Moscow, probably enclosed several interior circles. Without it was a vast extensive suburb, which reached to the distance of six miles, and included within its circuit all the convents and churches, the ancient ducal palace and other structures, that now make a splendid but solitary appearance, as they lie scattered in the adjacent plain.

Novogorod stretches on both sides of the Volkof, a beautiful river of considerable depth and rapidity, and somewhat broader than the Thames at Windsor. This river separates the town into two divisions, the trading part, and the quarter of St Sophia, which are united by means of a bridge, partly wooden and partly brick.

Novogorod Welicki, a province of Muscovy, bounded on the north by Ingria; on the east by part of the duchy of Belozero, and that of Tuera, which also bounds it on the south, with the province of Rzeva; and on the west by Plescow. It is full of lakes and forests; however, there are some places which produce corn, flax, hemp, honey, and wax.

Novogorod Serpskoi, a strong town of the Russian empire, and capital of a province of Siberia of the same name, seated on the river Dubiea, in E. Long. 33. 20. N. Lat. 52. 30.

NOVOGORODECK, a town of Lithuania, and capital of a palatinate of the same name. It is a large place, and situated in a vast plain, in E. Long. 25. 30. N. Lat. 53. 45.

NOURISHMENT. See Nutrition.

Nourishment of Vegetables. See Agriculture *Index*.

NOWED, in *Heraldry*, signifies "knotted," from the Latin *nodatus*; being applied to the tails of such creatures as are very long, and sometimes represented in coat armour as tied up in a knot.

NOX, in fabulous history, one of the most ancient deities among the heathens, daughter of Chaos. From her union with her brother Erebus, she gave birth to the Day and the Light. She was also the mother of the Parcæ, Hesperides, Dreams, of Discord, Death, Momus, Fraud, &c. She is called by some of the poets the mother of all things, of gods as well as of men; and she was worshipped with great solemnity by the ancients. She had a famous statue in Diana's temple at Ephesus. It was usual to offer her a black sheep, as she was the mother of the Furies. The cock was also offered to her, as that bird proclaims the approach of day during the darkness of the night. She is represented as mounted on a chariot, and covered with a veil bespangled with stars. The constellations generally went before her as her constant messengers. Sometimes she is seen holding two children under her arms; one of which is black, representing Death, and the other white, representing Sleep. Some of the moderns have described her as a woman veiled in mourning, and crowned with poppies, and carried on a chariot drawn by owls and bats.

NOYON, a town of France, situated on the declivity of a hill on the rivulet Vorse, which at a quarter of a league's distance falls into the Oyse, in the department of Oyse, in E. Long. 3. 0. N. Lat. 49. 38. about 66 miles north-east of Paris. It is an ancient place, being the *Noviodunum Belgarum* of the Latins. It contained 6033 inhabitants in 1800, and is well situated for inland trade, which consists here in wheat and oats, which they send to Paris. They have also

also manufactories of linen cloths, lawns, and tanned leather. There are eight parishes in it, two abbeys, and several monasteries of both sexes. It is the see of a bishop, suffragan to the metropolitan of Rheims; he has the title of count and peer of France, and his income is said to amount to about 15,000 livres per annum. The principal buildings are the episcopal palace, a cloister where the canons of the cathedral dwell, and the town-house. The latter is regularly built in a large square, in the middle of which there is a fountain, where the water conveyed to it from a neighbouring mountain runs continually through three conduits, and is received in a large bason built of very hard stone. They have also many other fountains, several market places, and two public gardens. Noyon is particularly remarkable for the birth of the famous John Calvin, who was born here on the 10th of July 1502, and died at Geneva the 27th of May 1564.

NUAYHAS, the AGUE TREE; a name given by the Indians to a sort of bamboo cane, the leaves of which falling into the water, are said to impregnate it with such virtue, that the bathing in it afterwards cures the ague. They use also a decoction of the leaves to dissolve coagulated blood, giving it internally, and at the same time rubbing the bruised part externally with it. It is said that this plant bears its flowers only once in its life; that it lives 60 years before those make their appearance; but that when they begin to show themselves, it withers away in about a month afterwards; that is, as soon as it has ripened the seed. There seems to be something of fiction in the account of many other particulars relating to this tree in the *Hortus Malabaricus*; but it seems certain, that the length of the stalks, or trunk, must be very great: for, in the gallery of Leyden, there is preserved a cane of it 28 feet long; and another not much shorter in the Ashmolean museum at Oxford, and which is more than eight inches in diameter: yet both these appear to be only parts of the whole trunk, they being nearly as large at one end as at the other.

NUBA, a race of black Pagans, in the neighbourhood of Sennaar, of whom we know nothing but what we have learned from Mr Bruce. That celebrated traveller passed a day or two among them, in his way from Abyssinia; and he tells us, that they are all soldiers of the *Mek* or king of Sennaar, cantoned in villages, which to the distance of four or five miles surround the capital. They are not the aborigines of that part of Africa; but "are either purchased or taken by force from Fazuclo, and the provinces to the south upon the mountains Dyre and Tegla." Though the slaves of a cruel and treacherous master, Mr Bruce represents them as a gentle, honest, and hospitable people; and he says expressly, that on a journey he had seldom passed a more comfortable night, than one in which he took refuge from a storm in a village of those Nuba. He had a good supper, and a clean neat hut to sleep in, while some of the Nuba watched for him all night, and took care of his beasts and his baggage. "Having settlements and provisions given them by the government of Sennaar, as also arms put into their hands, they never wish to desert, but live a very domestic and sober life, and are a much gentler sort of negro than their masters." (See SENNAAR). Though the established religion of Sennaar is that of Mahomet, the government has never attempted to convert the Nuba. On the contrary, a certain number of Pagan priests is maintained for them in every village, who have soldiers in pay to assist them in the affairs of their religion. This is a very singular instance of toleration among Mahometans, and what we should little have expected from such barbarous and sanguinary wretches as those who have the supreme power in Sennaar, had not our observing traveller informed us, that these men themselves know almost nothing of the religion which they profess, and are in their hearts rather Pagans than Mahometans.

The idolatry of the Nuba is described as a mixture of Sabiism and statue worship: but what is very uncommon, their worship is chiefly paid to the moon, while they pay no attention to the sun either rising or setting, advancing to the meridian or receding from it. It is an old observation, that the worship of every people is tinctured by their natural dispositions; and this is verified in the Nuba. "That their worship is performed with pleasure and satisfaction, is obvious (says our author) every night that the moon shines. Coming out from the darkness of their huts, they say a few words upon seeing her brightness, and testify great joy, by motions of their feet and hands, at the first appearance of the new moon." This is just what we should have expected from their gentleness and hospitality. They worship likewise a tree and a stone; but our author could never discover what tree or stone; only he learned that neither of them exists in Sennaar, but in the country where the Nuba are born. Such of them as are natives of the villages where he saw them, become, like their masters, nominal Mahometans.—The rest practise the idolatrous worship of their ancestors, and are much under the influence of their priests, from fear rather than from affection. They are immoderately fond of swine's flesh, and maintain great herds of small hogs, marked with black and white spots. Few of the Nuba advance higher than to be soldiers and officers in their own corps; and the Mek maintains about 12,000 of them near Sennaar to keep the Arabs in subjection. In a climate so violent as that which they inhabit, there is very little need of fuel; and it is happy for them that such is the case, for in the whole country there is not a single tree, or turf, or any thing resembling it. They do not, however, "eat their meat raw like the Abyssinians; but with the stalk of the dora or millet, and the dung of camels, they make ovens under ground, in which they roast their hogs whole, in a very cleanly manner, keeping their skins on till they are perfectly baked. They have neither flint nor steel with which to light their fire at first; but do it in a manner still more expeditious, by means of two sticks, brought, we are led to think, from Sennaar, and there picked out of the river when flooded. They make a small hole in one of these sticks, and point the other: then laying the former in a horizontal position, they apply the point of the latter to the hole; and, turning the perpendicular stick between their hands, as we do a chocolate mill, both sticks take fire and flame in a moment; so perfectly dry and prepared to take fire is every thing there on the surface of the earth."

NUBECULA, Little Cloud, in *Medicine*, a term sometimes used for a disease in the eye, wherein objects appear as through a cloud or mist.

The nubecula seems to arise from certain gross particles detained in the pores of the cornea, or swimming in the aqueous humour, and thus intercepting the rays of light.

Nubecula, or *Nubes*, is also used for what is otherwise called *albugo*. See Albugo.

Nubecula is used likewise for a matter in form of a cloud, suspended in urine.

NUBIA, a kingdom of Africa, bounded on the north by Egypt, on the east by the Red sea and part of Abyssinia, on the west by the kingdoms of Tagua, Gaoga, and the desert of Gerham. The river Nile runs through it; on the banks of which, and those of the other rivers, it is pretty fruitful, but in other places barren, sandy, and in want of water. To the west of the Nile is the desert of Bahouda, which is five days journey over, being the usual road from Egypt to Abyssinia. Money is of no use in this country in the way of trade, it being all carried on by way of exchange. Their bread and drink is made of a small round seed, called *dora* or *seff*, which is very ill tasted. Their houses have mud walls, being very low, and covered with reeds. The habit of the better sort is a vest without sleeves; and they have no coverings for their heads, legs, and feet. The common people wrap a piece of linen cloth about them, and the children go quite naked. They are a stupid debauched sort of people, having neither modesty, civility, nor religion, though they profess to be Mahometans.—The productions of this country are gold, elephants teeth, civet, and sandal wood; and they send a great many slaves into Egypt. The principal towns known to the Europeans are Dangola and Sennaar.

It is famous for a race of horses the most powerful and docile in the world. These animals are generally about sixteen hands high; and by Mr Bruce, who has given the most scientific account of them, they are said to be the breed which was introduced into Nubia at the Saracen conquest, and has been preserved unmixed to this day. Our author represents this as a much nobler animal than the Arabian horse. "What figure (says he*) the Nubian horse would make in point of fleetness is very doubtful, his make being so entirely different from that of the Arabian; but if beautiful symmetry of parts, great size and strength, the most agile, nervous, and elastic movements, great endurance of fatigue, docility of temper, and seeming attachment to men beyond that of any other domestic animal, can promise any thing for a stallion, the Nubian is above all comparison the most eligible in the world." He thinks, and justly thinks, that an attempt should at least be made to import them into this kingdom. "The expence (he says) would not be great, though there might be some trouble and application necessary: but if adroitly managed, there would not be much even of that. The Nubians are very jealous in keeping up the pedigree of their horses, which are black or white, but a vast proportion of the former to the latter." Our author never saw the colour which we call gray, i. e. dappled; but he has seen some bright bays, and some inclined to sorrel. All noble horses in Nubia are said to be descended of one of the five upon which Mahomet and his four immediate successors, Abu Becr, Omar, Atmen, and Ali, fled from Mecca to Medina the night of the Hegira. No one will pay much regard to this legendary tale, or believe that the strength and beauty of this breed of horses is owing to any virtue communicated to the first of them by the prophet and his apostles. Mr Bruce accounts for their excellence upon rational principles "The best horses of the Arabian breed are found (he says) in the tribe of Mowelli and Annecy, which is about 36° north latitude. Dangola, which is in 20° latitude, seemed to him to be the centre of excellence for this noble animal." Hence he infers, that the bounds in which the horse is in greatest perfection, are between the 20th and 36th degrees of latitude, and between 30 degrees of longitude east from Greenwich and the banks of the Euphrates. If to the effects of climate we add the manner of feeding the Nubian horses, we shall perhaps have the true cause of their superiority over all others. "They are kept fat upon dora, and suffered to eat nothing green but the short roots of grass that are to be found by the side of the Nile, after the sun has withered it. This is dug out where it is covered with earth, and appears blanched, and laid in small heaps once a-day on the ground before them."

* Travels, vol. iv. b. 8. ch. 10.

NUBIAN desert, a vast tract of barren rocks and burning sands, extending from Syene in Upper Egypt to Geon, the capital of Berber in Nubia. As Syene is in latitude 24° 0′ 45″ north, and Geon in latitude 17° 57′ 22″, the length of this desert from north to south is 6° 3′ 23″, or upwards of 420 English miles. Its breadth from east to west has not, as far as we know, been precisely ascertained. Through this horrid region, where nothing is to be seen which has the breath of life, must all travellers pass from Sennaar to Egypt; in danger every moment of perishing by thirst, being overwhelmed by moving columns of sand, suffocated by a hot and poisonous wind, or cut in pieces by troops of wandering Arabs. The last European of whom we have heard that made the journey and lived to give an account of it, is Mr Bruce; and the person must have neither taste nor sensibility who can read unmoved his manly narrative.

No single traveller, nor even a caravan, can enter with safety into this desert, but under the protection of a Hybear; whose title and office are thus explained by Mr Bruce: "A Hybear is a guide, from the Arabic word *Hubbar*, which signifies to inform, instruct, or direct, because they are used to do this office to the caravans travelling through the desert in all directions. They are men of great consideration, knowing perfectly the situation and properties of all kinds of water to be met with on the route; the distance of wells, whether occupied by enemies or not; and if so, the way to avoid them with the least inconvenience. It is also necessary that they should know the places occupied by the Simoom, and the seasons of its blowing (see Simoom), as well as those occupied by moving sands."—Under the conduct of one of these men, Mr Bruce, with infinite fortitude and address, passed through the desert in the year 1772, surmounting dangers at which one shudders in his closet. Of these, the following, which we shall give in the nervous language of the author, may serve as an instance.

"We were here (at a place called *Waadi al Halboub*)

at

at once surprised and terrified by a sight surely one of the most magnificent in the world. In that vast expanse of desert, from W. to NW. of us, we saw a number of prodigious pillars of sand at different distances, at times moving with great celerity, at others stalking on with a majestic slowness. At intervals we thought they were coming in a very few minutes to overwhelm us; and small quantities of sand did actually more than once reach us. Again they would retreat so as to be almost out of sight; their tops reaching to the very clouds. There the tops often separated from the bodies; and these once disjoined, dispersed in the air, and did not appear more. Sometimes they were broken in the middle as if struck with a large cannon shot. About noon they began to advance with considerable swiftness upon us, the wind being very strong at north. Eleven of them ranged alongside of us about the distance of three miles. The greatest diameter of the largest appeared to me at that distance as if it would measure 10 feet. They retired from us with a wind at SE. leaving an impression upon my mind to which I can give no name; though surely one ingredient in it was fear, with a considerable degree of wonder and astonishment."

If it be true, as the author of A Philosophical Inquiry into the Origin of our Ideas of the Sublime and Beautiful affirms, that "the passion raised by the sublime is astonishment, and that astonishment is that state of the soul in which all its motions are suspended with some degree of horror," surely a more sublime spectacle was never presented to mortal eyes, than that which was on this occasion presented to Mr Bruce. It must have been awfully majestic; but few, we believe, would choose the pleasure of contemplating such a scene of magnificence at the hazard of that dreadful death with which at every moment it threatened our traveller and his attendants. He, indeed, had firmness of mind to stand still and admire it; but his companions shrieked out; while some of them exclaimed that it was the day of judgment, and others that it was hell or the world set on fire. But for a more particular account of this phenomenon, as well as of the nature of the desert and the proper way of passing it, we must refer to the work from which this short sketch is taken*.

* *Bruce's Travels*, vol. iv.

NUCLEUS, in general, denotes the kernel of a nut, or even any seed enclosed within a husk. The term *nucleus* is also used for the body of a comet, otherwise called its *head*.

NUCTA, a dew, which falling in Egypt about St John's day, is by the superstitious natives of the country considered as miraculous, and the peculiar gift of that saint. Its effects are indeed so beneficial, that this belief is little surprising among a people so totally ignorant of natural causes as the modern Egyptians; for it is acknowledged, by the most enlightened travellers, to stop the plague, and announce a speedy and plentiful inundation of the country. These effects are thus rationally accounted for by Mr Bruce.

"In February and March, the sun is on its approach to the zenith of one extremity of Egypt, and of course has a very considerable influence upon the other. The Nile having now fallen low, the water in certain old cisterns, which, though they still exist, are suffered to accumulate all the filth of the river, becomes putrid, and the river itself has lost all its finer and volatile parts by the continued action of a vertical sun; so that instead of being subject to evaporation, it grows daily more and more inclined to putrefaction. About St John's day it receives a plentiful mixture of the fresh and fallen rain from Ethiopia, which dilutes and refreshes the almost corrupted river, and the sun near at hand exerts its influence upon the water, which is now become light enough to be exhaled, though it has still with it a mixture of the corrupted fluid. It is in February, March, or April only, that the plague begins in Egypt." Our philosophical traveller does not believe it an endemical disease; but assigns very sufficient reasons for thinking that it comes from Constantinople with merchandise or with passengers at the very time of the year when the air, by the long absence of dews, has attained a degree of putridity proper to receive it. In this state of the atmosphere, the infection continues to rage till the period of St John's day, when it is suddenly stopped by the dews occasioned by a refreshing mixture of rain water, which is poured into the Nile at the beginning of the inundation. The first and most remarkable sign of the change effected in the air, is the sudden stopping of the plague. Every person, though shut up from society for months before, buys, sells, and communicates with his neighbour without any sort of apprehension; and as far as our author could learn upon fair inquiry, it was never known that one fell sick of the plague after the anniversary of St John. He admits that some have died of it after that period; but of them the disease had got such hold, under the most putrid influence of the air, that they could not recover. To corroborate this theory, which attributes so much to the benign influence of the falling dew, he observes, that immediately after St John's day, the clothes of the many thousands who have died during the late continuance of the plague are publicly exposed in the market place; and that all these, though consisting of furs, cotton, silk, and woollen cloths, which are the stuffs most retentive of infection, imbibing the moist air of the evening and the morning, are handled, bought, put on and worn, without any apprehension of danger, and without a single accident being known to have happened to any one possessed of this happy confidence.

NUDITIES, in painting and sculpture, those parts of a human figure which are not covered with any drapery; or those parts where the carnation appears.

NULLITY, in *Law*, signifies any thing that is null or void: thus there is a nullity of marriage, where persons marry within the degrees, or where infants marry without consent of their parents or guardians.

NUMA POMPILIUS, the fourth son of Pompilius Pompo, an illustrious Sabine. He had married Tatia, the daughter of King Tatius, and together with her remained in his native country, preferring the tranquillity of a private life to the splendour of a court. Upon the death of his wife, with whom he had lived thirteen years, he gave himself up entirely to the study of wisdom; and, leaving the city of Cures, confined himself to the country, wandering from solitude to solitude, in search only of those woods and fountains which religion had made sacred. His recluse life gave rise to the fable, which was very early received among the Sabines, that Numa lived in familiarity with the nymph Egeria. Upon the death of Romulus, both the senate

senate and people strongly solicited him to be their king. They despatched Julius Proculus and Valerius Volesus, two senators of distinction, to acquaint Numa with their resolution, and make him an offer of the kingdom. The Sabine philosopher rejected at first their proposal; but being at last prevailed upon by the arguments and entreaties of the deputies, joined with those of his father and of Martius his near relation, he yielded; and having offered sacrifices to the gods, set out for Rome, where he was received by all ranks of people with loud shouts of joy. Spurius Vettius, the interrex for the day, having assembled the curiæ, he was elected in due form, and the election was unanimously confirmed by the senate.

The beginning of his reign was popular; and he dismissed the 300 bodyguards which his predecessor had kept around his person, and observed, that he did not distrust a people who had compelled him to reign over them. He was not, like Romulus, fond of war and military expeditions, but he applied himself to tame the ferocity of his subjects, to inculcate in their minds a reverence for the Deity, and to quell their dissensions by dividing all the citizens into different classes. He established different orders of priests, and taught the Romans not to worship the Deity by images; and from his example no graven or painted statues appeared in the temples or sanctuaries of Rome for the space of 160 years. He encouraged the report that was spread of his paying regular visits to the nymph Egeria, and made use of her name to give sanction to the laws and institutions which he had introduced. He established the college of the vestals, and told the Romans that the safety of the empire depended upon the preservation of the sacred *ancyle* or shield, which, as was generally believed, had dropped from heaven. He dedicated a temple to Janus, which, during his whole reign, remained shut as a mark of peace and tranquillity at Rome. After a reign of 42 years, in which he had given every possible encouragement to the useful arts, and in which he had cultivated peace, Numa died in the year of Rome 82. Not only the Romans, but also the neighbouring nations, were eager to pay their last offices to a monarch whom they revered for his abilities, moderation, and humanity. He forbade his body to be burnt according to the custom of the Romans; but he ordered it to be buried near Mount Janiculum, with many of the books which he had written. These books were accidentally found by one of the Romans, about 400 years after his death; and as they contained nothing new or interesting, but merely the reasons why he had made innovations in the form of worship and in the religion of the Romans, they were burnt by order of the senate. He left behind him one daughter called Pompilia, who married Numa Marcius, and became the mother of Ancus Marcius the fourth king of Rome. Some say that he had also four sons; but this opinion is ill founded. The principal laws of King Numa, mentioned by different authors, are, 1. That the gods should be worshipped with corn and a salted cake. 2. That whoever knowingly killed a free man, should be held as a parricide. 3. That no harlot should touch the altar of Juno; and if she did, that she should sacrifice a ewe-lamb to that goddess, with dishevelled hair. 4. That whoever removed a land-mark should be put to death. 5. That wine should not be poured on a funeral pile, &c.

NUMANTIA, a very noble city, the ornament of the Hither Spain, (Florus); celebrated for the long war of 20 years which it maintained against the Romans. The baseness and injustice of the Romans during this war were truly disgraceful to them, and altogether unworthy of a great and powerful people. The inhabitants obtained some advantages over the Roman forces, till Scipio Africanus was empowered to finish the war and to see the destruction of Numantia. He began the siege, with an army of 60,000 men, and was bravely opposed by the besieged, who were no more than 4000 men able to bear arms. Both armies behaved with uncommon valour, and the courage of the Numantines was soon changed into despair and fury. Their provisions began to fail, and they fed upon the flesh of their horses, and afterwards on that of their dead companions, and at last they were obliged to draw lots to kill and devour one another. The melancholy situation of their affairs obliged them to surrender to the Roman general. Scipio demanded them to deliver themselves up on the morrow; they refused, and when a longer time had been granted to their petitions, they retired and set fire to their houses and destroyed themselves, so that not even one remained to adorn the triumph of the conqueror. Some historians, however, deny that; and assert, that a number of Numantines delivered themselves into Scipio's hands, and that 50 of them were drawn in triumph at Rome, and the rest sold as slaves. The fall of Numantia was more glorious than that of Carthage or Corinth, though the place was much inferior to them. It was taken by the Romans, A. U. C. 629; and the conqueror obtained the surname of *Numanticus*.

NUMBER, an assemblage of several units, or things of the same kind. See ARITHMETIC, and METAPHYSICS, N° 205—208.

Number, says Malcolm, is either abstract or applicate: Abstract, when referred to things in general, without attending to their particular properties; and applicate, when considered as the number of a particular sort of things, as yards, trees, or the like.

When particular things are mentioned, there is always something more considered than barely their numbers; so that what is true of numbers in the abstract, or when nothing but the number of things is considered, will not be true when the question is limited to particular things: for instance, the number two is less than three; yet two yards is a greater quantity than three inches: and the reason is, because regard must be had to their different natures as well as number, whenever things of a different species are considered; for though we can compare the number of such things abstractedly, yet we cannot compare them in any applicate sense. And this difference is necessary to be considered, because upon it the true sense, and the possibility or impossibility, of some questions depend.

Number is unlimited in respect of increase; because we can never conceive a number so great but still there is a greater. However, in respect of decrease, it is limited; unity being the first and least number, below which therefore it cannot descend.

Number.

Kinds and distinctions of NUMBERS. Mathematicians, considering number under a great many relations, have established the following distinctions.

Broken numbers are the same with fractions.

Cardinal numbers are those which express the quantity of units, as 1, 2, 3, 4, &c. whereas ordinal numbers are those which express order, as 1st, 2d, 3d, &c.

Compound number, one divisible by some other number besides unity; as 12, which is divisible by 2, 3, 4, and 6. Numbers, as 12 and 15, which have some common measure besides unity, are said to be compound numbers among themselves.

Cubic number is the product of a square number by its root: such is 27, as being the product of the square number 9 by its root 3 All cubic numbers, whose root is less than 6, being divided by 6, the remainder is the root itself; thus 27÷6 leaves the remainder 3, its root; 215, the cube of 6, being divided by 6, leaves no remainder; 343, the cube of 7, leaves a remainder 1, which added to 6, is the cube root; and 512, the cube of 8, divided by 6, leaves a remainder 2, which added to 6, is the cube root. Hence the remainders of the divisions of the cubes above 216, divided by 6, being added to 6, always give the root of the cube so divided till that remainder be 5, and consequently 11, the cube root of the number divided. But the cubic numbers above this being divided by 6, there remains nothing, the cube root being 12. Thus the remainders of the higher cubes are to be added to 12 and not to 6, till you come to 18, when the remainder of the division must be added to 18; and so on *ad infinitum.*

Determinate number is that referred to some given unit, as a ternary or three: whereas an indeterminate one is that referred to unity in general, and is called *quantity.*

Homogeneal numbers are those referred to the same unit; as those referred to different units are termed *heterogeneal.*

Whole numbers are otherwise called *integers.*

Rational number is one commensurable with unity; as a number, incommensurable with unity, is termed *irrational*, or a *surd.*

In the same manner, a rational whole number is that whereof unity is an aliquot part; a rational broken number, that equal to some aliquot part of unity; and a rational mixed number, that consisting of a whole number and a broken one.

Even number, that which may be divided into two equal parts without any fraction, as 6, 12, &c. The sum, difference, and product, of any number of even numbers, is always an even number.

An evenly even number, is that which may be measured, or divided, without any remainder, by another even number, as 4 by 2.

An unevenly even number, when a number may be equally divided by an uneven number, as 20 by 5.

Uneven number, that which exceeds an even number, at least by unity, or which cannot be divided into two equal parts, as 3, 5, &c.

The sum or difference of two uneven numbers makes an even number; but the factum of two uneven ones makes an uneven number.

If an even number be added to an uneven one, or if the one be subtracted from the other; in the former case the sum, in the latter the difference, is an uneven number: but the factum of an even and uneven number is even.

The sum of any even number of uneven numbers is an even number; and the sum of any uneven number of uneven numbers is an uneven number.

Primitive or prime numbers are those divisible only by unity, as 5, 7, &c. And prime numbers among themselves, are those which have no common measure besides unity, as 12 and 19.

Perfect number, that whose aliquot parts added together make the whole number, as 6, 28; the aliquot parts of 6 being 3, 2, and 1, =6; and those of 28, being 14, 7, 4, 2, 1, =28.

Imperfect numbers, those whose aliquot parts added together make either more or less than the whole. And these are distinguished into abundant and defective: an instance in the former case is 12, whose aliquot parts 6, 4, 3, 2, 1, make 16; and in the latter case 16, whose aliquot parts 8, 4, 2, and 1, make but 15.

Plane number, that arising from the multiplication of two numbers, as 6, which is the product of 3 by 2; and these numbers are called the *sides of the plane.*

Square number is the product of any number multiplied by itself; thus 4, which is the factum of 2 by 2, is a square number.

Even square number added to its root makes an even number.

Figurate numbers, are such as represent some geometrical figure, in relation to which they are always considered; as triangular, pentagonal, pyramidal, &c. numbers.

Figurate numbers, are distinguished into orders, according to their place in the scale of their generation, being all produced one from another, viz. by adding continually the terms of any one, the successive sums are the terms of the next order, beginning from the first order which is that of equal units 1, 1, 1, 1, &c.; then the 2d order consists of the successive sums of those of the 1st order, forming the arithmetical progression 1, 2, 3, 4, &c; those of the third order are the successive sums of those of the 2d, and are the triangular numbers 1, 3, 6, 10, 15, &c.; those of the fourth order are the successive sums of those of the 3d, and are the pyramidal numbers 1, 4, 10, 20, 35, &c.; and so on as below:

Order.	*Names.*	*Numbers.*				
1.	Equals,	1,	1,	1,	1,	1, &c.
2.	Arithmeticals,	1,	2,	3,	4,	5, &c.
3.	Triangulars,	1,	3,	6,	10,	15, &c.
4.	Pyramidals,	1,	4,	10,	20,	35, &c.
5.	2d Pyramidals,	1,	5,	15,	35,	70, &c.
6.	3d Pyramidals,	1,	6,	21,	56,	126, &c.
7.	4th Pyramidals,	1,	7,	28,	84,	210, &c.

The above are all considered as different sorts of triangular numbers, being formed from an arithmetical progression whose common difference is 1. But if that common difference be 2, the successive sums will be the series of square numbers: if it be 3, the series will be pentagonal numbers, or pentagons; if it be 4, the series will be hexagonal numbers, or hexagons; and so on. Thus:

4

Arithmeticals.

Arithmeticals.	1st Sums, or Polygons.	2d Sums, or 2d Polygons.
1, 2, 3, 4,	Tri. 1, 3, 6, 10	1, 4, 10, 20
1, 3, 5, 7,	Sqrs. 1, 4, 9, 16	1, 5, 14, 30
1, 4, 7, 10,	Pent. 1, 5, 12, 22	1, 6, 18, 40
1, 5, 9, 13, &c.	Hex. 1, 6, 15, 28	1, 7, 22, 50

And the reason of the names triangles, squares, pentagons, hexagons, &c. is, that those numbers may be placed in the form of these regular figures or polygons.

But the figurate numbers of any order may also be found without computing those of the preceding orders; which is done by taking the successive products of as many of the terms of the arithmeticals, 1, 2, 3, 4, 5, &c. in their natural order, as there are units in the number which denominates the order of figurates required, and dividing those products always by the first product: thus, the triangular numbers are found by dividing the products 1×2, 2×3, 3×4, 4×5, &c. each by the 1st pr. 1×2; the first pyramids by dividing the products $1\times2\times3$, $2\times3\times4$, $3\times4\times5$, &c. by the first $1\times2\times3$. And, in general, the figurate numbers of any order n, are found by substituting successively 1, 2, 3, 4, 5, &c. instead of x in this general expression $\frac{x\,.\,x+1\,.\,x+2\,.\,x+3\,.\,\&c.}{1\,.\,2\,.\,3\,.\,4\,.\,\&c.}$; where the factors in the numerator and denominator are supposed to be multiplied together, and to be continued till the number in each be less by 1 than that which expresses the order of the figurates required. See Maclaurin's Fluxions, art. 351, in the notes; also Simpson's Algebra, p. 213; or Malcolm's Arithmetic, p. 396, where the subject of figurates is treated in a very extensive and perspicuous manner. *Hutton's Mathematical Dictionary.*

Polygonal or polygonous numbers, the sums of arithmetical progressions beginning with unity: these, where the common difference is 1, are called *triangular numbers;* where 2, *square numbers;* where 3, *pentagonal numbers;* where 4, *hexagonal numbers;* where 5, *heptagonal numbers*, &c.

Pyramidal numbers, the sums of polygonous numbers, collected after the same manner as the polygons themselves, and not gathered out of arithmetical progressions, are called *first pyramidal numbers;* the sums of the first pyramidals are called *second pyramidals*, &c.

If they arise out of triangular numbers, they are called *triangular pyramidal numbers;* if out of pentagons, *first pentagonal pyramidals.*

From the manner of summing up polygonal numbers, it is easy to conceive how the prime pyramidal numbers are found, viz. $\frac{(a-2)n^3+3n^2-(a-5)n}{6}$ expresses all the prime pyramidals.

The number nine has a very curious property, its products always composing either 9 or some lesser product of it. We have already given an account of this, with the examples from Hume, under the article Nine; and we need not repeat them. Did our limits permit us, we could instance in a variety of other numbers properties both curious and surprising. Such speculations are indeed by some men considered as trifling and useless: but perhaps they judge too hastily; for few employments are more innocent, none more ingenious, nor, to those who have a taste for them, more amusing.

Numbers were by the Jews, as well as the ancient Greeks and Romans, expressed by letters of the alphabet: hence we may conceive how imperfect and limited their arithmetic was, because the letters could not be arranged in a series, or in different lines, conveniently enough for the purposes of ready calculation. The invention of the cypher, or arithmetical figures, which we now make use of, has given us a very great advantage over the ancients in this respect.

Mankind we may reasonably suppose, first reckoned by their fingers, which they might indeed do in a variety of ways. From this digital arithmetic, very probably, is owing the number 10, which constitutes the whole set of arithmetical figures.

The letters chiefly employed by the Romans to express numbers were, M, for 1000; D, for 500; C, for 100; L, for 50; V, for 5; X, for 10; and I, for one.—M, probably signified 1000, because it is the initial of *mille;* D stands for 500, because it is *dimidium mille;* C signifies 100, as being the first letter of the word *centum;* L stands for 50, because it is the half of C, having formerly been wrote thus ∟; V signifies 5, because V is the fifth vowel; X stands for 10, because it contains twice V or V in a double form; I stands for one, because it is the first letter of *initium.* These however are fanciful derivations. See Numeral *Letters.*

The Jewish cabbalists, the Grecian conjurors, and the Roman augurs, had a great veneration for particular numbers, and the result of particular combinations of them. Thus three, four, six, seven, nine, ten, are full of divine mysteries, and of great efficacy.

Golden Number. See Chronology, N° 27.

Numbers, in *Poetry, Oratory*, &c. are certain measures, proportions, or cadences, which render a verse, period, or song, agreeable to the ear.

Poetical numbers consist in a certain harmony in the order, quantities, &c. of the feet and syllables, which make the piece musical to the ear, and fit for singing, for which all the verses of the ancients were intended. See Poetry.—It is of these numbers Virgil speaks in his ninth Eclogue, when he makes Lycidas say, *Numeros memini, si verba tenerem;* meaning, that although he had forgot the words of the verses, yet he remembered the feet and measure of which they were composed.

Rhetorical or prosaic numbers are a sort of simple unaffected harmony, less glaring than that of verse, but such as is perceived and affects the mind with pleasure.

The numbers are that by which the style is said to be easy, free, round, flowing, &c. Numbers are things absolutely necessary in all writing, and even in all speech. Hence Aristotle, Tully, Quintilian, &c. lay down abundance of rules as to the best manner of intermixing dactyles, spondees, anapests, &c. in order to have the numbers perfect. The substance of what they have said, is reducible to what follows: 1. The style becomes numerous by the alternate disposition and temperature of long and short syllables, so as that the multitude of short ones neither render it too hasty, nor that of long ones

too

Numbers, Numeral.

too slow and languid: sometimes, indeed, long and short syllables are thrown together designedly without any such mixture, to paint the slowness or celerity of any thing by that of the numbers; as in these verses of Virgil:

Illi inter sese magna vi brachia tollunt;

and

Radit iter liquidum, celeres neque commovet alas.

2. The style becomes numerous, by the intermixing words of one, two, or more syllables; whereas the too frequent repetition of monosyllables renders the style pitiful and grating. 3. It contributes greatly to the numerousness of a period, to have it closed by magnificent and well-sounding words. 4. The numbers depend not only on the nobleness of the words in the close, but of those in the whole tenor of the period. 5. To have the period flow easily and equally, the harsh concurrence of letters and words is to be studiously avoided, particularly the frequent meeting of rough consonants; the beginning the first syllable of a word with the last of the preceding; the frequent repetition of the same letter or syllable; and the frequent use of the like ending words. Lastly, The utmost care is to be taken, lest, in aiming at oratorial numbers, you should fall into poetical ones; and instead of prose, write verse.

Book of Numbers, the fourth book of the Pentateuch, taking its denomination from its numbering the families of Israel.

A great part of this book is historical, relating to several remarkable passages in the Israelites march through the wilderness. It contains a distinct relation of their several movements from one place to another, or their 42 stages through the wilderness, and many other things, whereby we are instructed and confirmed in some of the weightiest truths that have immediate reference to God and his providence in the world.—But the greatest part of this book is spent in enumerating those laws and ordinances, whether civil or ceremonial, which were given by God, but not mentioned before in the preceding books.

NUMERAL letters, those letters of the alphabet which are generally used for figures; as I, one; V, five; X, ten; L, fifty; C, a hundred; D, five hundred; M, a thousand, &c.

It is not agreed how the Roman numerals originally received their value. It has been supposed, as we have observed in the end of the article Number, that the Romans used M to denote 1000, because it is the first letter of *mille*, which is Latin for 1000; and C to denote 100, because it is the first letter of *centum*, which is Latin for 100. It has also been supposed, that D, being formed by dividing the old M in the middle, was therefore appointed to stand for 500, that is, half as much as the M stood for when it was whole; and that L being half a C, was, for the same reason, used to denominate 50. But what reason is there to suppose, that 1000 and 100 were the numbers which letters were first used to express? And what reason can be assigned why D, the first letter in the Latin word *decem*, ten, should not rather have been chosen to stand for that number, than for 500, because it had a rude resemblance to half an M?—But if these questions could be satisfactorily answered, there are other numeral letters which have never yet been accounted for at all. These considerations render it probable that the Romans, did not, in their original intention, use letters to express numbers at all; the most natural account of the matter seems to be this:

Numera

The Romans probably put down a single stroke, I, for one, as is still the practice of those who score on a slate or with chalk: this stroke, I, they doubled, trebled, and quadrupled, to express 2, 3, and 4: thus, II. III. IIII. So far they could easily number the strokes with a glance of the eye. But they presently found, that if more were added, it would soon be necessary to tell the strokes one by one: for this reason then, when they came to 5, they expressed it by joining two strokes together in an acute angle thus, V; which will appear the more probable, if it be considered that the progression of the Roman numbers is from 5 to 5, i. e. from the fingers on one hand to the fingers on the other.—Ovid has touched upon the original of this in his *Fastorum*, lib. iii. and *Vitruvius* has made the same remark.

After they had made this acute angle V. for five, they added the single strokes to it to the number of 4, thus, VI. VII. VIII. VIIII. and then as the strokes could not be further multiplied without confusion, they doubled their acute angle by prolonging the two lines beyond their intersection thus, X, to denote two fives, or ten. After this they doubled, trebled, and quadrupled, this double acute angle thus, XX. XXX. XXXX. they then, for the same reason which induced them first to make a single and then to double it, joined two single strokes in another form, and instead of an acute angle, made a right angle L, to denote fifty. When this 50 was doubled, they then doubled the right angle thus ⊏, to denote 100, and having numbered this double right angle four times, thus ⊏⊏ ⊏⊏⊏ ⊏⊏⊏⊏; when they came to the fifth number, as before, they reverted it, and put a single stroke before it thus I⊐, to denote 500; and when this 500 was doubled, then they also doubled their double right angle, setting two double right angles opposite to each other, with a single stroke between them, thus ⊏I⊐ to denote 1000: when this note for 1000 had been four times repeated, then they put down I⊐⊐ for 5000, ⊏⊏I⊐⊐ for 10,000, and I⊐⊐⊐ for 50,000, and ⊏⊏⊏I⊐⊐⊐ for 100,000, I⊐⊐⊐⊐ for 500,000 and ⊏⊏⊏⊏I⊐⊐⊐⊐ for one million.

That the Romans did not originally write M for 1000, and C for 100, but square characters, as they are written above, we are expressly informed by Paulus Manutius; but the corners of the angles being cut off by the transcribers for despatch, these figures were gradually brought into what are now numeral letters.—When the corners of ⊏I⊐ were made round, it stood thus CIↃ, which is so near the Gothic *m*, that it soon deviated into that letter; so I⊐ having the corner made round, it stood thus IↃ, and then easily deviated into D. ⊏ also became a plain C by the same means; the single rectangle which denoted 50, was without alteration, a capital L; the double acute angle was an X; the single acute angle a V consonant; and a plain single stroke, the letter I; and thus these seven letters, M, D, C, L, X, V, I, became numerals.

Numeral *Characters* of the Arabs, are those figures which are now used in all the operations of arithmetic in every nation in Europe. We have elsewhere shown that the Arabs derived the use of them most probably from

from India, (See Arithmetic, N° 5.). This opinion, however, though very generally received, has been controverted with some ingenuity. A writer in the Gentleman's Magazine, at a period when that miscellany was in its highest reputation, thus endeavours to prove that the Arabs derived their notations from the Greeks. "I maintain (says he) that the Indians received their numeral characters from the Arabians, and the Arabians from the Greeks, as from them they derived all their learning, which in some things they improved, but for the most part have altered. The numerical figures which they received from the Greeks are proofs of this alteration; which is so great, that without particular attention one can scarce discover in them the vestiges of their origin. But when we compare them carefully and without prejudice, we find in them manifest traces of the Greek figures. The Greek numerical figures were no other than the letters of their alphabet. A small stroke was the mark of unity. The B, being abridged of its two extremities, produced the 2. If you incline the γ a little on its left side, and cut off its foot, and make the left horn round towards the left side, you will produce a 3; the Δ makes the 4, by raising the right leg perpendicularly, and lengthening it a little below the base, and lengthening the base on the left side. The ε forms the 5, by turning the lowest semicircle towards the right, which before was turned towards the left side. The number 5 forms the 6, by having its head taken off, and its body rounded. Z, by taking away the base, makes the 7. If we make the top and bottom of H round, we shall form an 8. The θ is the 9 with a very little alteration. The cypher o was only a point, to which one of the figures was added to make it stand for ten times as much. It was necessary to mark this point very strongly; and in order to form it better, a circle was made, which was filled up in the middle; but that circumstance was afterwards neglected. Theophanes, an historian of Constantinople, who lived in the ninth century, says expressly, that the Arabians retained the Greek figures, having no characters in their language to represent all the numbers. The Greeks observed in their numbers the decuple progression, which the Arabians have retained. Certain characters are found in the Greek alphabet, which are not used in reading, but only in calculation, and for this reason, they are styled *Episemes*, that is to say, *notes, marks*, in order to distinguish them from letters. The number 6 derives its form from one of these episemes, which was called επισημον βαυ. This episeme forms the letter F among the Æolians and among the Latins. This was called the *Digamma*, so styled from its figure, which seems to have been one Γ placed upon another.

That this reasoning is plausible will hardly be questioned; but whether it be conclusive our readers must determine. It has not convinced ourselves; but through the whole of this work we wish to state candidly the different opinions held on every subject of curiosity and usefulness.

NUMERATION, or Notation, in *Arithmetic*, the art of expressing in characters any number proposed in words, or of expressing in words any number proposed in characters. See Arithmetic, N° 7.

NUMERICAL, Numerous, or *Numeral*, something belonging to numbers; as numerical algebra is that which makes use of numbers, instead of letters of the alphabet.—Also numerical difference is that by which one man is distinguished from another. Hence a thing is said to be numerically the same, when it is so in the strictest sense of the word.

NUMIDA, a genus of birds belonging to the order of gallinæ. See Ornithology *Index*.

NUMIDIA, an ancient kingdom of Africa, bounded on the north by the Mediterranean sea; on the south by Gætulia, or part of Libya Interior; on the west by the Mulucha, a river which separated it from Mauritania; and on the east by the Tusca, another river which bounded it in common with Africa Propria. Dr Shaw has rendered it probable, that the river which formerly went under the denominations of *Malva, Malvana, Mulucha*, and *Molochath*, is the same with that now called Mullooiah by the Algerines; in which case, the kingdom of Numidia must have extended upwards of 500 miles in length: its breadth, however, cannot be so well ascertained; but supposing it to have been the same with that of the present kingdom of Algiers, in the narrowest part it must have been at least 40 miles broad, and in the widest upwards of 100.

1 Ancient division.

This country included two districts; one inhabited by the *Massyli*, and the other by the *Massæsyli;* the latter being also called in after times, *Mauritania Cæsariensis*, and the former *Numidia Propria*. The country of the Massyli, or, as some call it, *Terra Metagonitis*, was separated from the proper territory of Carthage by its eastern boundary the river Tusca, and from the kingdom of the Massylia, or Mauritania Cæsariensis, by the river Ampsaga. It seems to correspond with that part of the province of Constantina lying between the Zaine and the Wed al Kibeer, which is above 130 miles long, and more than 100 broad. The sea coast of this province is for the most part mountainous and rocky, answering to the appellation given to it by Abulfeda, viz. *El Edwaa, the high or lofty*. It is far from being equal in extent to the ancient country of the Massæsyli, which, Strabo informs us, was yet inferior to the country of the Massyli. Its capital was Cirta, a place of very considerable note among the ancients.

2 Peopled by the descendants of Phut.

The most celebrated antiquarians agree, that the tract, extending from the isthmus of Suez to the lake Tritonis, was chiefly peopled by the descendants of Mizraim, and that the posterity of his brother Put, or Phut, spread themselves all over the country between that lake and the Atlantic ocean. To this notion Herodotus gives great countenance: for he tells us, that the Libyan Nomades, whose territories to the west were bounded by the Triton, agreed in their customs and manners with the Egyptians; but that the Africans, from that river to the Atlantic ocean, differed in almost all points from them. Ptolemy mentions a city called *Putea* near Adrametum; and Pliny, a river of Mauritania Tingitana, known by the name of *Fut*, or *Phut;* and the district adjacent to this river was called *Regio Phutensis*, which plainly alludes to the name of *Phut*. That word signifies *scattered*, or *dispersed*, which very well agrees with what Mela and Strabo relate of the ancient Numidians; so that we may, without any scruple, admit the aborigines of this country to have been the descendants of Phut.

3 Great part of the history unknown.

The history of Numidia, during many of the early ages, is buried in oblivion. It is probable, however, that as the Phœnicians were masters of a great part of the

Numidia. the country, these transactions had been recorded, and generally known to the Carthaginians. King Jarbas probably reigned here as well as in Africa Propria, if not in Mauritania, and other parts of Libya, when Dido began to build Byrsa. It appears from Justin, that about the age of Herodotus, the people of this country were called both *Africans* or *Libyans* and *Numidians*. Justin likewise intimates, that about this time the Carthaginians vanquished both the Moors or Mauritanians and the Numidians; in consequence of which they were excused from paying the tribute which had hitherto been demanded of them.

After the conclusion of the first Punic war, the African troops carried on a bloody contest against their masters the Carthaginians; and the most active in this rebellion, according to Diodorus Siculus, were a part of the Numidian nation named *Micatanians*. This so incensed the Carthaginians, that after Hamilcar had either killed or taken prisoners all the mercenaries, he sent a large detachment to ravage the country of those Numidians. The commandant of that detachment executed his orders with the utmost cruelty, plundering the district in a terrible manner, and crucifying all the prisoners without distinction that fell into his hands. This filled the rest with such indignation and resentment, that both they and their posterity ever afterwards bore an implacable hatred to the Carthaginians.

4
History of Syphax and Masinissa.

In the time of the second Punic war, Syphax king of the Massæsyli entered into an alliance with the Romans, and gave the Carthaginians a considerable defeat. This induced Gala, king of the Massyli, to conclude a treaty with the Carthaginians, in consequence of which his son Masinissa marched at the head of a powerful army to give Syphax battle. The contest ended in favour of Masinissa; 30,000 of the Massæsyli were put to the sword, and Syphax driven into Mauritania; and the like bad success attended Syphax in another engagement, where his troops were entirely defeated and dispersed.

Gala dying whilst his son Masinissa was acting at the head of the Numidian troops sent to the assistance of the Carthaginians in Spain, his brother Desalces, according to the established rules of succession in Numidia, took possession of the Massylian throne. That prince dying soon after his succession, Capusa his eldest son succeeded him. But he did not long enjoy his high dignity; for one Mezetulus, a person of the royal blood, but an enemy to the family of Gala, found means to excite a great part of his subjects to revolt. A battle soon took place between him and Capusa; in which the latter was slain with many of the nobility, and his army entirely defeated. But though Mezetulus thus became possessed of the sovereignty, he did not think proper to assume the title of *king*, but styled himself guardian to Lacumaces, the surviving son of Desalces, whom he graced with the royal title. To support himself in his usurpation, he married the dowager of Desalces, who was Hannibal's niece, and consequently of the most powerful family in Carthage. In order to attain the same end, he sent ambassadors to Syphax, to conclude a treaty of alliance with him. In the mean time Masinissa, receiving advice of his uncle's death, of his cousin's slaughter, and of Mezetulus's usurpation, immediately passed over to Africa, and went to the court of Bocchar king of Mauritania to solicit succours. Bocchar, sensible of the great injustice done Masinissa, gave him a body of 4000 Moors to escort him to his dominions. His subjects, having been apprised of his approach, joined him upon the frontiers with a party of 500 men. The Moors in pursuance of their orders, returned home, as soon as Masinissa reached the confines of his kingdom. Notwithstanding which, and the small body that declared for him having accidentally met Lacumaces at Thapsus with an escort going to implore Syphax's assistance, he drove him into the town, which he carried by assault after a faint resistance. However, Lacumaces, with many of his men, found means to escape to Syphax. The fame of this exploit gained Masinissa great credit, insomuch that the Numidians flocked to him from all parts. and amongst the rest, many of his father Gala's veterans, who pressed him to make a speedy and vigorous push for his hereditary dominions. Lacumaces having joined Mezetulus with a reinforcement of Massæsylians, which he had prevailed upon Syphax to send to the assistance of his ally, the usurper advanced at the head of a numerous army to offer Masinissa battle; which that prince, though much inferior in numbers, did not decline. Hereupon an engagement ensued; which notwithstanding the inequality of numbers ended in the defeat of Lacumaces. The immediate consequence of this victory of Masinissa was a quiet and peaceable possession of his kingdom; Mezetulus and Lacumaces, with a few that attended them, flying into the territories of Carthage. However, being apprehensive that he should be obliged to sustain a war against Syphax, he offered to treat Lacumaces with as many marks of distinction as his father Gala had Desalces, provided that prince would put himself under his protection. He also promised Mezetulus pardon, and a restitution of all the effects forfeited by his treasonable conduct, if he would make his submission to him. Both of them readily complied with the proposal, and immediately returned home; so that the tranquillity and repose of Numidia would have been settled upon a solid and lasting foundation, had not this been prevented by Asdrubal, who was then at Syphax's court. He insinuated to that prince, who was disposed to live amicably with his neighbours, "That he was greatly mistaken, if he imagined Masinissa would be satisfied with his hereditary dominions. That he was a prince of much greater capacity and ambition, than either his father Gala, his uncle Desalces, or any of his family. That he had discovered in Spain marks of a most rare and uncommon merit. And that, in fine, unless his rising flame was extinguished before it came to too great a head, both the Massæsylian and Carthaginian states would be infallibly consumed by it." Syphax, alarmed by these suggestions, advanced with a numerous body of forces into a district which had long been in dispute between him and Gala, but was then in possession of Masinissa. This brought on a general action between these two princes; wherein the latter was totally defeated, his army dispersed, and he himself obliged to fly to the top of Mount Balbus, attended only by a few of his horse. Such a decisive battle at the present juncture, before Masinissa was fixed in his throne, could not but put Syphax into possession of the kingdom of the Massyli. Masinissa in the mean time made nocturnal incursions from his post upon Mount Balbus, and plundered all the adjacent country, particularly that part of the Carthaginian teritory contiguous to Numidia. This district he not only thoroughly pillaged, but likewise laid waste with fire and sword, carrying off from thence

an

Numidia. an immense booty, which was bought by some merchants, who had put into one of the Carthaginian ports for that purpose. In fine, he did the Carthaginians more damage, not only by committing such dreadful devastations, but by massacring and carrying into captivity vast numbers of their subjects on this occasion, than they could have sustained in a pitched battle, or one campaign of a regular war. Syphax, at the pressing and reiterated instances of the Carthaginians, sent Bocchar, one of his most active commanders, with a detachment of 4000 foot, and 2000 horse, to reduce this pestilent gang of robbers, promising him a great reward if he could bring Masinissa either alive or dead. Bocchar, watching an opportunity, surprised the Massylians, as they were straggling about the country without any order or discipline; so that he took many prisoners, dispersed the rest, and pursued Masinissa himself, with a few of his men, to the top of the mountain where he had before taken post. Considering the expedition as ended, he not only sent many head of cattle, and the other booty that had fallen into his hands, to Syphax, but likewise all the force, except 500 foot and 200 horse. With this detachment he drove Masinissa from the summit of the hill, and pursued him through several narrow passes and defiles, as far as the plains of Clupea. Here he so surrounded him, that all the Massylians, except four, were put to the sword, and Masinissa himself, after having received a dangerous wound, escaped with the utmost difficulty. As this was effected by crossing a rapid river, in which attempt two of his four attendants perished in the sight of the detachment that pursued him, it was rumoured all over Africa, that Masinissa also was drowned; which gave inexpressible pleasure to Syphax and the Carthaginians. For some time he lived undiscovered in a cave, where he was supported by the robberies of the two horsemen that had made their escape with him. But having cured his wound by the application of some medicinal herbs, he boldly began to advance towards his own frontiers, giving out publicly that he intended once more to take possession of his kingdom. In his march he was joined by about 40 horse, and, soon after his arrival amongst the Massyli, so many people flocked to him from all parts, that out of them he formed an army of 6000 foot and 4000 horse. With these forces, he not only reinstated himself in the possession of his dominions, but likewise laid waste the borders of the Massæsyli. This so irritated Syphax, that he immediately assembled a body of troops, and encamped very commodiously upon a ridge of mountains between Cirta and Hippo. His army he commanded in person; and detached his son Vermina, with a considerable force, to take a compass, and attack the enemy in the rear. In pursuance of his orders, Vermina set out in the beginning of the night, and took post in the place appointed him, without being discovered by the enemy. In the mean time Syphax decamped, and advanced towards the Massyli, in order to give them battle. When he had possessed himself of a rising ground that led to their camp, and concluded that his son Vermina must have formed the ambuscade behind them, he began the fight. Masinissa being advantageously posted, and his soldiers distinguishing themselves in an extraordinary manner, the dispute was long and bloody. But Vermina unexpectedly falling upon their rear, and by this means obliging them to divide their forces, which were scarcely able before to oppose the main body under Syphax, they were soon thrown into confusion, and forced to betake themselves to a precipitate flight. All the avenues being blocked up, partly by Syphax, and partly by his son, such a dreadful slaughter was made of the unhappy Massyli, that only Masinissa himself, with 60 horse, escaped to the Lesser Syrtis. Here he remained, betwixt the confines of the Carthaginians and the Garamantes, till the arrival of Lælius and the Roman fleet on the coast of Africa. What happened immediately after this junction with the Romans, belongs to the article ROME.

It will be sufficient, therefore, in this place to observe, that, by the assistance of Lælius, Masinissa at last reduced Syphax's kingdom. According to Zonaras, Masinissa and Scipio, before the memorable battle of Zama, by a stratagem, deprived Hannibal of some advantageous posts; which, with a solar eclipse happening during the heat of the action, and not a little intimidating the Carthaginian troops, greatly contributed to the victory the Romans obtained. At the conclusion therefore of the second Punic war, he was amply rewarded by the Romans for the important services he had done them. As for Syphax, after the loss of his dominions, he was kept in confinement for some time at Alba; from whence being removed in order to grace Scipio's triumph, he died at Tibur in his way to Rome. Zonaras adds, that his corpse was decently interred; that all the Numidian prisoners were released; and that Vermina, by the assistance of the Romans, took peaceable possession of his father's throne. However, part of the Massæsylian kingdom had been before annexed to Masinissa's dominions, in order to reward that prince for his singular fidelity and close attachment to the Romans.

This seems to be countenanced by the epitomizer of Livy, who gives us sufficiently to understand, that Syphax's family, for a considerable time after the conclusion of the second Punic war, reigned in one part of Numidia. For he intimates, that Archobarzanes, Syphax's grandson, and probably Vermina's son, hovered with a powerful army of Numidians upon the Carthaginian frontiers a few years before the beginning of the third Punic war. This he seems to have done, either in order to cover them, or to enable the Carthaginians to make an irruption into Masinissa's territories. Cato, however, pretended that these forces, in conjunction with those of Carthage, had a design to invade the Roman dominions, which he urged as a reason to induce the conscript fathers to destroy the African republic.

Nothing further is requisite, in order to complete the history of this famous prince, than to exhibit to our readers view some points of his conduct towards the decline, and at the close, of life; the wise dispositions made after his death by Æmilianus, in order to the regulation of his domestic affairs; and some particulars relating to his character, genius, and habit of body, drawn from the most celebrated Greek and Roman authors.

By drawing a line of circumvallation around the Carthaginian army under Asdrubal, posted upon an eminence, Masinissa cut off all manner of supplies from them; which introduced both the plague and famine into their camp. As the body of Numidian troops employed

Numidia. ployed in this blockade was not near so numerous as the Carthaginian forces, it is evident, that the line here mentioned must have been extremely strong, and consequently the effect of great labour and art. The Carthaginians, finding themselves reduced to the last extremity, concluded a peace upon the following terms, which Masinissa dictated to them: 1. That they should deliver up all deserters. 2. That they should recal their exiles, who had taken refuge in his dominions. 3. That they should pay him 5000 talents of silver within the space of 50 years. 4. That their soldiers should pass under the jugum, each of them carrying off only a single garment. As Masinissa himself, though between 80 and 90 years of age, conducted the whole enterprise, he must have been extremely well versed in fortification, and other branches of the military art. His understanding likewise he must have retained to the last. This happened a short time before the beginning of the third Punic war. See CARTHAGE.

5
Masinissa displeased with the Romans;

Soon after, the consuls landed an army in Africa, in order to lay siege to Carthage, without imparting to Masinissa their design. This not a little chagrined him, as it was contrary to the former practice of the Romans; who, in the preceding war, had communicated their intentions to him, and consulted him on all occasions. When, therefore, the consuls applied to him for a body of his troops to act in concert with their forces, he made answer, "That they should have a reinforcement from him when they stood in need of it." It could not but be provoking to him to consider, that after he had extremely weakened the Carthaginians, and even brought them to the brink of ruin, his pretended imperious friends should come to reap the fruits of his victory, without giving him the least intelligence of it.

However, his mind soon returned to its natural bias, which was in favour of the Romans. Finding his end approaching, he sent to Æmilianus, then a tribune in the Roman army, to desire a visit from him. What he proposed by this visit, was to invest him with full powers to dispose of his kingdom and estate as he should think proper, for the benefit of his children. The high idea he had entertained of that young hero's abilities and integrity, together with his gratitude and affection for the family into which he was adopted, induced him to take this step. But, believing that death would not permit him to have a personal conference with Æmilianus upon this subject, he informed his wife and children in his last moments, that he had empowered him to dispose in an absolute manner of all his possessions, and divide his kingdom amongst his sons. To which he subjoined, "I require, that whatever Æmilianus may decree, shall be executed as punctually as if I myself had appointed it by my will." Having uttered these words, he expired, at about 90 years of age.

6
but leaves every thing to the disposal of Æmilianus.

This prince, during his youth, had met with strange reverses of fortune. However, says Appian, being supported by the Divine protection, he enjoyed an uninterrupted course of prosperity for a long series of years. His kingdom extended from Mauritania to the western confines of Cyrenaica; from whence it appears, that he was one of the most powerful princes of Africa. Many of the inhabitants of this vast tract he civilized in a wonderful manner, teaching them to cultivate their soil, and to reap those natural advantages which the fertility of some parts of their country offered them. He was of a more robust habit of body than any of his cotemporaries, being blessed with the greatest health and vigour; which was doubtless owing to his extreme temperance, and the toils he incessantly sustained. We are informed by Polybius, that sometimes he stood upon the same spot of ground from morning till evening, without the least motion, and at others continued as long in a sitting posture. He would remain on horseback for several days and nights together, without being sensible of the least fatigue. Nothing can better evince the strength of his constitution, than his youngest son, named *Stembal*, *Sthembo*, or *Stembonus*, who was but four years old at his decease. Though 90 years of age, he performed all the exercises used by young men, and always rode without a saddle. Pliny tells us, that he reigned above 60 years. He was an able commander, and much facilitated the reduction of Carthage. Plutarch from Polybius observes, that the day after a great victory won over the Carthaginians, Masinissa was seen sitting at the door of his tent, eating a piece of brown bread. Suidas relates, that to the last he could mount his horse without any assistance. According to Appian he left a numerous well disciplined army, and an immense quantity of wealth, behind him.

Masinissa, before his death, gave his ring to his eldest son Micipsa; but left the distribution of all his other effects and possessions amongst his children entirely to Æmilianus. Of 54 sons that survived him, only three were legitimate, to wit, Micipsa, Gulussa, and Mastanabal. Æmilianus arrived at Cirta after he had expired, divided his kingdom, or rather the government of it, amongst these three, though to the others he gave considerable possessions. To Micipsa, who was a prince of a pacific disposition, and the eldest son, he assigned Cirta, the metropolis, for the place of his residence, in exclusion of the others. Gulussa, the next to him, being a prince of military genius, had the command of the army, and the transacting of all affairs relating to peace or war committed to his care. And Mastanabal, the youngest, had the administration of justice, an employment suitable to his education, allotted him. They enjoyed in common the immense treasures Masinissa had amassed, and were all of them dignified by Æmilianus with the royal title. After he had made these wise dispositions, that young nobleman departed from Cirta, taking with him a body of Numidian troops, under the conduct of Gulussa, to reinforce the Roman army that was then acting against the Carthaginians.

Mastanabal and Gulussa died soon after their father, as appears from the express testimony of Sallust. We find nothing more remarkable of these princes, besides what has been already related, than that the latter continued to assist the Romans in the third Punic war, and that the former was pretty well versed in the Greek language. Micipsa therefore became sole possessor of the kingdom of Numidia. In his reign, and under the consulate of M. Platius Hypsæus and M. Fulvius Flaccus, according to Orosius, a great part of Africa was covered with locusts, which destroyed all the produce of the earth, and even devoured dry wood. But at last they were all carried by the wind into the African sea, out of which being thrown in vast heaps upon the shore, a plague ensued which swept away an infinite

Numidia. number of animals of all kinds. In Numidia only 800,000 men perished, and in Africa Propria 200,000; amongst the rest, 30,000 Roman soldiers quartered in and about Utica for the defence of the latter province. At Utica, in particular, the mortality raged to such a degree, that 1500 dead bodies were carried out of one gate in a day. Micipsa had two sons, Adherbal and Hiempsal, whom he educated in his palace, together with his nephew Jugurtha. That young prince was the son of Mastanabal; but his mother having been only a concubine, Masinissa had taken no great notice of him. However, Micipsa considering him as a prince of the blood, took as much care of him as he did of his own children.

7 History of Jugurtha.

Jugurtha possessed several eminent qualities, which gained him universal esteem. He was very handsome, endued with great strength of body, and adorned with the finest intellectual endowments. He did not devote himself, as young men commonly do, to a life of luxury and pleasure. He used to exercise himself, with persons of his age, in running, riding, hurling the javelin, and other manly exercises, suited to the martial genius of the Numidians; and though he surpassed all his fellow sportsmen, there was not one of them but loved him. The chase was his only delight; but it was that of lions and other savage beasts. Sallust, to finish his character, tells us, that he excelled in all things, and spoke very little of himself.

So conspicuous an assemblage of fine talents and perfections, at first charmed Micipsa, who thought them an ornament to his kingdom. However, he soon began to reflect, that he was considerably advanced in years, and his children in their infancy; that mankind naturally thirsted after power, and that nothing was capable of making men run greater lengths than a vicious and unlimited ambition. These reflections soon excited his jealousy, and determined him to expose Jugurtha to a variety of dangers, some of which, he entertained hopes, might prove fatal to him. In order to this, he gave him the command of a body of forces which he sent to assist the Romans, who were at that time besieging Numantia in Spain. But Jugurtha, by his admirable conduct, not only escaped all those dangers, but likewise won the esteem of the whole army, and the friendship of Scipio, who sent a high character of him to his uncle Micipsa. However, that general gave him some prudent advice in relation to his future conduct; observing, no doubt, in him certain sparks of ambition, which, if lighted into a flame, he apprehended might one day be productive of the most fatal consequences.

8 Is dreaded by King Micipsa,

Before this last expedition, Micipsa had endeavoured to find out some method of taking him off privately; but his popularity amongst the Numidians obliged that prince to lay aside all thoughts of this nature. After his return from Spain the whole nation almost adored him. The heroic bravery he had shown there, his undaunted courage, joined to the utmost calmness of mind, which enabled him to preserve a just medium between a timorous foresight and an impetuous rashness, a circumstance rarely to be met with in persons of his age, and above all the advantageous testimonials of his conduct given by Scipio, attracted an universal esteem. Nay, Micipsa himself, charmed with the high opinion the Roman general had entertained of his merit, changed his behaviour towards him; resolving, if possible, to win his affection by kindness. He therefore adopted him, and declared him joint heir with his two sons to the crown. Finding, some few years afterwards, that his end approached, he sent for all three to his bed side; where, in the presence of the whole court, he desired Jugurtha to recollect with what extreme tenderness he had treated him, and consequently to consider how well he had deserved at his hands.

9 who nevertheless entrusts him with the care of his children;

He then entreated him to protect his children on all occasions; who, being before related to him by the ties of blood, were now by their father's bounty become his brethren. In order to fix him the more firmly in their interest, he likewise complimented him upon his bravery, address, and consummate prudence. He further insinuated, that neither arms nor treasures constitute the strength of a kingdom; but friends, who are neither won by arms nor gold, but by real services and an inviolable fidelity. "Now, where (continued he) can we find better friends than in brothers? And how can that man who becomes an enemy to his relations, repose any confidence in, or depend upon strangers?" Then addressing himself to Adherbal and Hiempsal, "And you (said he) I enjoin always to pay the highest reverence to Jugurtha. Endeavour to imitate, and if possible surpass, his exalted merit, that the world may not hereafter observe Micipsa's adopted son to have reflected greater glory upon his memory than his own children." Soon after, Micipsa, who, according to Diodorus, was a prince of an amiable character, expired. Though Jugurtha did not believe the king to speak his real sentiments with regard to him, yet he seemed extremely pleased with so gracious a speech, and made him an answer suitable to the occasion. However, that prince at the same time was determined within himself to put in execution the scheme he had formed at the siege of Numantia, which was suggested to him by some factious and abandoned Roman officers, with whom he there contracted an acquaintance. The purport of this scheme was, that he should extort the crown by force from his two cousins, as soon as their father's eyes were closed; which they insinuated might easily be effected by his own valour, and the venality of the Romans. Accordingly, a short time after the old king's death, he found means to assassinate Hiempsal in the city of Thirmida where his treasures were deposited, and drive Adherbal out of his dominions That unhappy prince found himself obliged to fly to Rome, where he endeavoured to engage the conscript fathers to espouse his quarrel; but, notwithstanding the justice of his cause, they had not virtue enough effectually to support him. Jugurtha's ambassadors, by distributing vast sums of money amongst the senators, brought them so far over, that a majority palliated his inhuman proceedings. This encouraged those ministers to declare, that Hiempsal had been killed by the Numidians on account of his excessive cruelty; that Adherbal was the aggressor in the late troubles; and that he was only chagrined because he could not make that havock among his countrymen he would willingly have done. They therefore entreated the senate to form a judgment of Jugurtha's behaviour in Africa from his conduct at Numantia, rather than from the suggestions of his enemies. Upon which, by far the greatest part of the senate discovered themselves prejudiced

10 one of whom he murders, and drives out the other.

Numidia. prejudiced in his favour. A few, however, that were not lost to honour, nor abandoned to corruption, insisted upon bringing him to condign punishment. But as they could not prevail, he had the best part of Numidia allotted him, and Adherbal was forced to rest satisfied with the other.

11 Venality of the Romans. Jugurtha finding now by experience that every thing was venal at Rome, as his friends at Numantia had before informed him, thought he might pursue his towering projects without any obstruction from that quarter. He therefore, immediately after the last division of Micipsa's dominions, threw off the mask, and attacked his cousin by open force. As Adherbal was a prince of a pacific disposition, and almost in all respects the reverse of Jugurtha, he was by no means a match for him. The latter therefore pillaged the former's territories, stormed several of his fortresses, and overran a good part of his kingdom without opposition. Adherbal, depending on the friendship of the Romans, which his father in his last moments assured him would be a stronger support to him than all the troops and treasures in the universe, despatched deputies to Rome to complain of these hostilities. But whilst he lost his time in sending thither fruitless deputations, Jugurtha overthrew him in a pitched battle, and soon after shut him up in Cirta. During the siege of this city, a Roman commission arrived there, in order to persuade both parties to an accommodation; but finding Jugurtha untractable, the commissioners returned home without so much as conferring with Adherbal. A second deputation, composed of senators of the highest distinction, with Æmilius Scaurus, president of the senate, at their head, landed some time after at Utica, and summoned Jugurtha to appear before them. That prince at first seemed to be under dreadful apprehensions, especially as Scaurus reproached him with his enormous crimes, and threatened him with the resentment of the Romans if he did not immediately raise the siege of Cirta. However, the Numidian, by his address, and the irresistible power of gold, as was afterwards suspected at Rome, so mollified Scaurus, that he left Adherbal at his mercy. In fine, Jugurtha had at last Cirta surrendered to him, upon condition only that he should spare the life of Adherbal. But the merciless tyrant, in violation of the laws of nature and humanity as well as the capitulation, when he had got possession of the town, ordered him to be put to a most cruel death. The merchants likewise, and all the Numidians in the place capable of bearing arms, he caused without distinction to be put to the sword.

Every person at Rome inspired with any sentiments of humanity, was struck with horror at the news of this tragical event. However, all the venal senators still concurred with Jugurtha's ministers in palliating his enormous crimes. Notwithstanding which, the people, excited thereto by Caius Memmius their tribune, who bitterly inveighed against the venality of the senate, resolved not to let so flagrant an instance of villany go unpunished. This disposition in them induced the conscript fathers likewise to declare their intention to chastise Jugurtha. In order to this, an army was levied to invade Numidia, and the command of it given to the consul Calpurnius Bestia, a person of good abilities, but rendered unfit for the expedition he was to go upon by his insatiable avarice. Jugurtha being informed of the great preparations making at Rome to attack his dominions, sent his son thither to avert the impending storm. The young prince was plentifully supplied with money, which he had orders to distribute liberally amongst the leading men. But Bestia, proposing to himself great advantages from an invasion of Numidia, defeated all his intrigues, and got a decree passed, ordering him and his attendants to depart Italy in ten days, unless they were come to deliver up the king himself, and all his territories, to the republic by way of dedition. Which decree being notified to them, they returned without so much as having entered the gates of Rome; and the consul soon after landed with a powerful army in Africa. For some time he carried on the war there very briskly, reduced several strong holds, and took many Numidians prisoners. But upon the arrival of Scaurus, a peace was granted Jugurtha upon advantageous terms. That prince coming from Vacca, the place of his residence, to the Roman camp, in order to confer with Bestia and Scaurus, and the preliminaries of the treaty being immediately after settled between them in private conferences, everybody at Rome was convinced that the prince of the senate and the consul had to their avarice sacrificed the republic. The indignation therefore of the people in general displayed itself in the strongest manner. Memmius also fired them with his speeches. It was therefore resolved to despath the prætor Cassius, a person they could confide in, to Numidia, to prevail upon Jugurtha to come to Rome, that they might learn from the king himself which of their generals and senators had been seduced by the pestilent influence of corruption. Upon his arrival there, he found means to bribe one Bæbius Salca, a man of great authority amongst the plebeians, but of insatiable avarice, by whose assistance he escaped with impunity. Nay, by the efficacy of gold, he not only eluded all the endeavours of the people of Rome to bring him to justice, but likewise enabled Bomilcar, one of his attendants, to get Massiva, an illegitimate son of Micipsa, assassinated in the streets of Rome. That young prince was advised by many Romans of probity, wellwishers to the family of Masinissa, to apply for the kingdom of Numidia; which coming to Jugurtha's ears, he prevented the application by this execrable step. However, he was obliged to leave Italy immediately.

Jugurtha had scarce set foot in Africa, when he received advice that the senate had annulled the shameful peace concluded with him by Bestia and Scaurus. Soon after, the consul Albinus transported a Roman army into Numidia, flattering himself with the hopes of reducing Jugurtha to reason before the expiration of his consulate. In this, however, he found himself deceived; for that crafty prince, by various artifices so amused and imposed upon Albinus, that nothing of moment happened that campaign. This rendered him strongly suspected of having betrayed his country, after the example of his predecessors. His brother Aulus, who succeeded him in the command of the army, was still more unsuccessful; for after rising from before Suthul, where the king's treasures were deposited, he marched his forces into a defile, out of which he found it impossible to extricate himself. He therefore was obliged to submit to the ignominious ceremony of passing under the *jugum*, with all his men, and to quit Numidia entirely in ten days time, Numidia. time, in order to deliver his troops from immediate destruction. The avaricious disposition of the Roman commander had prompted him to besiege Suthul, the possession of which place he imagined would make him master of all the wealth of Jugurtha, and consequently paved the way to such a scandalous treaty. However, this was declared void as soon as known at Rome, as being concluded without the authority of the people. The Roman troops retired into Africa Propria, which they had now reduced into the form of a Roman province, and there took up their winter quarters.

In the mean time Caius Mamillius Limetanus, tribune of the people, excited the plebeians to inquire into the conduct of those persons by whose assistance Jugurtha had found means to elude all the decrees of the senate. This put the body of the people into a great ferment; which occasioned a prosecution of the guilty senators, that was carried on, for some time, with the utmost heat and violence. Lucius Metellus
12 Metellus sent against Jugurtha. the consul, during these transactions, had Numidia assigned him for his province, and consequently was appointed general of the army destined to act against Jugurtha. As he perfectly disregarded wealth, the Numidian found him superior to all his temptations; which was a great mortification to him. To this he joined all the other virtues which constitute the great captain; so that Jugurtha found him in all respects inaccessible. That prince therefore was now forced to regulate his conduct according to the motions of Metellus, with the greatest caution; and to exert his utmost bravery, in order to compensate for that hitherto so favourable expedient which now began to fail him. Marius, Metellus's lieutenant, being likewise a person of uncommon merit, the Romans reduced Vacca, a large opulent city, and the most celebrated mart in Numidia. They also defeated Jugurtha in a pitched battle; overthrew Bomilcar, one of his generals, upon the banks of the Muthullus; and, in fine, forced the Numidian monarch to take shelter in a place rendered almost inaccessible by the rocks and woods with which it was covered. However, Jugurtha signalized himself in a surprising manner, exhibiting all that could be expected from the courage, abilities, and attention of a consummate general, to whom despair administers fresh strength, and suggests new lights. But his troops could not make head against the Romans; they were again worsted by Marius, though they obliged Metellus to raise the siege of Zama. Jugurtha, therefore, finding his country everywhere ravaged, his most opulent cities plundered, his fortresses reduced, his towns burnt, vast numbers of his subjects put to the sword and taken prisoners, began to think seriously of coming
13 Who is betrayed by Bomilcar. to an accommodation with the Romans. His favourite Bomilcar, in whom he reposed the highest confidence, but who had been gained over to the enemy by Metellus, observing this disposition, found it no difficult matter to persuade him to deliver up his elephants, money, arms, horses, and deserters, in whom the main strength of his army consisted, into the hands of the Romans. Some of these last, in order to avoid the punishment due to their crime, retired to Bocchus king of Mauritania, and listed in his service. But Metellus ordering him to repair to Tisidium, a city of Numidia, there to receive farther directions, and he refusing a compliance with that order, hostilities were renewed with greater fury than ever. Fortune now seemed to declare in favour of Jugurtha: he retook Vacca, and massacred all the Roman garrison, except Turpilius the commandant. However, soon after, a Roman legion seized again upon it, and treated the inhabitants with the utmost severity. About this time, one of Mastanabal's sons, named *Gauda*, whom Micipsa in his will had appointed to succeed to the crown in case his two legitimate sons and Jugurtha died without issue, wrote to the senate in favour of Marius, who was then endeavouring to supplant Metellus. That prince having his understanding impaired by a declining state of health, fell a more easy prey to the base and infamous adulation of Marius. The Roman, soothing his vanity, assured him, that as he was the next heir to the crown, he might depend upon being fixed upon the Numidian throne, as soon as Jugurtha was either killed or taken; and that this must in a short time happen, when once he appeared at the head of the Roman army with an unlimited commission. Soon after, Bomilcar and Nabdalsa formed a design to assassinate Jugurtha, at the instigation of Metellus; but this being detected, Bomilcar and most of his accomplices suffered death. The plot however had such an effect upon Jugurtha, that he enjoyed afterwards no tranquillity or repose. He suspected persons of all denominations, Numidians as well as foreigners, of some black designs against him. Perpetual terrors sat brooding over his mind; insomuch that he never got a wink of sleep but by stealth, and often changed his bed in a low plebeian manner. Starting from his sleep, he would frequently snatch his sword, and break out into the most doleful cries: So strongly was he haunted by a spirit of fear, jealousy, and distraction! 14 A conspiracy against him.

Jugurtha having destroyed great numbers of his friends on suspicion of their having been concerned in the late conspiracy, and many more of them deserting to the Romans and Bocchus king of Mauritania, he found himself, in a manner, destitute of counsellors, generals, and all persons capable of assisting him in carrying on the war. This threw him into a deep melancholy, which rendered him dissatisfied with every thing, and made him fatigue his troops with a variety of contradictory motions. Sometimes he would advance with great celerity against the enemy, and at others retreat with no small swiftness from them. Then he resumed his former courage, but soon after despaired either of the valour or fidelity of the forces under his command. All his movements therefore proved unsuccessful, and at last he was forced by Metellus to a battle. That part of the Numidian army which Jugurtha commanded, behaved with some resolution; but the other fled at the first onset. The Romans therefore entirely defeated them, took all their standards, and made a few of them prisoners. But few of them were slain in the action; since, as Sallust observes, the Numidians trusted more to their heels than to their arms for safety in this engagement. 15 He is defeated by Metellus.

Metellus pursued Jugurtha and his fugitives to Thala. His march to this place being through vast deserts, was extremely tedious and difficult. But being supplied with leathern bottles and wooden vessels of all sizes taken from the hut of the Numidians, which were filled with water brought by the natives, who had submitted to him, he advanced towards the

city.

Numidia. city. He had no sooner begun his march, than a most copious shower of rain, a thing very uncommon in those deserts, proved a great and seasonable refreshment to his troops. This so animated them, that upon their arrival before Thala, they attacked the town with such vigour, that Jugurtha with his family, and treasures deposited therein, thought proper to abandon it. After a brave defence, it was reduced; the garrison, consisting of Roman deserters, setting fire to the king's palace, and consuming themselves, together with every thing valuable to them, in the flames. Jugurtha, being now reduced to great extremities, retired into Gætulia, where he formed a considerable corps. From thence he advanced to the confines of Mauritania; and engaged Bocchus king of that country, who had married his daughter, to enter into an alliance with him. In consequence of which, having reinforced his Gætulian troops with a powerful body of Mauritanians, he turned the tables upon Metellus, and obliged him to keep close within his entrenchments. Sallust informs us, that Jugurtha bribed Bocchus's ministers to influence that prince in his favour; and that having obtained an audience, he insinuated, that, should Numidia be subdued, Mauritania must be involved in its ruin, especially as the Romans seemed to have vowed the destruction of all the thrones in the universe. In support of what he advanced, he produced several instances very apposite to the point in view. However, the same author seems to intimate, that Bocchus was determined to assist Jugurtha against his enemies by the slight the Romans had formerly shown him. That prince, at the first breaking out of the war, had sent ambassadors to Rome, to propose an offensive and defensive alliance to the republic; which, though of the utmost consequence to it at the juncture, a few of the most venal and infamous senators, who were abandoned to corruption, prevented from taking effect. This undoubtedly wrought more powerfully upon Bocchus in favour of Jugurtha, than the relation he stood in to him: For both the Moors and Numidians adapted the number of their wives to their circumstances, so that some had 10, 20, &c. to their share; their kings therefore were unlimited in this particular, and of course all degrees of affinity resulting to them from marriage had little force. It is observable, that the posterity of those ancient nations have the same custom prevailing amongst them at this day.

16 Marius succeeds Metellus.

Such was the situation of affairs in Numidia, when Metellus received advice of the promotion of Marius to the consulate. But, notwithstanding this injurious treatment, he generously endeavoured to draw off Bocchus from Jugurtha, though this would facilitate the reduction of Numidia for his rival. To this end ambassadors were despatched to the Mauritanian court, who intimated to Bocchus, "That it would be highly imprudent to come to a rupture with the Romans without any cause at all; and that he had now a fine opportunity of concluding a most advantageous treaty with them, which was much preferable to a war. To which they added, that whatever dependence he might place upon his riches, he ought not to run the hazard of losing his dominions by embroiling himself with other states, when he could easily avoid this; that it was much easier to begin a war than to end it, which it was in the power of the victor alone to do; that, in fine, he would by no means consult the interest of his subjects if he followed the desperate fortunes of Jugurtha." To which Bocchus replied. "That for his part there was nothing he wished for more than peace; but that he could not help pitying the deplorable condition of Jugurtha; that if the Romans, therefore, would grant that unfortunate prince the same terms they had offered him, he would bring about an accommodation." Metellus let the Mauritanian monarch know, that it was not in his power to comply with what he desired. However, he took care to keep up a private negotiation with him till the new consul Marius's arrival. By this conduct he served two wise ends. First, He prevented Bocchus from coming to a general action with his troops; which was the very thing Jugurtha desired, as hoping that this, whatever the event might be, would render a reconciliation betwixt him and the Romans impracticable. Secondly, This inaction enabled him to discover something of the genius and disposition of the Moors; a nation of whom the Romans, till then, had scarcely formed any idea; which, he imagined, might be of no small service, either to himself or his successors, in the future prosecution of the war.

Jugurtha, being informed that Marius, with a numerous army, was landed at Utica, advised Bocchus to retire, with part of the troops, to some place of difficult access, whilst he himself took post upon another inaccessible spot with the remaining corps. By this measure, he hoped the Romans would be obliged to divide their forces, and consequently be more exposed to his efforts and attacks. He likewise imagined, that seeing no formidable body appear, they would believe the enemy in no condition to make head against them; which might occasion a relaxation of discipline, the usual attendant of a too great security, and consequently produce some good effect. However, he was disappointed in both these views. For Marius, far from suffering a relaxation of discipline to take place, trained up his troops, which consisted chiefly of new levies, in so perfect a manner, that they were soon equal in goodness to any consular army that ever appeared in the field. He also cut off great numbers of the Gætulian marauders, defeated many of Jugurtha's parties, and had like to have taken that prince himself near the city of Cirta. These advantages, though not of any great importance, intimidated Bocchus, who now made overtures for an accommodation; but the Romans, not being sufficiently satisfied of his sincerity, paid no great attention to them. In the mean time Marius pushed on his conquests, reducing several places of less note, and at last resolved to besiege Capsa. That this enterprise might be conducted with the greater secrecy, he suffered not the least hint of his design to transpire, even amongst any of his officers. On the contrary, in order to blind them, he detached A. Manlius, one of his lieutenants, with some light-armed cohorts, to the city of Lares, where he had fixed his principal magazine, and deposited the military chest. Before Manlius left the camp, that he might the more effectually amuse him, he intimated, that himself with the army should take the same route in a few days: but instead of that, he bent his march towards the Tanais, and in six days time arrived upon the banks of that river. Here he pitched his tents for a short time, in order to refresh his troops; which having done, he advanced to Capsa, and made himself master of it. As

17 He gains a great vantage over Jugurtha.

Numidia. As the situation of this city rendered it extremely commodious to Jugurtha, whose plan of operations, ever since the commencement of the war, it had exceedingly favoured, he levelled it with the ground after it had been delivered up to the soldiers to be plundered. The citizens likewise, being more strongly attached to that prince than any of the other Numidians, on account of the extraordinary privileges he indulged them with, and of course bearing a more implacable hatred to the Romans, he put to the sword or sold for slaves. The true motive of the consul's conduct on this occasion seems here to be assigned; though we are told by Sallust, in conformity to the Roman genius, that neither avarice nor resentment prompted him to so barbarous an action, but only a desire to strike a terror into the Numidians.

The Numidians, ever after this exploit, dreaded the very name of Marius; who now, in his own opinion, had eclipsed the glory of all his predecessor's great achievements, particularly the reduction of Thala, a city, in strength and situation, nearly resembling Capsa. Following his blow, he gradually presented himself before most of the places of strength in the enemy's country; many of which either opened their gates, or were abandoned, at his approach, being terrified with what had happened to the unfortunate citizens of Capsa. Others taken by force, he laid in ashes; and in short filled the greatest part of Numidia with blood, horror, and confusion. Then, after an obstinate defence, he reduced a castle that seemed impregnable, seated not far from Mulucha, where Jugurtha kept part of his treasures. In the mean time, Jugurtha not being able to prevail upon Bocchus, by his repeated solicitations, to advance into Numidia, where he found himself greatly pressed, was obliged to have recourse to his usual method of bribing the Mauritanian ministers, in order to put that prince in motion. He also promised him a third part of his kingdom, provided they could either drive the Romans out of Africa, or get all the Numidian dominions confirmed to him by treaty.

So considerable a cession could not fail of engaging Bocchus to support Jugurtha with his whole power. The two African monarchs, therefore, having joined their forces, surprised Marius near Cirta as he was going into winter quarters. The Roman general was so pushed on this occasion, that the barbarians thought themselves certain of victory, and doubted not but they should be able to extinguish the Roman name in Numidia. But their incaution and too great security enabled Marius to give them a total defeat; which was followed four days after by so complete an overthrow, that their numerous army, consisting of 90,000 men, by the accession of a powerful corps of Moors, commanded by Bocchus's son Volux, was entirely ruined. Sylla, Marius's lieutenant, most eminently distinguished himself in the last action, which laid the foundation of his future greatness. Bocchus, now looking upon Jgurtha's condition as desperate, and not being willing to run the risk of losing his dominions, showed a disposition to clap up a peace with Rome. However, the republic gave him to understand, that he must not expect to be ranked amongst its friends, till he had delivered up into the consul's hands Jugurtha, the inveterate enemy of the Roman name. The Mauritanian monarch, having entertained a high idea of an alliance

18 Jugurtha entirely defeated.

with that state, resolved to satisfy it in this particular; and was confirmed in his resolution by one Dabar, a Numidian prince, the son of Massugrada, and descended by his mother's side from Masinissa. Being closely attached to the Romans, and extremely agreeable to Bocchus, on account of his noble disposition, he defeated all the intrigues of Aspar, Jugurtha's minister. Upon Sylla's arrival at the Mauritanian court, the affair there seemed to be entirely settled. However, Bocchus, who was for ever projecting new designs, and, like, the rest of his countrymen, in the highest degree perfidious, debated within himself, whether he should sacrifice Sylla or Jugurtha, who were both then in his power. He was a long time fluctuating with uncertainty, and combated by a contrariety of sentiments. The sudden changes which displayed themselves in his countenance, his air, and his whole person, evidently showed how strongly his mind was agitated. But at last he returned to his first design, to which the bias of his mind seemed naturally to lead him. He therefore delivered up Jugurtha into the hands of Sylla, to be conducted to Marius; who, by that successful event, happily terminated this dangerous war. The kingdom of Numidia was now reduced to a new form: Bocchus, for his important services, had the country of the Massæsyli, contiguous to Mauritania, assigned him: which, from this time, took the name of *New Mauritania.* Numidia Propria, or the country of the Massyli, was divided into three parts; one of which was given to Hiempsal, another to Mandrestal, both descendants of Masinissa; and the third the Romans annexed to Africa Propria, or the Roman province adjacent to it. What became of Jugurtha after he had graced Marius's triumph, at which ceremony he was led in chains, together with his two sons, through the streets of Rome, we have already laid before our readers. See JUGURTHA.

Jugurtha's two sons survived him, but spent their lives in captivity at Venusia. However, one of them, named *Oxyntas*, was, for a short time, released from his confinement by Aponius, who besieged Acerræ in the war between the Romans and the Italian allies. That general brought this prince to his army, where he treated him as king, in order to draw the Numidian forces off from the Roman service. Accordingly those Numidians no sooner heard that the son of their old king was fighting for the allies, than they began to desert by companies; which obliged Julius Cæsar the consul to part with all his Numidian cavalry, and send them back into Africa. Some few years after this event, Pompey defeated Cneius Domitius Ahenobarbus, and Hiarbas one of the kings of Numidia, killing 17,000 of their men upon the spot. Not satisfied with this victory, that general pursued the fugitives to their camp, which he soon forced, put Domitius to the sword, and took Hiarbas prisoner. He then reduced that part of Numidia which belonged to Hiarbas, who seems to have succeeded Mandrestal above-mentioned; and gave it to Hiempsal, a neighbouring Numidian prince, descended from Masinissa, who had always opposed the Marian faction.

19 Transactions after the death of Jugurtha.

Suetonius informs us, that a dispute happened between Hiempsal and one Masintha, a noble Numidian, whom, it is probable, he had in some respect injured, when Julius Cæsar first began to make a figure in the world. The same author adds, that Cæsar warmly espoused

20 Cæsar insults Juba.

Numidia. espoused the cause of Masintha, and even grossly insulted Juba, Hiempsal's son, when he attempted to vindicate his father's conduct on this occasion. He pulled him by the beard, than which a more unpardonable affront could not be offered to an African. In short, he screened Masintha from the insults and violence of his enemies; from whence a reason may be assigned for Juba's adhering so closely afterwards to the Pompeian faction.

21
Juba defeats one of Cæsar's lieutenants.

In consequence of the indignity Cæsar had offered Juba, and the disposition it had occasioned, that prince did Cæsar great damage in the civil wars betwixt him and Pompey. By a stratagem he drew Curio, one of his lieutenants, into a general action, which it was his interest at that time to have avoided. He caused it to be given out over all Africa Propria and Numidia, that he was retired into some remote country at a great distance from the Roman territories. This coming to Curio's ears, who was then besieging Utica, it hindered him from taking the necessary precautions against a surprise. Soon after, the Roman general receiving intelligence that a small body of Numidians was approaching his camp, he put himself at the head of his forces in order to attack them, and for fear they should escape, began his march in the night, looking upon himself as sure of victory. Some of their advanced posts he surprised asleep, and cut them to pieces; which still farther animated him. In short, about daybreak he came up with the Numidians, whom he attacked with great bravery, though his men were then fasting, and vastly fatigued by their forced and precipitate march. In the mean time, Juba, who immediately after the propagation of the rumour above mentioned, had taken care to march privately, with the main body of the Numidian army, to support the detachment sent before to decoy Curio, advanced to the relief of his men. The Romans had met with a great resistance before he appeared; so that he easily broke them, killed Curio, with a great part of his troops, upon the spot, pursued the rest to their camp, which he plundered, and took many of them prisoners. Most of the fugitives, who endeavoured to make their escape on board the ships in the port of Utica, were either slain by the pursuers, or drowned. The remainder fell into the hands of Varus, who would have saved them; but Juba, who arrogated to himself the honour of this victory, ordered most of them to be put to the sword.

22
Juba overthrown by Cæsar.

This victory infused new life and vigour into the Pompeian faction, who thereupon conferred great honours upon Juba, and gave him the title of *king of all Numidia*. But Cæsar and his adherents declared him an enemy to the state of Rome, adjudging to Bocchus and Bogud, two African princes entirely in their interest, the sovereignty of his dominions. Juba afterwards, uniting his forces with those of Scipio, reduced Cæsar to great extremities, and would in all probability have totally ruined him, had he not been relieved by Publius Sittius. That general, having formed a considerable corps, consisting of Roman exiles, and Mauritanian troops sent him by Bocchus, according to Dio, or, as Cæsar, will have it, Bogud, made an irruption into Gætulia and Numidia, while Juba was employed in Africa Propria. As he ravaged these countries in a dreadful manner, Juba immediately returned with the best part of his army, to preserve them from utter destruction. However, Cæsar knowing his horse to be afraid of the enemy's elephants, did not think proper to attack Scipio in the absence of the Numidian, till his own elephants, and a fresh reinforcement of troops, hourly expected, arrived from Italy. With this accession of strength, he imagined himself able to give a good account, both of the Roman forces with which he was to cope, and the barbarians. In the mean time Scipio despatched reiterated expresses to Juba to hasten to his assistance; but could not prevail upon him to move out of Numidia, till he had promised him the possession of all the Roman dominions in Africa, if they could from thence expel Cæsar. This immediately put him in motion; so that, having sent a large detachment to make head against Sittius, he marched with the rest of his troops to assist Scipio. However, Cæsar at last overthrew Scipio, Juba, and Labienus, near the town of Thapsus, and forced all their camps. As Scipio was the first surprised and defeated, Juba fled into Numidia without waiting for Cæsar's approach; but the body of the Numidians detached against Sittius, having been broken and dispersed by that general, none of his subjects there would receive him. Abandoned therefore to despair he sought death in a single combat with Petreius, and having killed him, caused himself to be despatched by one of his slaves.

23
Numidia reduced to the form of a province.

After this decisive action, and the reduction of Africa Propria, Cæsar made himself master of Numidia, which he reduced to a Roman province, appointing Crispus Sallustius to govern it in quality of proconsul, with private instructions to pillage and plunder the inhabitants, and, by that means put it out of their power ever to shake off the Roman yoke. However, Bocchus and Bogud still preserved a sort of sovereignty in the country of the Massæsyli and Mauritania, since the former of those princes, having deserted Cæsar, sent an army into Spain to assist the Pompeians; and the latter, with his forces, determined victory to declare for Cæsar at the ever memorable battle of Munda. Bogud, afterwards siding with Antony against Octavius, sent a body of forces to assist him in Spain; at which time the Tingitanians revolting from him, Bocchus, with an army composed of Romans in the interest of Octavius, who passed over from Spain into Africa, and his own subjects, possessed himself of Mauritania Tingitana. Bogud fled to Antony; and Octavius, after the conclusion of the war, honoured the inhabitants of Tingi with all the privileges of Roman citizens. He likewise confirmed Bocchus king of Mauritania Cæsariensis, or the country of the Massæsyli, in the possession of Tingitana, which he had conquered, as a reward for his important services. In this he imitated the example of his great predecessor Julius Cæsar, who divided some of the fruitful plains of Numidia among the soldiers of P. Sittius, who had conquered great part of that country, and appointed Sittius himself sovereign of that district. Sittius, as has been intimated above, having taken Cirta, killed Sabura, Juba's general, entirely dispersed his forces, and either cut off or taken prisoners most of the Pompeian fugitives that escaped from the battle of Thapsus, highly deserved to be distinguished in so eminent a manner. After Bocchus's death, Mauritania and the Massæsylian Numidia were in all respects considered as Roman provinces.

Numismatographia.

NUMISMATOGRAPHIA, a term used for the description

description and knowledge of ancient coins and medals, whether of gold, silver, or brass. See COINS and MEDALS.

NUMITOR, the son of Procas king of Alba, and the brother of Amulius. Procas before his death made him and Amulius joint heirs to the crown, on condition of their reigning annually by turns: but Amulius, on getting possession of the throne, excluded Numitor, whose son Lausus he ordered to be put to death, and obliged Rhea Sylvia, Numitor's only daughter, to become a vestal. This princess becoming pregnant, declared that she was with child by the god Mars; and afterwards brought forth Remus and Romulus, who at length killed Amulius, and restored Numitor to the throne, 754 B. C. See REMUS and ROMULUS.

NUMMUS, a piece of money, otherwise called *sestertius*.

NUN, the son of Elishamah, and father of Joshua, of the tribe of Ephraim. The Greeks gave him the name of *Nane* instead of Nun. This man is known in sacred history only by being the father of Joshua.

NUN, a woman, in several Christian countries, who devotes herself, in a cloister or nunnery, to a religious life. See the article MONK.

There were women, in the ancient Christian church, who made public profession of virginity, before the monastic life was known in the world, as appears from the writings of Cyprian and Tertullian. These, for distinction's sake, are sometimes called *ecclesiastical virgins*, and were commonly enrolled in the canon or matricula of the church. They differed from the monastic virgins chiefly in this, that they lived privately in their fathers houses, whereas the others lived in communities: but their profession of virginity was not so strict as to make it criminal for them to marry afterwards, if they thought fit. As to the consecration of virgins, it had some things peculiar in it; it was usually performed publicly in the church by the bishop. The virgin made a public profession of her resolution, and then the bishop put upon her the accustomed habit of sacred virgins. One part of this habit was a veil, called the *sacrum velamen;* another was a kind of mitre or coronet worn upon the head. At present, when a woman is to be made a nun, the habit, veil, and ring of the candidate are carried to the altar; and she herself, accompanied by her nearest relations, is conducted to the bishop, who, after mass and an anthem, (the subject of which is "that she ought to have her lamp lighted, because the bridegroom is coming to meet her)," pronounces the benediction: then she rises up, and the bishop consecrates the new habit, sprinkling it with holy water. When the candidate has put on her religious habit, she presents herself before the bishop, and sings, on her knees, *Ancilla Christi sum*, &c.; then she receives the veil, and afterwards the ring, by which she is married to Christ; and lastly, the crown of virginity. When she is crowned, an anathema is denounced against all who shall attempt to make her break her vows. In some few instances, perhaps, it may have happened that nunneries, monasteries, &c. may have been useful as well to morality and religion as to literature: in the gross, however, they have been highly prejudicial; and however well they might be supposed to do when viewed in theory, in fact they are unnatural and impious. It was surely far from the intention of Providence to seclude youth and beauty in a cloistered ruin, or to deny them the innocent enjoyment of their years and sex.

NUNCIO, or NUNTIO, an ambassador from the pope to some Catholic prince or state, or a person who attends on the pope's behalf at a congress, or an assembly of several ambassadors.

NUNCUPATIVE, in the schools, something that is only nominal, or has no existence but in name.

NUNCUPATIVE Will or *Testament*, a will made verbally, and not put in writing. See the articles WILL and TESTAMENT.

NUNDINA, a goddess among the ancient heathens, supposed to have the care of the purification of infants. And because male infants were purified nine days after their birth, her name is derived from *nonus*, or the ninth, though female infants were purified the eighth day; which purification was called *lustration* by the Romans.

NUNDINAL, *Nundinalis*, a name which the Romans gave to the eight first letters of the alphabet used in their kalendar.

This series of letters, A, B, C, D, E, F, G, H, is placed and repeated successively from the first to the last day of the year: one of these always expressed the market days or the assemblies called *nundinæ*, *quasi novendinæ*, because they returned every nine days. The country people, after working eight days successively, came to town the ninth, to sell their several commodities, and to inform themselves of what related to religion and government. Thus the nundinal day being under A on the first, ninth, seventeenth, and twenty-fifth days of January, &c. the letter D will be the nundinal letter of the year following. These nundinals bear a very great resemblance to the dominical letters, which return every eight days, as the nundinals did every nine.

NUNDOCOMAR, a Rajah in Bengal, and head of the Bramins, who, in 1775, was condemned to an ignominious death by English laws newly introduced, in an English court of justice newly established, for a forgery charged to have been committed by him many years before. That he was guilty of the deed cannot be questioned; but there was surely something hard in condemning a man by an *ex post facto* law. He bore his fate with the utmost fortitude, in the full confidence that his soul would soon be reunited to the universal spirit whence it had sprung. See METAPHYSICS, Part III. Chap. IV. *Of the Immortality of the Soul.*

MONTE NUOVO, in the environs of Naples, blocks up the valley of Averno. "This mountain (Mr Swinburne tells us) arose in the year 1538; for after repeated quakings, the earth burst asunder, and made way for a deluge of hot ashes and flames, which rising extremely high, and darkening the atmosphere, fell down again and formed a circular mound four miles in circumference, and 1000 feet high, with a large cup in the middle. The wind rising afterwards, wafted the lighter particles over the country, blasted vegetation, and killed the animals who grazed; the consequence was, that the place was deserted, till Don Pedro de Toledo, viceroy of Naples, encouraged the inhabitants, by example and otherwise to return.

"Part of Monte Nuovo is cultivated, but the larger portion of its declivity is wildly overgrown with prickly broom, and rank weeds that emit a very fetid sulphureous smell. The crater is shallow, its inside clad with shrubs, and the little area at the bottom planted with fig and mulberry trees; a most striking specimen of the amazing vicissitudes that take place in this extraordinary country. I saw no traces of lava or melted matter, and few stones within.

"Near the foot of this mountain the subterraneous fires act with such immediate power, that even the sand at the bottom of the sea is heated to an intolerable degree."

NUPTIAL RITES, the ceremonies attending the solemnization of marriage, which are different in different ages and countries. We cannot omit here a custom which was practised by the Romans on these occasions; which was this: Immediately after the chief ceremonies were over, the new married man threw *nuts* about the room for the boys to scramble for. Various reasons have been assigned for it; but that which most generally prevails, and seems to be the most just, is, that by this act the bridegroom signified his resolution to abandon trifles, and commence a serious course of life; whence *nucibus relictis* in this sense became a proverb. They might also be an emblem of fertility.

The ancient Greeks had a person to conduct the bride from her own to the bridegroom's house; and hence he was called by the Greeks *Nymphagogus*, which term was afterwards used both by the Romans and the Jews.

NUREMBERG, an imperial city of Germany, capital of a territory of the same name, situated in E. Long. 11. N. Lat. 47. 30. It stands on the Regnitz, over which it has several bridges, both of wood and stone, at the bottom of a hill, 60 miles from Augsburg, 87 from Munich, 46 from Wurtzburg, and 50 from Ratisbon; and is thought by some to be the Segodunum, and by others the Castrum Noricum of the ancients.

The city has derived its name from the hill, upon which stands this castle, called, in Latin, Castrum Noricum, round which the city was begun to be built, and where the emperors formerly lodged; and here they lodge still, when they pass by that city. They there preserve, as precious relicks, the crown, sceptre, clothes, buskins, and other ornaments of Charlemagne (A), which served also the emperor Leopold, when he went thither after his election, to receive the homage of the city. The small river Regnitz, which runs through it, and those of Rednitz and Schwarzack, which pass by its walls, furnish the inhabitants, besides other advantages, with the means of making all sorts of stuffs, dyes, and other manufactures (B), and toys, which are carried and sold even in the Indies.

It is a large and well-built town, but not very populous. Its fortifications are a double wall, flanked with towers mounting cannon, and a deep ditch. The magistrates, and most of the inhabitants, are Lutherans. There are a great many churches and chapels in it. In that of St Sebald is a brass monument of the saint; and a picture, representing the creation of the world, by the celebrated Albert Durer, who was a native of the town; but the finest church in the town is that of St Giles. In that of the Holy Ghost are kept most of the jewels of the empire, together with the pretended spear with which our Saviour's side was pierced, a thorn of his crown, and a piece of the manger wherein he was laid. Here are also a great many hospitals, one in particular for foundlings, and another for pilgrims; with a gymnasium, an anatomical theatre, a granary, a fine public library, the old imperial fortress or castle, some remains of the old citadel of the burgraves of Nuremberg, several Latin schools, an academy of painting, a well furnished arsenal, a Teutonic house in which the Roman Catholic service is tolerated, and a mint. Mr Keysler says, there are upwards of 500 streets in it, about 140 fountains, 16 churches, 44 religious houses, 12 bridges, 10 market places, and 25,000 inhabitants; and that its territories, besides the capital and four other towns, contain above 500 villages, and about 160 mills on the Regnitz. The trade of this city, though upon the decline, is still very great, many of its manufactures being still exported to all parts of the world; among which may be reckoned a great variety of curious toys in ivory, wood, and metal, already mentioned. The city has also distinguished itself in the arts of painting and engraving. When the emperor Henry VI. assisted at a tournament in Nuremberg, he raised 38 burghers to the degree of nobility, the descendants of whom are called *patricians*, and have the government of the city entirely in their hands; the whole council, except eight masters of companies, who are summoned only on extraordinary occasions, consisting of them. Among the fine brass cannon in the arsenal, is one that is charged at the breech, and may be fired eight times in a minute; and two that carry balls of eighty pounds. The city keeps, in constant pay, seven companies, consisting each, in time of peace, of 100 men, but, in time of war, of 185; two troops of cuirassiers, each consisting of 85 men; and two companies of invalids. There are also 24 companies of burghers, well armed and disciplined. On the new bridge, which is said to have cost 100,000 guilders, are two pyramids, on the top of one of which is a dove with an olive branch in her bill, and on the other an imperial black eagle. Music also flourishes greatly in Nuremberg; and those who delight in mechanic

(A) These ornaments are, a mitred crown, enriched with rubies, emeralds, and pearls; the dalmatio of Charlemagne, richly embroidered; the imperial mantle powdered with embroidered eagles, and its border thick set with large emeralds, sapphires, and topazes; the buskins covered with plates of gold; the gloves embroidered; the apple, the golden sceptre, and sword. The ancient custom of the empire is, that the emperor is bound to assemble in this city the first diet that he holds after his election and coronation.

(B) There is in Nuremberg, and in the neighbouring villages depending upon it, an infinite number of workmen, very ingenious in making several kinds of toys of wood, which are carried through all the fairs of Germany, and from thence through all Europe. These toys are called Nurembergs; and they have so great a sale, that it even exceeds description. This employment affords a livelihood to the greatest part of the inhabitants of the city; and they make a very considerable profit from this traffic.

Nuremberg | Nursing.

mechanic arts and manufactures cannot anywhere better gratify their curiosity. As an imperial city, it has a seat and voice at the diets of the empire and circle, paying to the chamber of Wetzlar 812 rixdollars each term. The territory belonging to the city is pretty large, containing, besides two considerable forests of pine, called the *Sibald* and *Laurence forests*, several towns and villages.

We have mentioned already that certain families called patricians, to the exclusion of the rest, possess the offices of the senate. They are composed of 42 persons (C), over which two castellans, or perpetual seneschals, preside, the first of whom has his residence in the castle. These castellans assemble sometimes in the castle, with five or six of the chief members, to hold a secret council (D). And, as this city glories in being one of the first which embraced Lutheranism, it preserves the privilege of that in civil matters, not admitting any Catholics to the magistracy or freedom of the town; the Catholics there having the liberty only of remaining under the protection of the rest, and performing their religious worship in a commandery of Malta, and this but at certain hours, not to disturb the Lutherans, who likewise assemble there, although in possession of all the other churches.

This city is particularly noted for its antiquity, grandeur, fortifications, its triple walls of hewn stone, its large and deep moat, its fine houses, large churches, its wide streets, always clean, and for its curious and large library, and its magazine stored with every thing proper for its defence.

NURSERY, in *Gardening*, is a piece of land set apart for raising and propagating all sorts of trees and plants to supply the garden and other plantations.

NURSING OF CHILDREN. See LACTATIO.

The following observations and directions are said to be the result of long experience †. The child should be laid (the first month) upon a thin mattress, rather longer than itself, which the nurse will keep upon her lap, that the child may always lie straight, and only sit up as the nurse slants the mattress. To set a child quite upright before the end of the first month, hurts the eyes, by making the white part of the eye appear below the upper eyelid. Afterwards the nurse will begin to set it up and dance it by degrees. The child must be kept as dry as possible.

† *An. Reg.* vol. vi. p. 130.

The clothing should be very light, and not much longer than the child, that the legs may be got at with ease, in order to have them often rubbed in the day with a warm hand or flannel, and in particular the inside of them.

Rubbing a child all over takes off scurf, and makes the blood circulate. The one breast should be rubbed with the hands one way, and the other the other way, night and morning at least.

The ankle bones and inside of the knees should be rubbed twice a-day; this will strengthen those parts, and make the child stretch its knees and keep them flat, which is the foundation of an erect and graceful person.

A nurse ought to keep a child as little in her arms as possible, lest the legs should be cramped, and the toes turned inwards. Let her always keep the child's legs loose. The oftener the posture is changed, the better.

Tossing a child about, and exercising it in the open air in fine weather, is of the greatest service. In cities, children are not to be kept in hot rooms, but to have as much air as possible.

Want of exercise is the cause of large heads, weak and knotted joints, a contracted breast, which occasions coughs and stuffed lungs, an ill-shaped person, and waddling gait, besides a numerous train of other ills.

The child's flesh is to be kept perfectly clean, by constantly washing its limbs, and likewise its neck and ears, beginning with warm water, till by degrees it will not only bear, but like to be washed with cold water.

Rising early in the morning is good for all children, provided they awake of themselves, which they generally do: but they are never to be waked out of their sleep, and as soon as possible to be brought to regular sleeps in the day.

When laid in bed or cradle, their legs are always to be laid straight.

Children, till they are two or three years old, must never be suffered to walk long enough at a time to be weary.

Girls might be trained to the proper management of children, if a premium were given in free schools, workhouses, &c. to those that brought up the finest child to one year old.

If the mother cannot suckle the child, get a wholesome cheerful woman with young milk, who has been used to tend young children. After the first six months, small broths, and innocent foods of any kind, may do as well as living wholly upon milk.

A principal thing to be always attended to is, to give young children constant exercise, and to keep them in a proper posture.

With regard to the child's dress in the day, let it be a shirt; a petticoat of fine flannel, two or three inches longer than the child's feet, with a dimity top (commonly called a *bodice coat*), to tie behind; over that a surcingle made of fine buckram, two inches broad, covered over with satin or fine ticken, with a ribbon fastened to it to tie it on, which answers every purpose of stays, and has none of their inconveniences. Over this put a robe, or a slip and frock, or whatever you like best; provided it is fastened behind, and not much longer than the child's feet, that their motions may be strictly observed.

Two

(C) Of these 42 members, there are only 34 chosen from the patrician families; the other eight are taken from among the burghers, and make in a manner a small separate body.

(D) This secret council is composed of seven principal chiefs of the republic, and for that reason is called *septemvirate*. It determines the most important affairs; and is the depository of the precious stones of the empire, of the imperial crown, the ensigns, seals, and keys of the city.

Two caps are to be put on the head, till the child has got most of its teeth.

The child's dress for the night may be a shirt, a blanket to tie on, and a thin gown to tie over the blanket.

NUSANCE, or NUISANCE, in *Law*, a thing done to the annoyance of another.

Nuisances are either public or private.—A public nuisance is an offence against the public in general, either by doing what tends to the annoyance of all the king's subjects, or by neglecting to do what the common good requires: in which case, all annoyances and injuries to streets, highways, bridges, and large rivers, as also disorderly alehouses, bawdy-houses, gaming houses, stages for rope-dancers, &c. are held to be common nuisances.—A private nuisance is, when only one person or family is annoyed by the doing of any thing; as where a person stops up the light of another's house, or builds in such a manner that the rain falls from his house upon his neighbour's.

NUT, among botanists, denotes a PERICARPIUM of an extraordinary hardness, enclosing a kernel or seed.

NUTATION, in *Astronomy*, a kind of tremulous motion of the axis of the earth, whereby, in each annual revolution, it is twice inclined to the ecliptic, and as often returns to its former position.

NUTCRACKER. See CORVUS, ORNITHOLOGY *Index*.

NUTHATCH. See SITTA, ORNITHOLOGY *Index*.

NUTMEG, the fruit of a tree, and a well known spice. See MYRISTICA.

NUTRITION, in the animal economy, is the repairing the continual loss which the different parts of the body undergo. The motion of the parts of the body, the friction of these parts with each other, and especially the action of the air, would destroy the body entirely, if the loss was not repaired by a proper diet, containing nutritive juices; which being digested in the stomach, and afterwards converted into chyle, mix with the blood, and are distributed through the whole body for its nutrition.

In young persons, the nutritive juices not only serve to repair the parts that are damaged, but also to increase them; which is called *growth*.

In grown persons, the cuticle is everywhere constantly desquamating, and again renewing; and in the same manner the parts rubbed off, or otherwise separated from the fleshy parts of the body, are soon supplied with new flesh; a wound heals, and an emaciated person grows plump and fat.

Buffon, in order to account for nutrition, supposes the body of an animal or vegetable to be a kind of mould, in which the matter necessary to its nutrition is modelled and assimilated to the whole. But (continues he) of what nature is this matter which an animal or vegetable assimilates to its own substance? What power is it that communicates to this matter the activity and motion necessary to penetrate this mould? and, if such a force exist, would it not be by a similar force that the internal mould itself might be reproduced?

As to the first question, he supposes that there exists in nature an infinite number of living organical parts, and that all organized bodies consist of such organical parts; that their production costs nature nothing, since their existence is constant and invariable; so that the matter which the animal or vegetable assimilates to its substance, is an organical matter of the same nature with that of the animal or vegetable, which consequently may augment its volume without changing its form or altering the quality of the substance in the mould.

As to the second question: There exist (says he) in nature certain powers, as that of gravity, that have no affinity with the external qualities of the body, but act upon the most intimate parts, and penetrate them throughout, and which can never fall under the observation of our senses.

And as to the third question, he answers that the internal mould itself is reproduced, not only by a similar power, but it is plain that it is the very same power that causes the unfolding and reproduction thereof: for it is sufficient (proceeds he), that in an organized body that unfolds itself, there be some part similar to the whole, in order that this part may one day become itself an organised body, altogether like that of which it is actually a part.

NUX MOSCHATA. See MYRISTICA.

Nux Pistachia. See PISTACHIA, BOTANY *Index*.

Nux Vomica, a flat, compressed, round fruit, about the breadth of a shilling, brought from the East Indies. It is found to be a certain poison for dogs, cats, &c. and it is not to be doubted that it would also prove fatal to mankind. Its surface is not much corrugated; and its texture is firm like horn, and of a pale grayish-brown colour. It is said to be used as a specific against the bite of a species of water-snake. It is considerably bitter and deleterious; but has been used in doses from five to ten grains twice a-day or so, in intermittents, particularly obstinate quartans, and in contagious dysentery. The *strychnus Ignatii* is a tree of the same kind, producing gourd-like fruit, the seeds of which are improperly called St Ignatius's beans. These, as also the woods or roots of some such trees, called *lignum colubrinum*, or *snakewood*, are very narcotic bitters, like the nux vomica.

NUYTS, PETER, a native of Holland, and a leading character in that extraordinary transaction which happened between the Japanese and the Dutch about the year 1628. In 1627 Nuyts arrived in Batavia from Holland, and was in the same year appointed ambassador to the emperor of Japan by the governor and council of Batavia.

He repaired to that empire in 1628; and being a man of a haughty disposition, and extremely vain, he believed it practicable to pass upon the natives for an ambassador from the king of Holland. Upon his assuming this title he was much more honourably received, caressed, and respected, than former ministers had been. But he was soon detected, reprimanded, and reproached in the severest manner, sent back to the port, and ordered to return to Batavia with all the circumstances of disgrace imaginable; notwithstanding which, his interest was so great, that, instead of being punished as he deserved, he was immediately afterwards promoted to the government of the island of Formosa, of which he took possession the year following.

He entered upon the administration of affairs in that island with the same disposition that he had shown while ambassador, and with the most implacable resentment against

against the Japanese; neither was it long before an opportunity offered, as he thought, of revenging himself to the full. Two large Japanese ships, with upwards of 500 men on board, came into the port; upon which he took it into his head to disarm and unrig them, in the same manner as the Dutch vessels are treated at Japan. The Japanese did all they could to defend themselves from this ill usage; but at last, for want of water, they were forced to submit. Governor Nuyts went still farther. When they had finished their affairs at Formosa, and were desirous of proceeding, according to their instructions, to China, he put them off with fair words and fine promises till the monsoon was over. They began then to be very impatient, and desired to have their cannon and sails restored, that they might return home; but the governor had recourse to new artifices, and, by a series of false promises, endeavoured to hinder them from making use of the season proper for that voyage.

The Japanese, however, soon perceived his design; and at length, by a bold attempt, accomplished what by fair means and humble entreaty they could not obtain; for, by a daring and well concerted effort, they took him prisoner, and made him and one of the council sign a treaty for securing their liberty, free departure, and indemnity, which was afterwards ratified by the whole council. Nuyts was first confined in Batavia, and afterwards delivered up to the Japanese, notwithstanding the most earnest entreaties on his part to be tried, and even to suffer any kind of death where he was, rather than to be sent to Japan. He was sent there, however, in 1634. He was submitted to the mercy or discretion of the emperor; and the consequence was, that, though imprisoned, he was well used, and could go anywhere, provided his guards were with him, which was more than he could possibly have expected. He now looked for nothing but the continuance of his confinement for life. On a particular occasion, however, i. e. at the funeral of the emperor's father, at the request of the Dutch he was set free, and returned again to Batavia, to the surprise of that people, who, however, adopted ever after a very different conduct with respect to the Japanese.

NUZZER, or NUZZERANAH; a present or offering from an inferior to a superior. In Hindostan no man ever approaches his superior for the first time on business without an offering of at least a gold or silver rupee in his right hand; which, if not taken, is a mark of disfavour. Nuzzeranah is also used for the sum paid to the government as an acknowledgement for a grant of lands or any public office.

NYCHTHEMERON, among the ancients, signified the whole natural day, or day and night consisting of 24 hours, or 24 equal parts. This way of considering the day was particularly adopted by the Jews, and seems to owe its origin to that expression of Moses, in the first chapter of Genesis, "the evening and the morning were the first day."—Before the Jews had introduced the Greek language into their discourse, they used to signify this space of time by the simple expression of a night and a day.

It is proper here to observe, that all the eastern countries reckoned any part of a day of 24 hours for a whole day; and say thing a that was done on the third or seventh day, &c. from that last mentioned, was done after three or seven days. And the Hebrews, having no word which exactly answers to the Greek Νυχθημερον, signifying "a natural day of 24 hours," use *night and day*, or *day and night*, for it. So that to say a thing happened after three days and three nights, was, with them, the same as to say it happened after three days, or on the third day. This, being remembered, will explain what is meant by "the Son of Man's being three days and three nights in the heart of the earth."

NYCTALOPIA. See MEDICINE, N° 361.

NYCTANTHES, ARABIAN JASMINE, a genus of plants, belonging to the diandria class, and in the natural method ranking with the 44th order, *Sepiariæ*. See BOTANY *Index*.

NYCTASTRATEGI, among the ancients, were officers appointed to prevent fires in the night, or to give alarm and call assistance when a fire broke out. At Rome they had the command of the watch, and were called *nocturni triumviri*, from their office and number.

NYCTICORAX, the night raven; a species of ARDEA. See ARDEA, ORNITHOLOGY *Index*.

NYLAND, a province of Finland in Sweden, lying on the gulf of Finland, to the west of the province of Carelia.

NYL-GHAU, a species of quadrupeds belonging to the genus *Bos*, a native of the interior parts of India. See MAMMALIA *Index*.

NYMPH, in *Mythology*, an appellation given to certain inferior goddesses, inhabiting the mountains, wood, waters, &c. said to be the daughters of Oceanus and Tethys. All the universe was represented as full of these nymphs, who are distinguished into several ranks or classes. The general division of them is into celestial and terrestrial; the former of them were called *uraniæ*, and were supposed to be intelligences that governed the heavenly bodies or spheres. The terrestrial nymphs, called *epigeiæ*, presided over the several parts of the inferior world; and were divided into those of the water, and those of the earth. The nymphs of the water were the *oceanitides*, or nymphs of the ocean; the *nereids*, the nymphs of the sea; the *naiads* and *ephydriades*, the nymphs of the fountains; and the *limniades*, the nymphs of the lakes. The nymphs of the earth were the *oreades*, or nymphs of the mountains; the *napææ*, nymphs of the meadows; and the *dryads* and *hamadryads*, who were nymphs of the forests and groves. Besides these, we meet with nymphs who took their names from particular countries, rivers, &c. as the *cithæroniades*, so called from Mount Cithæron in Bœotia: the *dodonides*, from Dodona; *tiberiades*, from the Tiber, &c.—Goats were sometimes sacrificed to the nymphs; but their constant offerings were milk, oil, honey, and wine.

We have the following account of nymphs in Chandler's Greece. "They were supposed to enjoy longevity, but not to be immortal. They were believed to delight in springs and fountains. They are described as sleepless, and as dreaded by the country people. They were susceptible of passion. The Argonauts, it is related, landing on the shore of the Propontis to dine in their way to Colchos, sent Hylas, a boy, for water, who discovered a lonely fountain, in which the nymphs Eunica, Malis, and Nycheia, were preparing to dance; and these seeing him were enamoured, and, seizing him by the hand

hand as he was filling his vase, pulled him in. The deities, their copartners in the cave, are such as presided with them over rural and pastoral affairs.

"The old Athenians were ever ready to cry out, A god! or a goddess! The tyrant Pisistratus entered the city in a chariot with a tall woman dressed in armour to resemble Minerva, and regained the Acropolis, which he had been forced to abandon, by this stratagem; the people worshipping, and believing her to be the deity whom she represented. The nymphs, it was the popular persuasion, occasionally appeared; and nympholepsy is characterised as a frenzy, which arose from having beheld them. Superstition disposed the mind to adopt delusion for reality, and gave to a fancied vision the efficacy of full conviction. The foundation was perhaps no more than an indirect, partial, or obscure view of some harmless girl, who had approached the fountain on a like errand with Hylas, or was retiring after she had filled her earthen pitcher.

"Among the sacred caves on record, one on Mount Ida in Crete was the property of Jupiter, and one by Lebadea in Bœotia of Trophonius. Both these were oracular, and the latter bore some resemblance to that we have described. It was formed by art, and the mouth surrounded with a wall. The descent to the landing place was by a light and narrow ladder, occasionally applied and removed. It was situated on a mountain above a grove; and they related, that a swarm of bees conducted the person by whom it was first discovered. But the common owners of caves were the nymphs, and these were sometimes local. On Cithæron in Bœotia, many of the inhabitants were possessed by nymphs called *Sphragitides*, whose cave, once also oracular, was on a summit of the mountain. Their dwellings had generally a well or spring of water; the former often a collection of moisture condensed or exuding from the roof and sides; and this, in many instances, being pregnant with stony particles, concreted, and marked its passage by incrustation, the groundwork in all ages and countries of idle tales framed or adopted by superstitious and credulous people.

"A cave in Paphlagonia was sacred to the nymphs who inhabited the mountains about Heraclea. It was long and wide, and pervaded by cold water, clear as crystal. There also were seen bowls of stone, and nymphs and their webs and distaffs, and curious work, exciting admiration. The poet who has described this grotto, deserves not to be regarded, as servilely copying Homer; he may justly lay claim to rank as an original topographer.

"The piety of Archidamus furnished a retreat for the nymphs, where they might find shelter and provision, if distressed; whether the sun parched up their trees, or Jupiter enthroned in clouds upon the mountain top scared them with his red lightning and terrible thunder, pouring down a deluge of rain, or brightening the summits with his snow."

Nymph, among naturalists, that state of winged insects between their living in the form of a worm and their appearing in the winged or more perfect state.

The eggs of insects are first hatched into a kind of worms or maggots: which afterwards pass into the nymph state, surrounded with shells or cases of their own skins; so that, in reality, these nymphs are only the embryo insects, wrapt up in this covering; from

whence they at last get loose, though not without great difficulty.

During this nymph state the creature loses its motion. Swammerdam calls it *nympha aurelia*, or simply *aurelia*; and others give it the name of *chrysalis*, a term of the like import See the article Chrysalis.

Nymph-Band, situated about 10 leagues off the coast of the county of Waterford, and province of Munster in Ireland, is a great fishing place, and 11 leagues S. S. E. from the high head of Durgarvan. It abounds with cod, ling, skate, bream, whiting, and other fish; which was discovered by Mr Doyle, who on July 15. 1736 sailed to it, in company with seven men, on board the Nymph, a small vessel of about 12 tons. This place is well adapted for a fishing company, the great public advantages of which must be very evident.

NYMPHÆ, in *Anatomy*, two membranaceous parts, situated on each side the rima. See Anatomy *Index*.

NYMPHÆA, the Water-lily; a genus of plants belonging to the polyandria class, and in the natural method ranking under the 54th order, *Miscellaneæ*. See Botany *Index*.

Nymphæa (amongst the ancients), doubtful what structures they were; some take them to have been grottoes, deriving their name from the statues of the nymphs with which they were adorned; but that they were considerable works appears from their being executed by the emperors, (Ammian, Victor, Capitolinus) or by the city prefects. In an inscription, the term is written *nymfium*. None of all these nymphæa has lasted down to our time. Some years since, indeed, a square building of marble was discovered between Naples and Vesuvius, with only one entrance, and some steps that went down to it. On the right hand as you enter, towards the head, there is a fountain of the purest water; along which, by way of guard, as it were, is laid a naked Arethusa of the whitest marble; the bottom or ground is of variegated marble, and encompassed with a canal fed by the water from the fountain; the walls are set round with shells and pebbles of various colours; by the setting of which, as by so many strokes in a picture, are expressed the 12 months of the year, and the four political virtues; also the rape of Proserpine; Pan playing on his reed, and soothing his flock; besides the representations of nymphs swimming, sailing, and wantoning on fishes, &c.

It seems pretty evident that the nymphæa were public baths; for at the same time that they were furnished with pleasing grottoes, they were also supplied with cooling streams, by which they were rendered exceedingly delightful, and drew great numbers of people to frequent them. Silence seems to have been a particular requisite there, as appears by this inscription, *Nymphis loci, bibe, lava, tace*. That building between Naples and Vesuvius, mentioned above, was certainly one of these nymphæa.

NYMPHÆUM, (Plutarch); the name of a sacred place, near Apollonia in Illyricum, sending forth continually fire in detached streams from a green valley and verdant meadows. Dio Cassius adds, that the fire neither burns up nor parches the earth, but that herbs and trees grow and thrive near it, and therefore the place is called *nyphæum*: near which was an oracle of such a nature, that the fire, to show that the wish was granted

granted, consumed the frankincense thrown into it: but repelled it, in case the desire was rejected. It was there that a sleeping satyr was once caught and brought to Sylla as he returned from the Mithridatic war. This monster had the same features as the poets ascribe to the satyr. He was interrogated by Sylla and by his interpreters; but his articulations were unintelligible; and the Roman spurned from him a creature which seemed to partake of the nature of a beast more than that of a man.

NYMPHÆUM, in antiquity, a public hall magnificently decorated, for entertainments, &c. and where those who wanted convenience at home held their marriage feasts; whence the name.

NYMPHIDIUS, SABINUS, a person of mean descent, but appointed by Nero colleague of Tigellinus in the command of the prætorian guards. About the time, however, that the German legions revolted from this despicable prince, he was also betrayed by Nymphidius and abandoned by his guards.

Nymphidius began now to entertain thoughts of seizing the sovereignty himself. However, he did not immediately declare his ambitious views; but pretending to espouse the cause of Galba, assured the guards that Nero was fled, and promised them such sums as neither Galba nor any other was able to discharge. This promise secured for the present the empire to Galba, occasioned afterwards the loss of it, and finally, produced the destruction of Nymphidius and the guards themselves. After Nero's death, however, and on the acknowledgement of Galba as emperor, he renewed his ambition; and having, by his immense largesses, gained the affections of the prætorian guards, and persuading himself that Galba, by reason of his infirmities and old age, would never reach the capital, usurped all the authority at Rome. Presuming upon his interest, he obliged Tigellinus, who commanded, jointly with him, the prætorian guards, to resign his commission. He made several magnificent and extensive entertainments, inviting such as had been consuls or had commanded armies, distributed large sums among the people, and with shows and other diversions, which he daily exhibited, gained so great an interest with all ranks, that he already looked upon himself as sovereign. The senate, dreading his power, conferred extraordinary honours upon him, styled him their *protector*, attended him when he appeared in public, and had recourse to him for the confirmation of their degrees, as if he had been already invested with the sovereign power. This base compliance elated him to such a degree, that he usurped, not leisurely and by degrees, but all at once, an absolute authority. He acted as sovereign indeed, but he had not as yet openly declared his design of seizing the empire: his power, however, was great, and he used it in undermining Galba's power; he was, however, unsuccessful, and the disclosure of his designs was much against him. Galba was again acknowledged and proclaimed, and he, notwithstanding his artifices, detected and slain by the soldiers who were proclaiming Galba. See NERO.

NYON, a considerable town of Switzerland, in the canton of Bern, and capital of a bailiwick of the same name, with a castle. It stands delightfully upon the edge of the lake of Geneva, in the very point where it begins to widen, and in a most charming country commonly called *Pays de Vaud*. It was formerly called *Colonia Equestris Noiodunum;* and, as a proof of its antiquity, several Roman inscriptions, and other ancient remains, have been frequently discovered in the outskirts of the town. E. Long. 5. 10. N. Lat. 46. 24.

NYSA, or NYSSA, in *Ancient Geography*, a town of Ethiopia, at the south of Egypt. Some place it in Arabia. This city, with another of the same name in India, was sacred to the god Bacchus, who was educated there by the nymphs of the place, and who received the name of *Dionysus*, which seems to be compounded of Διος and Νυσα, the name of his father, and that of the place of his education. The god made this place the seat of his empire, and the capital of the conquered nations of the east. According to some geographers, there were no less than ten places of this name. One of these was famous on the coast of Eubœa, for its vines, which grew in such a uncommon manner, that if a twig was planted in the ground in the morning, it immediately produced grapes which were full ripe in the evening. A city of Thrace: another seated on the top of Mount Parnassus, and sacred to Bacchus.

NYSLOT, a strong town of Russia, in Livonia, with a castle; seated on the river Narva, among large marshes. E. Long. 26. 55. N. Lat. 58. 46.

NYSSA, a genus of plants, belonging to the polygamia class; and in the natural method ranking under the 12th order, *Holoraceæ*. See BOTANY *Index*.

NYU-CHE, or KIN, an empire which arose in Eastern Tartary in the beginning of the 13th century. From the founder of this empire the late Chinese emperor Kang-hi said that his family was descended. See CHINA and TARTARY.

O.

O, THE 14th letter and fourth vowel of our alphabet; pronounced as in the words *nose*, *rose*, &c. The sound of this letter is often so soft as to require it double, and that chiefly in the middle of words; as *goose*, *reproof*, &c. And in some words, this *oo* is pronounced like *u* short, as in *blood*, *flood*, &c.

As a numeral, O was sometimes used for 11 among the ancients; and with a dash over it thus, $\bar{o}$, for 11,000.

In the notes of the ancients, O. CON, is read *opus conductum;* O. C. Q. *opera consilioque;* O. D. M. *operæ, donum munus;* and O. LO. *opus locatum.*

O, Oak. The Greeks had two O's; viz. omicron, ο, and omega, ω; the first pronounced on the tip of the lips with a sharper sound; the second in the middle of the mouth, with a fuller sound, equal to *oo* in our language. The long and short pronunciation of our O are equivalent to the two Greek ones; the first, as in suppose; the second, as in *o*bey.

O is usually denoted long by a servile *a* subjoined, as *moan;* or by *e* at the end of the syllable, as *bone;* when these vowels are not used, it is generally short.

Among the Irish, the letter O, at the beginning of the name of a family, is a character of dignity annexed to great houses. Thus, in the history of Ireland, we frequently meet with the *O Neals*, *O Carrols*, &c. considerable houses in that island.

Camden observes, that it is the custom of the lords of Ireland to prefix an O to their names, to distinguish them from the commonalty.

The ancients used O as a mark of triple time; from a notion that the ternary, or number 3, was the most perfect of numbers, and therefore properly expressed by a circle, the most perfect of figures.

It is not, strictly speaking, the letter O, but the figure of a circle O, or double CↃ, by which the modern ancients in music used to express what they called *tempo perfecto*, or triple time. Hence the Italians call it *circolo.*

The seven antiphones, or alternate hymns of seven verses, &c. sung by the choir in the time of Advent, were formerly called *O*, from their beginning with such an exclamation.

O is an adverb of calling, or interjection of sorrow or wishing.

OAK, in *Botany*. See QUERCUS.

The oak has been long known by the title of *monarch of the woods*, and very justly. It is well known, and often very elegantly described, by the ancient poets. The following description from Virgil is exquisite:

Veluti annoso validam cùm robore quercum
Alpini Boreæ, nunc hinc, nunc flatibus illinc
Eruere inter se certant: it stridor, et alte
Consternunt terram concusso stipite frondes:
Ipsa hæret scopulis; et quantum vertice ad auras
Ætherias, tantum radice in Tartara tendit.
ÆN. iv. 441.

As o'er th' aerial Alps sublimely spread,
Some aged *oak* uprears his reverend head;
This way and that the furious tempests blow,
To lay the monarch of the mountains low;
Th' imperial plant, though nodding at the sound,
Though all his scatter'd honours strew the ground;
Safe in his strength, and seated on the rock,
In naked majesty defies the shock:
High as the head shoots tow'ring to the skies,
So deep the root in hell's foundation lies. PITT.

The ancient druids had a most profound veneration for oak trees. Pliny * says, that "the druids (as the Gauls call their magicians or wise men) held nothing so sacred as the misletoe, and the tree on which it grows, provided it be an oak. They make choice of oak groves in preference to all others, and perform no rites without oak leaves; so that they seem to have the name of druids from thence, if we derive their name from the Greek," &c. (See DRUIDS, Definition, and N° 11.) Maximus Tyrius says the Celtæ or Gauls worshipped Jupiter under the figure of a lofty oak (A).

Oak.

* Nat Hist. xvi. c. 4

This useful tree grows to such a surprising magnitude, that there were not many well authenticated instances of them in our own country, they would certainly appear difficult of belief. In the 18th volume of the Gentleman's Magazine we have the dimensions of a leaf twelve inches in length and seven in breadth, and all the leaves of the same tree were equally large. On the estate of Woodhall, purchased in 1775 by Sir Thomas Rumbold, Bart. late governor of Madras, an oak was felled which sold for 43l. and measured 24 feet round. We are also told of one in Millwood forest, near Chaddesley, which was in full verdure in winter, getting its leaves again after the autumn ones fell off. In Hunter's Evelyn's Sylva, we have an account of a very remarkable oak at Greendale; which Gough, in his edition of Camden, thus minutely describes: "The Greendale oak, with a road cut through it, still bears one green branch. Such branches as have been cut or broken off are guarded from wet by lead. The diameter of this tree at the top, whence the branches issue, is 14 feet 2 inches; at the surface of the ground 11½ feet; circumference there 35 feet; height of the trunk 53; height of the arch 10, width 6. Mr Evelyn mentions several more oaks of extraordinary size in Worksop park."

In the Gentleman's Magazine for 1773 we have an account of one differing very essentially from the common one; it is frequent about St Thomas in Devonshire, and is in that county called *Lucombe* oak, from one William Lucombe who successfully cultivated it near Exeter. It grows as straight and handsome as a fir; its leaves are evergreen, and its wood as hard as that of the common oak. Its growth is so quick, as to exceed in 20 or 30 years the altitude and girth of the common one at 100. It is cultivated in various places; Cornwall, Somersetshire, &c.

M. du Hamel du Monçeau, of the Royal Academy of Sciences at Paris (who wrote a treatise on husbandry), gave an account in the year 1749 of an oak which he had kept in water eight years, and which yielded fine leaves every spring. The tree had, he says, four or five branches; the largest 19 or 20 lines round, and more than 18 inches long. It throve more in the two first years than it would have done in the best earth; it afterwards lost its vigour, and rather decayed; which he attributed to a defect in the roots rather than to a want of aliment.

M.

(A) Camden informs us of a tradition (which, like most other traditions of this nature, seems to be founded in ignorance and fostered by credulity) respecting an oak near Malwood castle, where Rufus was killed, viz. that it budded on Christmas day, and withered before night. This tree, the same tradition reports to have been that against which Tyrrel's arrow glanced.

Oak.

M. de Buffon made some experiments on oak trees; the result of which is recorded in the Gentleman's Magazine, 1754. He had compared barked with unbarked trees, and proves, we think with success, from a variety of trials, that timber barked and dried standing, is always heavier and considerably stronger than timber kept in its bark.

The bark of oak trees was formerly thought to be extremely useful in vegetation. One load (Mr Mills in his Treatise on Husbandry informs us) of oak bark, laid in a heap and rotted, after the tanners have used it for dressing of leather, will do more service to stiff cold land, and its effects will last longer, than two loads of the richest dung; but this has been strenuously controverted. (See *Oak Leaves*).

The bark, in medicine, is also a strong astringent; and hence stands recommended in hæmorrhagies, alvine fluxes, and other preternatural or immoderate secretions; and in these it is sometimes attended with good effects. Some have alleged, that by the use of this bark every purpose can be answered which may be obtained from Peruvian bark. But after several very fair trials, we have by no means found this to be the case. Besides the bark, the buds, the acorns and their cups are used; as also the galls, which are excrescences caused by insects on the oaks of the eastern countries, of which there are divers sorts; some perfectly round and smooth, some rougher with small protuberances, but all generally having a round hole in them. All the parts of the oak are styptic, binding, and useful in all kinds of fluxes and bleedings, either inward or outward. The bark is frequently used in gargarisms, for the relaxation of the uvula, and for sore mouths and throats: it is also used in restringent clysters and injections, against the prolapsus uteri or ani. The acorns, beaten to powder, are frequently taken by the vulgar for pains in the side. The only officinal preparation is the aqua germinum quercus.

Oak Leaves. The use of oak bark in tanning, and in hot-beds, is generally known. For the latter of these purposes, however, oak leaves are now found to answer equally well, or rather better. In the notes to Dr Hunter's edition of Evelyn's Treatise on Forest Trees, we find the following directions for their use by W. Speechly: The leaves are to be raked up as soon as possible after they fall from the trees. When raked into heaps, they should immediately be carried into some place near the hot-houses, where they may lie to couch. Mr Speechly says, it was his custom to fence them round with charcoal hurdles, or any thing to keep them from being blown about the garden in windy weather. In this place they tread them well, and water them in case they happen to have been brought in dry. The heap is made six or seven feet thick, and covered over with old mats, or any thing else, to prevent the upper leaves from being blown away. In a few days the heap will come to a strong heat. For the first year or two in which he used these leaves, our author did not continue them in the heap longer than ten days or a fortnight: but by this method of management they settle so much when brought to the hot-house, that a supply was very soon required; and he afterwards found, that it was proper to let them remain five or six weeks in the heaps before they are brought to the hot-house. In getting them into the pine-pots, if they appear dry, they are to be watered, and again trodden down exceedingly well, in layers, till the pits are quite full. The whole is then covered with tan bark, to the thickness of two inches, and well trodden down, till the surface becomes smooth and even. On this the pine pots are to be placed in the manner they are to stand, beginning with the middle row first, and filling up the spaces between the pots with tan. In this manner we are to proceed to the next row, till the whole be finished; and this operation is performed in the same manner as when tan only is used. The leaves require no further trouble through the whole season; as they will retain a constant and regular heat for 12 months without stirring or turning; and our author informs us, that if he may judge from their appearance when taken out (being always entire and perfect) it is probable they would continue their heat through a second year; but, as an annual supply of leaves is easily obtained, the experiment is hardly worth making. After this, the pines will have no occasion to be moved but at stated times of their management, viz. at the shifting them in their pots, &c. when at each time a little fresh tan should be added to make up the deficiency arising from the settling of the beds; but this will be inconsiderable, as the leaves do not settle much after their long couching. During the first two years of our author's practice he did not use any tan, but plunged the pine pots into the leaves, and just covered the surface of the beds, when finished, with a little saw-dust, to give it a neatness. This method, however, was attended with one inconvenience; for, by the caking of the leaves, they shrunk from the sides of the pots, whereby they became exposed to the air, and at the same time the heat of the beds was permitted to escape.

"Many powerful reasons (says Mr Speechly) may be given why oak leaves are preferable to tanners bark.

"1. They always heat regularly; for during the whole time that I have used them, which is near seven years, I never once knew of their heating with violence; and this is so frequently the case with tan, that I affirm, and indeed it is well known to every person conversant in the management of the hot-house, that pines suffer more from this one circumstance, than all the other accidents put together, insects excepted.—When this accident happens near the time of their fruiting, the effect is soon seen in the fruit, which is exceedingly small and ill-shaped. Sometimes there will be little or no fruit at all; therefore gardeners who make use of tan only for their pines, should be most particularly careful to avoid an over-heat at that critical juncture—the time of showing the fruit.

"2. The heat of oak leaves is constant; whereas tanner's bark generally turns cold in a very short time after its furious heat is gone off. This obliges the gardener to give it frequent turnings in order to promote its heating. These frequent turnings, not to mention the expence, are attended with the worst consequences; for by the continual moving of the pots backwards and forwards, the pines are exposed to the extremes of heat and cold, whereby their growth is considerably retarded; whereas, when leaves are used, the pines will have no occasion to be moved but at the times of potting, &c. The pines have one peculiar advantage in this indisturbed situation; their roots grow through the bottoms of the pots, and mat among the leaves in a surprising manner. From the vigour of the plants when in this situation, it is highly probable that the leaves, even in this state, afford them an uncommon and agreeable nourishment.

"3. There is a saving in point of expence; which is no inconsiderable object in places where tan cannot be had but from a great distance.

"4. The last ground of preference is, that decayed leaves make good manure; whereas rotten tan is experimentally found to be of no value. I have often tried it both on sand and clay, and on wet and dry land; and never could discover in any of my experiments, that it deserved the name of a manure; whereas decayed leaves are the richest, and of all others the most proper manure for a garden. Leaves mixed with dung make excellent hot-beds; and I find that beds compounded in this manner, preserve their heat much longer than when made entirely with dung; and in both cases, the application of leaves will be a considerable saving of dung, which is a circumstance on many accounts agreeable."

Oak-Leaf Galls. These are of several kinds; the remarkable species called the *mushroom gall* is never found on any other vegetable substance but these leaves: and besides this there are a great number of other kinds.

The double gall of these leaves is very singular, because the generality of productions of this kind affect only one side of a leaf or branch, and grow all one way: whereas this kind of gall extends itself both ways, and is seen on each side of the leaf, in form of two protuberances, opposite the one to the other. These are of differently irregular shapes, but their natural figure seems that of two cones, with broad bases, and very obtuse points, though sometimes they are round, or very nearly so.

These make their first appearance on the leaf in April, and remain on it till June or longer. They are at first green, but afterwards yellowish, and are softer to the touch than many other of the productions of this kind; they are usually about the size of a large pea, but sometimes they grow to the bigness of a nut. When opened, they are found to be of that kind which are inhabited each by one insect only, and each contains one cavity. The cavity in this is, however, larger than in any other gall of the size, or even in many others of three times its size; the sides of it being very little thicker than the substance of the leaf.

It is not easy to ascertain the origin of the several species of flies which are at times seen in this manner to come out of the same species of galls. It seems the common course of nature, that only one species of insect forms one kind of gall; yet it may be, that two or three kinds may give origin to the same kind. There is, however, another occasion of our seeing different species come out of different galls of the same kind: and this is the effect of the enemies of the proper inhabitants.

It might appear that the parent fly, when she had formed a gall for the habitation of her worm offspring, had placed it in an impregnable fortress; but this is not the case; for it frequently happens, that a fly, as small perhaps as that which gave origin to the gall, produces a worm which is of the carnivorous kind, as the other feeds on vegetable juices. This little fly, well knowing that where there is one of these protuberances on a leaf, there is a tender and defenceless insect within, pierces the sides of the gall, and deposites her egg within it. This, when it hatches into a worm, feeds upon the proper inhabitant; and, finally, after devouring it, passes into the chrysalis state, and thence appears in the form of its parent fly, and is seen making its way out of the gall, in the place of the proper inhabitant.

On opening these leaf-galls, which are properly the habitation only of one animal, it is common to find two, the stronger preying upon the body of the other, and sucking its juices as it does those of the leaf: often it is found wholly employed in devouring its unoffending neighbour at once: this is probably the case when its time of eating is nearly over: and, in fine, when we find the gall inhabited by only one insect, or containing only one chrysalis, as it ought in its natural state to do, we are never certain that this is the proper inhabitant, as it may be one of these destroyers who has eaten up the other, and supplied its place. See APHIS, ENTOMOLOGY *Index*.

Oak Saw-dust is now found to answer the purposes of tanning, as well, at least, as the bark. See TANNING.

Oak of Jerusalem. See CHENOPODIUM, BOTANY *Index*.

OAKHUM, OCKHAM, or *Oakum*, in sea language, denotes the matter of old ropes untwisted and pulled out into loose hemp, in order to be used in caulking the seams, treenails, and bends of a ship, for stopping or preventing leaks.

OAKHAMPTON, a town of Devonshire, which sends two members to parliament, has 1440 inhabitants, and a manufacture of serge; situated in W. Long. 4. 5. N. Lat. 50. 48.

OANNES, a being in Chaldean mythology, represented as half a man and half a fish. According to Berosus and other fabulous writers, this monster was the civilizer of the Chaldeans; to whom he taught a system of jurisprudence so perfect as to be incapable of improvement. In discharging the duties of his office, he spent the day on dry land, but retired every night into the ocean or the river. See MYTHOLOGY, N° 25.

OAR, a long piece of timber, flat at one end and round or square at the other; and which being applied to the side of a floating vessel, serves to make it advance upon the water.

That part of the oar which is out of the vessel, and which enters into the water, is called the *blade* or *wash-plat;* and that which is within board is termed the *loom*, whose extremity being small enough to be grasped by the rowers, or persons managing the oars, is called the *handle*.

To push the boat or vessel forwards by means of this instrument, the rowers turn their backs forward, and, dipping the blade of the oar in the water, pull the handle forward so that the blade at the same time may move aft in the water: but since the blade cannot be so moved, without striking the water, this impulsion is the same as if the water were to strike the blade from the stern towards the head: the vessel is therefore necessarily moved according to this direction. Hence it follows, that she will advance with the greater rapidity, by as much as the oar strikes the water more forcibly. Thus it is evident, that an oar acts upon the side of a boat or vessel like a lever of the second class, whose fulcrum is the station upon which the oar rests on the boat's gunnel. In large vessels, this station is usually called the *row-port;* but in lighters and boats it is always termed the *row-lock*.

OARISTUS, or OARISTYS, a term in the Greek poetry, signifying a dialogue between a husband and his wife; such as that in the sixth book of the Iliad between Hector and Andromache.

Scaliger observes, that the oaristus is not properly any particular little poem, or entire piece of poetry; but always a part of a great one. He adds, that the passage now cited in Homer is the only proper oaristus extant in the ancient poets.

OASIS, the name of a fertile spot in the midst of a sandy desert. Many of those spots, or *oases*, in the African deserts are remarkable for their fertility.

OAT. See AVENA, BOTANY *Index*.

Mr Bruce gives the following account of the oats which he found growing wild in Aroossi, a small territory in Abyssinia, not far from the source of the Nile: "Wild oats (says he) grow up here spontaneously to a prodigious height and size, capable often of concealing both the horse and his rider, and some of the stalks being little less than an inch in circumference. They have, when ripe, the appearance of small canes. The inhabitants make no sort of use of this grain in any period of its growth: the uppermost thin husk of it is beautifully variegated with a changeable purple colour; the taste is perfectly good. I often made the meal into cakes in remembrance of Scotland." Our author informs us, that the Abyssinians could never be brought to relish these cakes, which they said were bitter, burnt their stomachs, and made them thirsty. He is, however, decidedly of opinion, that the wild oat of Aroossi is the oat in its original state; and that it has degenerated everywhere in Europe.

OATH, an affirmation or promise, accompanied with an invocation of God to witness what we say; and with an imprecation of his vengeance, or a renunciation of his favour, if what we affirm be false, or what we promise be not performed (A).

The laws of all civilized states have required the security of an oath for evidence given in a court of justice, and on other occasions of high importance (B); and the Christian religion utterly prohibits swearing, except when oaths are required by legal authority. Indeed no serious and reflecting theist, whether he admit the truth of revelation or not, can look upon swearing on trivial occasions as any thing else than a sin of a very heinous nature. To call upon that infinite and omnipresent Being, who created and sustains the universe, to witness all the impertinence of idle conversation, of which great part is commonly uttered at *random*, betrays a spirit so profane, that nothing short of experience could make us believe it possible for a creature endowed with reason and reflection to be habitually guilty of a practice so impious. No man can plead in extenuation of this crime, that he is tempted to swear by the importunity of any appetite or passion implanted in the human breast: for the utterance of a profane oath communicates no pleasure and removes no uneasiness: it neither elevates the speaker nor depresses the hearer.

Quakers and *Moravians*, swayed by these considerations, and by the sense which they put upon certain texts of Scripture, refuse to swear upon any occasion, even at the requisition of a magistrate, and in a court of justice. These scruples are groundless; and seem to proceed from an incapacity to distinguish between the proper use and abuse of swearing. It is unquestionably impious to call upon God to witness impertinences, or to use his tremendous name as a mere *expletive* in conversation; but it by no means follows, that we may not piously call upon him to witness truths of importance, or invoke his name with reverence and solemnity. No individual could, without gross profaneness, pray for a thousand times more wealth than he may ever have occasion to use; but it was never thought profane to pray "day by day for our daily bread, for rain from heaven, and fruitful seasons." If it be lawful to ask of God these earthly blessings, because he alone can bestow them; it cannot surely be unlawful, where the lives or properties of our

(A) The word *oath* is a corruption of the Saxon *eoth*. It is often in England called a *corporal oath*, because, in the days of popery, the person was sworn over the host or *corpus Christi*.

(B) The various oaths required by different nations at different times, and the various forms, &c. of imposing them, is a subject of very considerable extent and curiosity: An account of them does not fall within the plan of the present article; it would indeed extend it to an undue length; we cannot, however, omit observing, what is doubtless very remarkable, that the grand impostor Mahomet taught the Moslems, that their oaths might be dissolved. This wonderful doctrine is contained in the 66th chapter of the Koran; which, to free himself from his promise and oath to Hafsa his spouse, he pretended was revealed. What the use of oaths is in such circumstances, or what security they afford for performance, it is difficult to ascertain.

It is also very remarkable, that an oath respecting marriages was the cause of the first divorce at Rome. The circumstance happened about the year of the city 525, Posthumius Albinus and Spurius Carvilius being consuls. The censors of this year observing the population declining, and imagining it proceeded from interested marriages and promiscuous cohabitation, obliged all the citizens to swear, that they would not marry with any other view than that of peopling the republic. It raised, however, many scruples, and occasioned many domestic ruptures. Among the rest, one Carvilius Ruga, a man of distinction, imagined that he was bound by his oath to divorce his wife, whom he passionately loved, because she was barren, which was the first instance of a divorce at Rome from its foundation, though the marriage laws of the kings allowed it; it afterwards, however, became shamefully frequent. This is also a striking instance of the great attention paid to oaths among the Romans; it is remarked indeed by all writers, that they paid a most profound respect to them; and on that we know they founded their hopes of success in war.

Oath.

our neighbours, or the security of government is concerned, to invoke him with reverence to witness the truth of our assertions, or the sincerity of our intentions; because of our truth in many cases, and of our sincerity in all, none but he can be the witness.

The text of Scripture upon which the Quakers chiefly rest their argument for the unlawfulness of all swearing under the gospel, is our Saviour's prohibition (Mat. v. 34.): "I say unto you, swear not at all." But whoever shall take the trouble of turning over his Bible, and looking at the context, will perceive, that it is only in *ordinary conversation*, and by no means in courts of justice, that our Lord prohibits his followers from swearing at all. There is no evidence whatever, that swearing by *heaven*, by *the earth*, by *Jerusalem*, or by their own *heads*, was the form of a *judicial oath* in use among the Jews. On the contrary, we are told by *Maimonides* *, that "if any man swear by heaven or by earth, yet this is not an oath;" which surely he could not have said, had such been the forms of judicial swearing. Indeed they could not have admitted such forms into their courts without expressly violating the law of Moses, who commands them to "Fear the Lord (JEHOVAH) their God, to serve him, and to swear by his NAME." But the Jews, as every one knows, had such a reverence for the name *Jehovah*, that they would not pronounce it on slight occasions, and therefore could not swear by that name in common conversation. Hence, to gratify their propensity to common swearing, they invented such oaths as, by *heaven*, by *earth*, by *Jerusalem*, by *the life of thy head*, &c. and by this contrivance they thought to avoid the guilt of profaning the name JEHOVAH. These, however, being appeals to insensible objects, either had no meaning, or were in fact, as our Saviour justly argues, oaths by that God whose creatures they were; so that the Jew who swore them was still guilty of profaneness towards the very JEHOVAH whose name his superstition would not permit him to pronounce. But what puts it beyond all doubt that the use of judicial oaths is not wholly prohibited in the gospel, is the conduct of our Saviour himself as well as of his apostle St Paul. When Jesus was simply *asked* by the high priests, what it was which certain false witnesses testified against him? we are told by the evangelists, that "he held his peace:" but being *adjured* by the living God to declare whether he was the Christ, the Son of God, or not, he immediately answered the high priest, without objecting to the *oath* (for such it was) upon which he was examined. "St Paul, in his Epistle to the Romans †, says, '*God is my witness*, that, without ceasing, I make mention of you in my prayers;' and to the Corinthians, still more strongly, '*I call God for a record upon my soul*, that, to spare you, I came not as yet to *Corinth*.' Both these expressions are of the nature of oaths; and the author of the Epistle to the Hebrews speaks of the custom of swearing judicially without any mark of censure or disapprobation: 'Men verily swear by the greater; and an oath, for confirmation, is to them an end of all strife."

* See *Whitby on the Place.*

† *Paley's Moral Philosophy.*

But though a nation has an undoubted right to require the security of an oath upon occasions of real importance, we do not hesitate to say, that, in our opinion, it is something worse than bad policy to multiply oaths, and to hold out to the people temptations to perjure themselves. The security which an oath affords, depends entirely upon the reverence which attaches to it in the mind of him by whom it is given; but that reverence is much weakened by the frequency of oaths, and by the careless manner in which they are too often administered. An excellent moralist ‡ observes, with truth, that "the levity and frequency with which oaths are administered, has brought about a general inadvertency to the obligation of them, which both in a religious and political view is much to be lamented; and it merits (continues he) public consideration, whether the requiring of oaths on so many frivolous occasions, especially in the customs, and in the qualification for petty offices, has any other effect than to make them cheap in the minds of the people. A pound of tea cannot travel regularly from the ship to the consumer without costing *half a dozen oaths* at least; and the same security for the due discharge of his office, namely that of an oath, is required from a *church warden* and an *archbishop*, from a *petty constable* and the *chief justice* of England. Let the law continue its own sanctions, if they be thought requisite; but let it spare the solemnity of an oath: and where it is necessary, from the want of something better to depend upon, to accept a man's own word or own account, let it annex to prevarication penalities proportioned to the public consequence of the offence."

‡ *M[...] [...]ley.*

That these pernicious consequences of frequent oaths are not felt only in England, we have the evidence of another respectable writer, whose acuteness well qualified him to observe, whilst his station in society furnished him with the best opportunities of observing, the effects of repeated swearing upon the morals of Scotchmen. "Customhouse oaths (says Lord Kames §) have become so familiar among us, as to be swallowed without a wry face; and is it certain that bribery and perjury in electing parliament members are not approaching to the same cool state? men creep on to vice by degrees. Perjury, in order to support a friend, has become customary of late years; witness fictitious qualifications in the electors of parliament-men, which are made effectual by perjury: yet such is the degeneracy of the present time, that no man is the worse thought of upon that account. We must not flatter ourselves, that the poison will reach no farther: a man who boggles not at perjury to serve a friend, will in time become such an adept, as to commit perjury in order to ruin a friend when he becomes an enemy."

§ *S[...] of t[...] tory [...] Ma[...]*

Besides the frequency of oaths, we have mentioned the irreverent manner in which they are too often administered as one of the causes which make them cheap in the estimation of the people. In this view, the *form* of the oath, and the *ceremonies* with which it is required to be taken, are of considerable importance. "The forms of oaths in Christian countries (says Mr Paley) are very different; but in none I believe worse contrived either to convey the meaning or to impress the obligation of an oath, than in England. In that country the juror, after repeating the promise or affirmation which the oath is intended to confirm, adds, 'so help me God;' or more frequently the substance of the oath is repeated to the juror by the officer or magistrate who administers it; adding in the conclusion, 'so help you God.' The energy of the sentence resides in the particle

Oath.

particle *so: so*, i. e. *hac lege* 'upon condition of my speaking the truth, or performing this promise, may God help me, and not otherwise.' The juror, whilst he hears or repeats the words of the oath, holds his right hand upon a Bible, or other book containing the four gospels. The conclusion of the oath sometimes runs, '*ita me Deus adjuvet, et hæc sancta evangelia*,' or 'so help me God, and the contents of this book;' which last clause forms a connexion between the words and action of the juror, which before was wanting. The juror then kisses the book."

This obscure and elliptical form, the excellent author justly observes, is ill calculated to impress the juror with reverence: and he seems to think great preference due to the form of judicial oaths in Scotland. In that country the juror holds up his right hand towards heaven, and swears by Almighty God, and as he shall answer to God at the great day of judgment, "that he will tell the truth, the whole truth, and nothing but the truth, so far as he knows, or it shall be asked of him." This, if administered with dignity and reverence, is an oath sufficiently solemn and well calculated to have the proper effect upon the mind of the juror, as it brings immediately into his view the Author of his being, and the awful day of final retribution when every man shall receive the things done in his body according to that he hath done, whether it be good or evil. But when the magistrate, as is too often the case, repeats this solemn invocation without rising from his seat at the name of the Supreme Being, and in a tone of carelessness which may convey to the ignorant juror an opinion that he has himself no serious belief that there ever will be a great day of judgment, the form, however excellent, makes not its full impression.

But let us suppose the oath to be administered with the greatest dignity and reverence, the words of the promise itself appear to us by no means unexceptionable. In a trial on life and death, we should be glad to know what this oath binds the witness to declare. Is he to tell *all that he knows* touching the matter in question? or only all that shall be *asked* of him? If he be obliged, in virtue of his oath, to tell all that he knows, the clause—"or it shall be asked of you" is superfluous, and calculated to mislead. If he be bound to tell nothing more of the truth than what shall be asked of him, the word *or* should be changed into *and;* he should swear "to tell the truth, &c. so far as he knows, *and* it shall be asked of him." The court, we believe, considers the witness as bound to declare every thing which he knows touching the matter in question. The greater part of witnesses, on the other hand, consider themselves as bound no farther by their oath than to give true answers to such questions as shall be asked of them. They would do well, however, to remember, that as oaths are designed for the security of the *public*, they must be interpreted in the sense in which the public intends them, otherwise they afford no security. But the sense of the public is the law; and as it belongs to the court to declare what the mind of the law is, the witness, who has any doubt concerning the extent of the obligation imposed on him by the words of this oath, should apply to the court for a solution of that doubt, which will be a safe guide to him respecting the evidence which he is to give. Should the court, in resolving the doubts of a witness, give an opinion concerning the sense of any other part of the oath contrary to what he apprehends to be the design of the law in imposing it, he is bound to disregard such opinion; because it is only where he himself is doubtful that the court has a right to interfere, and because in all moral questions men must be finally determined by their own judgment and conscience.

There is one case, and but one, in which, whatever sense be put upon the words of the oath, no witness is obliged to declare the *whole* truth. It is when such declaration would tend to acuse himself of some legal crime; for as the laws of Scotland and England constrain no man to become his own accuser, they must be considered as imposing the oath of testimony with this tacit reservation. "The exception, however *, must be confined to *legal* crimes. A point of honour, of delicacy, or of reputation, may make a witness backward to disclose some circumstance with which he is acquainted; but is no excuse for concealment, unless it could be shown, that the law which imposes the oath, intended to allow this indulgence to such motives. The exception is also withdrawn by compact between the magistrate and the witness, when an accomplice is admitted to give evidence against the partners of his crime. But these are a sort of witnesses to whom a sensible jury will always listen with a very cautious ear.

* *Paley's Moral Philosophy.*

Oaths are either *assertory* or *promissory*. Assertory oaths are required both to confirm our veracity in evidence, and to give security to the public that we *believe* certain propositions conceived to be of public importance. An oath in *evidence* binds the juror to declare what he *knows* to be true, and nothing *but* what he knows to be true. An oath required to assure the public of our *belief* in the *truth* of any proposition, cannot, without the guilt of perjury, be taken by any man, who, at the time of swearing, has the slightest doubt whether the proposition be really true. Such an oath, however, though it unquestionably requires the sincerity of the juror's belief at the time when it is given, cannot oblige him to continue in that belief as long as he may live; for belief is not in any man's power: it is the necessary consequence of evidence, which *compels* the assent of the mind according as it appears to preponderate on the one side or on the other. No man, therefore, can be justly accused of perjury for holding opinions contrary to those which he may formerly have sworn to believe; because his belief at the time of emitting his oath may have been the necessary result of the evidence which then appeared before him; and his change of opinion may have resulted with the same necessity from superior evidence which had been since thrown into the opposite scale, and made it preponderate. On this account, we cannot help thinking, that all assertory oaths, except such as are necessary to confirm testimony respecting *facts*, ought either to be abolished or expressed with great caution. Of truths intuitively certain or capable of rigid demonstration, no man of common sense can entertain a doubt; and therefore the public never requires from individuals the solemnity of an oath as an assurance of their believing such truths. But with respect to the truth of propositions which admit of nothing superior to moral evidence on either side, a man of the most steady

steady virtue may think differently at different periods of his life; and in such cases, the effect of an oath, if it have any effect, can only be either, to shut the man's eyes against the light, or to make his integrity be causelessly questioned by those who shall observe his change of belief.

Promissory oaths cannot, without the guilt of perjury, be given by him, who, at the time of swearing, knows that it will not be in his power to fulfil the promise, or who does not seriously intend to fulfil it. A promissory oath cannot, without great guilt, be given by any man, who at the time of swearing believes the object of the promise to be in itself unlawful; for if he seriously mean to fulfil his oath, he calls upon Almighty God to witness his intention to commit a crime. Promissory oaths give to the public greater security than a simple promise; because the juror having the thoughts of God and of religion more upon his mind at the one time than at the other, offends with a higher hand, and in more open contempt of the divine power, knowledge, and justice, when he violates an oath, than when he breaks a promise. Yet it is certain that promissory oaths, though more solemn and sacred, cannot be binding, when the promise without an oath would not be so in an inferior degree; for the several cases of which, see PROMISE and ALLEGIANCE.

Coronation OATH. See KING.

OATHLAW, the name of a parish in Angus, about two miles from Forfar, chiefly remarkable for the remains of a Roman camp called *Battle-dykes* (vulgarly *Black-dykes*), which is about a mile west of the church.

OBADIAH, or the *Prophecy* of OBADIAH, a canonical book of the Old Testament, which is contained in one single chapter; and is partly an invective against the cruelty of the Edomites, who mocked and derided the children of Israel as they passed into captivity; and with other enemies, their confederates, invaded and oppressed those strangers, and divided the spoil amongst themselves; and partly a prediction of the deliverance of Israel, and of the victory and triumph of the whole church over her enemies.

OBADIAH, the prophet, is believed to have been the same with the governor of Ahab's house, mentioned in the first book of Kings, (xviii. 3, &c.) who hid and fed the hundred prophets whom Jezebel would have destroyed; and some say, that he was that Obadiah whom Josiah made overseer of the works of the temple, (2 Chron. xxxiv. 12.). The truth is, that when he lived or prophesied is wholly uncertain: though most writers make him cotemporary with Hosea, Amos, and Joel.

OBADIAH, a valiant man of David's army, who came to join him in the wilderness, with several others of the tribe of Gad, (1 Chron. xii. 9.).

This was also the name of one of those whom King Jehoshaphat sent into the cities of Judah to instruct the people in their religion, (2 Chron. xvii. 7.). It was also the name of one of the principal men of Judah, who signed the covenant that Nehemiah renewed with the Lord, (Nehem. x. 5.).

OBED-EDOM, son of Jeduthun, a Levite, (1 Chr. xvi. 38.) and father of Shemaiah, Jehozabad, Joah, Sacar, Nathaneel, Ammiel, Issachar, and Peulthai. He had a numerous family, says the Scripture, (1 Chron.

xxvi. 4.) because the Lord blessed him; and this is the occasion of the blessing. When David transferred the ark of the covenant to the city of Jerusalem, Uzzah having rashly laid hands on the ark, which he thought to be in danger of falling, was smitten of God, and died upon the spot. David, terrified at this accident, durst not remove the ark into the place he had provided for it in his own house, but set it up in the house of Obed-edom, which was near the place where Uzzah had been struck dead. But the presence of the ark not only created no temporal misfortune to the family of this Levite, but, on the contrary, the Lord heaped upon him all sorts of blessings; which encouraged David some months after to remove it to the place he had appointed for it. Afterwards Obed-edom and his sons were assigned to be keepers of the doors of the temple, (1 Chron. xv. 18, 21.). In the second book of Samuel, (vi. 10.) Obed-edom is called the Gittite, probably because he was of Gathrimmon, a city of the Levites beyond Jordan, (Josh. xxi. 24, 25.).

OBELISK, in *Architecture*, a truncated, quadrangular, and slender pyramid, raised as an ornament, and frequently charged either with inscriptions or hieroglyphics.

Obelisks appear to be of very great antiquity, and to have been first raised to transmit to posterity precepts of philosophy, which were cut in hieroglyphical characters: afterwards they were used to immortalize the great actions of heroes, and the memory of persons beloved. The first obelisk mentioned in history was that of Ramases king of Egypt, in the time of the Trojan war, which was 40 cubits high. Phius, another king of Egypt, raised one of 55 cubits; and Ptolemy Philadelphus, another of 88 cubits, in memory of Arsinoe. Augustus erected one at Rome in the Campus Martius, which served to mark the hours on a horizontal dial, drawn on the pavement. They were called by the Egyptian priests the *fingers of the sun*, because they were made in Egypt also to serve as styles or gnomons to marks the hours on the ground. The Arabs still call them *Pharaoh's needles*; whence the Italians call them *aguglia*, and the French *aiguilles*.

The famous obelisks called the *devil's arrows*, now reduced to three, the fourth having been taken down in the last century, stand about half a mile from the town of Borough-Bridge to the south-west, in three fields, separated by a lane, 200 feet asunder nearly, on high ground sloping every way. Mr Drake urges many arguments for their Roman antiquity, and plainly proves them to be natural, and brought from Plumton quarries about five miles off, or from Ickly 16 miles off. The cross in the town, 12 feet high, is of the same kind of stone. The eastermost or highest is 22 feet and a half high by 4 broad, and $14\frac{1}{2}$ in girth; the second $21\frac{1}{2}$ by $55\frac{1}{2}$; the third $16\frac{1}{2}$ by 84. Stukeley's measures differ. The flutings are cut in the stone but not through: the tallest stands alone, and leans to the south. Plot and Stukeley affirm them to be British monuments, originally hewn square. Dr Gale supposed that they were Mercuries, which have lost their heads and inscriptions; but in a MS. note in his Antoninus, he acknowledges that he was misinformed, and that there was no cavity to receive a bust.

On the north side of Penrith, in the churchyard, are two square obelisks, of a single stone each, 11 or 12 feet high,

high, about 12 inches diameter, and 12 by 8 at the sides, the highest about 18 inches diameter, with something like a transverse piece to each, and mortised into round base. They are 14 feet asunder, and between them is a grave enclosed between four semicircular stones of the unequal lengths of five, six, and four and a half, and two feet high, having on the outsides rude carving, and the tops notched. This is called the *Giant's grave*, and ascribed to Sir Ewen Cæsarius, who is said to have been as tall as one of the columns, and capable of stretching his arms from one to the other; to have destroyed robbers and wild boars in Englewood forest; and to have had a hermitage hereabouts called *Sir Hugh's parlour*; but the conjectures respecting them are extremely various and contradictory. A little to the west of these is a stone called the *Giant's Thumb*, six feet high, 14 inches at the base contracted to 10, which is no more than a rude cross, such as is at Longtown in Cumberland, and elsewhere; the circle of the cross 18 inches diameter.

Near the town of Forres in the north of Scotland there is a very fine obelisk, 22 feet in height, known by the name of the *Forres pillar*, or *Sweno's stone*. See Forres.

M. Pouchard, in the memoirs of the Academy of Inscriptions, gives a curious account of some celebrated Egyptian obelisks. See Gentleman's Magazine for June 1748.

OBJECT, in *Philosophy*, something apprehended or presented to the mind by sensation or imagination. See Metaphysics, Part I. Chap. I. Sect II.

Object-Glass of a Telescope, or *Microscope*, the glass placed at the end of the tube which is next the object. See Optics and Microscope.

OBJECTION, something urged to overthrow a position, or a difficulty raised against an allegation or proposition of a person we are disputing with.

OBJECTIVE, is used in the schools, in speaking of a thing which exists no otherwise than as an object known. The existence of such a thing is said to be objective.

OBIT, (Lat.) signifies a funeral solemnity, or office for the dead, most commonly performed when the corpse lies in the church uninterred: Also the anniversary office, (2 Cro. 51 Dyer 313.). The anniversary of any person's death was called the *obit*; and to observe such day with prayers and alms, or other commemoration, was the keeping of the obit. In religious houses they had a register, wherein they entered the obits or obitual days of their founders and benefactors; which was thence termed the *obituary*. The tenure of obit or chantry lands is taken away and extinct by 1 Edw. VI. c. 14. and 15 Car. II. c. 9.

OBLATE, flattened or shortened; as an oblate spheroid, having its axis shorter than its middle diameter; being formed by the rotation of an ellipse about the shorter axis. The earth, whose polar diameter is shorter than the equatorial, is an oblate spheroid.

OBLATI, in church history, were secular persons, who devoted themselves and their estates to some monastery, into which they were admitted as a kind of lay brothers. The form of their admission was putting the bell ropes of the church round their necks, as a mark of servitude. They wore a religious habit, but different from that of the monks.

OBLIGATION, in general, denotes any act whereby a person becomes bound to another to do something; as to pay a sum of money, be surety, or the like.

Obligations are of three kinds, viz. natural, civil, and mixed. Natural obligations are entirely founded on natural equity; civil obligations on civil authority alone, without any foundation in natural equity; and mixed obligations are those which, being founded on natural equity, are farther enforced by civil authority.

In a legal sense, obligation signifies a bond, wherein is contained a penalty, with a condition annexed, for the payment of money, &c. The difference between it and a bill is, that the latter is generally without a penalty or condition, though it may be made obligatory: and obligations are sometimes by matter of record, as statutes and recognizances. See the article Bond.

Moral Obligation. See Moral Philosophy, N° 58, &c.

OBLIQUE, in *Geometry*, something aslant, or that deviates from the perpendicular. Thus an oblique angle is either an acute or obtuse one, i. e. any angle except a right one.

Oblique Cases, in *Grammar*, are all the cases except the nominative. See Grammar.

Oblique Ascension, is that point of the equinoctial which rises with the centre of the sun, or star, or any other point of the heavens, in an oblique sphere.

Oblique Circle, in the stereographic projection, is any circle that is oblique to the plane of projection.

Oblique Descension, that point of the equinoctial which sets with the centre of the sun, or star, or any other point of the heavens, in an oblique sphere.

Oblique Line, that which, falling on another line, makes oblique angles with it, viz. one acute, and the other obtuse.

Oblique Planes, in *Dialling*, are those which decline from the zenith, or incline towards the horizon. See Dial.

Oblique Sailing, in *Navigation*, is when a ship sails upon some rhumb between the four cardinal points, making an oblique angle with the meridian; in which case she continually changes both latitude and longitude. See Navigation, Chap. VIII.

OBLIQUUS, in *Anatomy*, a name given to several muscles, particularly in the head, eyes, and abdomen. See Anatomy, *Table of the Muscles*.

OBLONG, in general, denotes a figure that is longer than broad; such is a parallelogram.

OBOLARIA, a genus of plants belonging to the didynamia class; and in the natural method ranking under the 40th order, *Personatæ*. See Botany *Index*.

OBOLUS, an ancient silver money of Athens, the sixth part of a drachma; worth somewhat more than a penny farthing sterling.—The word comes from the Greek οβελος, or οβιλος, "spit, or broach;" either because it bore such an impression; or because, according to Eustathius, it was in form thereof. But those now in the cabinets of the antiquaries are round.

Obolus, in *Medicine*, is used for a weight of ten grains, or half a scruple.

OBOTH, an encampment of the Hebrews in the wilderness. From Punon they went to Oboth, and from Oboth to Ije-abarim, (Num. xxi. 10. xxxiii. 43).

Ptolemy speaks of a city called Oboda, or Eboda, in Arabia Petræa, which is the same as Oboth. Pliny and the geographer Stephanus mention it also. Stephanus makes it belong to the Nabathæans, and Pliny to the Helmodeans, a people of Arabia. It was at Oboth that they worshipped the god Obodus, which Tertullian joins with Dusares, another god or king of this country.

OBREPTITIOUS, an appellation given to letters patent, or other instruments, obtained of a superior by surprise, or by concealing from him the truth.

OBSCURE, something that is dark and reflects little light in material objects, or that is not clear and intelligible in the objects of the intellect.

OBSECRATION, in *Rhetoric*, a figure whereby the orator implores the assistance of God or man.

OBSEQUIES, the same with funeral solemnities. See FUNERAL.

OBSERVATION, among navigators, signifies the taking the sun's or the stars meridian altitude, in order thereby to find the latitude.

OBSERVATORY, a place destined for observing the heavenly bodies; being generally a building erected on some eminence, covered with a terrace for making astronomical observations.

The more celebrated observatories are, 1. The Greenwich observatory, built in 1676, by order of Charles II. at the solicitation of Sir Jonas Moore and Sir Christopher Wren; and furnished with the most accurate instruments; particularly a noble sextant of seven feet radius, with telescopic sights.

2. The Paris observatory, built by the order of Louis XIV. in the fauxbourg St Jacques.

It is a very singular, and a very magnificent building, the design of Monsieur Perault: it is 80 feet high; and has a terrace at the top.

The difference in longitude between this and the Greenwich observatory is 2° 20′.

In it is a cave or cellar, of 170 feet descent, for experiments that are to be made far from the sun, &c. particularly such as relate to congelations, refrigerations, indurations, conservations, &c.

3. Tycho Brahe's observatory, which was in the little island Ween, or Scarlet Island, between the coasts of Schonen and Zealand in the Baltic. It was erected and furnished with instruments at his own expence, and called by him *Uraniburg*. Here he spent twenty years in observing the stars; the result is his catalogue.

4. Pekin observatory. Father Le Compte describes a very magnificent observatory, erected and furnished by the late emperor of China, in his capital, at the intercession of some Jesuit missionaries, principally Father Verbeist, whom he made his chief observer. The instruments are exceedingly large; but the division less accurate, and the contrivance in some respects less commodious, than that of the Europeans. The chief are, An armillary zodiacal sphere of six feet diameter; an equinoctial sphere of six feet diameter; an azimuthal horizon of six feet diameter; a large quadrant six feet radius; a sextant eight feet radius; and a celestial globe six feet diameter.

Observatories, as they are very useful, and indeed absolutely necessary for astronomers, so they have become far more common than they were. There is a very excellent one now at Oxford, built by the trustees of Dr Radcliffe, at the expence of nearly 30,000l. At Cambridge there is as yet no public observatory. Over the great gate of Trinity college, indeed, there is one which is called *Sir Isaac Newton's*, because this great philosopher had used it; but it is gone to decay. It were well if the university would repair and preserve it in memory of that truly great man. In St John's, too, there is a small one. The late ingenious Mr Cotes had used to give lectures in Sir Isaac Newton's on experimental philosophy. In Scotland there is an observatory at Glasgow belonging to the university: there is one erected on the Calton hill at Edinburgh; but it is in very bad repair (see EDINBURGH); and there is an excellent one at Dublin.

Plate CCCLXX.

5. Bramins observatory at Benares. Of this Sir Robert Barker gives the following account (Phil. Trans. vol. lxvii. p. 598.). "Benares in the East Indies, one of the principal seminaries of the Bramins or priests of the original Gentoos of Hindostan, continues still to be the place of resort of that sect of people; and there are many public charities, hospitals, and pagodas, where some thousands of them now reside. Having frequently heard that the ancient Bramins had a knowledge of astronomy, and being confirmed in this by their information of an approaching eclipse both of the sun and moon, I made inquiry, when at that place in the year 1772, among the principal Bramins, to endeavour to get some information relative to the manner in which they were acquainted with an approaching eclipse. The most intelligent that I could meet with, however, gave me but little satisfaction. I was told that these matters were confined to a few, who were in possession of certain books and records; some containing the mysteries of their religion; and others the tables of astronomical observations, written in the Shanscrit language, which few understood but themselves: that they would take me to a place which had been constructed for the purpose of making such observations as I was inquiring after, and from whence they supposed the learned Bramins made theirs. I was then conducted to an ancient building of stone, the lower part of which, in its present situation, was converted into a stable for horses, and a receptacle for lumber; but by the number of court-yards and apartments, it appeared that it must once have been an edifice for the use of some public body of people. We entered this building, and went up a staircase to the top of a part of it, near to the river Ganges, that led to a large terrace, where, to my surprise and satisfaction, I saw a number of instruments yet remaining, in the greatest preservation, stupendously large, immoveable from the spot, and built of stone, some of them being upwards of 20 feet in height; and although they are said to have been erected 200 years ago, the graduations and divisions on the several arcs appeared as well cut, and as accurately divided, as if they had been the performance of a modern artist. The execution in the construction of these instruments exhibited a mathematical exactness in the fixing, bearing, fitting of the several parts, in the necessary and sufficient supports to the very large stones that composed them, and in the joining and fastening each into the other by means of lead and iron.

"The situation of the two large quadrants of the instrument marked A in the plate, whose radius is nine feet two inches, by their being at right angles with a

gnomon

gnomon at twenty-five degrees elevation, are thrown into such an oblique situation as to render them the most difficult, not only to construct of such a magnitude, but to secure in their position for so long a period, and affords a striking instance of the ability of the architect in their construction: for by the shadow of the gnomon thrown on the quadrants, they do not appear to have altered in the least from their original position; and so true is the line of the gnomon, that, by applying the eye to a small iron ring of an inch diameter at one end, the sight is carried through three others of the same dimension, to the extremity at the other end, distant 38 feet 8 inches, without obstruction; such is the firmness and art with which this instrument has been executed. This performance is the more wonderful and extraordinary, when compared with the works of the artificers of Hindostan at this day, who are not under the immediate direction of an European mechanic; but arts appear to have declined equally with science in the east.

"Lieutenant Colonel Archibald Campbell, at that time chief engineer in the East India Company's service at Bengal, made a perspective drawing of the whole of the apparatus that could be brought within his eye at one view; but I lament he could not represent some very large quadrants, whose radii were about 20 feet, they being on the side from whence he took his drawing. Their description, however, is, that they are exact quarters of circles of different radii, the largest of which I judged to be 20 feet, constructed very exactly on the sides of stone walls, built perpendicular, and situated, I suppose, in the meridian of the place: a brass pin is fixed at the centre or angle of the quadrant, from whence, the Bramin informed me, they stretched a wire to the circumference when an observation was to be made; from which, it occurred to me, the observer must have moved his eye up or down the circumference, by means of a ladder or some such contrivance, to raise and lower himself, until he had discovered the altitude of any of the heavenly bodies in their passage over the meridian, so expressed on the arcs of these quadrants: these arcs were very exactly divided into nine large sections; each of which again into ten, making ninety lesser divisions or degrees; and those also into twenty, expressing three minutes each, of about two-tenths of an inch asunder; so that it is probable they had some method of dividing even these into more minute divisions at the time of observation.

"My time would only permit me to take down the particular dimensions of the most capital instrument, or the greater equinoctial sun-dial, represented by figure A, which appears to be an instrument to express solar time by the shadow of a gnomon upon two quadrants, one situated to the east, and the other to the west of it; and indeed the chief part of their instruments at this place appear to be constructed for the same purpose, except the quadrants, and a brass instrument that will be described hereafter.

"Figure B is another instrument for the purpose of determining the exact hour of the day by the shadow of a gnomon, which stands perpendicular to, and in the centre of, a flat circular stone, supported in an oblique situation by means of four upright stones and a cross piece; so that the shadow of the gnomon, which is a perpendicular iron rod, is thrown upon the division of the circle described on the face of the flat circular stone.

"Figure C is a brass circle, about two feet diameter, moving vertically upon two pivots between two stone pillars, having an index or hand turning round horizontally on the centre of this circle, which is divided into 360 parts; but there are no counter divisions on the index to subdivide those on the circle. This instrument appears to be made for taking the angle of a star at setting or rising, or for taking the azimuth or amplitude of the sun at rising or setting.

"The use of the instrument, figure D, I was at a loss to account for. It consists of two circular walls; the outer of which is about forty feet diameter, and eight feet high; the wall within about half that height, and appears intended for a place to stand on to observe the divisions on the upper circle of the outer wall, rather than for any other purpose; and yet both circles are divided into 360 degrees, each degree being subdivided into twenty lesser divisions, the same as the quadrants. There is a door-way to pass into the inner circle, and a pillar in the centre, of the same height with the lower circle, having a hole in it, being the centre of both circles, and seems to be a socket for an iron rod to be placed perpendicular into it. The divisions on these, as well as all the other instruments, will bear a nice examination with a pair of compasses.

"Figure E is a smaller equinoctial sun dial, constructed upon the same principle as the larger one A.

"I cannot quit this subject without observing, that the Bramins, without the assistance of optical glasses, had nevertheless an advantage unexperienced by the observers of the more northern climates. The serenity and clearness of the atmosphere in the night-time in the East Indies, except at the seasons of the monsoons or periodical winds changing, is difficult to express to those who have not seen it, because we have nothing in comparison to form our ideas upon: it is clear to perfection, a total quietude subsists, scarcely a cloud to be seen, and the light of the heavens, by the numerous appearance of the stars, affords a prospect both of wonder and contemplation.

"This observatory at Benares is said to have been built by the order of the emperor Ackbar: for as this wise prince endeavoured to improve the arts, so he wished also to recover the sciences of Hindostan, and therefore directed that three such places should be erected; one at Delhi, another at Agra, and the third at Benares."

OBSIDIANUS LAPIS, or OBSIDIAN, a mineral substance. See MINERALOGY *Index*.

OBSIDIONALIS, an epithet applied by the Romans to a sort of crown. See the article CROWN.

OBSTETRICS, or the OBSTETRIC ART, the same with MIDWIFERY.

OBSTRUCTION, in *Medicine*, such an obturation of the vessels as prevents the circulation of the fluids, whether of the sound and vital, or of the morbid and peccant kind, through them.

OBTURATOR. See ANATOMY, *Table of the Muscles*.

OBTUSE, signifies blunt, dull, &c. in opposition to acute or sharp. Thus we say, obtuse angle, obtuse-angled triangle, &c.

Oby || Occupancy.

OBY, or OB, a large and famous river of Asiatic Russia, which issues from the Altin lake (called by the Russians *Teleskoi Osero*), in latitude 52 degrees, and longitude 97 degrees. Its name signifies *Great;* and accordingly in Russia it is often styled the *Great River*. The Calmucks and Tartars call it *Umar*. Its stream is very large and smooth, its current being usually slow; and it is in general between two and three hundred fathoms broad; though in some places it is much wider, It affords plenty of fish, and is navigable almost to the lake from which it springs. After a long winding course through a vast tract of land, in which it forms several islands, it empties itself in latitude 67 degrees, and longitude 86 degrees, into a bay, which, extending near 400 miles farther, joins the Icy sea, in latitude 73. 30. and longitude 90. The springs from which this river rises, are not very copious: but it receives in its course the waters of a great number of considerable streams. Of these, the Tom and the Irtis are the most considerable: the Tom falls into it in latitude 58. and the Irtis in latitude 61. and longitude 86. The exact course of this river was unknown till the country was surveyed by the Russians: who have given us tolerable maps of it and of all Siberia. The Oby is the first great river eastward of the Oural mountains which bound Europe, and its course is upwards of 2000 miles in length.

OCCIDENT, in *Geography*, the westward quarter of the horizon; or that part of the horizon where the ecliptic, or the sun therein, descends into the lower hemisphere; in contradistinction to *orient*. Hence we use the word *occidental* for any thing belonging to the west; as occidental bezoar, occidental pearl, &c.

OCCIDENT *Estival*, that point of the horizon where the sun sets at midwinter, when entering the sign Capricorn.

OCCIDENT *Equinoctial*, that point of the horizon where the sun sets, when he crosses the equinoctial, or enters the sign Aries or Libra.

OCCIPITAL, in *Anatomy*, a term applied to the parts of the occiput, or back part of the skull.

OCCULT, something hidden, secret, or invisible. The occult sciences are magic, necromancy, cabbala, &c. Occult qualities, in philosophy, were those qualities of body or spirit which baffled the investigation of philosophers, and for which they were unable to give any reason; unwilling, however, to acknowledge their ignorance, they deceived themselves and the vulgar by an empty title, calling what they did not know *occult*.

OCCULT, in *Geometry*, is used for a line that is scarce perceivable, drawn with the point of the compasses or a leaden pencil. These lines are used in several operations, as the raising of plans, designs of building, pieces of perspective, &c. They are to be effaced when the work is finished.

OCCULTATION, in *Astronomy*, the time a star or planet is hid from our sight, by the interposition of the body of the moon or some other planet.

Blackst. Comment.

OCCUPANCY, in *Law*, is the taking possession of those things which before belonged to nobody. This is the true ground and foundation of all PROPERTY, or of holding those things in severalty, which by the law of nature, unqualified by that of society, were common to all mankind. But, when once it was agreed that every thing capable of ownership should have an owner, natural reason suggested, that he who could first declare his intention of appropriating any thing to his use, and, in consequence of such his intention, actually took it into possession, should thereby gain the absolute property of it; according to that rule of the law of nations, recognized by the laws of Rome, *Quod nullius est, id ratione naturali occupanti conceditur.*

This right of occupancy, so far as it concerns real property, hath been confined by the laws of England within a very narrow compass; and was extended only to a single instance; namely, where a man was tenant *pour autre vie*, or had an estate granted to himself only (without mentioning his heirs) for the life of another man, and died during the life of *cestuy que vie*, or him by whose life it was holden: in this case he that could first enter on the land, might lawfully retain the possession so long as *cestuy que vie* lived, by right of occupancy.

This seems to have been recurring to first principles, and calling in the law of nature to ascertain the property of the land, when left without a legal owner. For it did not revert to the granter, who had parted with all his interest, so long as *cestuy que vie* lived; it did not escheat to the lord of the fee; for all escheats must be of the absolute entire fee, and not of any particular estate carved out of it, much less of so minute a remnant as this: it did not belong to the grantee; for he was dead: it did not descend to his heirs; for there were no words of inheritance in the grant: nor could it vest in his executors; for no executors could succeed to a freehold. Belonging therefore to nobody, like the *hæreditas jacens* of the Romans, the law left it open to be seized and appropriated by the first person that could enter upon it, during the life of *cestuy que vie*, under the name of an occupant. But there was no right of occupancy allowed, where the king had the reversion of the lands: for the reversioner hath an equal right with any other man to enter upon the vacant possession; and where the king's title and a subject's interfere, the king's shall always be preferred. Against the king therefore there could be no prior occupant, because *nullum tempus occurrit regi*. And, even in the case of a subject, had the estate *pour autre vie* granted to a man *and his heirs* during the life of *cestuy que vie*, there the heir might, and still may enter and hold possession, and is called in law a *special occupant;* as having a special exclusive right, by the terms of the original grant, to enter upon and occupy this *hæreditas jacens*, during the residue of the estate granted: though some have thought him so called with no very great propriety; and that such estate is rather a descendible freehold. But the title of *common occupancy* is now reduced almost to nothing by two statutes; the one, 29 Car. II. c. 3. which enacts, that where there is no special occupant, in whom the estate may vest, the tenant *pour autre vie* may devise it by will, or it shall go to the executors, and be assets in their hands for payment of debts: the other that of 14 Geo. II. c. 20. which enacts, that it shall vest not only in the executors, but, in case the tenant dies intestate, in the administrators also: and go in course of a distribution like a chattel interest.

By these two statutes the title of *common occupancy* is utterly extinct and abolished: though that of *special occupancy*, by the heir-at-law, continues to this day; such heir

Occupancy. heir being held to succeed to the ancestor's estate, not by descent, for then he must take an estate of inheritance, but as an occupant, especially marked out and appointed by the original grant. The doctrine of common occupancy, may, however, be usefully remembered on the following account, amongst others: That, as by the common law no occupancy could be of incorporeal hereditaments, as of rents, tithes, advowsons, commons, or the like, (because, with respect to them, there could be no actual entry made, or corporeal seisin had; and therefore by the death of the grantee *pour autre vie* a grant of such hereditaments was entirely determined): so now, it is apprehended, notwithstanding those statutes, such grant would be determined likewise; and the hereditaments could not be deviseable, nor vest in the executors, nor go in a course of distribution. For the statutes must not be construed so as to create any new estate, or to keep that alive which by the common law was determined, and thereby to defeat the granter's reversion; but merely to dispose of an interest in being, to which by law there was no owner, and which therefore was left open to the first occupant. When there is a residue left, the statutes give it to the executors, &c. instead of the first occupant; but they will not create a residue on purpose to give it to the executors. They only mean to provide an appointed instead of a casual, a certain instead of an uncertain owner, of lands which before were nobody's; and thereby to supply this *casus omissus*, and render the disposition of the law in all respects entirely uniform; this being the only instance wherein a title to a real estate could ever be acquired by occupancy.

For there can be no other case devised, wherein there is not some owner of the land appointed by the law. In the case of a sole corporation, as a parson of a church, when he dies or resigns, though there be no *actual* owner of the land till a successor be appointed, yet there is a *legal*, *potential*, ownership, subsisting in contemplation of law; and when the successor is appointed, his appointment shall have a retrospect and relation backwards, so as to entitle him to all the profits from the instant that the vacancy commenced. And in all other instances, when the tenant dies intestate, and no other owner of the lands is to be found in the common course of descents, there the law vests an ownership in the king, or in the subordinate lord of the fee, by escheat.

So also, in some cases, where the laws of other nations give a right by occupancy, as in lands newly created, by the rising of an island in a river, or by the alluvion or dereliction of the sea; in these instances, the law of England assigns them an immediate owner. For Bracton tells us, that if an island arise in the *middle* of a *river*, it belongs in common to those who have lands on each side thereof; but if it be nearer to one bank than the other, it belongs only to him who is proprietor of the nearest shore: which is agreeable to, and probably copied from, the civil law. Yet this seems only to be reasonable, where the soil of the river is equally divided between the owners of the opposite shores: for if the whole soil is the freehold of any one man, as it must be whenever a several fishery is claimed, there it seems just (and so is the usual practice) that the islets, or little islands, arising in any part of the river, shall be the property of him who owneth the piscary and the soil. However, in case a new island rise in the *sea*, though the civil law gives it to the first occupant, yet our's gives it to the king. And as to lands gained from the sea; either by *alluvion*, by the washing up of sand and earth, so as in time to make *terra firma*; or by *dereliction*, as when the sea shrinks back below the usual water-mark; in these cases the law is held to be, that if this gain be by little and little, by small and imperceptible degrees, it shall go to the owner of the land adjoining. For *de minimis non curat lex*: and, besides, these owners being often losers by the breaking in of the sea, or at charges to keep it out, this possible gain is therefore a reciprocal consideration for such possible charge or loss. But if the alluvion or dereliction be sudden and considerable, in this case it belongs to the king: for as the king is lord of the sea, and so owner of the soil while it is covered with water, it is but reasonable he should have the soil when the water has left it dry. So that the quantity of ground gained, and the time during which it is gained, are what make it either the king's or the subject's property. In the same manner, if a river, running between two lordships, by degrees gains upon the one, and thereby leaves the other dry, the owner who loses his ground thus imperceptibly has no remedy: but if the course of the river be changed by a sudden and violent flood, or other hasty means, and thereby a man loses his grounds, he shall have what the river has left in any other place as recompense for this sudden lose. And this law of alluvions and derelictions, with regard to *rivers*, is nearly the same in the imperial law; from whence indeed those our determinations seem to have been drawn and adopted: but we ourselves, as islanders, have applied them to *marine* increases; and have given our sovereign the prerogative he enjoys, as well upon the particular reasons before mentioned, as upon this other general ground of prerogative, which was formerly remarked, that whatever hath no other owner is vested by law in the king. See PREROGATIVE.

Occupancy ‖ Ocean.

OCCUPANT, in *Law*, the person that first seizes, or gets possession of a thing.

OCCUPATION, in a legal sense, is taken for use or tenure: as in deeds it is frequently said, that such lands are, or were lately, in the tenure or occupation of such a person.—It is likewise used for a trade or mystery.

OCCUPIERS *of* WALLING, a term used in the salt-works for the persons who are the sworn officers that allot in particular places what quantity of salt is to be made, that the markets may not be overstocked, and see that all is carried fairly and equally between the lord and the tenant.

OCEAN, that huge mass of salt waters which encompasses all parts of the globe, and by means of which, in the present improved state of navigation, an easy intercourse subsists between places the most distant.

The ocean is distinguished into three grand divisions. 1. The Atlantic ocean, which divides Europe and Africa from America, which is generally about 3000 miles wide. 2. The Pacific ocean, or South sea, which divides America from Asia, and is generally about 10,000 miles over. And, 3. The Indian Ocean, which separates the East Indies from Africa, which is 3000 miles over. The other seas, which are called *oceans*, are only parts or branches of these, and usually receive their names from the countries they border upon.

 For

For the saltness, tides, &c. of the ocean, see the articles SEA, TIDES, &c.

OCEANIDES, in fabulous history, sea nymphs, daughters of Oceanus, from whom they received their names, and of the goddess Tethys or Thetis. They were 3000 according to Apollodorus, who mentions the names of seven of them; Asia, Styx, Electra, Donis, Eurynome, Amphitrite, and Metis. Hesiod speaks of the eldest of them, which he reckons 41, Pitho, Admete, Prynno, Ianthe, Rhodia, Hippo, Callirhoe, Urania, Clymene, Idyia, Pasithoe, Clythia, Zeuxo, Galuxaure, Plexaure, Perseis, Pluto, Thoe, Polydora, Melobosis, Dione, Cerceis, Xanthe, Acasta, Ianira, Telestho, Europa, Menestho, Petræa, Eudora, Calypso, Tyche, Ocyroe, Crisia, Amphiro, with those mentioned by Apollodorus, except Amphitrite. Hyginus mentions 16, whose names are almost all different from those of Apollodorus and Hesiod; which difference proceeds from the mutilation of the original text. The Oceanides, like the rest of the inferior deities, were honoured with libations and sacrifices. Prayers were offered to them, and they were entreated to protect sailors from storms and dangerous tempests. The Argonauts, before they proceeded to their expedition, made an offering of flour, honey, and oil, on the sea shore, to all the deities of the sea, and sacrified bulls to them, and entreated their protection. When the sacrifice was made on the sea shore, the blood of the victim was received in a vessel; but when it was in open sea, they permitted the blood to run down into the waters. When the sea was calm, they generally offered a lamb or a young pig; but if it was agitated by the winds and rough, a black bull was deemed the most acceptable victim.

OCEANUS, in Pagan mythology, the son of Cœlus and Terra, the husband of Thetis, and the father of the rivers and fountains, called *Oceanides*. The ancients called him the *father of all things*, imagining that he was produced by Humidity, which, according to Thales, was the first principle from which every thing was produced. Homer represents Juno visiting him at the remotest limits of the earth, and acknowledging him and Thetis as the parents of the gods. He was represented with a bull's head, as an emblem of the rage and bellowing of the ocean when agitated by a storm.

According to Homer, he was the father even of all the gods, and on that account he received frequent visits from them. He is often, indeed almost always, represented as an old man with a long flowing beard, and sitting upon the waves of the sea. He often holds a pike in his hand, while ships under sail appear at a distance, or a sea monster stands near him. Oceanus presided over every part of the sea, and even the rivers were subjected to his power. The ancients were superstitious in their worship of him, and revered with great solemnity a deity to whose care they entrusted themselves when going on any voyage.

OCEIA, a woman who presided over the sacred rites of Vesta for 57 years with the greatest sanctity. She died in the reign of Tiberius, and the daughter of Domitius succeeded her.

OCELLUS *the* LUCANIAN, an ancient Greek philosopher of the school of Pythagoras, who lived before Plato. His work περι του Παντος, or "The Universe," is the only piece of his which is come down entire to us; and was written originally in the Doric dialect, but was translated by another hand into the Attic. William Christian, and after him Lewis Nogarola, translated this work into Latin; and we have several editions of it, both in Greek and Latin.

OCELOT, the Mexican cat. See FELIS, MAMMALIA *Index*.

OCHLOCRACY, that form of government wherein the populace have the chief administration of affairs.

OCHNA, a genus of plants belonging to the polyandria class; and in the natural method ranking with those of which the order is doubtful. See BOTANY *Index*.

OCHRE, in *Natural History*, a mineral substance composed of oxide and carbonate of iron, and clay. See ORES OF IRON, MINERALOGY *Index*.

OCHROMA, a genus of plants belonging to the monadelphia class; and in the natural method ranking under the 37th order, *Columniferæ*. See BOTANY *Index*.

OCHUS, a king of Persia, son of Artaxerxes. He was cruel and avaricious; and in order to strengthen himself on his throne, he murdered all his brothers and sisters. His subjects revolted; but he reduced them to obedience, and added Egypt to his other dominions. Bagoas, his favourite eunuch, poisoned him for the insults he had offered to Apis the god of the Egyptians; and he gave his flesh to be eaten by cats, and made handles for knives with his bones. It seems to be not a little remarkable, that all those monsters who disgraced humanity by their crimes, and sunk themselves below the level of brutes, have met with condign punishment; and this in general seems true, whether we refer to ancient or modern times.—A man of Cyzicus, who was killed by the Argonauts.—A prince of Persia, who refused to visit his native country for fear of giving all the women each a piece of gold.—A river of India or of Bactriana.—A king of Persia: He exchanged his name for that of Darius Nothus. See PERSIA.

OCKLEY, SIMON, an eminent orientalist, and professor of Arabic in Cambridge, was born at Exeter in 1678. He was educated at Cambridge, and distinguished himself by uncommon skill in the Oriental languages. Having taken a degree in divinity, he was presented by Jesus College with the vicarage of Swavesey in 1705, and in 1711 was chosen Arabic professor of the university. He had a large family, and his latter days were rendered unhappy by pecuniary embarrassments. He died in 1720. His principal works are, 1. *Introductio ad linguas Orientales*, a small volume. 2. *The History of the present Jews throughout the world*, from the Italian of Leo Modena. 3. *The Improvement of Human Reason*, from the Arabic. 4. *The History of the Saracens*, in 2 vols. 8vo. This last work is justly valued for its accuracy and erudition, and has been highly commended by Samuel Johnson. A great part of his materials were drawn from Arabic manuscripts in the Bodleian library at Oxford.

OCRA, a viscous vegetable substance well known in the West Indies, where it is used to thicken soup, particularly that kind called pepper pot, as well as for other purposes.

OCRISIA, in fabulous history, the wife of Corniculus, was one of the attendants of Tanaquil the wife of Tarquinius

Tarquinius Priscus. As she was throwing into the flames, for offerings, some of the meats that were served on the table of Tarquin, she suddenly saw, as is reported, in the fire, what Ovid calls *obscœni forma virilis*. She informed the queen of it; and when by her command she had approached near it, she conceived a son who was named Servius Tullius, and was educated in the king's family. He afterwards suceeded to the vacant throne. Some suppose that Vulcan had assumed that form which was presented to the eyes of Ocrisia, and that this god was the father of the sixth king of Rome.

OCTAETERIS, a cycle or term of eight years, in the Grecian chronology, at the conclusion of which three entire lunar months were added. The cycle was in use till Meton's invention of the golden number or cycle of 19 years.

OCTAGON, or OCTOGON, in *Geometry*, is a figure of eight sides and angles; and this, when all the sides and angles are equal, is called a *regular octagon*, or one that may be inscribed in a circle.

OCTAGON, in *Fortification*, denotes a place that has eight bastions. See FORTIFICATION.

OCTAHEDRON, or OCTAEDRON, in *Geometry*, one of the five regular bodies, consisting of eight equal and equilateral triangles.

OCTANDRIA (οκτω, "eight," and ανηρ, a "man or husband,") the 8th class in Linnæus's sexual system; consisting of plants which are furnished with eight stamina. See BOTANY *Index*.

OCTANT, the eighth part of a circle.

OCTANT, or OCTILE, in *Astronomy*, that aspect of two planets, wherein they are distant an eighth part of a circle, or 45° from each other.

OCTAPLA, in matters of sacred literature, denotes a Polyglot Bible, consisting of eight columns, and as many different versions of the sacred text; viz. the original Hebrew both in Hebrew and Greek characters, Greek versions, &c.

OCTATEUCH, an appellation given to the eight first books of the Old Testament.

OCTAVE, in *Music*. See INTERVAL.

OCTAVIA, daughter of Caius Octavius and sister to Augustus Cæsar. See the following article. She was one of the most illustrious ladies of ancient Rome; her virtues and her beauty were equally conspicuous.—Prideaux says she was much handsomer than Cleopatra. She married Claudius Marcellus, and after his death M. Antony. Her marriage with Antony was a political match, to reconcile her brother and him together. Antony proved for some time attentive to her: but when he had seen Cleopatra, he neglected and despised her: and when she attempted to withdraw him from this illegal amour by going to meet him at Athens, she was rebuked and totally banished from his presence. This affront was highly resented by her brother; and though Octavia endeavoured to pacify him by palliating Antony's behaviour, yet he resolved to revenge her cause by arms. After the battle of Actium and the death of Antony, Octavia, forgetful of her own injuries, took into the house all the children of her husband, and treated them with extraordinary tenderness. Marcellus, her son by her first husband, was married to a niece of Augustus, and openly intended as a successor to his uncle. His sudden death plunged all the family into the greatest grief. Virgil, whom Augustus patronized, undertook of himself to pay a melancholy tribute to the memory of a young man whom Rome had looked upon as her future father and patron. He was desired to repeat his composition in the presence of the emperor and his sister. Octavia burst into tears even when the poet began; but when he mentioned *Tu Marcellus eris*, she swooned away. This tender and pathetic encomium upon the merit and the virtues of young Marcellus she liberally rewarded; and Virgil received 10,000 sesterces, according to some 78l. 2s. 6d. for every one of the verses. Octavia had two daughters by Antony, Antonia Major and Antonia Minor.—The elder married L. Domitius Ahenobarbus, by whom she had Cn. Domitius, who was the father of the emperor Nero by Agrippina the daughter of Germanicus. Antonia Minor, who was as virtuous and as beautiful as her mother, married Drusus the son of Tiberius, by whom she had Germanicus, and Claudius who reigned before Nero. The death of Marcellus constantly preyed upon the mind of Octavia, who died of grief or melancholy, about 11 years before the Christian era. Her brother paid great regard to her memory, and pronounced her funeral oration himself. The Roman people also showed their regard to her virtues, by wishing to pay her divine honours.—A daughter of the emperor Claudius by Messalina. She was betrothed to Silanus, but by the intrigues of Agrippina, she was married to the emperor Nero in the 16th year of her age. She was soon after divorced under pretence of barrenness; and the emperor married Poppæa, who exercised her enmity upon Octavia by procuring her to be banished into Campania. She was afterwards recalled by the people; but Poppæa, who was determined on her ruin, caused her again to be banished to an island, where she was ordered to kill herself by opening her veins. Her head was cut off and carried to Poppæa.

OCTAVIANUS, or OCTAVIUS CÆSAR, was nephew of Julius Cæsar the dictator, being the son of Accia his sister by Octavius a senator, and afterwards became the second emperor of Rome. He was born in the year of the city 691, during the consulship of Cicero. His uncle Julius Cæsar adopted him, and left him the greatest part of his fortune. When he was but 20 years of age, he was raised to the consulship. His youth and inexperience were ridiculed by his enemies; notwithstanding which obstacle, his prudence and valour raised his consequence. He made war against his opponents on pretence of avenging the assassination of his uncle. He engaged in five civil wars with great success, viz. The wars of Mutina, Perusia, Philippi, Sicily, and Actium: the first and last of which were against M. Antony; the second against L. Antony, brother of the triumvir; the third was against Brutus and Cassius; and the fourth against Sext. Pompey, son of Pompey the Great. He united his forces with Antony's at the battle of Philippi; and had he not been supported by the activity and bravery of his colleague, he would doubtless have been totally ruined in that engagement. In his triumvirate with Antony and Lepidus, he obtained the western parts of the Roman empire; and, like his other colleagues, more firmy to establish his power, he proscribed his enemies and cut them off. The triumvirate lasted for 10 years. He had given his sister Octavia in marriage

Octavianus. marriage to Antony, to make their alliance more lasting; but when Cleopatra had charmed this unfortunate man, Octavia was repudiated. Augustus immediately took up arms to avenge the wrongs of his sister; but perhaps more eager to remove a man whose power and existence kept him in continual fear and constant dependence. Both parties met at Actium to decide the fate of Rome. Antony was supported by all the power of the east, and Augustus by Italy. Cleopatra fled from the battle with 60 ships; and her flight ruined the interest of Antony, who followed her into Egypt. The conqueror soon after went into Egypt likewise, besieged Alexandria, and honoured with a magnificent funeral his unfortunate colleague and the celebrated queen, whom the fear of being led in the victor's triumph at Rome had driven to commit suicide. After he had established peace all over the world, he shut the gates of the temple of Janus, A. U. C. 753. He was twice determined to lay down the supreme power immediately after the victory obtained over Antony, and on account of his ill health; but his two faithful friends Mecænas and Agrippa dissuaded him, and contended, that if he did he would leave it to be the prey of the most powerful, and expose himself to the greatest dangers. He died at Nola in the 76th year of his age, after he had held the sovereign power for 57 years.—He was an active emperor, and consulted the good of the Romans with the greatest anxiety and care. He visited all the provinces except Africa and Sardinia, and his consummate prudence and experience occasioned many salutary laws. He is, however, accused of licentiousness and adultery; but the goodness of his heart, the fidelity of his friendship, and the many good qualities which the poets whom he patronized have perhaps truly celebrated, made some, though in the eye of strict religion and true morality but little, amends for his natural foibles. He was ambitious of being esteemed handsome; and as he was publicly reported to be the son of Apollo according to his mother's declaration, he wished his flatterers to represent him with the figure and attributes of that god. Like Apollo, his eyes were clear, and he affected to have it thought that they possessed some divine irradiation, and was well pleased if, when he fixed his eyes upon any body, they held down their eyes, as if overcome by the glaring brightness of the sun. He distinguished himself by his learning; he was a complete master of the Greek language, and wrote some tragedies, besides memoirs of his life and other works, which are now lost. He married four times; but he was unhappy in all these connexions; and his only daughter Julia disgraced herself and her father by the debauchery and licentiousness of her manners. He recommended at his death his adopted son Tiberius as his successor. He left his fortune partly to him and to Drusus, and made donations to the army and Roman people. The title of Augustus was conferred upon him by the senate after the battle of Actium and the final destruction of the Roman republic. The title continued afterwards, being given to his successors in the empire. Virgil is said to have written his Æneid at the desire of Augustus, whom he represents under the amiable and perfect character of Æneas. The name of Octavius was very common at Rome; it was the name of a variety of men of very considerable rank.

OCTOBER, in *Chronology*, the eighth month of Romulus's year, which the name implies; but tenth in the kalendar of Numa, Julius Cæsar, &c. The senate gave this month the name *Faustinus*, in compliment to Faustina, the wife of the emperor Antoninus; Commodus would have it called *Invictus;* and Domitian named it *Domitianus;* but in spite of all these attempts it still retains its original name. This month was sacred to Mars, and under his protection.

October Equus, a horse annually sacrificed to Mars in the month of October, either because the horse is a warlike animal, or to punish him for the taking of Troy. A race was run with chariots, drawn by two horses, previous to the sacrifices, and he that ran quickest was adjudged to be the victim.

OCTOSTYLE, in the ancient architecture, is the face of an edifice adorned with eight columns.

OCULUS, the Eye, in *Anatomy*. See there, No. 145.

OCYMOPHYLLON, a name given by Buxbaum to a new genus of plants, the characters of which are these: The flower is of the stamineous kind, having no petals; this stands upon the embyro fruit, which afterwards becomes an oblong quadrangular seed-vessel, divided into four cells, and containing roundish and very small seeds; its leaves are like those of the common ocymum or basil, whence its name; and its place of growth is in damp marshes. Boccone has described it under the improper name of *glaux*, calling it the *great, green-flowered, marsh glaux*.

OCYMUM, Basil; a genus of plants belonging to the didynamia class; and in the natural method ranking under the 42d order, *Verticillatæ*. See Botany *Index*.

OCZAKOW, or Oczakoff, a town in southern Russia in the province of Cherson, and formerly belonging to Turkey. It had a Turkish garrison of 20,000 men, but was taken by the Russians in 1737, and all those that resisted were put to the sword. The Russians themselves lost 18,000 men in the assault. The Turks returned the same year with 70,000 men to retake it; but were obliged to retire, after the loss of 20,000. In 1738, the Russians withdrew their garrison, and demolished the fortifications. It is seated on the river Bog, to the west of the Nieper, or rather where they both unite and fall into the Black sea. It is 42 miles south-west of Bialagrod, and 190 north by east of Constantinople. It has been again lately a subject of contest between the Russians and Turks, but finally remains in the possession of the latter. Its population has diminished, and its importance sunk, since the rise of Odessa. E. Long. 30. 50. N. Lat. 46. 50.

ODA, in the Turkish seraglio, signifies a class, order, or chamber. The grand signior's pages are divided into five classes or chambers. The first, which is the lowest in dignity, is called the *great oda*, from the greater number of persons that compose it; these are the juniors, who are taught to read, write, and speak the languages. The second is called the *little oda*, where from the age of 14 or 15 years, till about 20, they are trained up to arms, and the study of all the polite learning the Turks are acquainted with. The third chamber, called *kilar oda*, consists of 200 pages, who, besides their other exercises, are under the command of the kilardgi-bachi, and serve in the pantry and fruitery.

fruitery. The fourth consists only of 24, who are under the command of the khazineda-bachi, and have charge of the treasure in the grand signior's apartment, which they never enter with clothes that have pockets. The fifth is called *kas oda* or *privy-chamber*; and is composed of only 40 pages, who attend in the prince's chamber. Every night eight of these pages keep guard in the grand signior's bedchamber while he sleeps: they take care that the light, which is constantly kept in the room, does not glare in his eyes, lest it should awake him: and if they find him disturbed with troublesome dreams, they cause him to be awakened by one of their agas.

Oda-Bachi, or *Oddabassi*, an officer in the Turkish soldiery, equivalent to a serjeant, or corporal among us. The common soldiers and janizaries called *oldachis*, after having served a certain number of years, are always preferred, and made biquelairs; and of biquelairs in time become odobachis, i. e. corporals of companies, or chiefs of certain divisions whose number is not fixed; being sometimes ten, and sometimes twenty.

Their pay is six doubles per month; and they are distinguished by a large felt, a foot broad, and above a foot long, hanging on the back, with two long ostrich feathers.

ODDLY ODD. A number is said to be oddly-odd, when an odd number measures it by an odd number. So 15 is a number oddly-odd, because the odd number 3 measures it by the odd number 5.

ODE, in *Poetry*, a song or composition proper to be sung. See POETRY.

ODED, a prophet of the Lord, who being at Samaria when the Israelites of the ten tribes returned from the war with their king Pekah, together with 200,000 of the people of Judah captives, he went out to meet them, and said, "You have seen that the Lord God of your fathers was in wrath against Judah; he has therefore delivered them into your hands, and you have slain them inhumanly; so that your cruelty has ascended up into heaven; and more than this, you would make slaves of the children of Judah, who are your brethren, and would add this sin to the many others you have committed: therefore, hear the counsel that I give you; send back these captives, lest the Lord should pour out his fury upon you." Oded having done speaking, some of the chiefs of Samaria seconded him, and by their remonstrances prevailed with the Israelites to set the captives at liberty (2 Chron. xxviii). See AHAZ.

The enlargement of the captives being obtained, the principal men of Samaria took care of them, gave them clothes and food and other necessary assistance. After which they furnished them with horses, because the greatest part of them were so tired and exhausted that they were not able to walk. Thus they conducted them to Jericho, which was in the confines of the land of Judah. This is all that is come to our knowledge concerning the prophet Oded.

ODENSEE, the capital of the isle of Funen, a place of such high antiquity, that some Danish writers derive its foundation and name from Odin the god and hero of the Gothic nations. "Its name certainly occurs (says Mr Coxe) in the earliest ages of the Danish history; and it was a town of great note long before Copenhagen existed. Odensee stands upon a small river, not navigable, and about two miles from the bay of Stegestrand. Many of the houses are ancient, bearing dates about the middle of the 16th century; but part is newly built: it contains about 5200 inhabitants, who carry on some commerce, exporting chiefly grain and leather; the latter is much esteemed, and its goodness is supposed to arise from a certain property in the river water, in which it is soaked for tanning. The Danish cavalry are supplied from thence with the greatest part of their leathern accoutrements.

"Odensee is the seat of a bishop, which was founded by Harold Blaatand in 980, and is the richest in Denmark next to Copenhagen. It has a school, endowed by the celebrated Margaret of Valdemar, in which a certain number of scholars, from six to 16 years of age, are instructed gratis: they live and board in the town, and each receives a yearly pension; other scholarships have been also founded by private persons. The whole number amounted to 70. There is also a gymnasium, instituted by Christian IV. for the admission of students at the age of 16. The seminary was still further improved by the liberality of Holberg the Danish historian, who protected letters with the same zeal with which he cultivated them. It is now greatly fallen from its former flourishing state, containing, when I passed through the town, only eight students. The cathedral is a large old brick building, which has nothing remarkable except some costly monuments of a private Danish family. The church, which formerly belonged to the convent of Recolets, contains the sepulchre of John king of Denmark, and of his son Christian II." E. Long. 10. 27. N. Lat. 55. 28.

ODENATUS, a celebrated prince of Palmyra, who very early inured himself to bear fatigues, and by hunting leopards and wild beasts, accustomed himself to the labours of a military life. He was a faithful friend to the Romans; and when Aurelian had been taken prisoner by Sapor king of Persia, Odenatus warmly interested himself in his cause, and solicited his release, by writing to the conqueror, and by sending him presents. The king of Persia was offended at this liberty of Odenatus, he tore the letter, and ordered the presents that were offered to be thrown into a river, and in order to punish Odenatus, who had the impudence, as he called it, to pay homage to so great a monarch as himself, he commanded him to appear before him, on pain of being devoted to instant destruction with all his family if he dared to refuse. Odenatus despised this haughty summons of Sapor, and opposed force by force. He obtained some considerable advantages over the troops of the Persian king, and took his wife prisoner, with a great and rich booty. These services were observed with gratitude by the Romans; and Gallienus, the then emperor, named Odenatus as his colleague on the throne, and gave the title of *Augutsus* to his children, and to his wife the celebrated Zenobia. Odenatus invested with new power, resolved to signalize himself more conspicuously by conquering the barbarians of the north: but his exulting was of short duration: he perished by the dagger of one of his own relations, whom he had slightly offended at a domestic entertainment.—He died at Emessa about the 267th year of the Christian era. Zenobia succeeded to his titles and honours.

ODER, a river of Germany, which has its source near

Oder || Odin.

near a town of the same name in Silesia, and on the confines of Moravia. It runs north through that province, and then into the marche of Brandenburg and Pomerania, where it forms a large lake, afterwards falling into the Baltic sea by three mouths; between which lie the islands Usedom and Wolin. It passes by several towns; as Ratibor, Oppelen, Breslau, Glogau and Grossen, in Silesia; Francfort, Lebus, and Custrin, in Brandenburg; and Gartz, Stetin, Cammin, Wallin, Usedom, and Wolgast, in Pomerania.

ODESSA, a seaport town in the government of Cherson in southern Russia. It is situated on the Black sea, between the embouchures of the Dneiper and the Dneister, and has increased with wonderful rapidity. In 1795 there were but a few houses. In 1804, the number of inhabitants was 15,000, and in 1816 they have been stated to be 35,000. It is now the great entreport for the commerce of southern Russia. In the first six months of 1816, 498 vessels entered the port, and 246 departed, the latter carrying away Russian produce to the amount of 15,220,000 roubles. The port was naturally only an open road, but has been improved by works at a great expence, and rendered capable of holding 600 vessels. The principal exports consist of corn, salt beef, timber, &c. This port promises to become as important for the southern provinces as Petersburgh for the northern. The improvements made in the navigation of the Dneister, have induced the Poles to send a considerable portion of their produce down that river, whence it is conveyed by lighters to Odessa, and then shipped for the various markets in the Levant and the south of Europe.

ODEUM, in Grecian antiquity, a music theatre built by Pericles; the inside of which was filled with seats and ranges of pillars, and on the outside the roof descended shelving downwards from a point in the centre, with many bendings, in imitation of the king of Persia's pavilion. Here the musical prizes were contended for; and here also, according to Aristophanes, was a tribunal.

ODIN (see FREA), in *Mythology*, called also in the dialect of the Anglo-Saxons, *Woden* or *Wodan*, a name given by the ancient Scythians to their supreme god, and assumed, about 70 years before the Christian era, by Sigge, a Scythian prince, who conquered the northern nations, made great changes in their government, manners, religion, and enjoyed great honours, and had even divine honours paid him. According to the account given of this conqueror by Snorro, the ancient historian of Norway, and his commentator Torfæus, Odin was a Scythian, who withdrew himself, with many others in his train, by flight, from the vengeance of the Romans, under the conduct of Pompey; and having officiated as a priest in his own country, he assumed the direction of the religious worship, as well as the civil government, of the nations which he conquered. Having subdued Denmark, Sweden, and Norway, he retired to Sweden, where he died. There is nothing certain in this account; but it is probable, that the god, whose prophet or priest this Scythian pretended to be, was named *Odin*, and that the ignorance of succeeding ages confounded the deity with his priest, composing out of the attributes of the one, and the history of the other, the character of the northern conqueror. He deluded the people by his enchantments and skill in magic: having cut off the head of one Mimer, who in his lifetime was in great reputation for wisdom, he caused it to be embalmed, and persuaded the Scandinavians that he had restored it to the use of speech; and he caused it to pronounce whatever oracles he wanted. The Icelandic chronicles represent Odin as the most eloquent and persuasive of men; they ascribe to him the introduction of the art of poetry among the Scandinavians, and likewise the invention of the Runic characters. He had also the address to persuade his followers, that he could run over the world in the twinkling of an eye; that he had the direction of the air and tempests; that he could transform himself into all sorts of shapes, could raise the dead, could foretel things to come, deprive his enemies, by enchantment, of health and vigour, and discover all the treasures concealed in the earth. They add, that by his tender and melodious airs, he could make the plains and mountains open and expand with delight; and that the ghosts thus attracted, would leave their infernal caverns, and stand motionless about him. Nor was he less dreadful and furious in battle; changing himself into the shape of a bear, a wild bull, or a lion, and amidst ranks of enemies committing the most horrid devastation, without receiving any wound himself.

Dr Henry gives this account of him: "Odin is believed to have been the name of the one true God among the first colonies who came from the east and peopled Germany and Scandinavia, and among their posterity for several ages. But at length a mighty conqueror, the leader of a new army of adventurers from the east, overrun the north of Europe, erected a great empire, assumed the name of *Odin*, and claimed the honours which had been formerly paid to that deity. From thenceforward this deified mortal, under the name of *Odin* or *Wodin*, became the chief object of the idolatrous worship of the Saxons and Danes in this island, as well as of many other nations. Having been a mighty and successful warrior, he was believed to be the god of war, who gave victory, and revived courage in the conflict. Having civilized in some measure, the countries which he conquered, and introduced arts formerly unknown, he was also worshipped as the god of arts and artists. In a word, to this Odin his deluded worshippers impiously ascribed all the attributes which belong only to the true God: to him they built magnificent temples, offered many sacrifices, and consecrated the fourth day of the week, which is still called by his name in England and in all the other countries where he was formerly worshipped. Notwithstanding all this, the founders of all the kingdoms of the Anglo-Saxon heptarchy pretended to be descended from Wodin, and some of them at the distance only of a few generations."

ODIN's Fire. We have this account of it in Gough's Camden. "In Evie parish, in the Orkneys, near the sea, are some rocks, which frequently in the night appear on fire; and the church of St Michael there was often seen full of lights, called fires sent by St Odin to guard their tombs, but now ceased. This may be a meteor, or some inflammable matter on the cliffs, as at Charmouth, Dorset."

De Odio et Atia. See *False Imprisonment.*

The writ *de odio et atia* was anciently used to be directed to the sheriff, commanding him to inquire whether a prisoner charged with murder was committed upon just cause of suspicion, or merely *proper odium et atium*, for hatred and ill will; and if upon the inquisition due cause of suspicion did not then appear, then there issued another writ for the sheriff to admit him to bail. This writ, according to Bracton, ought not to be denied to any man; it being expressly ordered to be made out *gratis*, without any denial, by *magna charta*, c. 26. and statute Westm. 2. 13 Edw. I. c. 29. But the statute of Glocester, 6 Edw. I. c. 9. restrained it in the case of killing by misadventure or self-defence, and the statute 28 Edw. III. c. 9. abolished it in all cases whatsoever: but as the stat. 42 Ed. III. c. 1. repealed all statutes then in being, contrary to the great charter, Sir Edward Coke is of opinion that the writ *de odio et atia* was thereby revived. See *Habeas Corpus.*

ODO, St, second abbot of Cluny in France, was illustrious for learning and piety in the 10th century. The sanctity of his life contributed greatly to enlarge the congregation of Cluny; and he was so esteemed, that popes, bishops, and secular princes, usually chose him the arbiter of their disputes. He died about the year 942, and his works are printed in the Bibliotheque of Cluny.

Odo Cantianus, so called as being a native of Kent in England, was a Benedictine monk in the 12th century, in which order his learning and eloquence raised him to the dignity of prior and abbot. Archbishop Becket was his friend; and his panegyric was made by John of Salisbury. He composed Commentaries on the Pentateuch, and the Second Book of Kings; Moral Reflections on the Psalms; treatises entitled, *De Onere Philistini; De Moribus Ecclesiasticis; De Vitiis et Virtutibus Animæ*, &c.

ODOACER, according to Ennodius, was meanly born, and only a private man in the guards of the emperor Augustulus, when (A. D. 476, under the consulship of Basilicus and Armatus) the barbarians chose him for their leader. The barbarians thought, as they often defended Italy, they had a right at least to part of it; but upon demanding it they were refused, and the consequence was a revolt. Odoacer is said to have been a man of uncommon parts, capable alike of commanding an army or governing a state. Having left his own country when he was very young, to serve in Italy, as he was of a stature remarkably tall, he was admitted among the emperor's guards, and continued in that station till the above year; when, putting himself at the head of the barbarians in the Roman pay, who, though of different nations, had unanimously chosen him for their leader, he marched against Orestes, and his son Augustulus, who still refused to share any of the lands in Italy. The Romans were inferior both in numbers and valour, and were easily conquered: Orestes was ordered to be slain; but the emperor Augustulus was spared, and, though stripped of his dignity, was treated with humanity, and allowed a liberal sum for his own support and for that of his relations. Odoacer was proclaimed king of Italy; but assumed neither the purple nor any other mark of imperial consequence. He was afterwards defeated and slain by Theodoric the Ostrogoth. See Ostrogoth.

ODOMETER, an instrument for measuring the distance passed over in travelling. See Pedometer.

ODONTALGIA, the Toothach. See Medicine, N° 210.

ODONTOIDE, in *Anatomy*, an appellation given to the process of the second vertebra of the neck, from its resemblance to a tooth.

ODOROUS, or Odoriferous, appellations given to whatever smells strongly, whether they be fetid or agreeable; but chiefly to things whose smell is brisk and pleasant.

ODYSSEY, the name of an epic poem composed by Homer, which, when compared with the Iliad, exhibits its author as the setting sun, whose grandeur remains without the heat of his meridian beams.

The poet's design in the Odyssey was to paint the miseries of a kingdom in the absence of its supreme governor, and the evil consequences resulting from a disregard of law, and of that subordination without which society cannot exist. With this view he sets before his countrymen the adventures of a prince who had been obliged to forsake his native country, and to head an army of his subjects in a foreign expedition; and he artfully contrives, without interrupting the narrative, to make the reader acquainted with the state of the country in the absence of its sovereign. The chief having gloriously finished the enterprise in which he was engaged, was returning with his army; but in spite of all his eagerness to be at home, he was detained on the way by tempests for several years, and cast upon several countries differing from each other in manners and in government. In these dangers his companions, not strictly obeying his orders, perish through their own fault. In the mean time the grandees of his country abuse the freedom which his absence gave them; consume his estate; conspire to destroy his son; endeavour to compel his queen to accept one of them for her husband; and indulge themselves in every species of violence, from a persuasion that he would never return. In this they were disappointed. He returns; and discovering himself only to his son and some others who had maintained their allegiance, he is an eye witness of the insolence of his enemies, punishes them according to their deserts, and restores to his island that tranquillity and repose to which it had been a stranger during the many years of his absence.

Such is the fable of the Odyssey, in which there is no opportunity of displaying that vigour and sublimity which characterize the Iliad. "It descends from the dignity of gods and heroes*, and warlike achievements; but in recompense we have more pleasing pictures of ancient manners. Instead of that ferocity which reigns in the other poem, this presents us with the most amiable images of hospitality and humanity; entertains us with many a wonderful adventure; and instructs us by such a constant vein of morality and virtue which runs through the poem," sometimes in precepts, and always in the conduct of the hero, that we should not wonder if Greece, which gave the appellation of *wise* to men who uttered single sentences of truth, had given to Homer the title of *the father of virtue*, for introducing into his work such a

* Blair's Lectures.

a number of moral maxims. As a poem, however, the Odyssey has its faults. The last twelve books are tedious and languid; and we are disappointed by the calm behaviour of Penelope upon the discovery of her long lost husband.

OECONOMICS, the art of managing the affairs of a family or community; and hence the person who takes care of the revenues and other affairs of churches, monasteries, and the like, is termed *œconomus*.

OECONOMISTS, a sect of French philosophers, who obtained this name in consequence of directing their attention and researches to objects of political economy, and in particular to the improvement of the departments of finance. The views of those philosophers, among whom are reckoned the celebrated names of Voltaire, d'Alembert, Diderot, and Condorcet, have been variously represented; by some as directly hostile to all regular government, and by others as unfriendly to religion.

OECONOMY, denotes the prudent conduct, or discreet and frugal management, whether of a man's own estate or that of another.

Animal OECONOMY, comprehends the various operations of nature in the generation, nutrition and preservation of animals *. The doctrine of the animal economy is nearly connected with physiology, which explains the operation and action of the several parts of the human body, their use, &c. See ANATOMY and PHYSIOLOGY.

* See *Generation, Nutrition*, &c.

OECUMENICAL, signifies the same with *general* or *universal*; as, œcumenical council, bishop, &c.

OEDEMA, or PHLEGMATIC TUMOUR, in *Medicine* and *Surgery*, a sort of tumour attended with paleness and cold, yielding little resistance, retaining the print of the finger when pressed with it, and accompanied with little or no pain.

This tumour obtains no certain situation in any particular part of the body, since the head, eyelids, hands, and sometimes part, sometimes the whole body, is afflicted with it. When the last mentioned is the case, the patient is said to be troubled with a cachexy, leucophlegmatia, or dropsy. But if any particular part is more subject to this disorder than another, it is certainly the feet, which are at that time called *swelled* or *œdematous feet*.

OEDERA, in *Botany*, a genus of plants belonging to the syngenesia class. See BOTANY *Index*.

OEDIPUS, the unfortunate king of Thebes, whose history is partly fabulous, flourished about 1266 B. C. It is said he was given by his father to a shepherd, who was ordered to put him to death, in order to prevent the misfortunes with which he was threatened by an oracle. But the shepherd, being unwilling to kill him with his own hands, tied him by the feet to a tree, that he might be devoured by wild beasts. The infant was however found in this situation by another shepherd named *Phorbas*, who carried him to Polybus king of Corinth; where the queen, having no children, educated him with as much care as if he had been her own son. When he was grown up, he was informed that he was not the son of Polybus; on which, by order of the oracle, he went to seek for his father in Phocis; but scarce was he arrived in that country, when he met his father on the road, and killed him without knowing him. A short time after, having delivered the country from the monster called the *Sphinx*, he married Jocasta, without knowing that she was his mother, and had four children by her; but afterwards, being informed of his incest, he quitted the throne, and, thinking himself unworthy of the light, put out his eyes. Eteocles and Polynices, who were celebrated among the Greeks, were born of this incestuous marriage.

OEGWA, a town on the Gold coast of Africa, situated, according to Artus, on the brow of an eminence, raising itself by a gentle ascent to a considerable height, and defended by rocks, against which the waves beat with the utmost violence, the noise of which is heard at a great distance.

Barbot affirms, that Oegwa contains above 500 houses disjoined by narrow crooked streets; and that from the sea it has the appearance of an amphitheatre. Des Marchias reduces the number of houses to 200, in the centre of which stands a large square building, the repository of their gold dust and other commodities. The houses are built of earth and clay, but convenient and well furnished with chairs, stools, mats, carpets, earthen pots, and even looking-glasses, which last they purchase from the Europeans. No part of the coast is better provided with all kinds of eatables, which are sent in from the adjacent cantons, and sold in public markets. Every thing is bought and sold with gold dust, which is the standard of all other commodities, and brought hither in great abundance from all quarters of Fetu, Abrambo, Assiento, and Mandingo. The gold is sold by weight, and the quantity determined by nice scales, made in the country before it was frequented by the Europeans: a proof that those negroes are not wholly ignorant of the more refined principles of mechanics. Next to gold, the chief commerce of the place consists in the sale of fish, of which they catch prodigious quantities on the coast. Although the natives are brave and warlike, yet in time of peace no people are more industrious, their whole time being employed in catching fish or cultivating the fruits of the earth. They are extremely expert in throwing the line, and fishing by the hook; nor is their intrepidity in combating the elements, and pursuing their employments in all kinds of weather, less astonishing. Every day in the week, except Wednesday, which is sacred to the Fetiche, they employ in their several occupations, and no season of the year is exempted from fishing. Their canoes weather storms which would endanger the largest shipping; and the negroes have the dexterity of making their advantage of those seasons, which oblige others to discontinue their labours, by throwing their lines with the same success in tempestuous as in calm weather.

OELAND, an island of Sweden, seated in the Baltic sea, between the continent of Gothland and the isle of Gothland. It lies between 56° and 57° of north latitude, and between 17° and 18° of east longitude. It is about 60 miles in length, and 15 in breadth; having a wholesome air, and a fertile soil, with rising hills, and several castles. It has no town of any great note.

OENANTHE, WATER DROPWORT, a genus of plants belonging to the pentandria class; and in the natural method ranking under the 45th order *Umbellatæ*. See BOTANY *Index*.

OENOPTÆ, in Grecian antiquity, a kind of censors

sors at Athens, who regulated entertainments, and took care that none drank too much, nor too little.

OENOS, in *Ornithology*, the name used by authors for the stock-dove, or wood pigeon, called also by some *vinago*, somewhat larger than the common pigeon, but of the same shape and general colour. Its neck is of a fine changeable hue, as differently opposed to the light; and its breast, shoulders, and wings, are of a fine purplish hue, or red wine colour, from whence it has its name *vinago*.

OENOTHERA, TREE-PRIMROSE, a genus of plants belonging to the octandria class; and in the natural method ranking under the 17th order, *Calycanthemæ*. See BOTANY *Index*.

OENOTRIA, an ancient name of Italy; so called from the *Oenotri*, (Virgil); inhabiting between Pæstum and Tarentum, (Ovid). Originally Arcadians, (Dionysius Halicarnasseus), who came under the conduct of Oenotrus son of Lycaon, 17 generations before the war of Troy, or 459 years, at 27 years each generation, and gave name to the people. Cato derives the name from *Oenotrus*, king of the Sabines and Etruscans; but Varro from *Oenotrus*, king of the Latins; and Servius from the Greek name for wine, for which Italy was famous; of which opinion is Strabo.

OENOTRIDES (Strabo, Pliny), two small islands in the Tuscan sea, over against Velia, a town of Lucania, called *Pontia* and *Iscia*; now *Penza* and *Ischia*, on the coast of the Principato Citra, or to the west of Naples. So called from the *Oenotri*, an ancient people of Italy.

OESEL, an island of the Baltic sea, at the entrance of the gulf of Livonia. It is about 70 miles in length, and 50 in breadth, and contains 10 parishes. It is defended by the fortresses of Airensburg and Sonneburg. It lies between 22° and 24° of east longitude, and between 58° and 59° of north latitude.

OESOPHAGUS, in *Anatomy*, the GULA, or *Gullet*, is a membranaceous canal, reaching from the fauces to the stomach, and conveying into it the food taken in at the mouth. See ANATOMY, N° 92.

OESTRUS, a genus of insects belonging to the order of diptera. See ENTOMOLOGY *Index*.

OETA, in *Ancient Geography*, a mountain of Thessaly, extending from Thermopylæ westward to the Sinus Ambracius, and in some measure cutting at right angles the mountainous country stretching out between Parnassus to the south, and Pindus to the north. At Thermopylæ it is very rough and high, rising and ending in sharp and steep rocks, affording a narrow passage between it and the sea from Thessaly to Locris (Strabo), with two paths over it; the one above Trachis, very steep and high; the other through the country of the Ænianes, much easier and readier for travellers; by this it was that Leonidas was attacked in rear by the Persians (Pausanias). Here Hercules laid himself on the funeral pile (Silius Italicus, Ovid); the spot thence called *Pyra* (Livy), who says that the extreme mountains to the east are called *Oeta*; and hence the poets allege, that day, night, sun, and stars, arose from Oeta (Seneca, Statius, Silius Italicus, Catullus, Virgil's *Culex*)—circumstances which show the height of this mountain.

OETING, a town of Germany, in Upper Bavaria, under the jurisdiction of Buckhausen. It is divided into the upper and the lower town, and seated on the river Inn, eight miles west of Buckhausen. E. Long. 12. 47. N. Lat. 48. 0. There is a great resort of pilgrims to the old chapel.

OETING, or *Oetingen*, a town of Germany, in the circle of Suabia, and capital of a county of the same name, seated on the river Wirnitz. E. Long. 10. 45. N. Lat. 48. 52.

OETING, a county of Germany, in the circle of Suabia, bounded on the north and east by Franconia; on the south by the duchy of Neuburg; and on the west by that of Wirtemberg. It is about 40 miles from east to west, and 20 from north to south.

OFFA's DYKE, an intrenchment cast up by Offa, a Saxon king, to defend England against the incursions of the Welsh. It runs through Hertfordshire, Shropshire, Montgomeryshire, Denbighshire, and Flintshire.

OFFANTO, a river of Italy, in the kingdom of Naples. It rises in the Apennine mountains, in the Farther Principato: and passing by Conza, and Monte Verde, it afterwards separates the Capitanata from the Basilicata and the Terra-di-Bari, and then it falls into the gulf of Venice, near Salpe.

OFFENCE, in *Law*, an act committed against the law, or omitted where the law requires it.

OFFERINGS. The Hebrews had several kinds of offerings, which they presented at the temple. Some were free-will offerings, and others were of obligation. The first fruits, the tenths, the sin offerings, were of obligation; the peace offerings, vows, offerings of wine, oil, bread, salt, and other things, which were made to the temple or to the ministers of the Lord, were offerings of devotion. The Hebrews called all offerings in general *corban*. But the offerings of bread, salt, fruits and liquors, as wine and oil, which were presented to the temple, they called *mincha*. The sacrifices are not properly offerings, and are not commonly included under that name. See CORBAN and SACRIFICE.

The offerings of grain, meal, bread, cakes, fruits, wine, salt, and oil, were common in the temple. Sometimes these offerings were alone, and sometimes they accompanied the sacrifices. Honey was never offered with the sacrifices; but it might be offered alone in the quality of first fruits. Now these were the rules that were observed in the presenting of those offerings, called in Hebrew *mincha*, or *korbon mincha*; in the Septuagint, *offerings of sacrifice*; and the same by St Jerome, *oblationem sacrificii*; but by our translators, *meat offerings* (Lev. ii. 1, &c.). There were five sorts of these offerings: 1. Fine flour or meal. 2. Cakes of several sorts, baked in an oven. 3. Cakes baked upon a plate. 4. Another sort of cakes, baked upon a gridiron, or plate with holes in it. 5. The first fruits of the new corn, which were offered either pure and without mixture, or roasted or parched in the ear or out of the ear.

The cakes were kneaded with oil olive, or fried with oil in a pan, or only dipped in oil after they were baked. The bread offered to be presented upon the altar, was to be without leaven; for leaven was never offered upon the altar, nor with the sacrifices. But they might make presents of common bread to the priests and ministers of the temple. See CAKE, &c.

The offerings now mentioned were appointed on account

count of the poorer sort, who could not go to the charge of sacrificing animals. And even those that offered living victims were not excused from giving meal, wine, and salt, which was to go along with the greater sacrifices. And also those that offered only oblations of bread or of meal, offered also oil, incense, salt, and wine, which were in a manner the seasoning of it. The priest in waiting received the offerings from the hand of him that offered them; laid a part of them upon the altar, and reserved the rest for his own subsistence: that was his right as a minister of the Lord. Nothing was burnt quite up but the incense, of which the priest kept back nothing for his own share.

When an Israelite offered a loaf to the priest, or a whole cake, the priest broke the loaf or the cake into two parts, setting that part aside that he reserved to himself, and broke the other into crumbs; poured oil upon it, salt, wine, and incense; and spread the whole upon the fire of the altar. If these offerings be accompanied by an animal for a sacrifice, it was all thrown upon the victim, to be consumed along with it.

If these offerings were the ears of new corn, either of wheat or barley, these ears were parched at the fire or in the flame, and rubbed in the hand, and then offered to the priest in a vessel; over which he put oil, incense, wine, and salt, and then burnt it upon the altar, first having taken as much of it as of right belonged to himself.

The greatest part of these offerings were voluntary, and of pure devotion. But when an animal was offered in sacrifice, they were not at liberty to omit these offerings. Every thing was to be supplied that was to accompany the sacrifice, and which served as a seasoning to the victim. There are some cases in which the law requires only offerings of corn, or bread: for example, when they offered the first fruits of their harvest, whether they were offered solemnly by the whole nation, or by the devotion of private persons.

As to the quantity of meal, oil, wine, or salt, which was to go along with the sacrifices, we cannot easily see that the law had determined it. Generally the priest threw an handful of meal or crumbs upon the fire of the altar, with wine, oil, and salt in proportion, and all the incense. All the rest belonging to him, the quantity depended upon the liberality of the offerer. We observe in more places than one, that Moses appoints an assaron, or the tenth part of an ephah of meal, for those that had not wherewithal to offer the appointed sin offerings (Lev. v. 11. xiv. 21.). In the solemn offerings of the first fruits for the whole nation, they offered an entire sheaf of corn, a lamb of a year old, two tenths or two assarons of fine meal mixed with oil, and a quarter of a hin of wine for the libation. (Lev. xxiii. 10, 11, 12, &c.)

In the sacrifice of jealousy (Numb. v. 15.), when a jealous husband accused his wife of infidelity, the husband offered the tenth part of a fatum of barley-meal, without oil or incense, because, it was a sacrifice of jealousy, to discover whether his wife was guilty or not.

The offerings of the fruits of the earth, of bread, of wine, oil, and salt, are the most ancient of any that have come to our knowledge. Cain offered to the Lord of the fruits of the earth, the first fruits of his labour (Gen. iv. 3, 4.). Abel offered the firstlings of his flocks, and of their fat. The heathen have nothing more ancient in their religion, than these sorts of offerings made to their gods. They offered clean wheat, flour, and bread.

OFFICE, a particular charge or trust, or a dignity attended with a public function. See HONOUR.—The word is primarily used in speaking of the offices of judicature and policy; as the office of secretary of state, the office of a sheriff, of a justice of peace, &c.

OFFICE also signifies a place or apartment appointed for officers to attend in, in order to discharge their respective duties and employments; as the secretary's office, ordnance office, excise office, signet office, paper office, pipe office, six clerks office, &c.

OFFICE, in *Architecture*, denotes all the apartments appointed for the necessary occasions of a palace or great house; as kitchen, pantries, confectionaries, &c.

OFFICE, in the canon law, is usual for a benefice, that has no jurisdiction annexed to it.

Duty upon OFFICES *and Pensions*, a branch of the king's extrordinary perpetual revenue, consisting in a payment of 1s. in the pound (over and above all other duties) out of all salaries, fees, and perquisites of offices and pensions payable by the crown. This highly popular taxation was imposed by stat. 31 Geo. II. c. 22. and is under the direction of the commissioners of the land tax.

OFFICER, a person possessed of a post or office. See the preceding article.

The great officers of the crown, or state, are, The lord high steward, the lord high chancellor, the lord high treasurer, the lord president of the council, the lord privy seal, the lord chamberlain, the lord high constable, and the earl marshal; each of which see under its proper article.

Non-commissioned OFFICERS, are serjeant majors, quartermaster serjeants, serjeants, corporals, drum and fife majors; who are nominated by their respective captains, and appointed by the commanding officers of regiments, and by them reduced without a court-martial.

Orderly non-commissioned OFFICERS, are those who are orderly, or on duty for that week; who, on hearing the drum beat for orders, are to repair to the place appointed to receive them, and to take down in writing, in the orderly-book, what is dictated by the adjutant, or serjeant major: they are then immediately to show these orders to the officers of the company, and afterwards warn the men for duty.

Flag OFFICERS. See *FLAG Officers*, and ADMIRALS.

Commission OFFICERS, are such as are appointed by the king's commission. Such are all from the general to the cornet and ensign inclusive. They are thus called in contradistinction to non-commissioned officers. See *Non-commissioned* OFFICERS.

General OFFICERS, are those whose command is not limited to a single company, troop, or regiment; but extends to a body of forces composed of several regiments; such are the general, lieutenant general, major general, and brigadier.

OFFICERS *of the Household*. See the article HOUSEHOLD.

Staff OFFICERS, are such as, in the king's presence, bear a white staff or wand; and at other times, on their

their going abroad, have it carried before them by a footman bare-headed: such are the lord steward, lord chamberlain, lord treasurer, &c. The white staff is taken for a commission; and, at the king's death, each of these officers breaks his staff over the herse made for the king's body, and by this means lays down his commission, and discharges all his inferior officers.

Subaltern OFFICERS, are all who administer justice in the name of subjects; as those who act under the earl marshal, admiral, &c. In the army, the subaltern officers are the lieutenants, cornets, ensigns, serjeants, and corporals.

OFFICIAL, in the canon law, an ecclesiastical judge, appointed by a bishop, chapter, abbot, &c. with charge of the spiritual jurisdiction of the diocese.

OFFICIAL, is also a deputy appointed by an archdeacon as his assistant, who sits as judge in the archdeacon's court.

OFFICINAL, in *Pharmacy*, an appellation given to such medicines, whether simple or compound, as are required to be constantly kept in the apothecaries shops. The *officinal simples* are appointed by the College of Physicians; and the manner of making the compositions directed in their pharmacopœia. See MATERIA MEDICA.

OFFING, or OFFIN, in the sea language, that part of the sea a good distance from shore, where there is deep water, and no need of a pilot to conduct the ship: thus, if a ship from shore be seen sailing out to seaward, they say, *she stands for the offing;* and if a ship, having the shore near her, have another a good way without her, or towards the sea, they say, *that ship is in the offing.*

OFF-SETS, in *Gardening*, are the young shoots that spring from the roots of plants; which being carefully separated, and planted in a proper soil, serve to propagate the species.

OFF-SETS, in *Surveying*, are perpendiculars let fall, and measuring from the stationary lines to the hedge, fence, or extremity of an enclosure.

OGEE, or O. G. in *Architecture*, a moulding consisting of two members, the one concave and the other convex; or like an S. See ARCHITECTURE.

OGHAMS, a particular kind of stenography, or writing in cypher, practised by the Irish; of which there were three kinds: The first was composed of certain lines and marks, which derived their power from their situation and position, as they stand in relation to one principal line, over or under which they are placed, or through which they are drawn; the principal line is horizontal, and serveth for a rule or guide, whose upper part is called the left, and the under side the right; above, under, and through which line, the characters or marks are drawn, which stand in the place of vowels, consonants, diphthongs, and triphthongs. Some authors have doubted the existence of this species of writing in cypher, called *Ogham* among the Irish; but these doubts are perhaps ill founded: for several MSS. in this character still exist, from which Mr Astle has given a plate of them.

OGIVE, in *Architecture*, an arch or branch of a Gothic vault; which, instead of being circular, passes diagonally from one angle to another, and forms a cross with the other arches. The middle, where the ogives cross each other, is called the *key;* being cut in form of a rose, or a *cul de lampe*. The members or mouldings of the ogives are called *nerves*, *branches*, or *reins;* and the arches which separate the ogives, *double arches*.

OGYGES, king of the Thebans, or, according to others, of Ogygia and Actæ, afterwards called *Bœotia* and *Attica*. He is recorded to have been the first founder of Thebes and Eleusis. The famous deluge happened in his time, in which some say he perished with all his subjects, 1796, B. C.

OGYGIA (Homer), the island of Calypso; placed by Pliny in the Sinus Scylaceus, in the Ionian sea, opposite to the promontory Lacinium; by Mela in the strait of Sicily, calling it *Æœa;* which others place at the promontory Circeium, and call it the island of *Circe*. Also the ancient name of Thebes in Bœotia.

OHIO, a river of North America. It is formed by the junction of the Alleghany and Monongahela rivers, which unite at Pittsburg, and take the name of Ohio. After a course of 1188 miles, it falls into the Mississippi in lat. 37. receiving fifteen rivers in its progress. During the high water of spring and autumn it is navigated by ships of 300 tons, and at all seasons by boats. The rapids at Louisville are the only obstruction; but the navigation will be continued here by a canal.

OHIO, the name of one of the United States of North America. It has the river Ohio on the south, Lake Erie and the Michigan territory on the north, Pennsylvania on the east, and Indiana on the west. It covers an area of 40,000 square miles. The surface is generally undulating, and towards the middle of the state is broken by low hills. The soil, which rests on limestone, has generally a great depth, and is remarkably fertile. It is watered by many large rivers, which are well stored with fish, and nearly all navigable. There are several salt springs, and coal is abundant. The mean heat of the climate at Cincinnati is $54\frac{1}{2}$ of Fahrenheit. The population in 1800 was only 42,156; but in 1810 had increased to 230,760, and in 1816 was estimated at 450,000. There are besides about 3000 Indians in the north-western parts. Slavery does not exist in this state. The average crop of Indian corn is reckoned 45 bushels an acre, of wheat 22, of rye 25, of oats 35, and of barley 30. Flax and hemp are cultivated, and a little tobacco, but cotton does not thrive. Vines, however, have been found to succeed. The price of good cleared land varies from two dollars to forty, according as it is near market towns. In 1810 there were three millions of pounds of maple sugar made in this state; a single tree yielding about 10 pounds. This territory was formed into a state and admitted into the Union in 1802. See UNITED STATES, SUPPLEMENT.

OHETEROA, one of the South sea islands lately discovered, is situated in W. Long. 150. 47. S. Lat. 22. 27. It is neither fertile nor populous, nor has it any harbour or anchorage fit for shipping; and the disposition of the people is hostile to such as visit them.

OIL, an unctuous inflammable substance, drawn from several natural bodies, as animal and vegetable substances. See CHEMISTRY and MATERIA MEDICA *Index*.

For the construction of an oil mill, see Gray's Experienced Millwright; and for an account of a very simple apparatus for expressing oils from different seeds at Bangalore in the East Indies, see Phil. Mag. vol. xxx. p. 329.

Rock Oil. See PETROLEUM, MINERALOGY *Index*.

OINTMENT, in *Pharmacy*. See UNGUENT, MATERIA MEDICA *Index*.

OISE, a department of France, comprising the northern part of what was formerly the Isle of France. The surface is diversified, the soil fertile, producing corn and fruits, but not the vine. There are numerous manufactures of cloth, linen, flannel, &c. The territorial extent of the department is 2294 square miles, or 1,139,190 *arpents*. The population in 1800 was 369,086; and the amount of contributions for the year 1802 was 4,714,895 francs. It is divided into four subprefectures, 35 cantons, and 738 communes. Beauvais is the chief town.

OKEHAM, the capital of Rutlandshire, in England, seated in a rich and pleasant valley, called the *vale of Catmus*. It is well built, contained 1111 inhabitants in 1811, has a good church, a free-school, and an hospital. W. Long. 0. 45. N. Lat. 52. 40.

OKINGHAM, or *Woxingham*, a town of Berkshire, in England, containing 1419 inhabitants, and noted for the manufacture of silk stockings. W. Long. 0. 50. N. Lat. 51. 26.

OKRA, the fruit of a species of hibiscus, which is employed in the West Indies in making soups. See BOTANY *Index*.

OLAUS MAGNUS. See MAGNUS.

OLAX, a genus of plants, belonging to the triandria class. See BOTANY *Index*.

OLD AGE. See LONGEVITY. Many methods have been proposed for lengthening life, and rendering old age comfortable. Cornaro's Treatise on this subject is known to every body, and needs not be quoted. To some of our readers the following set of resolutions will perhaps be new, and may certainly be useful.

The old men should resolve, except the reasons for a change be invincible, to live and to die in the public profession of the religion in which they were born and bred. To avoid all profane talk and intricate debates on sacred topics. To endeavour to get the better of the intrusions of indolence of mind and body, those certain harbingers of enfeebling age. Rather to wear out, than to rust out. To rise early, and as often as possible to go to bed before midnight. Not to nod in company, nor to indulge repose too frequently on the couch in the day. To waste as little of life in sleep as may be, for we shall have enough in the grave. Not to give up walking; nor to ride on horseback to fatigue. Experience, and a late medical opinion, determine to ride five miles every day: Nothing contributes more to the preservation of appetite, and the prolongation of life. Cheyne's direction to the valetudinary, "to make exercise a part of their religion," to be religiously observed. To continue the practice of reading, pursued for more than fifty years, in books on all subjects; for variety is the salt of the mind as well as of life. Other people's thoughts, like the best conversation of one's companions, are generally better and more agreeable than one's own. Frequently to think over the virtues of one's acquaintance, old and new. To admit every cheerful ray of sunshine on the imagination. To avoid retrospection on a past friendship, which had much of love in it; for memory often comes when she is not invited. To try to think more of the living and less of the dead; for the dead belong to a world of their own. To live within one's income, be it large or little. Not to let passion of any sort run away with the understanding. Not to encourage romantic hopes nor fears. Not to drive away hope, the sovereign balm of life, though he is the greatest of all flatterers. Not to be under the dominion of superstition or enthusiasm. Not wilfully to undertake any thing for which the nerves of the mind or the body are not strong enough. Not to run the race of competition, or to be in another's way. To avoid being jostled too much in the street, being overcome by the noise of the carriages, and not to be carried even by curiosity itself into a large crowd. To strive to embody that dignified sentiment, "to write injuries in dust, but kindnesses in marble." Not to give the reins to constitutional impatience, for it is apt to hurry on the first expressions into the indecency of swearing. To recollect, that he who can keep his own temper may be master of another's. If one cannot be a stoic, in bearing and forbearing, on every trying occasion, yet it may not be impossible to pull the check-string against the moroseness of spleen or the impetuosity of peevishness. Anger is a short madness. Not to fall in love, now on the precipice of threescore, nor expect to be fallen in love with. A connexion between summer and winter is an improper one. Love, like fire, is a good servant, but a bad master. Love is death, when the animal spirits are gone. To contrive to have as few vacant hours upon one's hands as possible, that idleness, the mother of crimes and vices, may not pay its visit. To be always doing of something, and to have something to do. To fill up one's time, and to have a good deal to fill up: for time is the materials that life is made of. If one is not able by situation, or through the necessity of raising the supplies within the year, or by habit (for virtue itself is but habit), to do much ostentatious good, yet do as little harm as possible. To make the best and the most of every thing. Not to indulge too much in the luxury of the table, nor yet to underlive the constitution. The gout, rheumatism, and dropsy, in the language of the Spectator, seem to be hovering over the dishes. Wine, the great purveyor of pleasure, and the second in rank among the senses, offers his service, when love takes his leave. It is natural to catch hold of every help, when the spirits begin to droop. Love and wine are good cordials, but are not proper for the beverage of common use. Resolve not to go to bed on a full meal. A light supper and a good conscience are the best receipts for a good night's rest, and the parents of undisturbing dreams. Not to be enervated by the flatulency of tea. Let the second or third morning's thought be to consider of the employment for the day; and one of the last at night to inquire what has been done in the course of it. Not to let one's tongue run at the expence of truth. Not to be too communicative nor unreserved. A close tongue, with an open countenance, are the safest passports through the journey of the world. To correct the error of too much talking, and restrain the narrativeness of the approaching climacteric. Not to like or dislike too much at first sight. Not to wonder, for all wonder is ignorance that possession falls short of expectation. The longing of twenty years may be disappointed in the unanswered gratification of a single hour.

hour. Whilst we are wishing, we see the best side; after we have taken possession, the worst. Resolve to attend to the arguments on both sides, and to hear every body against every body. The mind ought not to be made up, but upon the best evidence. To be affectionate to relations, which is a kind of self-love, in preference to all other acquaintance. But not to omit paying the commanding respect to merit, which is superior to all the accidental chains of kindred. Not to debilitate the mind by new and future compositions. Like the spider, it may spin itself to death. The mind, like the field, must have its fallow season. The leisure of the pen has created honourable acquaintance, and pleased all it has wished to please. To resolve not to be too free of promises, for performances are sometimes very difficult things. Not to be too much alone, nor to read, nor meditate, or talk too much on points that may awaken tender sensations, and be too pathetic for the soul. To enjoy the present, not to be made too unhappy by reflection on the past, not to be oppressed by invincible gloom on the future. To give and receive comfort, those necessary alms to a distressed mind. To be constantly thankful to providence for the plenty hitherto possessed, which has preserved one from the dependence on party, persons, and opinions, and kept one out of debt. The appearance of a happy situation, and opportunities of tasting many wordly felicities (for content has seldom perverted itself into discontent), has induced many to conclude, that one must be pleased with one's lot in life; and it occasions many to look with the eye of innocent envy. To resolve more than ever to shun every public station and responsibility of conduct. To be satisfied with being master of one's self, one's habits, now a second nature, and one's time. Determined not to solicit, unless trampled upon by fortune, to live and die in the harness of trade, or a profession. To take care that pity (humanity is not here meant) does not find out one in the endurance of any calamity. When pity is within call, contempt is not far off. Not to wish to have a greater hold of life, nor to quit that hold. The possible tenure of existence is of too short possession for the long night that is to succeed: therefore not a moment to be lost. Not to lose sight even for a single day, of these good and proverbial doctors—diet—merryman—and quiet. Resolved to remember and to recommend, towards tranquillity and longevity, the three oral maxims of Sir Hans Sloane —"Never to quarrel with one's self—one's wife—or one's prince." Lastly, Not to put one's self too much in the power of the elements, those great enemies to the human frame; namely, the sun—the wind—the rain—and the night air.

Old Man of the Mountain. See Assassins.

OLDCASTLE, Sir John, called the *Good Lord Cobham*, was born in the reign of Edward III. and was the first author as well as the first martyr among the English nobility: he obtained his peerage by marrying the heiress of that Lord Cobham who with so much virtue and patriotism opposed the tyranny of Richard II. By his means the famous statute against provisors was revived, and guarded against by severer penalties; he was one of the leaders of the reforming party; was at great expence in procuring and dispersing copies of Wickliffe's writings among the people, as well as by maintaining a number of his disciples as itinerant preachers. In the reign of Henry V. he was accused of heresy; the growth of which was attributed to his influence. Being a domestic in the king's court, the king delayed his prosecution that he might reason with him himself; but not being able to reclaim him to the church of Rome, he in great displeasure resigned him to its censure. He was apprehended and condemned for heresy; but escaping from the Tower, lay concealed for four years in Wales, until the rumour of a pretended conspiracy was raised against him, and a price set upon his head: he was at last seized and executed in St Giles's Fields; being hung alive in chains upon a gallows, and burned by a fire placed underneath. He wrote "Twelve Conclusions, addressed to the Parliament of England."

OLDENBURG, a duchy in the north-west of Germany, with a capital of the same name. It lies within the kingdom of Hanover. The royal house of Denmark derived its origin from the family to which this territory belonged, and retained the title. The account given by historians is as follows.

On the death of Christopher king of Denmark, &c. in 1448, without issue, there was a great contest about the succession; and a variety of factions were raised, particularly in Sweden and Norway, for the promotion of different persons; and various animosities and numerous discords were excited by the several parties, in order each to obtain their own ends.

As soon as these intrigues were known in Denmark, the senate resolved to proceed to the election of a king; for it did not appear expedient to commit the government of affairs to the queen dowager, at a time when they had every thing to fear from the two neighbouring crowns. At this time a lord of great weight, property, and ambition, sought the queen in marriage, the more easily to pave his way to the throne. But as for a great number of years there was no precedent for electing a king out of the body of nobility, though agreeable to law, the queen entered into the views of the senate, and declared she would give her hand to no prince who should not be judged deserving of the crown by the supreme council of the nation.

The advantages which would have accrued from annexing the duchy of Sleswick and Holstein to the crown, made the senate first cast their eyes on Adolphus. This matter required no long deliberation; all saw the conveniences resulting from such an union, and gave their assent. Immediately an embassy was despatched with the offer to Adolphus; but that prince consulting the good of his subjects, whose interest would have been absorbed in the superior weight of Denmark, declined it, with a moderation and disinterestedness, altogether uncommon among princes. However, that he might not be wanting in respect to the senate, he proposed to them his nephew Christian, second son to Theodoric, count of Oldenburg, a prince bred up at the court of Adolphus from his infancy. The proposition was so agreeable to the senate, that, without loss of time, the ambassadors were sent to Theodoric, to demand either of his sons he should pitch upon for their king. Theodoric's answer to the ambassadors was remarkable: "I have three sons, says he, of very opposite qualities. One is passionately fond of pleasure and women; another breathes nothing but war, without regarding the justice of the cause;

cause; but the third is moderate in his disposition, prefers peace to the din of arms, yet stands unrivalled in valour, generosity, and magnanimity." He said he painted these characters for the senate's information, desiring they would choose which of the young princes they believed would render the kingdom happiest. It was a matter which would admit of no hesitation: with one voice the senate declared for that prince whose panegyric the father had so warmly drawn; and under these happy auspices commenced the origin of the grandeur of the house of Oldenburg, at this day seated on the throne of Denmark.

OLDENBURG, *Henry*, a learned German of the 17th century, was descended from the noble family of his name, who were earls of the county of Oldenburg, in the north part of Westphalia, for many generations. He was born in the duchy of Bremen in the Lower Saxony; and during the long English parliament in King Charles I.'s time, was appointed consul for his countrymen, at London, after the usurpation of Cromwell; but being discharged of that employ, he was made tutor to the lord Henry O'Bryan, an Irish nobleman, whom he attended to the university of Oxford, where he was admitted to study in the Bodleian library in the beginning of the year 1656. He was afterwards tutor to William lord Cavendish, and was acquainted with Milton the poet. During his residence at Oxford, he became also acquainted with the members of that body there, which gave birth to the Royal Society; and upon the foundation of this latter, he was elected fellow; and when the society found it necessary to have two secretaries, he was chosen assistant secretary to Dr Wilkins. He applied himself with extraordinary diligence to the business of his office, and began the publication of the Philosophical Transactions with N° I. in 1664. In order to discharge this task with greater credit to himself and the society, he held a correspondence with more than seventy learned persons, and others, upon a vast variety of subjects, in different parts of the world. This fatigue would have been insupportable, had not he, as he told Dr Lister, managed it so as to make one letter answer another; and that to be always fresh, he never read a letter before he had pen, ink, and paper, ready to answer it forthwith; so that the multitude of his letters cloyed him not, nor ever lay upon his hands. Among others, he was a constant correspondent of Mr Robert Boyle, with whom he had a very intimate friendship; and he translated several of that ingenious gentleman's works into Latin.

Mr Oldenburg continued to publish the Transactions, as before, to N° xxxvi. June 25. 1677. After which the publication was discontinued till the January following, when it was again resumed by his successor in the secretary's office, Mr Nehemiah Grew, who carried it on till the end of February 1678. Our author dying at his house at Charleton, near Greenwich in Kent, in the month of August that year, was interred there.

OLDENLANDIA, a genus of plants belonging to the tetrandria class. See BOTANY *Index*.

OLDHAM, JOHN, an eminent English poet in the 17th century, son of a Nonconformist minister, was educated under his father, and then sent to Edmond hall in Oxford. He became usher to the free-school at Croydon in Surry; where he received a visit from the earls of Rochester and Dorset, Sir Charles Sedley, and other persons of distinction, merely upon the reputation of some verses of his which they had seen in manuscript. He was tutor to several gentlemen's sons successively; and having saved a small sum of money, came to London, and became a perfect votary to the bottle, being an agreeable companion. He was quickly found out here by the noblemen who had visited him at Croydon, who brought him acquainted with Mr Dryden. He lived mostly with the earl of Kingston at Holme Pierpoint in Nottinghamshire, where he died of the small-pox in 1683, in the 30th year of his age. His acquaintance with learned authors appears by his satires against the Jesuits, in which there is as much learning as wit discovered. Mr Dryden esteemed him highly. His works are printed in 2 vols 12mo. They chiefly consist of satires, odes, translations, paraphrases of Horace and other authors, elegiac verses, imitations, parodies, familiar epistles, &c.

OLD-HEAD, a promontory situated in the county of Cork, and province of Munster, four miles south of Kinsale, in the barony of Courcies, Ireland, which runs far into the sea, and on which is a lighthouse for the convenience of shipping. A mile from its extremity is an ancient castle of the lords of Kinsale, built from one side of the isthmus to the other, which defended all the lands towards the head: this place was formerly called *Duncearma*, and was the old seat of the Irish kings. The isthmus, by the working of the sea, was quite penetrated through, so as to form a stupendous arch, under which boats might pass from one bay to the other. Among the rocks of this coast there are aviaries of good hawks: also the sea eagles or ospreys build their nests and breed there.

OLDMIXON, JOHN, was descended from an ancient family in Somersetshire: he was a violent party-writer and malevolent critic, who would scarcely have been remembered, if Pope, in resentment of his abuse, had not condemned him to immortality in his Dunciad. His party-writings procured him a place in the revenue at Liverpool, where he died at an advanced age in the year 1745. Besides his fugitive temporary pieces, he wrote a History of the Stuarts, in folio; a Critical History of England, 2 vols 8vo; a volume of Poems, some dramatic pieces, &c.; none of them worthy of notice, his principal talent being that of falsifying history.

OLD-WIFE, or *Wrasse*. See LABRUS, } ICHTHYOLOGY *Index*.
OLD-WIFE *Fish*. See BALISTES, }

OLD-WOMAN'S ISLAND, a narrow slip of land, about two miles long, separated from Bombay in the East Indies by an arm of the sea, which, however, is passable at low water. It terminates at one extremity in a small eminence, on which a look-out house is kept for vessels. Near the middle are three tombs kept constantly white as land marks into the harbour. From the end of the island a dangerous ledge of rocks shoots forth, which are not very easily cleared. It produces only pasture for a few cattle.

OLEA, the *olive-tree*; a genus of plants belonging to the diandria class; and in the natural method ranking under the 44th order, *Sepiariæ*. See BOTANY *Index*.

OLEAGINOUS, something that partakes of the nature of oil, or out of which oil may be expressed.

OLEANDER,

OLEANDER, or Rose Bay, *nerium*; a genus of plants belonging to the pentandria class. See Botany *Index*.

OLECRANUM, or Olecranon, in *Anatomy*, the protuberance of the ulna, which prevents the joint of the elbow from being bent back beyond a certain length. See Anatomy, N° 51.

OLENUS, a Greek poet, older than Orpheus, came from Xanthe, a city of Lycia. He composed several hymns, which were sung in the island of Delos upon festival days. Olenus is said to have been one of the founders of the oracle at Delphi; to have been the first who filled at that place the office of priest of Apollo; and to have given responses in verse; but the truth of these assertions is very doubtful.

OLERON, an island of France, on the coast of Aunis and Saintogne, about five miles from the continent. It is 12 miles in length, and five in breadth; and is very fertile, containing about 12,000 inhabitants, who are excellent seamen. It is defended by a castle, which is well fortified; and there is a lighthouse placed there for the direction of ships. It is 14 miles south-east of Rochelle. W. Long. 1. 26. N. Lat. 46. 3.

Sea Laws of Oleron, certain laws relative to maritime affairs, made in the time of Richard I. when he was at the island of Oleron. These laws, being accounted the most excellent sea laws in the world, are recorded in the black book of the admiralty. See Selden's *Mare Clausum*.

OLEUM palmæ christi, commonly called *castor oil*, is extracted from the kernel of the fruit produced by the *Ricinus Americanus*. See Ricinus, Botany and Materia Medica *Index*.

OLFACTORY nerves. See Anatomy, N° 139 and 143.

OLGA, queen of Igor, the second monarch of Russia, who flourished about the year 880, having succeeded his father Ruric, who died in 878. Olga was born in Plescow, and was of the best family in that city. She bore him one son, called *Swetoslaw*. Igor being murdered by the Drewenses, or Drewliani, Olga revenged his death. She went afterwards, for what reason we know not, to Constantinople, where she was baptized, and received the name of *Helena*.

The emperor John Zimisces was her godfather, and fell in love with her as we are told; but she, alleging their spiritual alliance, refused to marry him. Her example made some impression upon her subjects, a good number of whom became converts to Christianity; but none upon her son, who reigned for a long time after her death, which happened at Pereslaw, in the 80th year of her age, 14 years after her baptism. The Russians to this day rank her among their saints, and commemorate her festival on the 11th of July.

OLIBANUM, in *Pharmacy*, a gummy resin, (the product of the *juniperus lycia* Lin.), brought from Turkey and the East Indies, usually in drops or tears. See Materia Medica *Index*.

OLIGARCHY, a form of government wherein the administration of affairs is confined to a few hands.

OLIO, or Oglio, a savoury dish, or food, composed of a great variety of ingredients; chiefly found at Spanish tables.

The forms of olios are various. To give a notion of this strange assemblage, we shall here add one from an approved author.

Take rump of beef, neats tongues boiled and dried, and Bologna sausages; boil them together, and, after boiling two hours, add mutton, pork, venison, and bacon, cut in bits; as also turnips, carrots, onions and cabbage, borage, endive, marigolds, sorrel, and spinach; then spices, as saffron, cloves, mace, nutmeg, &c. This done, in another pot put a turkey or goose, with capons, pheasants, wigeons and ducks, partridges, teals, and stock-doves, snipes, quails, and larks, and boil them in water and salt. In a third vessel, prepare a sauce of white wine, strong broth, butter, bottoms of artichokes, and chesnuts, with cauliflowers, bread, marrow, yolks of eggs, mace, and saffron. Lastly, Dish the olio by first laying out the beef and veal, then the venison, mutton, tongues, and sausages, and the roots over all; then the largest fowls, then the smallest, and lastly pour on the sauce.

OLISIPO, (Pliny, Antonine, Inscriptions); a town of Lusitania, situated on the north side of the frith of the Tagus; of such antiquity, that Solinus thought it was built by Ulysses; and Mela, probably to favour this opinion, writes, according to the common copies, *Ulyssipo*; both of them perhaps deceived by the similarity of sound. It was a municipium, with the surname *Felicitas Julia*, a privilege granted by the munificence of Augustus (Inscriptions, Pliny). Now Lisbon, capital of Portugal, situated on the north bank of the Tagus, distant about ten miles from its mouth. See Lisbon.

OLIVAREZ, Count de, by name *Don Gaspar de Guzman*, favourite and minister to Don Philip IV. of Spain, about 1620; a man of great parts and boundless ambition. Philip no sooner became king, than he became the subject of this his favourite. The king had abilities, it is true, but they lay dormant; and whilst he spent his time in listless inactivity, the whole government was under the direction of Olivarez. The count's management, indeed, was sufficiently dexterous in accomplishing his own designs; for by the best framed excuses, and on the most plausible pretexts, he removed all such as he thought stood in his way; nor did he stop there, but sometimes persecuted his rivals even to death, of which Don Rodrigo Calderona was a melancholy instance, an instance which at that time excited universal compassion. This minister, in short, had a genius of no common kind; added to which, he had a disposition which spurned all controul.

He had persecuted the late ministry for their pusillanimity in the management of affairs; he therefore thought it necessary, and it was certainly prudent, to pursue new measures. His self-sufficiency, though unbounded, was concealed under the veil of assumed modesty, and he was careful to make it appear that he was wholly taken up with the things of his own province. His politics were of a refined perhaps, but not of a very useful, tendency; for his imprudence, or his wrong notions on the subject, made him renew a war with Holland, contrary to the universal opinion of the council and the people. By the same imprudence, or by something worse, he provoked England, and obliged her to endeavour to humble the pride and lessen the authority of the house of Austria. Thus far he had been of little

Olivarez.

service to his country, having only provoked the resentment of the most powerful states, particularly England, France, Holland, &c. to conspire for its ruin. It is remarkable that Olivarez, notwithstanding this, never lost his credit; and indeed things so turned about in the end, that though Spain for a whole year was put to the severest trials, it acquired a degree of fame which sufficiently, in the general opinion, overbalanced some little loss. Olivarez too was particularly fortunate in making the peace; in which transaction he gained a very considerable advantage over Richelieu, so that things appeared to be still in a very favourable train. Fortune, however, was not always quite so indulgent to the schemes of this minister: he again drew Spain into a war with Mantua, contrary to the sentiments of the wisest men; from which is justly dated its declension, if not its ruin.

On the whole, Olivarez seems to have been always averse to peace; and with such a restless disposition, it is undoubtedly wonderful that he held his place so long and with so few complaints as he did.

It was certainly owing to his ambition and obstinacy, that an almost general war was excited about the year 1627, and which, as we have said, proved so fatal to Spain. So averse, indeed, does he appear to have been to peace, that he used every means in his power to prevent the restoration of it in Italy; and for this very purpose he sent Feria into Milan, whom he knew to be a man of such a temper and abilities as suited his purposes; for he was naturally averse to quiet. He endeavoured to break the alliances of the duke of Mantua by various stratagems; but they did not succeed: the schemes of Olivarez and the intrigues of Feria being totally defeated. Our minister had soon after this another cause of mortification, on Richelieu's being created a duke and peer of France, and unanimously admitted among the Venetian nobility; which could not fail to be a severe stroke on Olivarez, who considered him as his implacable enemy.

The people at length began to see and be displeased with his conduct; and with reason, had they known it all, for it was in many instances cruel and detestable. Indeed the differences which at that time had so long subsisted between France and Spain were the effect of the private animosity between him and Richelieu. Things, however, so turned about, and Spain was so unusually successful, that the faults of the minister were overlooked for the time; but this unexpected good fortune had no other effect than that of making him far more insolent than ever. He was, in every instance, one of the most headstrong and obstinate men in the world: he had set his heart on the reduction of Casal in Italy, and he was determined on it at whatever hazard; this foolish enterprise was, however, unaccountably defeated, and the Spanish army experienced a total defeat.

The revolt of the Catalans, whom he wished to deprive of their privileges, was the next consequence of his folly: he had privately employed the marquis de los Velez to extinguish this rebellion; but the cruelty of the measures used for this purpose only inflamed it the more. The revolution of Portugal, another disastrous event, was also the result of his obstinacy and rigour.

This series of ill fortune, which ought to have opened the eyes of the Catholic king and his ministers, seemed to infatuate both. The great secret by which Olivarez had governed his master was being the companion, or at least the confidant, of his pleasures. While he affected to deceive the world with a specious appearance of religion and piety, he was not only immersed in vice himself, but encouraged and promoted it in his prince, to the scandal of his subjects, and the prejudice of his affairs. At this time, of all others the most improper, Olivarez produced a bastard of his, hitherto called *Julian*; he had taken so little care of this son, that, not able to subsist in Spain, he had passed over to the Indies, where, in very mean stations, he had scarcely got bread. On him he now bestowed the name of *Don Henrico de Guzman*; and bringing him with great pomp and splendour to court, either flattered or forced the constable of Castile to give him his daughter; in consideration of which alliance he was to devolve upon him his duchy of St Lucar. In the beginning of his administration, by some accident or other, he presented to the king a memorial, in relation to an affair upon which his majesty had already received one from Don Balthasar de Zuniga: upon comparing them, they contradicted each other flatly. The king ordered a person of great quality to inquire thoroughly into this business; in consequence of which Don Balthasar's memorial appeared to be the truth, and that of Olivarez the reverse of it. The king was very angry; but the count regained his favour, by procuring for him the fair actress Calderona. By this woman he had a son, of whom no great notice was taken; but now, to obscure the folly of the count duke, this youth, scarce in the 14th year of his age, was produced, with the title of *Don Juan of Austria*, and declared generalissimo of the army against Portugal; while the heir apparent to the crown, Don Balthasar, was left under the tuition, or rather in the custody of the countess of Olivarez; at which conduct the queen was chagrined, the people enraged, and the world in general astonished.

His schemes now began to be entirely broken and defeated everywhere and in every kind; he fell under the displeasure of the queen, the emperor, the grandees, and the people all at once, and experienced the disgrace he had long merited. His ill fortune, which came upon him with the force of a torrent, did not, however, wholly overpower him; he was indeed obliged to conceal himself, in order to avoid the rage of the populace: but he had still confidence enough to offer an apology for his conduct, which possessed no inconsiderable share of wit and humour, well tempered with spirit and masterly reasoning. It was not, however, of any consequence to him; for he was banished to Toro, where, worn out by infirmities, or overcome by despair, he ended his days about the year 1645.

Olivarez || Olive Press.

OLIVE, the fruit of the olive tree. See OLEA, BOTANY *Index*.

OLIVE Press. In order to obtain the olive oil, the olives are first bruised in a rough trough, under a millstone, rolling perpendicularly over them; and when sufficiently mashed, put into the maye or trough, *m*, of an olive press, where *a a* are the upright beams, or cheeks; *b*, the female, and *c*, the male screw; *f*, the board on which the screw passes; *g*, a cubical piece of wood, called a *block*; *h*, the peel, a circular board, to be put under the block. By turning the screw, all the liquor

Plate CCCLXX.

liquor is pressed out of the mashed olives, and is called *virgin oil;* after which, hot water being poured upon the remainder in the press, a coarser oil is obtained. Olive oil keeps only about a year, after which it degenerates.

Olive Colour, a yellow mingled with black.

OLIVET, or *Mount of Olives*, in *Ancient Geography*, was situated to the east of the city of Jerusalem, and parted from the city only by the brook Kidron, and by the valley of Jehoshaphat, which stretches out from the north to the south. It was upon this mount that Solomon built temples to the gods of the Ammonites (1 Kings xi. 7.) and of the Moabites, out of complaisance to his wives, who were natives of these nations. Hence it is that the mount of Olives is called the *mountain of corruption* (2 Kings xxiii. 13.). Josephus says, that this mountain is at the distance of five stadia, or furlongs, from Jerusalem, which makes 625 geometrical paces, or the length of a Sabbath-day's journey, says St Luke (Acts i. 12.). The mount of Olives had three summits, or was composed of three several mountains, ranged one after another from north to south. The middle summit is that from whence our Saviour ascended into heaven. It was upon that towards the south that Solomon built temples to his idols. The summit which is most to the north is distant two furlongs from the middlemost. This is the highest of the three, and is commonly called Galilee.

In the time of King Uzziah, the mount of Olives was so shattered by an earthquake, that half of the earth that was on the western side fell down, and rolled four furlongs or 500 paces from thence, towards the mountain which was opposite to it on the east; so that the earth blocked up the highways, and covered the king's gardens.

Mr Maundrell tells us that he and his company going out of Jerusalem at St Stephen's gate, and crossing the valley of Jehoshaphat, began immediately to ascend the mountain; that being got above two-thirds of the way up, they came to certain grottoes cut with intricate windings and caverns under ground, which were called the sepulchres of the prophets; that a little higher up were twelve arched vaults under ground, standing side by side, and built in memory of the apostles, who are said to have compiled their creed in this place; that 60 paces higher they came to the place where Christ is said to have uttered his prophecy concerning the final destruction of Jerusalem; and a little on the right hand, to another, where he is said to have dictated a second time the Lord's prayer to his disciples; that somewhat higher is the cave of a saint called *Pelagia*; a little above that, a pillar denoting the place where an angel gave the Blessed Virgin three days warning of her death; and at the top of all, the place of our blessed Lord's ascension.

OLIVETAN, Robert, related to the famous Calvin, printed at Neufchatel in 1535, in folio, a version of the Bible into French, the first which had been translated from the original Hebrew and Greek. It is written in an uncouth and barbarous style, and is far from being faithful. The characters in which it is printed are Gothic, and the language of it is no less so. It is valued only because it is rare. Calvin is thought to have had a very considerable share in this translation. Olivetan survived his publication but a short time; for he was poisoned at Rome the year after, of which his translation is alleged to have been the cause. Olivetan's Bible, revised by John Calvin and N. Malinger, was reprinted at Geneva, in 1540, in quarto. This edition is still rarer than the former. It is called the *Bible de l'Epee*, because the printer had a sword for his sign.

OLIVIER, Claude Matthieu, advocate of the parliament of Aix, was born at Marseilles, in 1701, and appeared at the bar with eclat. He had a chief hand in the establishment of the academy of Marseilles, and was one of its original members. He possessed a quick and lively genius. A few hours retirement from society and from his pleasures were frequently sufficient to enable him to speak and write, even on important causes; but his works commonly bore marks of haste. Given to excess in every thing, he would employ a fortnight in studying the Code and the Digest, or in storing his mind with the beauties of Demosthenes, Homer, Cicero, or Bossuet: and then abandon himself for another fortnight, frequently a whole month, to a life of frivolity and dissipation. He died in 1736, at the age of 35. He published, 1. *L'Histoire de Philippe roi de Macedoine, et pere d'Alexandre le Grand*, 2 vols 12mo. No writer has so ably handled the history of the age of Philip, the interests of the different nations of Greece, and their manners and customs: but the conduct of the work is extremely defective. The digressions are too frequent, and often tedious. The style is in no respect suitable to a history. It is in general dry, unconnected, and like the style of a dissertation. Sometimes, however, we find in it passages full of fire and beauty, and turns of expression truly original. A disease of the brain, with which he was attacked, and under which he laboured several years, preventing him from putting his last hand to the work. 2. *Mémoire sur les secours donnés aux Romains par les Marseillois pendant la 2de Guerre Punique.* 3. *Mémoire sur les secours donnés aux Romains par les Marseillois durant la Guerre contre les Gaulois.*

OLMUTZ, a town of Germany, in Moravia, with a bishop's see, and a famous university, and containing 11,000 inhabitants. The public buildings are very handsome, particularly the Jesuits college. It is a trading place and very strong; and yet it was taken, with the whole garrison, by the king of Prussia in 1741. In July 1758 he besieged it again; and when he had almost taken the place, he was obliged to raise the siege, to go and meet the Russian army. It is seated on the river Morava. E. Long. 17. 35. N. Lat. 49. 30.

OLYMPIA, Maldachini Donna, a woman of a very uncommon character. She flourished about the middle of the 17th century. She was sister-in-law to Pope Innocent X. and had the address to acquire an unlimited power over this vain, weak, and injudicious ecclesiastic. Her son Camillo was promoted to the cardinalate, under the title of Pamphilio; but falling in love with the princess Rossana, a beautiful young widow, he laid aside his hat, and married. The crime, if it was one, was esteemed by the Romans in general at least venial. The pope, however, was displeased; and Olympia procured their banishment, being afraid lest her daughter-in-law should lessen her authority in the *sacred court*. This authority, equally unnatural and uncommon, reflected neither honour on her who held it, nor on the man who allowed her to hold it. Such elevated situations, Olympia. situations, however, whether they are the reward of merit, the effect of chance, or acquired by cunning, are seldom very secure. Olympia, who had procured the disgrace of many who did not deserve it, and who had herself long merited such a fate, at length experienced both disgrace and banishment. This was obtained by means of Cardinal Panzirollo, a great favourite of the pope's. The immediate cause of it was this: The pope had determined, in order to lessen his own trouble, to adopt a nephew, and to make him a *Cardinal Patron*, in order to give audience to ambassadors and ministers, and in his absence to preside at the council. For this purpose, at the recommendation of his favourite, his holiness make choice of Astalli, brother of the marquis Astalli, who had married a niece of Olympia. Olympia indeed was slightly consulted on the affair, and showed no disapprobation of the appointment. The pope, however, no sooner got him fixed in his new office, than he showed his own weakness by repenting of it. Olympia too was displeased, and by her solicitations procured the disgrace of Astalli, before he had enjoyed either the honours or emoluments of his office. Panzirollo, however, soon managed matters so as to turn the scales: he prevailed on the pope again to countenance and honour Astalli; and, what was more, had influence sufficient to persuade him to disgrace Olympia, and to banish her the court. She had indeed abused her authority in a most scandalous manner, and had gained such an absolute ascendant over the pope, that in every thing his will had been subservient to her dictates.—Her avarice and ambition were unbounded: she disposed of all benefices, which were kept vacant till she fully informed herself of their value: she rated an office of 1000 crowns for three years, at one year's revenue, and if for life, at 12 years purchase, one half of which sum she required to be paid in advance: she gave audience upon public affairs, enacted new laws, abrogated those of former popes, and sat in council with Innocent, with bundles of memorials in her hands. It was generally said that they lived together in a criminal correspondence, and that she had charmed him by some secret incantation. In the Protestant countries the loves and intrigues of Innocent and Donna Olympia were represented upon the stage; and severe sarcasms were daily put into the hands of Pasquin at Rome.—As she had usurped such an absolute authority, the new cardinal nephew saw the necessity of ruining her credit; he therefore seconded the endeavours of Panzirollo.—He insinuated to the pope, that his reputation had suffered greatly among the Catholics by her scandalous proceedings, and that his nuncios were treated with disrespect and contempt at the courts of the emperor, France, and Spain. Upon these representations, Innocent at length, but with great reluctance banished Olympia, and was reconciled to Prince Camillo and the princess Rossana; though some authors affirm that her banishment was no more than a political retreat, and that she still in private directed the affairs of the pope. A woman of Olympia's character, however, with such unbounded ambition, such an extravagant lust for power, and such an ambitious desire of wealth, and who had once possessed so great an ascendancy over such a man as Innocent, was not so easily to be put off. She was banished in 1650; but in 1653, she again assumed the supreme direction of affairs just as before her disgrace. She again accomplished the disgrace of Astalli, and procured the promotion of Azzolini to the office of secretary of the briefs. In 1654, his holiness resigned himself entirely into the hands of this assuming woman; who, observing his infirmities daily increasing, redoubled her rapacity, disposing of benefices to the highest bidders in all parts of Italy. She was again, however, in hazard of being displaced by a new favourite, viz. the cardinal de Retz; and had not the pope's dissolution prevented it, it would in all probability quickly have taken place. During his last illness he received nothing but from the hands of Donna Olympia, who was at great pains to prolong his life, watched continually at his bed side, and prevented the ambassadors or others from disturbing him with discourses upon business. She is said, during the last ten days of his life, when he continued without the use of reason, to have amassed about half a million of crowns. She did not find the succeeding pope (Alexander VII.) so easy to be played upon as his weak predecessor: a number of memorials were sent in against her, and his holiness was well disposed to attend to them: he ordered her to retire from Rome, and at the same time began to examine witnesses respecting her conduct. She was cut off, however, before the trial was finished, by the plague, which, in 1636, afflicted Rome and its neighbourhood. Her estate was not confiscated as was generally expected; and the prince Pamphilio was allowed to succeed her. The pope only reserved for his own relations about million of crowns.

OLYMPIA, in *Ancient Geography*, with the surname *Pisatis* (Strabo); so called from the territory of Pisa in Elis; described by Strabo, "as the temple of Jupiter Olympius, before which stands a grove of wild olive trees, in which is the stadium, or foot-course, so called because the eighth part of a mile; and by which the Alpheus, coming down from Arcadia, runs." Olympia, however, was famous not merely for the temple of Jupiter, but also for a temple of Juno, 63 feet long, with columns round it of the Doric order; and a Metroum or temple of the mother of the gods, a large Doric edifice; with holy treasuries. These, and the porticoes, gymnasium, prytaneum, and many more buildings, chiefly in the enclosure, with the houses of the priests and other inhabitants, made Olympia no inconsiderable place. The stadium was in the grove of wild olive trees, before the great temple; and near it was the hippodrome or course for the races of horses and chariots. The Alpheus flowed by from Arcadia with a copious and very pleasant stream, which was received on the coast by the Sicilian sea.

The temple of Jupiter was of the Doric order, 68 feet high to the pediment, 95 wide, and 230 long; the cell encompassed with columns. It was erected with the country stone; the roof not of earth baked, but of Pentelic marble; the slabs disposed as tiles; the way to it up a winding staircase. The two pediments were enriched with sculpture; and one had over the centre a statue of Victory gilded; and underneath a votive buckler of gold. At each corner was a gilded vase. Above the columns were fixed 21 gilded bucklers, offered at the conclusion of the Achæan war by the Roman general Mummius. The gates in the two fronts were

were of brass, and over them were carved the labours of Hercules. Within the cell were double colonnades, between which was the approach to the image.

The Jupiter of Olympia was accounted alone sufficient to immortalize its maker, Phidias. It was of ivory and gold, the head crowned with olive. In the right hand was a statue of Victory; in the left a flowered sceptre, composed of various metals, on which was an eagle. The sandals were of gold, as also the vestment, which was curiously embossed with lilies and animals. The throne was gold inlaid with ebony and ivory, and studded with jewels, intermixed with paintings and exquisite figures in relievo. The pillars between the feet contributed to its support. Before it were walls, serving as a fence, decorated principally with the exploits of Hercules; the portion opposite to the door of a blue colour. It was the office of a family descended from Phidias, called *phædruntæ* or *the polishers*, to keep the work bright and clean. The veil or curtain was cloth rich with the purple dye of Phœnicia and with Assyrian embroidery, an offering of King Antiochus, and was let down from above by loosening the strings. The image impressed on the spectator an opinion that it was higher and wider than it measured. Its magnitude is such, that though the temple was very large, the artist seemed to have erred in the proportions. The god, sitting, nearly touched the ceiling with his head; suggesting an idea, that if he were to rise up, he would destroy the roof. A part of the pavement before it was of black marble, enclosed in a rim of Parian or white, where they poured oil to preserve the ivory.

The altar of Jupiter Olympius was of great antiquity, and composed of ashes from the thighs of the victims, which were carried up and consumed on the top with wood of the white poplar tree. The ashes also of the prytaneum, in which a perpetual fire was kept on a hearth, were removed annually on a fixed day, and spread on it, being first mingled with water from the Alpheus. The cement, it was affirmed, could be made with that fluid only; and therefore this river was much respected, and esteemed the most friendly of any to the god. On each side of the altar were stone steps. Its height was 22 feet. Girls and women, when allowed to be at Olympia, were suffered to ascend the basement, which was 125 feet in circumference. The people of Elis sacrificed daily, and private persons as often as they chose.

Religion flourished at Olympia, and many deities were worshipped besides Jupiter. Pausanius has enumerated above 60 altars of various shapes and kinds. One of the unknown gods stood by the great altar. The people of Elis offered on all these monthly; laying on them boughs of olive; burning incense, and wheat mixed with honey; and pouring libations of such liquors as the ritual prescribed. At the latter ceremony sometimes a form of prayer was used, and they sung hymns composed in the Doric dialect.

Olympia was situated on an eminence, between two mountains called *Ossa* and *Olympus*. Though its ancient splendour is gone, the place reminds the traveller of what it once was. It is in the Morea, being now a small place called *Longinico*, 50 miles south of Lepanto, in E. Long. 22. 0. N. Lat. 37. 40.

OLYMPIAD, the space of four years, whereby the Greeks reckoned time.—The first Olympiad fell, according to the accurate and learned computation of some of the moderns, exactly 776 years before the first year of Christ, or 775 before the year of his birth, in the year of the Julian period 3938, and 22 years before the building of the city of Rome. The games were exhibited at the time of the full moon next after the summer solstice; therefore the Olympiads were of unequal length, because the time of the full moon differs 11 days every year, and for that reason they sometimes began the next day after the solstice, and at other times four weeks after. The computation by Olympiads ceased, as some suppose, after the 304th, in the year 440 of the Christian era. It was universally adopted not only by the Greeks, but by many of the neighbouring countries; though still the Pythian games served as an epoch to the people of Delphi and to the Bœotians; the Nemæan games to the Argives and Arcadians; and the Isthmian to the Corinthians and the inhabitants of the Peloponnesian isthmus. To the Olympiads history is much indebted. They have served to fix the time of many momentous events; and indeed before this method of computing time was observed, every page of history is mostly fabulous, and filled with obscurity and contradiction, and no true chronological account can be properly established and maintained with certainty.

OLYMPIAS, a celebrated woman, who was daughter of a king of Epirus, and who married Philip king of Macedonia, by whom she had Alexander the Great. Her haughtiness, and more probably her infidelity, obliged Philip to repudiate her, and to marry Cleopatra, the niece of King Attalus. Olympias was sensible of this injury, and Alexander showed his disapprobation of his father's measures, by retiring from the court to his mother. The murder of Philip, which soon followed this disgrace, and which some have attributed to the intrigues of Olympias, was productive of the greatest extravagances. The queen paid the greatest honour to her husband's murderer. She gathered his mangled limbs, placed a crown of gold on his head, and laid his ashes near those of Philip. The administration of Alexander, who had succeeded his father, was in some instances offensive to Olympias; but when the ambition of her son was concerned, she did not scruple to declare publicly that Alexander was not the son of Philip, but that he was the offspring of an enormous serpent who had supernaturally introduced himself into her bed. When Alexander was dead, Olympias seized the government of Macedonia; and, to establish her usurpation, she cruelly put to death Aridæus, with his wife Eurydice, as also Nicanor the brother of Cassander, with 100 leading men of Macedon, who were inimical to her interest. Such barbarities did not long remain unpunished: Cassander besieged her in Pydna, where she had retired with the remains of her family, and she was obliged to surrender after an obstinate siege. The conqueror ordered her to be accused, and to be put to death. A body of 200 soldiers were ordered to put the bloody commands into execution, but the splendour and majesty of the queen disarmed their courage; and she was at last massacred by those whom she had cruelly deprived of their children, about 316 years before the Christian era.

OLYMPIC GAMES, wese solemn games among the ancient Greeks, so called from Olympian Jupiter, to whom they were dedicated; and by some said to be first

first instituted by him, after his victory over the sons of Titan; others ascribe their institution to Hercules, not the son of Alcmena, but one of much greater antiquity; others to Pelops; and others to Hercules the son of Alcmena. By whomsoever they were instituted, we know that, at a period rather early, they had fallen into disuse. The wars which prevailed among the Greeks, for a while, totally interrupted the religious ceremonies and exhibitions with which they had been accustomed to honour the common gods and heroes; but the Olympic games were restored on the following occasion. Amidst the calamities which afflicted or threatened Peloponnesus, Iphitus, a descendant of Oxylus, to whom the province of Eleia * had fallen in the general partition of the peninsula, applied to the Delphic oracle. The priests of Apollo, ever disposed to favour the views of kings and legislators, answered agreeably to his wish, that the festivals anciently celebrated at Olympia, on the Alpheus, must be renewed, and an armistice proclaimed for all the states willing to partake of them, and desirous to avert the vengeance of heaven. Fortified by this authority, and assisted by the advice of Lycurgus, Iphitus took measures, not only for restoring the Olympic solemnity, but for rendering it perpetual. The injunction of the oracle, was speedily diffused through the remotest parts of Greece by the numerous votaries who frequented the sacred shrine. The armistice was proclaimed in Peloponnesus, and preparations were made in Eleia for exhibiting shows and performing sacrifices. In the heroic ages, feats of bodily strength and address were destined to the honour of deceased warriors; hymns and sacrifices were reserved for the gods: but the flexible texture of Grecian superstition, easily confounding the expressions of respectful gratitude and pious veneration, enabled Iphitus to unite both in his new institution.

* *Gillies's History of Greece.*

The festival, which lasted five days, began and ended with a sacrifice to Olympian Jove. The intermediate time was chiefly filled up by the gymnastic exercises, in which all freemen of Grecian extraction were invited to contend, provided they had been born in lawful wedlock, and had lived untainted by any infamous immoral stain. The preparation for this part of the entertainment was made in the gymnasium of Elis, a spacious edifice, surrounded by a double range of pillars, with an open area in the middle. Adjoining were various apartments, containing baths, and other conveniences for the combatants. The neighbouring country was gradually adorned with porticoes, shady walks and groves, interspersed with seats and benches; the whole originally destined to relieve the fatigues and anxiety of the candidates for Olympic fame; and frequented in later times, by sophists and philosophers, who were fond to contemplate wisdom, and communicate knowledge, in those delightful retreats. The order of the athletic exercises, or combats, was established by Lycurgus, and corresponded almost exactly to that described by Homer, in the 23d book of the Iliad, and eighth of the Odyssey. Iphitus, we are told, appointed the other ceremonies and entertainments; settled the regular return of the festival at the end of every fourth year, in the month of July; and gave to the whole solemnity that form and arrangement, which it preserved with little variation above a thousand years; a period exceeding the duration of the most famous kingdoms and republics of antiquity. Among the benefactors of Olympia, at a much later period, was reckoned Herod, who was afterwards king of Judæa. Seeing, on his way to Rome, the games neglected or dwindling into insignificance from the poverty of the Eleans, he displayed vast munificence as president, and provided an ample revenue for their future support and dignity.

The care and management of the Olympics belonged for the most part to the Eleans; who on that account enjoyed their possessions without molestation, or fear of war or violence. They appointed a certain number of judges, who were to take care that those who offered themselves as competitors should perform their preparatory exercises; and these judges, during the solemnity, sat naked, having before them a crown of victory, formed of wild olive, which was presented to whomsoever they adjudged it. Those who were conquerors were called *Olympionices*, and were loaded with honours by their countrymen. At these games women were not allowed to be present; and if any woman was found, during the solemnity, to have passed the river Alpheus, she was to be thrown headlong from a rock. This, however, was sometimes neglected; for we find not only women present at the celebration, but also some among the combatants, and some rewarded with the crown. The preparations for these festivals were great. No person was permitted to enter the lists, if he had not regularly exercised himself ten months before the celebration at the public gymnasium of Elis. No unfair dealings were allowed; whoever attempted to bribe his adversary was subjected to a severe fine; and even the father and relations were obliged to swear that they would have recourse to no artifice which might decide the victory in favour of their friends. No criminals, nor such as were connected with impious and guilty persons, were suffered to present themselves as combatants. The wrestlers were appointed by lot. Some little balls superscribed with a letter were thrown into a silver urn, and such as drew the same letter were obliged to contend one with the other. He who had an odd letter remained the last; and he often had the advantage, as he was to encounter the last who had obtained the superiority over his adversary. In these games were exhibited running, leaping, wrestling, boxing, and the throwing of the quoit, which was called altogether πενταθλον, or *quinquertium*. Besides these, there were horse and chariot races, and also contentions in poetry, eloquence, and the fine arts. The only reward that the conqueror obtained was a crown of olive. This, as some suppose, was in memory of the labours of Hercules, which were accomplished for the universal good of mankind, and for which the hero claimed no other reward but the consciousness of having been the friend of mankind. So small and trifling a reward stimulated courage and virtue, and was the source of greater honours than the most unbounded treasures. The statues of the conquerors, called *Olympionicæ*, were erected at Olympia in the sacred wood of Jupiter.

Their return home was that of a warlike conqueror; they were drawn in a chariot by four horses, and every where received with the greatest acclamations. Their entrance into their native city was not through the gates: to make it more grand and more solemn, a breach was made in the walls. Painters and poets were employed in celebrating their names; and indeed the

victories

victories severally obtained at Olympia are the subjects of the most beautiful odes of Pindar. The combatants were naked. A scarf was originally tied round their waste; but when it had entangled one of the adversaries, and been the cause that he lost the victory, it was laid aside, and no regard was paid to decency. The Olympic games were observed every fifth year, or, to speak with greater exactness, after a revolution of four years, and in the first month of the fifth year, and they continued for five successive days. As they were the most ancient and most solemn of all the festivals of the Greeks, it will not appear wonderful that they drew so many people, not only inhabitants of Greece, but of the neighbouring islands and countries.

Such is the account of Grecian writers, who have, doubtless, often ascribed to positive institution many inventions and usages naturally resulting from the progressive manners of society. When we come to examine the Elean games in their more improved state, together with the innumerable imitations of them in other provinces of Greece, there will occur reasons for believing, that many regulations, referred by an easy solution to the legislative wisdom of Iphitus or Lycurgus, were introduced by time or accident, continued through custom, improved by repeated trials, and confirmed by a sense of their utility *. Yet such an institution as the Olympiad, even in its least perfect form, must have been attended with manifest advantages to society. It is sufficient barely to mention the suspension of hostilities which took place, not only during the celebration of the festival, but a considerable time both before and after it. Considered as a religious ceremony, at which the whole Grecian name was invited, and even enjoined to assist, it was well adapted to facilitate intercourse, to promote knowledge, to soften prejudice, and to hasten the progress of civilization and humanity. Greece, and particularly Peloponnesus, was the centre from which the adventurous spirit of its inhabitants had diffused innumerable colonies through the surrounding nations. To these widely separated communities, which, notwithstanding their common origin, seemed to have lost all connexion and correspondence, the Olympiad served as a common bond of alliance and point of re-union. The celebrity of this festival continually attracted to it the characters most distinguished for genius and enterprise, whose fame would have otherwise been unknown and lost in the boundless extent of Grecian territory. The remote inhabitants, not only of European Greece, but of Asia and Africa, being assembled to the worship of common gods, were formed to the sense of a general interest, and excited to the pursuit of national honour and prosperity. Strangers of similar dispositions might confirm in Elis the sacred and indissoluble ties of hospitality. If their communities were endangered by any barbarous power, they might here solicit assistance from their Grecian brethren. On other occasions they might explain the benefits which, in peace or war, their respective countries were best qualified to communicate. And the Olympic festival might thus serve the purpose of resident ambassadors, and other institutions alike unknown to antiquity.

* *Gillies's History of Greece.*

OLYMPUS, the name of several mountains.—One bounding Bithynia on the south.—Another in the island of Cyprus, on whose top was a temple of Venus, which women were not permitted either to enter or to see (Strabo).—A third, Olympus of Galatia (Livy).—A fourth, of Lycia, with a noble cognominal town, near the sea coast (Strabo, Cicero), extinct in Pliny's time, there remaining only a citadel; the town was destroyed by P. Servilius Isauricus (Florus), having been the retreat of pirates. From this mountain there was an extensive prospect of Lycia, Pamphilia, and Pisidia (Strabo).—A fifth, Olympus of Mysia (Ptolemy); thence surnamed *Olympena*, anciently *Minor;* one of the highest mountains, and surnamed *Mysius* (Theophrastus;) situated on the Propontis, and thence extending more inland.—A sixth, on the north of Thessaly, or on the confines of Macedonia; famous for the fable of the giants (Virgil, Horace, Seneca); reckoned the highest in the whole world, and to exceed the flight of birds (Apuleius), which is the reason of its being called *heaven*, than which nothing is higher: the serenity and calmness which reign there are celebrated by Homer, Lucan, and Claudian.

OLYRA, a genus of plants belonging to the monœcia class; and in the natural method ranking under the 4th order, *Gramina*. See BOTANY *Index*.

OMAR EBN AL KHATTAB, successor of Abu Becr.—The Mohammedan imposture, like every other falsehood of its kind, copies after the truth as far as was thought convenient or proper; and miracles being the grand proof of revelation, it was to be expected that all pretences to that should assume at least the appearances of them. Few systems of faith are more absurd than Mohammed's; yet, though he disclaimed miracles, it was supported, as we are told by later writers, by a variety of them, which, however, unfortunately for the creed they were contrived to support, are too trifling, absurd, and contradictory, to deserve the smallest attention.

They tell us, but upon grounds too vague and indeterminate to command belief, that Omar was miraculously converted to this faith: a man he is reported to have been, before this event, truly respectable, and in particular a violent opposer of the Arabian prophet. Mohammed, it seems, felt this opposition, and regretted it; he therefore, with the fervour, and as it happened, with the success of a true prophet, according to his followers account, prayed for the conversion of this his dangerous antagonist. Omar, it is said, had no sooner read the 20th chapter of the Koran than he was convinced: upon which he instantly repaired to Mohammed and his followers, and declared his conversion. It is said, that at one time he intended to murder the prophet; and various causes are assigned for the prevention of this shocking piece of sacrilege. After his wonderful conversion, the Mohammedan writers inform us that he was surnamed *Al Faruk*, or the "divider;" because, say they, when a certain Moslem was condemned by Mohammed for his iniquitous treatment of a Jew, and appealed afterwards from the sentence of the prophet to Omar, he cut him in two with his scimitar for not acquiescing in the decision of so upright a judge: which circumstance when Mohammed heard, he gave him the surname of *Al Faruk*, or "the divider;" because, by this action, he had shown himself capable of perfectly distinguishing between truth and falsehood. Al Kodai affirms, that 39 of Omar's adherents followed his example the same day he professed himself a votary of Mohammed.

Omar. The conversion of Hamza and Omar Ebn Al Khattab happened in the year preceding the first flight of the Moslems into Ethiopia, or the fourth year of Mohammed's mission, according to Abulfeda. He was unquestionably a great acquisition to the prophet, and enabled him to carry on his schemes to far more purpose than he could possibly have done without him, or if he had continued his enemy. Omar at length found his services in the cause he had undertaken sufficiently honoured and amply rewarded; for on the death of Abu Becr, who had succeeded the impostor himself, he was promoted to the regal and pontifical dignity. The title first assigned him was the *caliph of the caliph of the apostle of God;* or in other words *the successor of the successor of Mohammed:* but the Arabs considering that this title, by the addition to be annexed to it at the accession of every future caliph, would be too long, they, by universal consent, saluted him *the emperor of the believers;* which illustrious title, at this juncture conferred on Omar, descended afterwards to all the successors of that prince. Our readers will not expect us to follow the caliph with minute exactness through the transactions of his reign. This would indeed swell our article beyond all proportion. We shall therefore confine ourselves to some of the leading facts.

His arms appear to have been particularly successful; the Persians he conquered, and Jerusalem submitted to his power; nor does he appear to have been checked in a single instance. In consequence, however, of his success, an attempt was made to assassinate him. The fact is thus related: Wathek Ebn Mosafer, a resolute young Arab, was procured by the king of Ghaffan, and sent to Medina for this very purpose. Some time after his arrival, observing Omar to fall asleep under a tree on which he had placed himself, so as not to be discovered by any person, he drew his dagger, and was upon the point of stabbing him, when, lifting up his eyes, he saw a lion walking round about him, and licking his feet. Nor did the lion cease to guard the caliph till he awoke; but then instantly went away. This phenomenon struck Wathek with a profound reverence for Omar, whom he now revered as the peculiar care of heaven. He therefore came down from the tree, on which the lion had forced him to remain, kissed the caliph's hand, confessed his crime, and embraced the Mohammedan religion; being so strongly affected with the wonderful deliverance he had been an eye witness of. His life, however, was at length ended by assassination; for about two years after the conclusion of the Nobawandian war, in which the Arabs probably still farther extended their conquests, though no account of their military operations during that period has reached us, that is in the 23d year of the Hegira, according to Abu Jaafar Al Tabari, the caliph Omar Ebn Al Khattab was assassinated by a Persian slave; of which horrid fact the Arab writers have handed down the following particulars: Abu Lulua, a Persian of the Magian sect, whose name was *Firuz*, one of Al Mogheira Ebn Al Shaabah's slave, was obliged by his master to pay daily two dirhems, in conformity to the Mohammedan custom, for the free exercise of this religion. Firuz resenting this treatment, complained of it to the caliph, and desired that some part at least of the tribute exacted of him might be remitted; but this favour being refused by Omar, the Persian threatened his destruction; which he soon after effected, by stabbing him thrice in the belly with a dagger, while he was in the mosque at Medina performing his morning devotions. The Arabs then present perceiving that the villain had imbrued his hands in the blood of their sovereign, immediately rushed upon him; but he made so desperate a defence, that he wounded 13 of the assailants, and seven of them mortally. At last one of the caliph's attendants threw his vest over him, and seized him; upon which he stabbed himself and soon after expired. According to Theophanes, this Firuz was an apostate or renegade, and consequently had before embraced the Mohammedan religion: but this assertion is by no means probable; because on his becoming a convert to Islamism, he must have been manumitted by his master, and on his relapsing into Magiism, he would have been put to death by the caliph's order: neither of which particulars are consistent with what we find related by the Arab historians, and even by our Greek chronographer himself. Omar languished three days and then died, in the month of Dhu'lhajja, and the 23d year of the Hegira, which began in the year of our Lord 643. Authors are not agreed with regard to the duration of his caliphate. The Arab historians, whom we are inclined to follow, say that he reigned between 10 and 11 years. Theophanes affirms, that he was murdered in the 12th year of his caliphate, and Dionysius Telmarensis extends the length of his reign to 12 complete years. Only one of the wounds given him by Firuz was mortal, and that he received under his navel. At his death he was 63 years old; which, as we are told by an Arab author, was the age of Mohammed himself, Abu Becr, and Ayesha, one of the prophet's wives, when they died. When Omar fell in the mosque, Abd'alrahman Ebn Awf, one of Mohammed's first converts, supplied his place during the remainder of the service; and three days before his death, Sahib Ebn Tarsib, at his command, officiated for him. His body was interred in Ayesha's apartment, near that of the prophet Mohammed. We are informed by Eutychius, that during his caliphate he performed the pilgrimage to Mecca nine times. His extensive conquests made the Moslem empire one of the most powerful and formidable monarchies in the world. His disposition is represented to us, with evident partiality indeed, as one of the best possible, and his temperance has always been highly extolled.

Omar, Ombi. OMBI, a city of ancient Egypt, afterwards called *Arsinoe* and *Crocodilopolis*, was the capital of one of the nomes into which that country was divided, and is remarkable, in the annals of idolatry, for the hatred of its inhabitants to the religion of their neighbours the citizens of Tentyra.

The genius of paganism was so complying with respect to the objects of religious worship, that although each nation, each city, and almost every family, had its own tutelar god, we know not a single instance, out of Egypt of one tribe of Pagans persecuting another for worshipping gods different from theirs. The Jews and Christians were indeed persecuted by the Romans, not however for worshipping the true God, but because, together with him, they would not worship Jupiter, Juno, and all the rabble of heathen divinities.

The reason of the almost universal tolerance of idolaters to one another, and of the intolerance of all to the

the Jews and Christians, is very obvious. Not a single Pagan, a very few philosophers perhaps excepted, ever thought of paying his adoration to the Supreme and self-existent Being, but to inferior divinities, to whom it was supposed that the care of particular persons, families, cities, and nations, was consigned by the God of the universe. The consequence was, that, as no person denied the divinity of his neighbour's object of worship, an intercommunity of gods was everywhere admitted, and all joined occasionally in adoring the gods of the various nations. By the Jews and Christians this communion was rejected as in the highest degree impious; and it could not well be maintained between the citizens of Ombi and those of Tentyra.

That brutes were worshipped in Egypt is universally known (see POLYTHEISM); and Diodorus the Sicilian informs us, in a passage quoted by Eusebius *, that "the cities and nomes of Egypt being at one time prone to rebellion, and to enter into conspiracies against monarchical government, one of their most politic kings contrived to introduce into the neighbouring nomes the worship of different animals; so that while each reverenced the deity which itself held sacred, and despised that which its neighbours had consecrated, they could hardly be brought to join cordially in one common design to the disturbance of the government."

* *Prep. Evang.* p. 32. Steph. ed.

In this distribution of gods he conferred upon Ombi the *crocodile*, and upon Tentyra, the mortal enemy of that monster, the *ichneumon*. The consequence of which was, that while the Ombites worshipped the crocodile, the Tentyrites took every opportunity of slaughtering him, insomuch that, according to Strabo, the very voice of an inhabitant of Tentyra put the crocodile to flight. This, we confess, is a very improbable fact; but it is certain that the mutual hatred of those cities, on account of their hostile gods, rose to such a height, that whenever the inhabitants of the one were engaged in the more solemn rites of their religion, those of the other were sure to embrace the opportunity of setting fire to their houses, and rendering them every injury in their power to inflict. And what may, to a superficial thinker, appear extraordinary, though it will excite no wonder in the breast of him who has studied mankind, this animosity continued between the inhabitants of the two cities long after the crocodile and ichneumon had lost their divinity.

The conduct of the Egyptian monarch was admirably calculated for preventing the nation from combining against the government; and it extended its influence over the whole kingdom. Diodorus informs us, that he assigned to each nome an animal to worship, which was hated, killed, and sometimes fed upon by the inhabitants of the neighbouring nome; and we know, upon higher authority than his, that the Israelites could not offer sacrifices in Egypt, because the bullock was deemed sacred over the whole country.

OMBRE, a celebrated game at cards, borrowed from the Spaniards, and played by two, by three, or by five persons, but generally by three. When three play at this game, nine cards are dealt to each party; the whole ombre pack being only 40: because the eights, nines, and tens, are thrown out of the pack. There are two sorts of counters for stakes, the greater and the lesser; the last having the same proportion to the other as a penny to a shilling: of the greater counters each man stakes one for the game; and one of the lesser for passing for the hand, when eldest, and for every card taken in. As to the order and value of the cards, the ace of spades, called *spadillo*, is always the highest trump, in whatsoever suit the trump be; the *manille*, or black duce, is the second; and the *basto*, or ace of clubs, is always the third: the next in order is the king, the queen, the knave, the seven, the six, the five, four, and three. Of the black there are 11 trumps; of the red, 12. The least small cards of the red are always the best, and the most of the black; except the duce and red seven, both of which are called the *manilles*, and are always second when the red is a trump. The red ace, when a trump, enters into the fourth place, and is called *punto;* otherwise it is only called an ace. The three principal cards are called *matadores;* which have this privilege, that they are not obliged to attend an inferior trump when it leads; but for want of a small trump, the person may renounce trumps, and play any other card; and when these are all in the same hand, the others pay three of the greater counters a-piece; and with these three for a foundation, he may count as many matadores as he has cards in an uninterrupted series of trumps; for all which the others are to pay one counter a-piece. He who hath the first hand is called *ombre*, and has his choice of playing the game, of naming the trump, and of taking in as many and as few cards as he pleases; and after him the second, &c. But if he does not name the trump before he looks on the cards he has taken in, any other may prevent him, by naming what trump he pleases. He that has the first hand should neither take in, nor play, unless he has at least three sure tricks in his hand: for, as he wins the game who wins most tricks, he that can win five of the nine has a sure game: which is also the case if he wins four, and can so divide the tricks as that one person may win two, and the other three.

If a person play without discarding or changing any cards, this is called *playing sans prendre;* and if another win more tricks than he, he is said to *win codille*. The oversights in the course of the game are called *beasts*. And if the ombre wins all the nine tricks, it is called *winning the vole*.

In ombre by five, which many, on account of its not requiring so close an attention, prefer to that by three, only eight cards a-piece are dealt; and five tricks must be won, otherwise the ombre is beasted. Here the person who undertakes the game, after naming the trump, calls a king to his assistance; upon which the person in whose hand the king is, without discovering himself, is to assist him as a partner, and to share his fate. If, between both, they can make five tricks, the ombre wins two counters, and the auxiliary king only one; but when the counters are even, they divide them equally. If the ombre venture the game without calling in any king, this too is called *playing sans prendre;* in which case the other four are all against him, and he must win five tricks alone, or be beasted. The rest is much the same as by three.

OMBRE *de soleil*, "Shadow of the sun," in *Heraldry*, is when the sun is borne in armory, so as that the eyes,

eyes, nose, and mouth, which at other times are represented, do not appear; and the colouring is thin, so that the field can appear through it.

OMBRIA, the ancient name of a province of Italy, in the territory of the pope, now called *Spoletto* and *Perugia*.

OMBRO, or LOMBRO, a town of Italy, in the duchy of Tuscany, and territory of the Siennois, situated near the Tuscan sea, a little south of the lake of Castiglione, 45 miles south-west of Sienna.

OMBROMETER, an instrument to measure the quantity of rain that falls. We have the description and figure of one in Phil. Trans. N° 473. p. 12. It consists of a tin funnel, whose surface is an inch square, with a flat board, and a glass tube set into the middle of it in a groove. The rise of the water in the tube, whose capacity at different times must be measured and marked, shews the quantity of rain that has fallen.

OMELET, or AMLET, a kind of pancake or fricassee of eggs, with other ingredients, very usual in Spain and France. It may be made as follows: The eggs being beaten, are to be seasoned with salt and pepper, and then fried in butter made boiling hot; this done, gravy is to be poured on, and the whole stewed with chives and parsley shred small: when one side is fried enough, it is to be turned on the other.

OMEN, is a word which, in its proper sense, signifies a sign or indication of some future event, taken from the language of a person speaking without any intent to prophecy. Hence Tully says, "Pythagorei non solum voces deorum observarunt, sed etiam hominum, quæ vocent *omina*;" "the Pythagoreans attend to the discourse not only of gods, but also of men, which they call *omens*." This sort of omen was supposed to depend much upon the will of the person concerned in the event; whence the phrases *accepit omen*, *arripuit omen*. Such were the original *omens*; but they were afterwards derived from *things* as well as from words. Thus Paterculus, speaking of the head of Sulpicius on the rostrum, says it was *velut omen imminentis proscriptionis*, "the omen of an impending proscription." Suetonius says of Augustus, that he believed implicitly in certain omens; and that, *si mane sibi calceus perperam, ac sinister pro dextero induceretur ut dirum*, "If his shoes were improperly put on in the morning, especially if the left shoe was put upon his right foot, he held it for a bad omen." Omen was used in a still larger sense, to signify an *augury*; as in the following line of Tully. "Sic aquilæ clarum firmavit Jupiter *omen*;" "thus Jove confirmed the bright omen of the eagle." It was lastly used, in the most generic sense of all, for a portent or prodigy; as in the third book of the Æneid, where a myrtle torn up by Æneas dropped blood. Upon this appearance, says the hero,

> ———Mihi frigidus horror
> Membra quatit, gelidusque coit formidine sanguis.

And the same thing being repeated upon his breaking a branch from another tree, he prayed to the gods to avert the *omen*.

> Multa movens animo Nymphas venerabar agrestes,
> Gradivumque patrem, Geticis qui præsidet arvis,
> Rite secundarent visus, *omen*que levarent (A.)

The portentous or supernatural omens were either external or internal. Of the former sort were those showers of blood so frequently occurring in the Roman history, which were much of the same nature with this adventure of Æneas, which he calls MONSTRA DEUM. Of the second sort were those sudden consternations, which, seizing upon men without any visible cause, were imputed to the agency of the god *Pan*, and hence called *panic fears*. But indeed there was hardly any thing, however trivial, from which the ancients did not draw omens. That it should have been thought a direful omen when any thing befel the temples, altars, or statues of the GODS, need excite no wonder; but that the meeting of a eunuch, a negro, a bitch with whelps, or a snake lying in the road, should have been looked upon as portending bad fortune, is a deplorable instance of human weakness, and of the pernicious influence of superstition on the mind.

It is more than probable that this practice of making ordinary events ominous of good or bad fortune took its rise in Egypt, the parent country of almost every superstition of paganism; but wherever it may have arisen, it spread itself over the whole inhabited globe, and at this day prevails in a greater or less degree among the vulgar of all nations.

In England, it is reckoned a good omen, or a sign of future happiness, if the sun shines on a couple coming out of the church after having been married. It is also esteemed a good sign if it rains whilst a corpse is burying:

> Happy is the bride that the sun shines on;
> Happy is the corpse that the rain rains on.

To

(A) Instead of translating those short quotations, we shall here give Dryden's version of the whole of this portentous adventure, as we are persuaded that the mere English reader, who alone can wish for a translation, will be glad to have the fullest account of the bleeding myrtle, together with its effects on the mind of the hero. It is as follows:

> Not far, a rising hillock stood in view;
> Sharp myrtles on the sides and corners grew.
> There, while I went to crop the sylvan scenes,
> And shade our altar with their leafy greens,
> I pull'd a plant (with horror I relate
> A prodigy so strange, and full of fate):
> The rooted fibres rose; and from the wound
> Black bloody drops distill'd upon the ground.
> Mute and amaz'd, my hair with terror stood;
> Fear shrunk my sinews, and congeal'd my blood.
> Mann'd once again, another plant I try;
> That other gush'd with the same sanguine dye.
> Then, fearing guilt for some offence unknown,
> With prayers and vows the Dryads I atone,
> With all the sisters of the woods, and most
> The god of arms, who rules the Thracian coast:
> That they, or he, these omens would avert,
> Release our fears, and better signs impart.

Omen.

To break a looking glass is extremely unlucky; the party to whom it belongs will lose his best friend.

If, going a journey on business, a sow cross the road, you will probably meet with a disappointment, if not a bodily accident, before you return home. To avert this you must endeavour to prevent her crossing you; and if that cannot be done, you must ride round on fresh ground. If the sow is attended with her litter of pigs, it is lucky, and denotes a successful journey.

It is unlucky to see first one magpye, and then more; but to see two denotes marriage or merriment; three, a successful journey; four, an unexpected piece of good news; five, you will shortly be in a great company. To kill a magpye, will certainly be punished with some terrible misfortune.

If in a family, the youngest daughter should be married before her elder sisters, they must all dance at her wedding without shoes: this will counteract their ill luck, and procure them husbands.

If you meet a funeral procession, or one passes by you, always take off your hat: this keeps all evil spirits attending the body in good humour.

If, in eating, you miss your mouth, and the victuals fall, it is very unlucky, and denotes approaching sickness.

It is lucky to put on a stocking the wrong side outwards: changing it alters the luck.

When a person goes out to transact any important business, it is lucky to throw an old shoe after him.

It is unlucky to present a knife, scissars, razor, or any sharp or cutting instrument, to one's mistress or friend, as they are apt to cut love and friendship. To avoid the ill effects of this, a pin, a farthing, or some trifling recompense, must be taken. To find a knife or razor, denotes ill luck and disappointment to the party.

In the Highlands of Scotland, it is thought unlucky if a person setting out upon a journey stumble over the threshold, or be obliged to return for any thing forgotten. If a sportsman see any person stepping over his gun or fishing rod, he expects but little success in that day's diversion. *Sneezing* is also deemed ominous. If one sneeze when making a bed, a little of the straw or heath is taken out and thrown into the fire, that nothing may disturb the rest of the person who is to sleep in the bed. Among the same people, success in any enterprise is believed to depend greatly upon the first creature that presents itself after the enterprise is undertaken. Thus, upon going to shoot, it is reckoned lucky to meet a horse, but very unfortunate to see a hare, if she escape; and upon meeting any creature deemed unlucky, the best means of averting the omen is to roll a stone towards it. The Greeks attributed the same efficacy to the rolling of a stone, though they greatly preferred *killing* the ominous animal, that the evil portended might fall on its own head*.

The motions and appearances of the clouds were not long ago considered as certain signs by which the skilful Highlander might attain to the knowledge of futurity. On the evening before *new year's day*, if a black cloud appeared in any part of the horizon, it was thought to prognostic a plague, a famine, or the death of some great man in that part of the country over which it should appear to set; and in order to ascertain the place threatened by the omen, the motions of this cloud were often watched through the whole night, if it happened to continue so long visible above the horizon.

By the believers in this superstition there are days, as well as words and events, which are deemed ominous of good or bad fortune. The first day of every quarter, midsummer, and new year's day, are reckoned the most fortunate days in the year for accomplishing any design. In the isle of Mull, ploughing, sowing, and reaping, are always begun on *Tuesday*, though the most favourable weather for these purposes be in this way frequently lost. That day of the week on which the third of May falls, is deemed unlucky throughout the whole year. In Morven, none will upon any account dig peat or turf for fuel on *Friday*; and it is reckoned unlucky to number the people or cattle belonging to any family, and doubly so if the number be taken on Friday. The age of the moon is also much attended to by the vulgar Highlanders. It is alleged, that during the increase things have a tendency to grow and stick together: and hence, in the isle of Sky, fences which are there made of turf, are built only at that time; whilst turf or peat for fuel are never, even in the most favourable weather, either made or stacked up but while the moon is in its wane. An opinion prevails in some places, that if a house take fire during the increase of the moon, the family to which it belongs will prosper in the world: but that if the fire happen while the moon is in the decrease, the family will from that time decline in its circumstances, and sink into poverty.

In attributing such influence to the moon, the superstitious Highlanders have the honour to agree with the philosophic Virgil, who in his Georgics gives the following sage instructions to the husbandman:

Ipsa dies alios alio dedit ordine Luna
Felices, operum. Quintam fuge:
* * * *

Septima post decimam felix et ponere vitem,
Et prensos domitare boves, et licia telæ
Addere: nona fugæ melior, contraria furtis.

The lucky days in each revolving moon
For labour choose: the *fifth* be sure to shun.
* * * *

The *seventh* is, next the *tenth*, the best to join
Young oxen to the yoke, and plant the vine.
Then weavers stretch your stays upon the weft:
The *ninth* is good for travel, bad for theft.

DRYDEN.

From this coincidence of the superstition of the Roman poet with that of the natives of Mull and Morven, we are strongly inclined to adopt the hypothesis of the gentlemen who favoured us with this accurate account of Highland omens. He justly observes, that this superstitious practice of auguring good or ill from trifling events, and from the particular phases of the moon, has no connexion whatever with popish priestcraft: he shows that the Romish clergy, even in the darkest age, were at pains to eradicate it as idle and impious; and he therefore infers that it must be a relick of Druidism handed down by tradition from an era prior to the introduction of Christianity into the Highlands and isles of Scotland. That the Druids were

* See Potter's *Antiquities*, vol. i. p. 346.

were acquainted with the particular doctrines of Pythagoras has been shown elsewhere (see DRUIDS); that Virgil was no stranger to the Pythagorean philosophy is known to every scholar; that Pythagoras and his followers were addicted to the dotages of MAGIC has been made apparent in that article; and therefore it appears to us probable at least, that the attention paid to pretended omens, not only in the Highlands, but also in the low country of Scotland, and indeed among the vulgar in every country of Europe, is a remnant of one of the many superstitions which the Druids imposed upon their deluded followers. That it is contrary to every principle of sound philosophy, all philosophers will readily acknowledge; and whoever has studied the writings of St Paul must be convinced that it is inconsistent with the spirit of genuine Christianity.

OMENTUM, or EPIPLOON, the *Cawl*, in *Anatomy*, a membranaceous part, usually furnished with a large quantity of fat; being placed under the peritonæum, and immediately above the intestines. See ANATOMY, Nº 90.

OMER, in Jewish antiquity. See CORUS.

ST OMER's, a strong, fortified, large, town of France, in the department of the Straits of Calais, with a castle and a bishop's see, and containing 20,109 inhabitants in 1800. It is a fortress of considerable importance, surrounded on one side with a large morass; and about it there are many sluices, which serve to carry the water off when it is overflowed. In the midst of the morass there is a sort of floating islands covered with verdure and trees. The cathedral is a handsome structure; and there are other fine buildings, with a rich Benedictine abbey. The French became masters of this place in 1679. It is seated on the river Aa, and on the side of a hill, eight miles north-west of Aire, and 135 north of Paris. E. Long. 2. 20. N. Lat. 54. 45.

OMOA, a Spanish town and fortification on the south side of the bay of Honduras, N. Lat. 15. 50. W. Long. 89. 50. from London. It is the key to the bay; and such is the depth of the water, that ships of any burden may ride in the harbour with safety. It is a place of the utmost importance to Spain, as the register ships to and from Guatimala are sent to it in the time of war. The town was first established in 1751, under the command of Don Joseph Antonio de Palmo. At that period the inhabitants were about 20 white men, 60 mulattoes and free negroes, and 200 slaves to the king of Spain; and the military force consisted of about 30 soldiers, besides officers. The fort was originally composed of sand confined in boarded coffers, and faced with half-burnt bricks. It was defended by 12 fine brass 24 pounders mounted, four or five iron guns of different bores, and some field-pieces. The Spaniards, sensible of the importance of the place, afterwards fortified it at an incredible expence, the stone of which the walls are built having been raised from the sea, and brought from the distance of 20 leagues. The outworks were not completely finished in the year 1779, though 1000 men had then been employed upon them for 20 years.

Towards the end of that year an expedition was undertaken against this fortress, in consequence of one formed by the Spaniards against the British logwood cutters in the bay of Honduras and on the Mosquito shore. The latter, finding themselves hard pressed by their enemies, applied to General Dulling governor of Jamaica for assistance; who accordingly sent a detachment to their relief under Captain Dalrymple, with necessary supplies of arms, ammunition, and artillery. Before their arrival, however, the Spaniards had taken possession of St George's Key, the chief settlement of the British in these parts, which they plundered, and took a number of prisoners; but those who escaped, being joined by a body of their countrymen, retook it, and forced the enemy to retire. In the mean time Captain Dalrymple, who had been informed of the loss of the place, was hastening to the relief of the inhabitants, and in his way fell in with Admiral Parker, who was in quest of some register ships; but which, retreating into the harbour of Omoa, were too strongly protected by the fort there to be attacked by sea. As the Spaniards, however, had now been compelled to abandon St George's Key, it was proposed to unite the British forces by sea and land, and to attempt the conquest of this fortress. As the force under Captain Dalrymple was too inconsiderable to attempt the fort by land, it was augmented by the marines of the squadron and a strong party of the settlers; though, after all, it did not exceed the number of the garrison who opposed them.

The troops were landed at about nine miles distance from the fort in the dusk of the evening, with a design to march directly forward, in order to surprise and carry it by escalade in the night time. No roads, however, being found, they were obliged to explore their way through narrow foot-paths, morasses, and over mountains so beset with precipices, that they were obliged, in order to avoid them, to make use of lights made of the cabbage tree. In consequence of these impediments they were yet at a considerable distance from the fort, when the approach of day discovered them to the enemy. An engagement ensued, in which the Spaniards were quickly routed and driven into the town: from whence as they continued to fire upon the British, it was found necessary to set fire to it, though very much against the inclination of the assailants.

In the mean time the squadron took the opportunity, while the town was in flames, to come into the bay, and approach the fort with an intention to batter it; but the garrison returned the fire so briskly, that no impression could be made by that of the squadron, which was detained by want of wind from approaching sufficiently near. The troops then, being masters of the ground adjacent to the fort, erected several batteries in such situations as were most proper for annoying it; but though they carried on their operations with great vigour, it was still found that heavier artillery than any they possessed would be requisite, the walls being no less than 18 feet in thickness; in consequence of which they resolved still to attempt the place by escalade.

The attempt was made on the 21st of October, early in the morning. The troops entered the ditch, which fortunately for them happened to be dry, and fixed their scaling ladders against the walls, which were near 30 feet high. Two seamen mounted first; and, with admirable courage and presence of mind, stood by the ladder which they had mounted, to guard it till others ascended;

ed; and boldly presented their pieces against a large party drawn up to receive them, though they prudently retained their fire till their comrades came up.

The squadron, now drawing near, kept up a heavy and continual fire upon the fort, while the Spaniards were struck with such surprise at the excessive celerity and boldness of the assailants, that they remained motionless and unable to oppose their enemies, notwithstanding the exhortation and example of their officers. From this panic they never recovered; and while the seamen and soldiers continued to scale the walls with amazing quickness, the Spaniards never made any effort to defend themselves. About 100 of them escaped over the walls on the opposite side of the fort; the remainder surrendered at discretion.

The whole of this transaction reflected the highest lustre both on the conduct and courage of the British; and an instance of heroism is related in a British sailor to which history affords nothing superior. This man, having scaled the walls, had armed himself with a cutlass in each hand. Thus armed, he met with a Spanish officer unarmed, and just roused from sleep. The generous tar scorned to take advantage of his condition, and therefore presented him with one of his own cutlasses saying, "You are now on a footing with me!" The officer, however, was too much struck with admiration at his conduct to accept the offer, and took care to make the circumstance sufficiently known.—The value of the booty taken on this occasion amounted to three millions of dollars; but the loss most sensibly felt by the Spaniards was that of 250 quintals of quicksilver, a commodity indispensably necessary in extracting the precious metals from their ores. They offered therefore to ransom it at any price: but though the retention of it was far from affording a profit equal to that offered by the Spaniards, the British commanders absolutely refused to part with it, on account of the advantages the enemy would derive from having the metal in their possession. For the same reason they refused to accept of any ransom for the fort, though the governor offered to lay down 300,000 dollars for it. The Spanish military and the inhabitants were treated with the utmost humanity; their personal effects remaining untouched; and this generosity must have appeared to greater advantage, when contrasted with the behaviour of their own countrymen at Honduras, where the British were treated with remarkable severity. The church plate and ornaments were restored, on condition that the terms of capitulation should be faithfully kept.

In a short time, however, it appeared that it would have been better to have accepted of a ransom for the fort, as from circumstances at that time it could not be retained in the possession of Britain. A garrison was indeed left for its defence on the departure of the British squadron; but as it was very inconsiderable, on account of the small number of men that could be spared, the Spaniards quickly determined to make an attempt to regain the fort. For this purpose a body of 2000 men were collected, who invested it on the 25th of November. The British defended it with the utmost bravery; keeping up a constant fire on the enemy, and obliging them to retire for shelter, and take up their quarters behind a hill. Here they made preparations for an assault, in which their numbers left the success, as they supposed, by no means dubious. The garrison was therefore summoned to surrender, with a promise of the honours of war and a safe conveyance to Great Britain, denouncing at the same time the utmost vengeance in case of a refusal; which being refused, the necessary preparations were made for an escalade.

The condition of the garrison was now such as could afford very little hope of being able to make any effectual resistance. They were but 85 in number, most of whom were become incapable of duty either from illness or excessive fatigue. They were now also obliged to make one centinel answer for five, by shifting his place, and challenging as many times. There was no surgeon to attend the sick and wounded; nor had they even any water but what came from a sloop of war that lay abreast of the fort. In this desperate situation, they resolved, notwithstanding the menaces of the Spanish commander to render the place as unserviceable as they could. For this purpose they spiked up all the guns; destroying the stores and ammunition that could not be carried off: they even locked the gates of the fort, after which they embarked without the loss of a single man. All this was performed in defiance of the large force that besieged them; and the exploit, when duly considered, must appear not less a matter of astonishment than the extraordinary manner in which the fort had been taken. The officer who commanded in this remarkable retreat was Captain Hulke of the navy.

OMOPHAGIA, an ancient Greek festival, in honour of Bacchus, surnamed *Omophagos*, i. e. eater of raw flesh. This festival was observed in the same manner with the other festivals of Bacchus, in which they counterfeited madness. What was peculiar to it, was, that the worshippers used to eat the entrails of goats, raw and bloody, in imitation of the god, who was supposed to do the same thing.

OMPHACINE OIL, a viscous brown juice extracted from green olives. With this oil the ancient *athletæ*, when going to wrestle, anointed themselves; and when that gymnastic exercise was over, they rolled themselves in the sand, which, mixing with the oil and sweat on their bodies, constituted the *strigmenta* so highly esteemed in the cure of several diseases. This precious medicine was carefully scraped off the body of the athleta with a kind of instrument something like a comb, which was called *strigilis;* and such was the demand for the scrapings, that they were a very lucrative article of trade.

OMPHALE, in fabulous history, a queen of Lydia, daughter of Jardanus. She married Tmolus, who at his death left her mistress of his kingdom. Omphale had been informed of the great exploits of Hercules, and wished to see so illustrious a hero. Her wish was soon gratified. After the murder of Eurytus, Hercules fell sick, and was ordered to be sold as a slave, that he might recover his health and the right use of his senses. Mercury was commissioned to sell him, and Omphale bought him, and restored him to liberty. The hero became enamoured of his mistress, and the queen favoured his passion, and had a son by him, whom some call Agelaus and others Lamon. From this son were descended Gyges and Crœsus; but this opinion is different from the account which makes these Lydian monarchs spring from Alcæus, a son of Hercules, by one of the female servants of Omphale. Hercules is represented by the poets as so desperately enamoured of the queen, that, to conciliate her esteem, he spins by her side among her women, while she covers herself with the lion's skin, and arms herself with the club of the hero, and often strikes him with her sandals, for the uncouth manner with which he holds the distaff, &c. Their fondness was mutual. As they once travelled together, they came to a grotto on Mount Tmolus, where the queen dressed herself in the habit of her lover, and obliged him to appear in a female garment. After they had supped, they both retired to rest in different rooms, as a sacrifice on the morrow to Bacchus required. In the night Faunus, or rather Pan, who was enamoured of Omphale, introduced himself into the cave. He went to the bed of the queen, but the lion's skin persuaded him that it was the dress of Hercules; and therefore he repaired to the bed of Hercules, in hopes to find there the object of his affections. The female dress of Hercules deceived him, and he laid himself down by his side. The hero was awakened, and kicked the intruder into the middle of the cave. The noise awoke Omphale, and Faunus was discovered lying on the ground, greatly disappointed and ashamed.

OMPHALEA, a genus of plants belonging to the monœcia class; and in the natural method ranking with those of which the order is doubtful. See BOTANY *Index*.

OMPHALO-MESENTERIC, in *Anatomy*. All fœtuses are wrapped up in at least two coats or membranes; most of them have a third, called *allantoides*, or *urinary*.

Some, as the dog, cat, hare, &c. have a fourth, which has two blood-vessels, viz. a vein and an artery, called *omphalo-mesenterics*, because passing along the string to the navel, and terminating in the mesentery.

OMRAH, a man of the first rank in the Mogul empire; a nobleman. It is the plural of the Arabic *ameer*.

ON, in *Ancient Geography*, a city of Egypt sacred to the sun, and by the Greeks, on that account, called *Heliopolis*. (See HELIOPOLIS). It was remarkable for the wisdom and learning of its priesthood, and for the spacious building in which they cultivated the studies of philosophy and astronomy. The priests of On were esteemed more noble than all the other priests of Egypt. They were always privy counsellors and ministers of state; and therefore, when Pharaoh resolved to make Joseph *prime* minister, he very wisely gave him in marriage a daughter of the priest of *On*, thereby incorporating him into the most venerable cast in Egypt. Bishop Warburton thinks that the superior nobility of the priests of *On* was chiefly owing to their high antiquity and great learning. That they were much given to the study of astronomy, we know from the testimony of Strabo; and indeed nothing is more probable than that they should be attached to the study of that system over which their god, the SUN, presided, not only in his *moral* but also in his *natural* capacity. The learned prelate affirms, that "whether they received the doctrine from original tradition, or invented it at hazard (which last supposition he thinks more probable, though we are of a very different opinion), it is certain they taught that the Sun is in the centre of its system, and that all the other bodies move round it in perpetual revolutions. This noble theory (he continues) came with the rest of the Egyptian learning into Greece (being brought thither by Pythagoras, who received it from Oenuphis *, a priest of *On*); and after having given the most distinguished lustre to his school, it sunk into obscurity, and suffered a total eclipse throughout a long succession of learned and unlearned ages; till these times restored its ancient splendour, and immoveably fixed it on the unerring principles of science."

* *Plut. de Is. et Osir.* p. 632. Steph. ed.

If it be true, as some philosophers allege, that Moses appears from the first chapter of Genesis to have been acquainted with the true solar system, this account of the origin of that system is extremely probable. As it is of no importance to the civil or religious constitution of a state whether the system of Ptolemy or that of Copernicus be admitted by the people, we cannot reasonably suppose that the Jewish lawgiver was taught astronomy by a revelation from Heaven. But there can be no doubt of his knowing as much of that science as the priests of *On*; for we know that he was instructed in all the wisdom of the Egyptians; and therefore, if he held the sun to be in the centre of the system, it is morally certain that the same thing was held by that priesthood.

ONANIA, or ONANISM, terms employed to denote the crime of self-pollution, mentioned in Scripture to have been committed by Onan, and punished in him with death.

This practice, however common, hath among all nations been reckoned a very great crime. In Scripture, besides the instance of Onan above mentioned, we find self-polluters termed *effeminate*, *unclean*, *filthy*, and *abominable*. Even the heathens, who had not the advantage of revelation, were of the same opinion, as appears from the following lines of Martial.

Hoc nihil esse putes! scelus est, mihi crede; sed ingens
Quantum vix animo concipis ipse tuo.

You think 'tis nothing! 'tis a crime, believe!
A crime so great you scarcely can conceive.

Dr Tissot has published a treatise on the pernicious effects of this shameful practice, which appears to be no less baneful to the mind than to the body. He begins with observing, that, by the continual waste of the human body, aliments are required for our support. These aliments, however, require certain preparations in the body itself; and when by any means we become so altered that these preparations cannot be effected, the best aliments then prove insufficient for the support of the body. Of all the causes by which this morbid alteration is brought on, none is more common than too copious evacuations; and of all evacuations, that of the semen is the most pernicious when carried to excess. It is also to be observed, that though excess in natural venery is productive of very dangerous disorders, yet an equal evacuation by self-pollution, which is an unnatural way, is productive of others still more to be dreaded. The consequences enumerated by Dr Tissot are as follow:

1. All the intellectual faculties are weakened; the memory fails; the ideas are confused, and the patient sometimes

sometimes even falls into a slight degree of insanity. They are continually under a kind of inward restlessness, and feel a constant anguish. They are subject to giddiness; all the senses, especially those of seeing and hearing, grow weaker and weaker, and they are subject to frightful dreams.

2. The strength entirely fails, and the growth in young persons is considerably checked. Some are afflicted with almost continual watching, and others dose almost perpetually. Almost all of them become hypochondriac or hysteric, and are afflicted with all the evils which attend these disorders. Some have been known to spit calcareous matters; and others are afflicted with coughs, slow fevers, and consumptions.

3. The patients are affected with the most acute pains in different parts of the body, as the head, breast, stomach, and intestines; while some complain of an obtuse sensation of pain all over the body on the slightest impression.

4. There are not only to be seen pimples on the face, which are one of the most common symptoms; but even blotches, or suppurative pustules, appear on the face, nose, breast, and thighs; and sometimes fleshy excrescences arise on the forehead.

5. The organs of generation are also affected; and the semen is evacuated on the slightest irritation, even that of going to stool. Numbers are afflicted with an habitual gonorrhœa, which entirely destroys the vigour of the constitution, and the matter of it resembles a fetid sanies. Others are affected with painful priapisms, dysuries, stranguries, and heat of urine, with painful tumours in the testicles, penis, bladder, and spermatic cord; and impotence in a greater or less degree is the never-failing consequence of this detestable vice.

6. The functions of the intestines are sometimes totally destroyed; and some patients complain of costiveness, others of diarrhœa, piles, and the running of a fetid matter from the fundament.

With regard to the cure, the first step is to leave off those practices which have occasioned the disease; which our author asserts is no easy matter; as, according to him, the soul itself becomes polluted, and can dwell on no other ideas; or if she does, the irritability of the parts of generation themselves quickly recal ideas of the same kind. This irritability is no doubt much more to be dreaded than any pollution the soul can have received; and by removing it, there will be no occasion for exhortations to discontinue the practice. The principal means for diminishing this irritability are, in the first place, to avoid all stimulating, acrid, and spiced meats. A low diet, however, is improper, because it would further reduce the body, already too much emaciated. The food should therefore be nutritive, but plain, and should consist of flesh rather roasted than boiled, rich broths, &c.

ONCA and ONCE. See FELIS, MAMMALIA *Index*.

ONEEHOURA and ONEEHOW, two small islands of that cluster which was discovered by Captain Cook, and by him called the *Sandwich Islands*. (See SANDWICH ISLANDS). *Oneehoura* is very small, and its chief produce is yams. *Oneehow* is considerably larger, being about ten miles over. It is remarkable for the great quantity of excellent yams which it produces, and for a sweet root called *tee* or *tea*, which is generally about the thickness of a man's wrist, though sometimes much larger. This root, which the natives commonly bake previous to their bringing it to market, is of a wet clammy nature, and with proper management makes excellent beer.

ONEGA, a river and lake of the Russian empire, between Muscovite Carelia, the territory of Cargapol, and Swedish Carelia. It is 100 miles in length and 40 in breadth, having a communication with the lake Ladoga, and consequently with Petersburgh. The river, which has its source in Cargapol, and gives its name to a country full of woods, falls into the White sea.

ONEGLIA, a sea-port town of Italy, in the territory of Genoa, with the title of a principality; but belonging to the king of Sardinia, as well as the province, which abounds in olive trees, fruit, and wine. It has often been taken and retaken in the wars of Italy, being an open place. It was taken by the French in 1794, and united to the republic, forming a part of the department of Stura. In 1814 it was restored to Sardinia. E. Long. 7. 51. N. Lat. 43. 58.

ONEIROCRITICA, the art of interpreting dreams; or a method of foretelling future events by means of dreams. See DREAM, DIVINATION, &c.—The word is formed from the Greek ονειρος, "dream," and κριτικη, of κρισις, judgment." Some call it *oneirocratica*; and derive it from ονειρος and κρατεω, "I possess, I command."

It appears from several passages of Scripture, that there was, under the Jewish dispensation, such a thing as foretelling future events by dreams; but then there was a particular gift or revelation required for that purpose.

Hence it has been inferred, that dreams are really significative, and do forebode something to come; and all that is wanting among us is the *oneirocritica*, or the art of knowing what; yet it is the opinion of many, that dreams are mere chimeras; bearing indeed some relation to what has passed, but none to what is to come. As to the case of Joseph, it was possible for God, who knew all things, to discover to him what was in the womb of fate; and to introduce that, he might take the occasion of a dream.

ONEIROCRITICS, a title given to interpreters of dreams, or those who judge of events from the circumstances of dreams.

There is no great regard to be had to those Greek books called *oneirocritics*; nor do we know why the patriarch of Constantinople, and others, should amuse themselves with writing on so pitiful a subject.

Rigault has given us a collection of the Greek and Latin works of this kind; one attributed to Astrampsichus; another to Nicephorus, patriarch of Constantinople; to which are added the treatises of Artemidorus and Achmet. But the books themselves are little else than reveries; a kind of waking dreams, to explain and account for sleeping ones.

The secret of oneirocriticism, according to them all, consists in the relation supposed to be between the dream and the thing signified; but they are far from keeping to the relations of agreement and similitude; and frequently have recourse to others of dissimilitude and contrariety. Concerning oneirocritics and oneirocritica;

rocritica, the unlearned reader will find much information in Warburton's Divine Legation of Moses, and the books to which he refers.

ONESIÆ THERMÆ, were, according to Strabo, *excellent baths*, and *salutary waters*, at the foot of the Pyrenees in Aquitania. Near the river Aturus stands at this day the town Bagneres, famous for its waters, which appear to be the *Onesiæ* of Strabo: situated in the county of Bigorre in Gascony, near the river Adour.

ONIÆ OPPIDUM and *Templum* (Josephus); so called from Onias, the high-priest of the Jews in Egypt; who built a temple in imitation of that at Jerusalem, by permission of the king of Egypt, on the spot where stood the temple of Diana Agrestis in Leontopolis: it was encompassed with a brick wall, and had a large tower like that at Jerusalem (Josephus); it was the metropolis of the Nomos Heliopolites, (Ptolemy); because in Strabo's time Heliopolites was fallen to decay.

ONGLEE, in *Heraldry*, an appellation given to the talons or claws of beasts or birds when borne of a different colour from that of the body of the animal.

ONION. See ALLIUM, BOTANY *Index*; and for the mode of its cultivation, see GARDENING *Index*.

ONISCUS, a genus of insects belonging to the order of aptera. See ENTOMOLOGY *Index*.

ONKELOS, surnamed the *Proselyte*, a famous rabbi of the first century, and the author of the Chaldee Targum on the Pentateuch. He flourished in the time of Jesus Christ, according to the Jewish writers; who all agree that he was, at least in some part of his life, contemporary with Jonathan Ben Uzziel, author of the second Targum upon the prophets. Dean Prideaux thinks he was the elder of the two, for several reasons: the chief of which is the purity of the style in his Targum, therein coming nearest to that part of Daniel and Ezra which is in the Chaldee, and is the truest standard of that language, and consequently is the most ancient; since that language, as well as others, was in a constant flux, and continued deviating in every age from the original: nor does there seem to be any reason why Jonathan Ben Uzziel, when he undertook his Targum, should pass over the law, and begin with the prophets, but that he found Onkelos had done this work before him, and with a success which he could not exceed.

Azarias, the author of a book entitled *Meor Enaim*, or the *light of the eyes*, tells us, that Onkelos was a proselyte in the time of Hillel and Samnai, and lived to see Jonathan Ben Uzziel one of the prime scholars of Hillel. These three doctors flourished 12 years before Christ, according to the chronology of Gauz; who adds, that Onkelos was contemporary with Gamaliel the elder, St Paul's master, who was the grandson of Hillel, who lived 28 years after Christ, and did not die till 18 years before the destruction of Jerusalem. However, the same Gauz, by his calculation, places Onkelos 100 years after Christ; and to adjust his opinion with that of Azarias, extends the life of Onkelos to a great length. The Talmudists tell us that he assisted at the funeral of Gamaliel, and was at a prodigious expence to make it most magnificent. Dean Prideaux observes, that the Targum of Onkelos is rather a version than a paraphrase; since it renders the Hebrew text word for word, and for the most part accurately and exactly, and is by much the best of all this sort: and therefore it has always been held in esteem among the Jews much above all the other Targums: and being set to the same musical notes with the Hebrew text, is thereby made capable of being read in the same tone with it in their public assemblies.—From the excellency and accuracy of Onkelos's Targum, the dean also concludes him to have been a native Jew, since without being bred up from his birth in the Jewish religion and learning, and long exercised in all the rites and doctrines thereof, and being also thoroughly skilled in both the Hebrew and Chaldee languages, as far as a native Jew could be, he can scarce be thought thoroughly adequate to that work which he performed; and that the representing him as a proselyte seems to have proceeded from the error of taking him to have been the same with Akilas, or Aquila, of Pontus, author of the Greek Targum or version of the prophets and Hagiographia, who was indeed a Jewish proselyte.

ONOCLEA, a genus of plants belonging to the cryptogamia class and order of *Filices*. See BOTANY *Index*.

ONOMANCIA, or rather ONOMANTIA, a branch of divination, which foretels the good or bad fortune of a man, from the letters in his name. See the article DIVINATION and NAME.

From much the same principle the young Romans toasted their mistresses as often as there were letters in their names: Hence Martial says,

Nævia sex cyathis, septem Justina bibatur.

ONOMATOPOEIA, in grammar and rhetoric, a figure where words are formed to resemble the sound made by the things signified; as the buzz of bees, the cackling of hens, &c. Resemblances of this kind are often fancied when they are not real, though, no doubt, there are in every language some words of which the sound is very like to that which those words are employed to express. Yet, to the mortification of grammarians and rhetoricians, conjunctions, which have been justly pronounced no parts of speech, are the only sounds uttered by men that are wholly natural, and these are fewer than is commonly supposed. See GRAMMAR and LANGUAGE.

ONONIS, a genus of plants, belonging to the diadelphia class. See BOTANY *Index*.

ONOPORDUM, a genus of plants belonging to the syngenesia class; and in the natural method ranking under the 49th order, *Compositæ*. See BOTANY *Index*.

ONOSANDER, a Greek author and Platonic philosopher, who wrote Commentaries on Plato's Politics, which are lost: but his name is particularly famous for a treatise entitled Λογος Στρατηγικος, "Of the duty and virtues of the general of an army;" which has been translated into Latin, Italian, Spanish, and French. The time when he lived is not precisely known; but is imagined to be in the reign of the emperor Claudius.

ONOSMA, a genus of plants, belonging to the pentandria class; and in the natural method ranking under the 41st order, *Asperifoliæ*. See BOTANY *Index*.

ONTARIO, a lake of North America, in the country of the Iroquois, 160 miles in length, and from 60 to 70 in breadth. Many rivers run into this lake: and the

the great river St Lawrence passes through it. It is the lowest of the great chain of American lakes, and contains 19 islands, most of them small.

ONTOLOGY. See METAPHYSICS, N° 3.

ONYCOMANCY, or, as some write it, ONYMANCY; a kind of divination by means of the nails of the fingers.——The word is formed from the Greek ονυξ, "nail," and μαντεια, "divination."

The ancient practice was to rub the nails of a youth with oil and soot, or wax; and to hold up the nails thus smeared against the sun.—Upon them were supposed to appear figures or characters, which showed the thing required.

ONYX, a mineral substance ranked among gems, which derives its name from the colour resembling that of the nail of the finger. See CARNELIAN, under MINERALOGY, p. 167.

OONALASHKA, one of the islands of the Northern Archipelago, visited by Captain Cook in his last voyage. The native inhabitants of this island are, to all appearances, a very peaceable people, having been much polished by the Russians, who now keep them in a state of subjection. As the island furnishes them with subsistence, so it does, in some measure, with clothing, which is chiefly composed of skins. The upper garment, which is made like a waggoner's frock, reaches down to the knees. Besides this, they wear a waistcoat or two, a pair of breeches, a fur cap, and a pair of boots, the legs of which are formed of some kind of strong gut; but the soles and upper-leathers are of Russia leather. Fish and other sea animals, birds, roots, berries, and even sea weed, compose their food. They dry quantities of fish during the summer, which they lay up in small huts for their use in winter. They did not appear to be very desirous of iron, nor to want any other instrument, except sewing needles, their own being formed of bone. With these they sew their canoes, and make their clothes, and also work their curious embroidery. They use, instead of thread, the fibres of plants, which they split to the thickness required. All sewing is performed by the females, who are shoemakers, tailors, and boat-builders. They manufacture mats and baskets of grass, which are both strong and beautiful. There is indeed a neatness and perfection in most of their works, that shows they are deficient neither in ingenuity nor perseverance.

Though the climate is sometimes severe, Captain Cook did not observe a fire-place in any of their habitations. They are lighted as well as heated by lamps; which, though simple, effectually answer the purpose for which they are intended. They consist of a flat stone, hollowed on one side like a plate; in the hollow part they put the oil, mixed with some dry grass, which serves for a wick. Both sexes often warm themselves over one of these lamps, by placing it between their legs, under their garments, and sitting thus over it for several minutes. W. Long. 163. 29. N. Lat. 53. 5.

OONELLA, and OONEMAH, two islands of the same archipelago with Oonalashka; the former of which lies to the north-east of that island, being separated from it by a navigable strait; the other is more to the westward, being in W. Long. 168. 30. and N. Lat. 54. 30. The circumference of Oonella is about seven leagues, and the produce of both much the same with that of Oonalashka.

OPACITY, in *Philosophy*, a quality of bodies which renders them impervious to the rays of light.

OPAH, commonly called the *king fish*. See ZEUS, ICHTHYOLOGY *Index*.

OPAL, in *Natural History*, a species of gems. See MINERALOGY, p. 169.

OPALIA, in *Antiquity*, feasts celebrated at Rome in honour of the goddess Ops. Varro says they were held on the 19th of December, which was one of the days of the Saturnalia: these two feasts were celebrated in the same month, because Saturn and Ops were husband and wife: the vows offered to the goddess were made sitting on the ground.

OPARO, or OPARRO, a small island in S. Lat. 27° 36′, and in E. Long. 215° 49′, which was discovered by Vancouver. This island was supposed to be about six miles and a half long, and it was out of sight of any other land. It is composed of craggy mountains, forming in several places perpendicular cliffs from their summits to the sea, having narrow valleys or chasms interposed. On some of the highest hills were observed some kind of works, resembling fortified places; but as the discoverers did not land on the island, they could not learn their nature and use. In their language and appearance the natives resembled those of the Friendly islands; they seemed acquainted with the use of iron, preferring it to beads and other trinkets, and showed a hospitable disposition. There appeared to be anchoring ground near the north-west end of the island.

OPERA, a dramatic composition set to music, and sung on the stage, accompanied with musical instruments, and enriched with magnificent dresses, machines and other decorations.—This species of drama is of modern invention. In its present state it was not known even in Italy before the beginning of the last century; and at its introduction into England, a century afterwards, it divided the wits, literati, and musicians of the age. By those who were esteemed the best judges of the art, the English language was considered as too rough and inharmonious for the music of the opera; and, on the other hand, critics, whose taste was built on the basis of common sense, looked upon a drama in a foreign and unknown tongue as the greatest of all absurdities. Many of them, however, pleaded for operas in the English language; and it is well known that Addison, who was one of the opposers of the Italian opera on the London stage, wrote in his native tongue the opera of Rosamond. This is confessedly a beautiful poem; but, in the opinion of Dr Burney, it adds nothing to Addison's fame, as it shows his total ignorance of the first principles of music, and of course his unfitness for the task he had undertaken.

In questions respecting the fine arts there is no appeal from the general taste; and therefore, as the French opera, which is in the language of the country where it is acted, has always been admired by persons of liberal education, it doubtless has merit considered as a drama; but how the dramas of this kind which are composed in Italian should find admirers in England among persons who understand not a word of the language, it is to us a matter of astonishment. The music of them may deserve and command the admiration of every one who has

has an ear; and the action of the singers may be perfectly suitable to the subject represented; but of this suitableness the majority of the audience can be no judges.

Even when the language is thoroughly understood, we should imagine, that, to make an opera agreeable to good sense, much would depend upon the choice of the subject; for it is surely absurd to have persons of all ranks, and on every occasion, perpetually accompanied with the regular responses of symphony. To hear Cæsar, Scipio, or Macbeth, when forming plans to ensure victory, or hatching plots of treason and murder, talking in recitative and keeping time with fiddles, would surely disgust every person whose sense had not all evaporated in sound; but when the subject represented naturally admits of music in real life, we can suppose an opera to afford to persons of taste one of the most exquisite and refined entertainments of which human nature is capable. For a further account of the opera, see MUSIC, page 497, and POETRY, N° 133, &c.

OPERATION, in general, the act of exerting or exercising some power or faculty, upon which an effect follows.

OPERATION, in *Surgery* and *Medicine*, denotes a methodical action of the hand on the human body, in order to re-establish health.

OPHIDIUM, a genus of fishes belonging to the order of apodes. See ICHTHYOLOGY *Index*.

OPHIOGLOSSUM, ADDER'S TONGUE, a genus of plants, belonging to the cryptogamia class, and to the order *Filices*. See BOTANY *Index*.

OPHIOLOGY.

INTRODUCTION.

1 Definition. THE term *ophiology* is composed of two Greek words, namely οφις, a *serpent*, and λογος, a *discourse*, and consequently denotes that branch of zoology which treats of serpents. The latter constitute an order in the class of amphibious animals. They are covered with scales, breathe by means of lungs, and are destitute of feet and fins.

2 Historical notices of ophiological writers. The hideous aspect of some of the species, and the poisonous properties of others, long contributed to prevent any deliberate investigation of their structure, constitution, and modes of existence. 3 Ancient. Hence the ancients, who at best had very imperfect notions of classification, sometimes indicate different species under the same name, or bestow different appellations on the same species, and moreover blend their vague descriptions with the embellishments or absurdities of fable.

4 Modern. Among the moderns, few naturalists have directed their researches to the history of serpents. "It must be acknowledged," observes Dr Russel, "that it offers no attractive allurements; and that those who, from other avocations, can only spare transient attention to subjects of natural history, are more likely to prefer objects less disgusting, and experiments accompanied with less cruelty and personal danger. Even the eager and resolute naturalist has to contend with many difficulties in this path of research. He cannot at once divest himself of the abhorrence, next to innate, of these reptiles; nor can he soon acquire a dexterity in handling them, with that calmness requisite for his own safety. The search for plants, for birds, or even insects, is comparatively pastime, or pleasurable occupation; but in the actual pursuit of the disgusting race of serpents, he stands in need of assistants, who are not at all times to be procured; and if he rely solely on the diligence of such as he may employ, he will find himself exposed to the chagrin of incessant disappointment."

5 Seba. Seba has indeed presented us with a numerous catalogue; but his species are too multiplied, and his descriptions too concise. 6 Catesby. Catesby was more solicitous to design and colour his serpents, than to unfold their discriminating characters. 7 Gronovius. The descriptions of Gronovius are for the most part well and accurately detailed; but they are unprovided with the specific names.

8 Linnæus. Linnæus, availing himself of the works to which we have just alluded, of the discoveries of Garden, and of his own discernment, published his method of distinguishing the species by the number of scaly plates on the abdomen, and beneath the tail. Experience has indeed proved, that these do not always constitute an infallible criterion, and that more obvious marks, such as the relative size of the head, the length of the body and tail, &c. must sometimes be resorted to: it must, however, be allowed, that the celebrated Swedish naturalist paved the way to a far more accurate nomenclature of serpents than had yet appeared, and that the value of his scientific distinctions is greatly enhanced by the interesting notices on the same subject, which are inserted in his *Amœnitates Academicæ*, and in the first and second volumes of his *Adolphian Museum*.

9 La Cépède. The count de la Cépède has in some respects improved the Linnæan arrangement, and exhibited a more complete catalogue than any of his predecessors. 10 Shaw. Dr Shaw has likewise displayed his usual sagacity in the second part of the third volume of his General Zoology, which is allotted to his exposition of the serpent tribes. 11 Owen, Klein, &c. To these we may add, Owen on the natural history of serpents, Klein's Tentamen Herpetologiæ, Blumenbach's Beyträg zur Naturgeschichte der Schlangen, Schneider's Allgemeine Betrochtungen uber die Eintheilung und Kennzeichen der Schlangen, Merian's Beytrage zur geschichte der Amphibien, Laurenti's Specimen Medicum, continens Synopsin Reptilium, Bonaterre's Ophiologie, in the Encyclopédie Méthodique, Latreille's Histoire Naturelle des Reptiles, Russel's Account of Indian Serpents, &c. &c.

Anatomy and Physiology of Serpents.

12 Body. THE body of serpents is very long when compared with its thickness; and is sometimes quite cylindrical, or rounded, sometimes compressed on the sides, sometimes flat on the under surface, and sometimes attenuated towards the tail. It is usually covered with scales; but sometimes naked, either rough, or slippery to the touch,

Anatomy of Serpents.

and banded, spotted, or reticulated; the skin exhibiting great varieties in the tints and distribution of the colours.

13 Head. The head is either distinct from the trunk, or confounded with it, and is convex, or flattened, oval, triangular, or heart-shaped, and furnished with plates, or imbricated scales. It includes the mouth, snout, jaws, lips, teeth, tongue, eyes, and nostrils. There is no visible external ear; though animals of this order doubtless possess the faculty of hearing.

14 Mouth. The mouth is that cavity which is situated between the jaws. It is very large in proportion to the size of the head, and is capable of being widely extended.
15 Snout. The snout is the anterior part of the head: it is slanting,
16 Jaws. elongated, obtuse, truncated, or reflexed. The jaws, which are either of equal or unequal length, are composed of two bones, which do not, as ours, open in the manner of a pair of hinges, but are held together at the roots, by a stretching muscular skin, so as to open as widely as the animal chooses to stretch them. By this contrivance serpents are enabled to swallow animals
17 Lips. thicker than themselves. The lips are entire, notched,
18 Teeth. or reflexed. The teeth, in the jaws, are generally sharp-pointed, and, in serpents not poisonous, are disposed in three rows in the upper jaw, one row exterior and two interior. The under jaw is sometimes provided with a
19 Fangs. single row. The noxious species are furnished with canine teeth, or fangs, of a tubular structure, situated in the projecting part of the upper jaw, commonly of a much larger size than the other teeth, and frequently accompanied by smaller or subsidiary fangs, apparently destined to supply the principal ones, when lost either by age or accident. The fangs are situated in a peculiar bone, so articulated with the rest of the jaw, as to elevate or depress them at the pleasure of the animal. In a quiescent state they are recumbent, with their points directed inwards or backwards; but, in the moment of irritation, their position is altered by the mechanism of the above-mentioned bone, in which they are rooted,
20 Tongue. and they become almost perpendicular. The tongue is usually straight and slender, composed of two long and rounded fleshy substances, which terminate in sharp points, and are very pliable. They unite at about two thirds length, and the root is connected to the neck by two tendons, which give the whole organ a great variety and facility of motion. In most species, the tongue is almost wholly inclosed in a sheath, or integument, from which the animal can dart it out of its mouth, without opening its jaws; the upper mandible having a small notch, through which it can pass. Some of the viper kinds have tongues a fifth part of the length of their bodies, and, as they are constantly darting them out, terrify those who are ignorant of the real situation of
21 Eyes. the poison. The eyes are small, when compared with the length of the body, and greatly vary in respect of liveliness and colour. In some species the upper eyelid is wanting, while others have a nictitating membrane, or skin, which keeps the organ clean, and preserves the sight. In all, the substance of the eye is hard and horny, the crystalline humour occupying a great part of the globe. The pupil is susceptible of considerable contraction and dilatation, and the iris is often of a
22 Nostrils. golden or fine red colour. The nostrils are two openings at the extremity of the snout, for receiving the sensation of smell.

The trunk is that part of the body which reaches from the nape to the vent. It is scaly, annulated, tuberculated, or wrinkled; and comprehends the back, sides, belly, anus, organs of generation, and scales. The 23 Trunk.
back is the upper part of the trunk, commencing at the 24 Back.
nape and terminating immediately above the vent. In most species it is rounded, but in some carinated or fur- 25
rowed. The sides are the lateral portions of the trunk, Sides.
from the extremity of the jaws to the vent. The belly, 26 Belly.
or abdomen, is the lower part of the body, from the head to the tail, the want of a diaphragm precluding a breast. The anus is an opening, usually transverse, 27 Anus.
placed at the extremity of the lower surface of the trunk, forming the line of demarcation between the latter and the tail, and affording a passage to the liquid and solid excrements. The penis of the male, and the ovary of the female, are also situated in this common vent, from which they are extended only during the 28
season of pairing. The scales, properly so called, are Scales.
round, oval, oblong, and attenuated at the extremities, rhomboidal, smooth, or carinated. The broad undivided plates on the belly and head, are termed *scuta*, and the smaller or divided plates beneath the tail, are called *squamæ subcaudales* or *scutella*, *subcaudal scales* or *platelets*.

29 Tail. The tail is attenuated, obtuse, square, in the form of a triangular pyramid, flattened or compressed at the sides.

30 Skeleton. As serpents have neither limbs nor breast, the structure of their skeleton is much less complex than that of quadrupeds. The bones of the head are from eight to ten. The skull, which is sometimes flat and sometimes convex, is very hard and compact, and exhibits four principal sutures, which are with difficulty separated. The bones of the trunk consist of a series of vertebræ, incased in one another, and articulated with the ribs. The caudal vertebræ are disposed in the same manner, and provided with similar processes; but they are unconnected with ribs, and gradually diminish in size as they approach to the end of the tail. In most quadrupeds, the joints in the back-bone seldom exceed thirty or forty; whereas in serpents they often amount to 145, from the head to the vent, and 25 more from that to the tail. The number of these joints must give the back-bone a surprising degree of pliancy, which is still increased by the manner in which one is locked into the other. In man and quadrupeds, the flat surfaces of the bones are laid one against the other, and bound tight by sinews; but in serpents the bones play one within the other, like ball and socket, so that they have free motion in every direction.

31 Muscles. The remarkable strength and agility, manifested by serpents, depend on the vigorous muscles with which they are provided. Several of these are inserted along and beneath the skull, and about the upper and lower jaws. Four, which are denominated *lateral*, have their origin behind the head, and descend, by each side, to the extremity of the tail. Each vertebra has also its corresponding intercostal muscle, which serves the same purposes as in other animals.

32 Viscera. The internal organs, or viscera of individuals of this order of animals, nearly correspond to those of others, and, consequently, need not long detain us.

33 Brain. The brain is divided into five small portions, which are round, and somewhat elongated. The two first are placed

Anatomy of Serpents.

placed between the eyes, and give origin to the olfactory nerves; other two are situated in the middle region of the skull; and the last, which is a little farther back, appears to be the commencement of the spinal marrow.

34 Tracheal artery. The tracheal artery, composed of distinct and cartilaginous rings, has its origin at the top of the gullet, and communicates with the lungs, under the heart.

35 Lungs. The lungs are not lobed, but consist of a cellular and membranous substance, abundantly furnished with blood vessels.

36 Oesophagus. The œsophagus is formed of a single membrane, extends to the orifice of the stomach, is of an equal diameter throughout, and susceptible of an extraordinary degree of dilatation.

37 Stomach. The stomach, which is of a larger capacity, is formed of two concentric tunics, which closely adhere, and which are internally covered with folds or wrinkles.

38 Heart. The heart has two ventricles, and is small in proportion to the size of the body. As the circulation of the blood is independent of the lungs, the animal is enabled to remain for a considerable time under water. It cannot, however, make this element its constant residence; because occasional supplies of fresh air are necessary to preserve in its blood those qualities which are necessary to motion and vitality. In serpents, therefore, as well as in viviparous quadrupeds, respiration is essential to life. This function they do not perform by a rapid succession of alternate dilatations and contractions of the lungs; but, having this viscus remarkably large in proportion to their bodies, they are able to fill it with a considerable provision of air; and as they expire very slowly, some time will elapse before they are obliged to inspire again.

39 Intestinal canal. The intestinal canal is narrow, sinuous, and internally divided by many transverse partitions.

40 Kidneys. The kidneys are particularly large, and composed of small continuous glands, blended with excretory vessels.

41 External senses. That animals of the serpent-kind possess the use of the five external senses, can scarcely admit of dispute. We have indeed, remarked, that most of the species appear to want an external auditory passage; but it is certain that they are often directed to birds, by listening to their notes; and many indicate a degree of sensibility to the sounds of musical instruments. Their sense of smell, with a few remarkable exceptions, is neither very active nor acute; but, in most, that of sight is quick and penetrating. The soft and nervous texture of the tongue and palate would induce a suspicion, that they enjoy the sense of taste in a pre-eminent degree; yet, as they generally swallow their food in large portions, they seldom avail themselves of the delicacy of these organs. Being unprovided with feet, hands, or feelers, their sense of touch is probably very imperfect; and even when they twine very closely round an object, the interposition of their scales will render their feeling of its surface vague and obtuse.

42 Sexual union. The sexual union of serpents usually takes place in the sunny days of spring, is very close and ardent, and varies in duration from an hour to several days, according to the species, but terminates without any permanent attachment.

43 Oviparous. The females of some are oviparous, and of others viviparous. The eggs of the former vary in respect of size, colour, and number, according to the species and constitution of the individual; and they are deposited, not in continuous succession, but at intervals, and sometimes with the appearance of much suffering on the part of the female. Sergerus relates, that he saw a female snake, after twisting herself, and rolling on the ground in an unusual manner, bring forth an egg. He immediately took her up, and facilitated the extrusion of thirteen more, the laying of all which consumed an hour and a half; for, after depositing each, she rested for some time. When he remitted his assistance, the process was more slow and difficult; and the poor animal seemed to receive his good offices with gratitude, which she expressed by gently rubbing her head against his hands. The mother never hatches these eggs, but leaves them exposed in some warm situation, as in holes with a southern aspect, on dry sand, under moss or foliage, on a dunghill, near an oven, &c. The outer covering of the egg is a thin compact membrane, and the young serpent is spirally rolled in its albuminous liquid.

Physiology of Serpents.

The viviparous species differ considerably, both with respect to their periods of gestation, and the number of their offspring. 44 Viviparous. Thus, vipers which go about three months with young, generally breed twice a-year, and produce from twenty to twenty-four, while the blind-worm, which is pregnant about a month, brings forth sometimes seven, and sometimes ten at a birth. When young serpents are hatched or produced, they are abandoned to the resources of their own instinct, and often perish before they have acquired sufficient experience to shun the snares which are laid for them by quadrupeds, birds, and reptiles.

In regard to the different stages of growth of the different species, little precise information seems to have been obtained: and, though some arrive at a very large size, their dimensions have, no doubt, been much exaggerated. 45 Growth.

The young of the viper, at the moment of parturition, measures from twelve to fifteen lines; and two or three years elapse before they are capable of reproducing their kind. 46 Size. Adanson however concludes, from ocular observation, that the largest serpent in Senegal may measure from forty to fifty feet in length, and from a foot to a foot and a half in breadth. Leguat assures us, that he saw one in Java, that was fifty feet long. Carli asserts, that they grow to upwards of forty feet. Mr Wentworth, a gentleman who had large concerns in the Berbices, informs us, that he one day sent out a soldier, with an Indian, to kill wild fowl for the table; and they accordingly went some miles from the fort. In pursuing their game, the Indian, who generally marched before, beginning to tire, went to rest himself on the fallen trunk of a tree, as he supposed it to be; but, when he was just going to sit down, the huge monster began to move, and the poor savage, perceiving that he had approached a Boa, dropped down in an agony. The soldier perceiving what had happened, levelled at the serpent's head, and by a lucky aim shot it dead. He continued his fire, however, until he was assured that the animal was killed; and then going up to rescue his companion, he found him killed by the fright. The animal was brought to the fort, and was found to measure thirty-six feet. Mr W. caused the skin to be stuffed, and sent it as a present to the Prince of Orange. We are told, that when Regulus led his army along the banks of the Bagrada, in Africa, an enormous serpent disputed his passage across the river. If we can give credit to Pliny, this reptile was 120 feet long, and had destroyed many of the soldiers, when it was overcome in turn by the battering engines. Its spoils were carried

to

to Rome, and the general was decreed an ovation for his success. The skin was preserved for years after in the capitol, where Pliny says that he saw it.

47 **Voice.** In regard to voice, some serpents are apparently silent, and others have a peculiar cry; but hissing is the sound which they most commonly utter, either as a call to their kind, or a threat to their enemies. In countries where they abound, they are generally silent in the middle of the day; but, in the cool of the evening, they issue from their retreats with continued hissings.

48 **Masses of food.** The masses of food which serpents are enabled to swallow, would appear quite miraculous, did we not reflect on the lax structure of their jaws, their power of crushing their victims, and the viscid humour, or saliva, which lubricates the crude morsel in its passage down an extensile œsophagus. In spite of all these circumstances, the quantity of aliment is sometimes so voluminous, that it sticks in the gullet, when only partly immersed in the stomach, and the animal lies stretched and nearly motionless, in its retreat, till the swallowed portion be digested, and the extruded half introduced, to undergo the same process.

49 **Capability of abstinence.** But, though serpents thus occasionally gorge themselves with food, as their blood is colder than that of most other terrestrial animals, and circulates slowly, their powers of digestion are feeble and tardy, so that they can endure weeks, and even months of abstinence. Nay, so tenacious are they of the vital principle, that they exist and grow in mephitic marshes, continue to breathe, for a considerable time, in the exhausted receiver of an air-pump, and frequently exhibit symptoms of life after one part of the body has been severed from the other. Vipers are often kept in boxes, for six or eight months, without any food whatever; and there are little serpents sometimes sent to Europe from Cairo, which live for several years in glasses, and never eat at all.

50 **Age.** The natural term of the existence of serpents, is not accurately known; but it has been conjectured, that some of the larger kinds may complete a century. The first failure of their strength is the almost immediate forerunner of their dissolution; for, when deprived of the requisite elasticity of frame to spring on their prey, and of the requisite force to combat their enemies, they shrink into their recesses, and die of hunger, or are easily devoured by the ichneumon, stork, and other powerful assailants.

51 **Hybernation.** In the more northerly and temperate regions of the globe, the serpent tribes, towards the end of autumn, fall into a state of torpor, more or less profound, according to the greater or less intensity of the cold; and in this condition they remain, nearly lifeless, till the approach of spring reanimates their stiffened frame.

52 **Renewal of skin.** Soon after its resuscitation, the serpent works itself out of its old epidermis, by rubbing itself against the ground, or by wedging itself between any two substances that are sufficiently close to each other. The exuviæ come off entire, being loosened first about the head; and are always found turned inside out. It is some time before the scales acquire a sufficient degree of hardness to defend the animal against external injury; and, during this interval, it generally confines itself to its retreat.

Generic and Specific Exposition of the Order.

Gen. I. Crotalus. *Rattle-Snake.* 53 **Crotalus.**

54 **Generic characters.** Scuta on the abdomen, scutæ and squamæ beneath the tail, rattle terminating the tail.

The animals of this genus inhabit America, where they prey on the smaller birds, lizards, and insects. They are furnished with poisonous fangs, and have a broad head, covered with large scales. Their snout is obtusely rounded.

55 **Horridus.** *Banded Rattle-Snake, Common Rattle-Snake,* or *Boiquira.*—The characters are, 167 abdominal, and 23 subcaudal scuta. The ordinary length of this species is from three to four or five feet, and the greatest thickness that of a man's arm. The prevailing colour is a yellowish brown, marked with cross and irregular bands of a deeper shade, and two or three longitudinal stripes from the head down the neck; the under parts are of a dingy brown, with many dusky variegations and freckles. The mouth is capable of great distension. The tongue is black, slender, bipartite, and inclosed in a kind of sheath, from which the snake darts forth the double point, and vibrates it with great velocity. The rattlesnake is viviparous, producing in June about twelve young, which, by September, acquire the length of about twelve inches. These, it is said to preserve from danger, like the viper in Europe, by receiving them into its mouth, and swallowing them. In confirmation of this assertion, we shall quote the words of M. de Beauvois, who, during his residence in America, bestowed particular attention on the history of amphibious reptiles.

"Among the information which I endeavoured to obtain in my travels with respect to serpents in general, there was one point which greatly excited my curiosity. Several persons, and one among the rest to whom I owe a debt of gratitude for civilities and marks of friendship, which will for ever rest engraven on my heart, had informed me, that the female rattle-snake concealed its young ones in its body; that when they were alarmed by any noise, or by the approach of man, they took refuge in the body of their mother, into which they entered by her mouth. This fact had been already ascertained with respect to the viper of Europe; but in consequence of the unfavourable and repulsive dispositions inspired by this kind of reptile, and in order to render it still more hideous, an absurd interpretation was given to this fact. It was pretended, that this serpent eats its little ones after having given them birth. Curious to verify this fact related of the boiquira, I was constantly occupied with this idea, and began to despair of ever making the observation, when, at a moment in which I thought the least of it, accident furnished me the means. Having fallen sick among the Indians, I found myself obliged to remain a few days with one of them in the neighbourhood of Pine-log. During my convalescence, I took a walk every morning in the neighbourhood, and one day when I was following a pretty broad path, I perceived, at a distance, a serpent lying across the road in the sun. I had a stick in my hand, and drew near to kill it; but what was my surprise, when, in the moment that I was about to give the blow, the

Crotalus. the reptile perceived me, coiled up itself, and opened its large mouth, into which five serpents, which I had not till then observed, because they were lying along its body, rushed into the gulf which I had conceived opened for myself. I retired to one side, and hid myself behind a tree. The reptile had crawled a few paces, but hearing no further noise, and not perceiving me, stretched itself out afresh. In a quarter of a hour the young ones came out again. Satisfied with this observation, I advanced anew towards the animal, with intention to kill it and examine the interior of its stomach: but it did not permit me to approach so near as it did the first time, the young ones entered with still greater precipitation into their retreat, and the boiquira fled into the grass. My satisfaction and astonishment were so great, that I did not think of following it."

The rattle consists of a number of pieces, inserted into each other, all alike in shape and size, hollow, and of a thin, elastic, brittle substance, similar to the exterior part of the scuta. Their form is nearly that of an inverted quadrilateral pyramid, with the corners rounded off. The first piece, or that nearest the body, may be considered as a kind of case, which contains the three last vertebræ of the tail, on which it appears to be moulded, and has three convex, circular elevations corresponding with them; the two last of these elevations are fitted into the two first of the next piece; so that of every piece except the last, the first only of the elevations is exposed to view, the two others being inclosed in those of the following, in which they have room to play from side to side. These several pieces have no muscles, nerves, nor ligaments, nor are they connected either with each other, or with the body of the serpent any otherwise than by the mode of insertion already described. Thus they derive no nourishment from the animal, and are merely an appendage which can have no other motion than what is communicated to it by that of the tail. These several pieces of which the rattle consists, appear to have been separately formed. Dr Van Meurs imagines them to be no other than the old epidermis of the tail, which, when its nourishment is intercepted by the new skin formed beneath it, grows hard and brittle. Hence, he supposes, that whenever this part acquires a new skin, a new piece of the rattle is added to the former, which is thus detached from the vertebræ, and shoved farther from the tail. The number of these pieces, however, affords no certain criterion of the animal's age, because those which are most remote from the tail, become so dry and brittle, that they are very liable to be broken off and lost.

The two principal fangs are placed without the jaws, on a separate bone, and the smaller ones attached to muscles and tendons. These fangs may be couched, or raised, at the pleasure of the animal, and are furnished with an opening near the root, and a slit towards the point, so that on pressing gently with the finger on the side of the gum, the poison, which is yellowish, is perceived to issue from the hollow of the tooth, through the slit. The vesicle which contains the poison, is externally of a triangular form, and of a tendinous texture; internally, it is cellular; and its interior part terminates in a small duct, communicating with the sacculus which covers the perforated teeth. It is furnished with a constrictor muscle, for the purpose of expressing its contents. The virulence of the latter may be inferred from various experiments reported in the Philosophical Transactions, and other publications. A rattle-snake of about four feet long, being fastened to a stake, bit three dogs, the first of which died in less than a quarter of a minute; the second, which was bitten a short time afterwards, in about two hours, and the third, which was bitten about half an hour afterwards, showed the visible effects of the poison in three hours, and likewise died. Other experiments were instituted; and lastly, in order to try if the snake could poison itself, it was provoked to bite a part of its own body, and actually expired in less than twelve minutes. Our limits will not permit us to enumerate various other instances of the almost instantaneous effects of this poison, which is most to be dreaded in hot weather, and when the animal is much irritated. The rattle-snake, however, is rather afraid of man, and will not venture to attack him unless provoked. It moves slowly, for the most part with its head on the ground, but if alarmed, it throws its body into a circle, coiling itself with the head erect in the centre, and with its eyes flaming in a terrific manner. In cases of slight bites, the Indians usually suck the wound. They have likewise recourse to the juices of various herbs, and to the root of *polygala seneka*; but these applications produce little effect, without scarification and ligatures. According to Dr Barton, the rude and simple practice of the western settlers, is, first, to throw a tight ligature above the part into which the poison has been introduced, at least as often as the circumstances of the case admit of such an application. The wound is next scarified, and a mixture of salt and gunpowder, or either of these articles, separately, laid on the part. Over the whole is put a piece of the bark of *juglans alba*, or white walnut-tree, which acts as a blister. At the same time, a decoction or infusion of one or more stimulant vegetables, with large quantities of milk, are administered internally: the doctor is, nevertheless, of opinion, that the beneficial effects of this mode of treatment are chiefly to be ascribed to the external applications. If the fang has penetrated a vein or artery, or attacked the region of the throat, the bite commonly proves fatal, and the patient expires in dreadful agony. "Where a rattle-snake, (says Catesby), with full force, penetrates with his deadly fangs, and pricks a vein, or artery, inevitable death ensues; and that, as I have often seen, in less than two minutes." "The Indians, (he continues), know their destiny the minute they are bit; and, when they perceive it mortal, apply no remedy, concluding all efforts in vain." Dr Barton, however, inclines to think, that this assertion should be received with considerable limitation, and that the application of ligatures, &c. even in cases apparently the most desperate, should not be neglected. According to Clavigero, the most effectual method is thought to be, the holding of the wounded part some time in the earth. But if the poison be once received into the general mass of the blood, it is almost needless to have recourse to medicines. A considerable degree of nausea is usually the first alarming symptom; the pulse becomes full, strong, and greatly agitated; the whole body swells; the eyes are suffused with blood; a hemorrhage frequently proceeds from the eyes, nose, and ears; large quantities of blood are sometimes thrown out on the surface of the body, in the form of sweat; the teeth vacillate in their sockets; and the pains and groans of

Crotalus. of the unhappy sufferer too plainly indicate, that the moment of dissolution is near at hand.

The following remarkable case is related by Mr Hector St John. A farmer was one day mowing with his negroes, when he accidentally trod on a rattle-snake, which immediately turned on him, and bit his boot. At night, when he went to bed, he was attacked with sickness, his body swelled, and before a physician could be called in, he died. All his neighbours were surprised at his sudden death; but the body was interred without examination. A few days after one of the sons put on the father's boots, and, at night, when he pulled them off, he was seized with the same symptoms, and died on the following morning. The physician arrived, and, unable to divine the cause of so singular a disorder, seriously pronounced both the father and son to have been bewitched. At the sale of the effects a neighbour purchased the boots, and on putting them on, experienced the like dreadful symptoms with the father and son. A skilful physician, however, being sent for, who had heard of the foregoing accidents, suspected the cause, and by applying proper remedies, recovered the patient. The fatal boots were now carefully examined, and the two fangs of the snake were discovered to have been left in the leather, with the poison-bladders adhering to them. They had penetrated entirely through, and both the father and son had imperceptibly scratched themselves with their point in pulling off the boots.

We are informed by Dr Barton, that a gentleman of Philadelphia had a large rattle-snake brought to him alive, which he so managed by a string, that he could easily lead it into, or out of a close cage. On the first day, he suffered this snake to bite a chicken, which had been allured to the mouth of the cage by crumbs of bread. In a few hours, the bird mortified, and died. On the second day, another chicken was bitten in the same manner, and survived the injury much longer than the first. On the third day, the experiment was made on a third chicken, which swelled much, but, nevertheless, recovered. On the fourth day several chickens were suffered to be bitten, without receiving any injury. These simple experiments enable us to assign a reason, why persons who have actually been bitten by the rattle-snake, have sometimes experienced very inconsiderable, or no bad consequences from the wound; they shew in what manner many vegetables have acquired a reputation for curing the bites of serpents, without our being obliged to impeach the veracity of those from whom our information is derived; and lastly, they teach us the physiological fact, that the poison of this reptile is secreted very slowly.

It has been observed by M. Gauthier, that the poison stains linen with a green hue, which is deeper in proportion as the linen has been impregnated with lixivium.

The pretended fascinating power of the rattle-snake is now generally discredited; and Dr Barton, professor of natural history in the university of Pensylvania, reduces the whole to the fluttering of old birds in defence of their young, and too near an approach to the formidable enemy. In confirmation of this opinion, he observes, that he can trace no allusion to the alleged fascinating faculty, in the ancient writers of Greece and Rome; that he doubts if it is credited by the American Indians; that Linnæus was extremely credulous; that the enchanting power of the rattlesnake is questioned by some eminent European naturalists; that the breath of this reptile is not remarkably infectious or pestiferous; that it often fails in catching birds; that the latter, and squirrels, are not its principal food; and that it is even devoured by some of the larger kinds of birds.

Mr Peale, an intelligent and zealous naturalist, kept a rattle-snake alive for five years and a half. "Curious to inquire, (says M. Beauvois), how this animal seizes his prey, he (Mr Peale) has confined several birds in the same cage with him, and the hungry reptile has made many attempts to take hold of the bird. This experiment has been repeated many times, and every time with the same effect. I have seen, myself, one of these birds in the cage; but whether the reptile was not hungry, or was sensible of its want of power, it remained perfectly tranquil, while the bird was perfectly at ease. It gave no indication which could make it be believed that it was either enchanted or affrighted; and the air did not appear different, if we might judge from its behaviour from that which is found in an ordinary close cage. The bird remained two days in the same situation, without the least attention paid to it by the reptile, who, in the mean time, ate a dead one which was presented to him.

"Another living bird was put into the cage with the serpent: far from being alarmed, it amused itself with pecking in the bottom, and picking up a few grains which it found there: often changing place in its accustomed manner, and even resting itself on the back of the boiquira, which made no extraordinary movements. This experiment was made several times.

"Mr Peale, his children, and myself, have often examined the reptile. We never perceived it to send out the slightest suffocating odour. It is in vain to object, that the living birds thus given it were not of the kind fitted for its nourishment; for it has eaten the same birds, when presented to it dead, and it is not useless to remark, that it never refused one of them."

Catesby mentions an individual of this species, which was about eight feet long, and weighed from eight to nine pounds. It was seen gliding into a gentleman's house, and terrified all the domestic animals.

Mr St John, whom we have quoted above, once saw a tamed rattle-snake, as gentle as it is possible to conceive a reptile to be. It went to the water, and swam wherever it pleased, and when the boys to whom it belonged called it back, their summons was readily obeyed. They often stroked it with a soft brush: and this friction seemed to cause the most pleasing sensations; for it would turn on its back to enjoy it, as a cat does before the fire. We need scarcely add, that it had been deprived of its fangs.

Rattle-snakes abound in America, from Brazil to near Lake Champlain: but they are gradually disappearing in the more populous districts. According to Pennant, they affect woods and lofty hills, especially where the strata are rocky or chalky, as at the pass near Niagara. They particularly frequent the sides of rills, to prey on such small animals as resort thither to quench their thirst. In summer, they are generally found in pairs; in winter, they collect in multitudes, and retire under ground, beyond the reach of frost. Tempted by the warmth of a spring-day, they often creep out, weak and languid. A person has seen a piece of ground covered with them, and killed with a rod between sixty and

Crotalus. and seventy, till, overpowered with the stench, he was obliged to retire. They are most easily dispatched by a blow with a stick on the spine.

The American Indians often regale on the rattle-snake. When they find it asleep, they put a small forked stick over its neck, which they keep immoveably fixed to the ground, giving the snake a piece of leather to bite; and this they pull back several times with great force, until they perceive that the poison fangs are torn out. They then cut off the head, skin the body, and cook it, as we do eels. The flesh is said to be white and excellent. Hogs also sometimes devour the rattle-snake; but horses, dogs, and most other animals, regard it with antipathy and horror.

56 Durissus. *Striped Rattle-snake*, or *White Rattle-snake*.—172 abdominal, and 21 subcaudal scuta. From a foot and a half, to four feet and a half long. Distinguished from the preceding by a pattern of pale yellow streaks, forming a series of large rhombs, or lozenges, down the back. Has often been confounded with the former, on account of the same general aspect, constitution, and habits.

57 Dryinas. *Wood Rattle-snake*.—165 abdominal, and 30 subcaudal scuta. Of a lighter tinge than the two preceding, and marked with yellowish variegations on the back.—This species has been hitherto very imperfectly described; and Seba erroneously quotes it as a native of Ceylon.

58 Miliaris. *Miliary* or *Small Rattle-snake*.—132 abdominal, and 32 subcaudal scuta. Gray, with a triple row of black spots, and a red spot between each of the dorsal ones. The smallest of the genus; its ordinary length being about eighteen inches. From this circumstance, and the faint sound of its rattle, it is more dangerous than the larger species. It is also alleged that its bite is more active. Its poison, according to Lebeau, is most successfully combated by the volatile alkali. It is confined to the temperate regions of North America, particularly to Carolina, Louisiana, and Florida.

59 Atricaudatus. *Black-tailed Rattle-snake*.—170 abdominal, and 26 subcaudal scuta. The head greenish-gray, with two brown and oblong spots on the hinder part. The body of a reddish gray, speckled with brown points, and crossed by 24 lengthened patches, or bands, brown, and irregular, and accompanied, on each side, by two spots of a brighter colour. The back is marked by a longitudinal, fawn-coloured stripe. Scales very numerous, rhomboidal, and carinated.—From three to four feet long; a very venomous species; discovered by Bosc, in Carolina, and described in Daudin's Natural History of Reptiles.

60 Boa.

Gen. 2. Boa.

61 Characters. Scuta on the abdomen, and under the tail; but no rattle.

The boa tribe of serpents is very numerous, and contains some species which are remarkable for their huge dimensions. Their head is covered, like that of the crotali; but their tail terminates in a point. Their immense size has rendered them the objects of terror rather than of observation to mankind; while the quantity of food requisite for their sustenance, has precluded their multiplication within a limited range of country. Hence a considerable degree of confusion attaches to their history; and a rational suspicion arises, that, with the progress of culture and population, some of the more formidable sorts have either been exterminated, or driven from the haunts of men. Some naturalists have asserted, that individuals belonging to this genus have been found in Spain, Italy, and the south of France; but they appear to have mistaken some of the larger sorts of coluber for the boa, which last is a native of Asia, Africa, and America.

62 Constrictor. *Great* or *Constrictor Boa*.—240 abdominal, and 60 subcaudal scuta. The more ordinary disposition of its colouring is yellowish gray with a large, chesnut-coloured, chain-like pattern down the back, and triangular spots on the sides. A considerable degree of variety, however, is occasioned by the circumstances of age, sex, and climate; and even the number of scuta is by no means constant. Nature has bestowed on this celebrated reptile, uncommon strength and beauty, but has wisely withholden from it the poisonous properties of some of the smaller species. It frequently attains to twenty, or even thirty feet in length. Except, however, when stimulated by the calls of hunger, it is a sluggish and harmless animal, affecting moist and shady situations, and, occasionally, devouring large animals, which it crushes in its contorted folds. In the German Ephemerides, we have an account of a combat between one of these huge serpents and a buffalo, by a person who assures us, that he was himself a spectator. The serpent had for some time, been waiting near the brink of a pool, in expectation of prey, when a buffalo was the first animal that appeared. Having darted on the affrighted beast, it instantly began to wrap him round in its voluminous twistings, and, at every twist, the bones of the buffalo were heard to crack almost as loud as the report of a gun. It was in vain that the quadruped struggled and bellowed; its enormous enemy twined it so closely, that at length all its bones were crushed to pieces, like those of a malefactor on the wheel, and the whole body reduced to one uniform mass. The serpent then untwined its folds, to swallow its prey at leisure. To prepare for this, and also to make it slip down more smoothly, it licked the whole body over, and smeared it with a mucilaginous matter. It then began to swallow it at the end that offered the least resistance; the throat dilating to such an extraordinary degree, as to admit a substance which was thrice its own thickness.

In the Bombay Courier, of August 31. 1799, it is stated, that as a Malay prow anchored for the night, close under the island of Celebes, one of the crew went on shore, in quest of betel nut in the woods, and on his return, lay down to sleep, as it is supposed, on the beach. In the course of the night, he was heard by his comrades, to scream out for assistance. They immediately went on shore; but an immense snake of this species had already crushed him to death. The attention of the monster being entirely occupied with his prey, the people went boldly up to it, cut off its head, and took both it and the body of the man on board their boat. The snake had seized the poor fellow by the right wrist, where the marks of the teeth were very distinct; and the mangled corpse bore evident signs of being crushed. The length of the snake was about thirty feet, its thickness equal to that of a moderately sized man; and, on extending its jaws, the gape was found

Boa. found wide enough to admit a body of the size of a man's head.

The female deposits a considerable number of eggs, which seldom exceed three inches in their greatest diameter, on the sand, or under leaves exposed to the sun's rays.

In some districts of Africa, the great boa is regarded as an object of veneration, and on the coast of Mozambique, is worshipped as a god.

In a very interesting notice of this species, communicated to us by John Corse Scott, Esq. mention is made of a live individual, which was discovered in a field, near the cattle, by some labourers, in the province of Tipperah in Bengal. This snake, which measured fifteen feet and three inches in length, and eighteen inches in circumference, was stunned by repeated blows, before it could be secured, and tied with cords to a long bamboo. It was pretty active after it was untied, and made frequent darts at any person coming near it. On presenting a long stick, it repeatedly seized and bit it with great fierceness. On dissection, the heart was found to be of the size of a sheep's, with the communication open between the two ventricles. The liver was small in proportion, being about the size of the human pancreas, and, like it, divided into several lobes. The œsophagus, from the mouth to the pylorus, measured nine feet three inches, and its width was sufficient to admit a man's head with ease. The head was small, in proportion to the size of the animal, the eyes were dark and heavy, and the nostrils large; but there was no perceptible organ of hearing. From the mechanism of the jaws, they were capable of being distended so as to admit a substance or animal much thicker than the snake itself. This mechanism, and the absence of grinders, obviously prove, that the food is swallowed entire, without mastication. In a gorged individual of this species, Mr S. found an entire guana, and in another, a fawn, of a year old; but the bones of these quadrupeds were unbroken.

63 *Scytale.* *Spotted Boa.*—250 abdominal, and 70 subcaudal scuta. Cinereous, with large, round, black spots on the back, and smaller ones, with white centres, on the sides, and oblong markings, interspersed with smaller variegations on the abdomen. Of a size scarcely inferior to the preceding, and of similar manners. It is a native of several parts of South America, and, like other snakes, occasionally eaten by the Indians.

64 *Cenchris.* *Ringed Boa.*—265 abdominal, and 57 subcaudal scuta. General cast ferruginous, with large dark rings on the back, and blackish kidney-shaped spots, with white centres on the sides. The *aboma* of several writers. Grows to a large size, and is a native of South America, where it is treated with divine honours.

65 *Canina.* *Canine* or *Green Boa.*—203 abdominal, and 77 subcaudal scuta. Green, with cross, waving, and white dorsal bands. It has its specific name from the form of its head, which resembles that of a dog. Though destitute of poison fangs, it inflicts a severe bite, when provoked. It measures from four to twelve feet in length, inhabits South America, and is celebrated for its beauty.

66 *Phrygia.* *Embroidered Boa.*—A remarkably elegant species, native of the East Indies, and omitted by Linnæus. White, with a cinereous tinge on the back, and the body marked with black lace-like variegations. Boa.

Garden Boa.—290 abdominal, and 123 subcaudal scuta. Yellowish gray, with brown variegations, resembling in form the parterres of an old-fashioned garden, the body somewhat compressed, and the sides marked with cuneiform spots. From two to three or four feet long, and native of South America. 67 *Hortulana.*

Fasciated Boa.—233 abdominal, and 36 subcaudal scuta. Yellow, with dusky blue transverse bands. The body somewhat triangular, upwards of five feet in length, and five inches in the thickest part. Native of India, and very poisonous. 68 *Fasciata.*

An individual of this species was sent to Dr Russel, in a very languid and extenuated state. Being set at liberty, it remained for some time without moving, but soon began to crawl slowly towards a dark corner. A chicken being presented, it seemed not to regard it, though the bird fluttered about it, and even rested a toe on its head. The chicken was then put on the snake's back, and clung so fast with its toes, that when attempted to be separated, the snake was dragged a little way, without offering to resent the insult. An hour after, the chicken was again presented; but the snake shewing no disposition to bite, its jaws were forced asunder, and the naked thigh of the chicken so placed, that the jaws closed on part of it. The chicken, when disengaged, shewed immediate symptoms of poison: it couched, purged once or twice, and was not able to stand. In the course of the first ten minutes, after several ineffectual efforts to rise, it rested its beak on the ground; and the head was seized with paralysis. After 15 minutes, it showed a frequent disposition to lie down; but remained couched some minutes longer. In 20 minutes it lay down on one side, and, convulsions supervening soon after, it expired within 26 minutes.

Viperine Boa.—209 abdominal, and 19 subcaudal scuta. Gray, with a black waving dorsal band, edged with white; the sides spotted with black. About a foot and a half in length, including the tail, which is only one inch and a half long. Native of India, where its bite is said to produce a slow wasting of the fingers and toes. As, however, it has no fangs, and produces no deleterious effects on brute animals: the truth of the report seems to be very questionable. 69 *Viperina.*

Lineated Boa.—209 abdominal, and 47 subcaudal scuta. Blackish line, with white dotted, transverse, arched lines, and whitish abdomen. Slender, native of India, and highly poisonous. 70 *Lineata.*

Annulated Boa.—About two feet in length, somewhat ferruginous, with black rounded spots, included in rings on the back, reniform ocellated spots on the sides, and waving dusky variegations on the abdomen. Native of South America, figured by Madame Merian, and preserved in the Hunterian Museum, at Glasgow. 71 *Annulata.*

The other species belonging to this genus are, *enydris*, *ophryas*, *regia*, *murina*, *horatta*, *hipnale*, *contortrix*, and *palpebrosa*.

Gen. 3. Coluber, *Snake* (properly so called). 72 Coluber.

Scuta, or undivided plates, under the abdomen; squamæ, or broad alternate scales, under the tail. The latter 73 Characters.

Coluber.

ter, although alternate, are reckoned by pairs; but, in many instances, the number is still undetermined, and it sometimes varies in the same species.

This tribe contains about 200 species, which greatly differ from one another in size and habit. The poisonous sorts, which constitute about one-fifth of the whole, are generally distinguished from the rest by their large, flattish, subcordate heads, and rather short bodies and tails; whereas most of the harmless species have small heads, with longer bodies and tails in proportion. Laurenti and Latreille have ranged the former under the genus *Vipera*, and the latter under that of *Coluber*: but Linnæus, Daubenton, La Cépède, &c. include both sorts under *Coluber*. This family of serpents is widely diffused over various quarters of the world.

74 *Berus.* *Common Viper.*—146 abdominal scuta, 39 subcaudal scales. Attains to the length of two, or even of three feet. The ground colour of the body is a dingy yellow, deeper in the female than in the male. The back is marked with rhomboidal, as the sides are with triangular, black spots. Its black belly, the greater thickness of the head, and the more abrupt termination of the tail, sufficiently distinguish it from the common snake, with which it has been often confounded.

The viper arrives at maturity in six or seven years, and produces 10 or 12 live young at the end of the second or third. Mr White of Selborne killed and cut up a pregnant female, and found in the abdomen 15 young ones, about the size of full grown earth-worms. No sooner were they freed from confinement, than they twisted and wriggled about, set themselves up, and gaped very wide when touched with a stick, exhibiting manifest tokens of menace and defiance, though as yet no fangs were visible, even with the help of glasses.—That the young, for some time after birth, retreat, when alarmed, into the mouth of the mother, seems to be a fact satisfactorily ascertained.

Vipers are capable of supporting long abstinence, feed on reptiles, worms, and young birds, and become torpid in winter. Their poison rarely proves fatal to man, and is most successively counteracted by olive oil, thoroughly rubbed on the wounded part. They are usually caught by wooden tongs, at the end of the tail, as, in that position, they cannot wind themselves up to injure their enemy. Their flesh was formerly in high esteem, as a remedy for various diseases, particularly as a restorative. Of late years, however, it has lost much of its ancient credit, and is rarely prescribed by modern practitioners.

The common viper inhabits Europe and Siberia, and is by no means uncommon in Great Britain, being the only poisonous animal in the island, frequenting dry and stony districts, and especially the chalky countries. It abounds in some of the Hebrides, and is called *adder* by the Scots.

This species is subject to several varieties, which we cannot stop to enumerate. The *prester*, or *black viper*, resembles the *berus*, in almost every particular but colour; though Linnæus, and other eminent naturalists, rank it as a distinct species.

75 *Cacodæmon.* *American Black Viper.*—About the length of the preceding, but much thicker, black, and remarkable for the largeness of its head, which it distends, with a horrid hiss, when irritated. Its bite is reckoned as dangerous as that of the rattlesnake. It is a native of Carolina, chiefly frequenting higher grounds.

Egyptian Viper.—118 abdominal scuta, and 22 subcaudal scales. Somewhat ferruginous, spotted with brown; whitish beneath, with a short mucronated tail. Rather smaller than the common species. Imported in considerable quantities to Venice, for the use of the apothecaries in the composition of theriaca, &c. Native of Egypt, and supposed by some to be the asp of Cleopatra; but it is very difficult to ascertain the true asp of the ancients.

Charasian Viper.—Rufous, with the snout acuminated above, and the body marked with short, subconfluent, dusky, and transverse streaks. Nearly allied to the common species, and described by Charas, a celebrated anatomist of serpents in his day, but who contended, in opposition to Redi, that the symptoms caused by the viperine bite, proceeded from what he termed the *enraged spirits* of the creature, and not from the supposed poisonous fluid.

Redi's Viper.—152 abdominal scuta, and 32 subcaudal scales. Of an iron brown colour with a quadruple transverse series of short, subconfluent, brown streaks on the back. In other respects nearly allied to the common viper, but said to be more poisonous. It occurs in Austria and Italy, and is the sort which Redi chiefly employed in his experiments relative to animal poison.

Asp.—155 abdominal scuta, and 37 subcaudal scales. Somewhat rufous, with roundish, alternate, dusky spots on the back, and subconfluent ones near the tail. About three feet long, the head rather large, and covered with small carinated scales. Native of France, particularly of the northern provinces of that country. It is very doubtful if this be the genuine *coluber aspis* (Lin.); and still more so if it be the *asp* of the ancients.

Greek Viper.—155 abdominal scuta, and 46 subcaudal scales. Gray, with a fourfold series of transverse spots, those on the middle yellowish, and those on the sides dusky. Nearly a cubit in length, very thick towards the middle, and the head large and depressed. Inhabits Greece and the Grecian islands. According to Forskäl, its bite proves fatal by inducing insuperable sleep.

Cerastes, or *Horned Viper.*—150 abdominal plates, and 25 subcaudal scales. Pale yellowish, or reddish brown, with a few round, distant, or oblong spots, of a deeper tinge, scattered along the upper parts of the body, and the belly of a pale leaden hue. The two curved processes, situated above the eyes, give the animal a more than ordinary appearance of malignity. Its length varies from about 15 inches to two feet. It is found in many parts of Africa, especially affecting dry places and sandy deserts, and inflicting a dangerous wound on those who happen to approach it.

Horn-nose Snake.—127 abdominal plates, 32 subcaudal scales. Olive brown, with blackish variegations, a row of pale dorsal spots, surrounded by black, and a waving pale band on the sides. This fierce and forbidding species, which has its denomination from two large and pointed processes on the tip of the nose, is supposed to inhabit the interior part of Africa.

Megæra, or *Spear-headed Snake.*—224 abdominal plates,

plates, and 68 subcaudal scales. Brown, with yellow variegations, flat cordate head, and a large orifice on each side, between the eyes and nostrils. Native of Martinico, whence it is frequently called *yellow Martinico snake*. Measures, when full grown, five or six feet, has very large fangs, and inflicts a dangerous wound.

84 *Naja*. *Spectacle Snake*, or *Cobra de Capello*.—193 abdominal plates, 60 subcaudal scales. "Its general length (says Dr Shaw), seems to be three or four feet, and the diameter of the body about an inch and a quarter: the head is rather small than large, and is covered on the fore part with large smooth scales; resembling, in this respect, the majority of innoxious serpents: the back part, sides, and neck, with smaller ovate scales; and the remainder of the animal, on the upper parts, with small, distinct, oval scales, not ill resembling the general form of a grain of rice. At a small distance beyond the head is a lateral swelling or dilatation of the skin, which is continued to the distance of about four inches downwards, where the outline gradually sinks, into the cylindric form of the rest of the body. This part is extensile at the pleasure of the animal; and, when viewed from above, while in its most extended state, is of a somewhat cordated form, or wider at the upper than at the lower part: it is marked above by a very large and conspicuous patch or spot, greatly resembling the figure of a pair of spectacles; the mark itself being white, with black edges, and the middle of each of the rounded parts black. This mark is more or less distinct in different individuals, and also varies occasionally in size and form, and in some is even altogether wanting. The usual colour of the animal is a pale ferruginous brown above, the under parts being of a bluish white, sometimes slightly tinged with pale brown or yellow: the tail, which is of a moderate length, tapers gradually, and terminates in a slender sharp-pointed extremity.

This formidable reptile has obtained its Portuguese title of *cobra de capello*, or *hooded snake*, from the appearance which it presents when viewed in front in an irritated state, or when prepared to bite; at which time it bends the head rather downwards, and seems hooded, as it were, in some degree, by the expanded skin of the neck. In India it is everywere exhibited publicly as a show, and is, of course, more universally known in that country than almost any other of the race of reptiles. It is carried about in a covered basket, and so managed by its proprietors as to assume, when exhibited, a kind of dancing motion; raising itself up on its lower part, and alternately moving its head and body from side to side for some minutes, to the sound of some musical instrument which is played during the time. The Indian jugglers, who thus exhibit the animal, first deprive it of its fangs, by which means they are secured from the danger of its bite."

The *cobra de capello* is one of the most formidable and dangerous of the serpent tribe, though it is devoured with impunity by the *viverra ichneumon*. Dr Russel describes ten varieties of this species, and enters into many curious details relative to the effects of its poison on dogs and other animals. He never knew it prove mortal to a dog in less than 27 minutes, nor to a chicken in less than half a minute. Hence its poison, fatal as it is, seems to be less speedy in its operation than that of the rattlesnake.

Russellian Snake.—168 abdominal plates, 59 subcaudal scales. Brownish yellow; spots on the back acutely ovate, blackish, and edged with white; those on the sides smaller. About four feet long; native of India, and very poisonous. A chicken bitten in the pinion, by an individual of this species, was instantly infected, seized with convulsions, and expired in 38 seconds. Immediately after the chicken, a stout dog was bitten in the thigh. Within less than five minutes he appeared stupified; the thigh was drawn up, and he frequently moved it, as if in pain. He remained, however, standing, and ate some bread that was offered to him. In about 10 minutes the thigh became paralytic; in 15 minutes he entirely lost the use of it, and lay down howling in a dismal manner, frequently licking the wound, and making, at intervals, ineffectual attempts to rise. In 19 minutes, after a short cessation, he again began to howl, moaned often, and breathed laboriously, till his jaws closed. The few succeeding minutes were passed, alternately, in agony and stupor; and, in 26 minutes after the bite, he expired. A second dog, of much smaller size, was next bitten, and expired in the space of six hours. A rabbit was next exposed to the bite, and died in less than an hour. After this, another chicken was bitten in the pinion, and expired in less than six minutes. These experiments were all made with the same snake, in the course of the same morning. 85 *Russellii*.

Crimson-sided Snake.—188 abdominal, and 7 anal plates, 45 subcaudal scales. Violet black, with the abdomen and sides of a beautiful crimson, the plates margined with black. A singular and elegant species, with the proportions nearly those of the common English snake; poisonous; and a native of New Holland. 86 *Porphyriacus*.

Hæmachate Snake.—132 abdominal plates, 43 subcaudal scales. Red, clouded with white above, yellowish white beneath. Two feet or more in length; tail extremely short, and tapering to a point. Native of India; elegant, and poisonous. 87 *Hæmachates*.

Water Viper.—Brown above, banded with black and yellow beneath. "This serpent (says Catesby) is called, in Carolina, the *water rattlesnake*; not that it hath a rattle, but it is a large snake, and coloured not much unlike the rattlesnake, and the bite said to be as mortal. This snake frequents the water, and is never seen at any great distance from it: the back and head are brown; the belly transversely marked with black and yellow alternately, as are the sides of the neck; the neck is small, the head large, and armed with the like destructive weapons as the rattlesnake. It is very nimble, and particularly dexterous in catching fish. In summer great numbers are seen lying on the branches of trees hanging over rivers, from which, at the approach of a boat, they drop down into the water, and often into the boat on the men's heads. They lie in this manner to surprise either birds or fish, after which last they plunge, and pursue them with great swiftness, and catch some of a large size, which they carry on shore, and swallow whole. One of these I surprised swimming ashore, with a large catfish in its mouth. The tail is small towards the end, and terminates in a blunt horny point, about half an inch in length, and which, though harmless, 88 *Aquaticus*.

Coluber. harmless, is considered as of dreadful efficacy by the credulous vulgar, who believe, that the animal is able, with this weapon, not only to kill men and other animals, but even to destroy a tree by wounding it with it; the tree withering, turning black, and dying."

89 *Elegantissimus.* *Superb Snake.*—White, the head variegated with black, and the body marked above by a quintuple series of ocellated red spots. About two feet long, and poisonous.

90 *Argus.* *Argus Snake.*—Chesnut brown, yellow beneath, and banded above, by transverse rows of ocellated red spots. Above five feet in length; native of Arabia and Brazil, and very poisonous.

91 *Javanicus.* *Java Snake.*—312 abdominal plates, 93 subcaudal scales. Gray, the head striped with blue, and the body crossed by blue stripes, with gold-coloured edges. Frequent in the rice fields of Java, where it grows to the length of nine feet; but, in the more elevated and wooded situations, it attains to a still greater size, and is capable of devouring some of the larger animals. Splendid and innoxious.

92 *Natrix.* *Common* or *Ringed Snake.*—170 abdominal plates, 60 subcaudal scales. Olive brown, with a black patch, accompanied by a yellow one, on each side of the neck, a row of narrow black spots down each side, and dusky abdomen.

This species is pretty generally diffused over Europe, and is not uncommon in our own island, affecting moist and warm woods, basking or sleeping in the sunshine, and becoming torpid in winter. The female deposits a chain of from 12 to 20 eggs, about the size of those of the blackbird, connected by bunches of a gluey matter in dunghills, or warm recesses, near stagnant waters. The young come forth in the following spring. The common snake reappears in March or April, when it casts its skin so completely, that the spoil exhibits even the exterior pellicle of the eye. To adopt the language of Mr White, in his Naturalist's Calendar, "It would be a most entertaining sight, could a person be an eye-witness to such a feat, and see the snake in the act of changing his garment. As the convexity of the eyes in the slough is now inward, that circumstance alone is a proof that the skin has been turned; not to mention that now, the present inside is much darker than the outer. If you look through the scales of the snake's eye from the concave side, viz. as the reptile used them, they lessen objects much. Thus it appears, that snakes crawl out of the mouth of their own sloughs, and quit the tail part last, just as eels are skinned by a cookmaid. While the scales of the eyes are growing loose, and a new skin is forming, the creature, in appearance, must be blind, and find itself in a very awkward and uneasy situation."

This species occasionally frequents the water, and preys chiefly on frogs, mice, small birds, insects, worms, &c. It is not only perfectly harmless, but even capable of being domesticated. Mr White mentions, that he knew a gentleman who had one in his house quite tame. Though usually as sweet as any other animal, yet, whenever a stranger, or a dog or cat entered, it would begin to hiss, and soon filled the room with an almost insupportable odour. Mr Revett Shepphard of Caius college, Cambridge, had a common snake in his rooms near three months. "He kept it (says Mr Bingley) in a box of bran; and, during all that time, he never could discover that it ate any thing, although he frequently put both eggs and frogs, the favourite food of this species, into the box. Whenever he was in the room he used to let the animal out of its prison; it would first crawl several times round the floor, apparently with a desire to escape; and when it found its attempts fruitless, it would climb up the tables and chairs, and not unfrequently even up the chair of its owner as he sat at his table. At length it became so familiar as to lie in a serpentine form on the upper bar of his chair; it would crawl through his fingers, if held at a little distance before its head, or lie at full length upon his table, while he was writing or reading, for an hour or more at a time. When first brought into the room, it used to hiss and dart out its forked tongue; but in no instance emitted any unpleasant vapour. It was, in all its actions, remarkably cleanly. Sometimes it was indulged with a run upon the grass, in the court of the college; and sometimes with a swim in a large bason of water, which it seemed to enjoy very much. When this gentleman left the university, he gave his bedmaker orders to turn it out into the fields, which, he believes, was done."

Black Snake.—186 abdominal plates, 92 subcaudal scales. Glossy black, with a very long slender body. Five or six feet long, and not venomous, though often confounded by the ignorant and the timid with the rattlesnake. Native of North America. Its speed and activity, according to Brickell, are astonishing. Sometimes it will climb trees in quest of the tree-frog, or, for other prey, glide at full length along the ground: on other occasions it presents itself half erect, and appears to great advantage. It is so fond of milk, that it has been seen eating it out of the same dish with children, though they often gave it blows with their spoons on the head when it was too greedy. It persecutes rats with wonderful agility, pursuing them even to the roofs of barns and outhouses, and is therefore a great favourite among the Americans. 93 *Constrictor.*

Fasciated or *Wampum Snake.*—Blue above, paler, and variegated with brighter blue beneath. Its colours resemble those of the strings of Indian money, called *wampum*, composed of shells cut into regular pieces, and strung with a mixture of blue and white. Native of Carolina and Virginia, sometimes growing to the length of five feet, and perfectly innocent. 94 *Fasciatus.*

Blue Green Snake.—217 abdominal plates, 122 subcaudal scales. Bright blue green, with a purple tinge on the back, and whitish abdomen. A very beautiful species, about three feet long, harmless, and a native of Surinam. 95 *Viridissimus.*

Coach-whip Snake.—Brown, with pale abdomen; very long and slender, inoffensive, and native of North America. It runs with extreme swiftness, in pursuit of flies, &c. and is very easily tamed. 96 *Flagellum.*

Ornamented Snake.—Habit long, and very slender; colour jet black, with white flower-shaped spots, and white abdomen. This very elegant species inhabits some of the West India islands, and, according to Seba, is also found in Java and Ceylon. 97 *Ornatus.*

Domicella Snake.—118 abdominal plates, 60 subcaudal scales. A very elegant and harmless species, of a slender habit, with many jet-black cross bands, and a blackish line on the abdomen. It is alleged that the Indian ladies sometimes carry it in their bosoms. 98 *Domicella.*

Boaform.

99 Boæformis. *Boæform Snake.*—252 abdominal plates, 62 subcaudal scales. Whitish, with brown variegations; white beneath, with very short scuta, the under part of the tail variegated with black and white. Native of India, and so strong, that it can numb the hand by wreathing round the arm. Its bite, however, is not poisonous.

100 Domesticus. *Domestic Snake.*—245 abdominal plates, 94 subcaudal scales. Gray, spotted with brown, and a double black spot between the eyes. Native of Barbary, where it is domesticated for the purpose of destroying the smaller noxious animals.

101 Fasciolatus. *Fasciolated Snake.*—192 abdominal plates, 62 subcaudal scales. Cinereous, with whitish cross bands, and glaucous abdomen. Native of India, and not poisonous, as vulgarly believed.

102 Lineatus. *Lineated Snake.*—169 abdominal plates, 84 subcaudal scales. This beautiful and inoffensive species, though subject to considerable variety of aspect, may be generally distinguished by its bluish-green ground, and three or five brown linear stripes, of which that in the middle is broadest. It inhabits several parts of India, and is from two to three feet long.

103 Elegans. *Elegant Snake.*—202 abdominal plates, 146 subcaudal scales. Yellowish gray, with three broad reticulated blackish bands, a broad fillet on the abdomen, and the head freckled with brown. Length about two feet; tail very long and narrow. Native of South America. Well figured by Seba.

104 Mycterizans. *Long-snouted Snake.*—192 abdominal plates, 167 subcaudal scales. Slender, with a sharp-pointed snout; colour grass green, with a yellow line on each side of the abdomen. About three feet and a half in length, and half an inch in diameter. Native of North America, where it is often seen on trees, running very quickly in pursuit of insects.

105 Ahætulla. *Iridescent Snake.*—163 abdominal plates, 150 subcaudal scales. Tinge blue green, and gilded, accompanied with iridescent hues, with pale abdomen, and black streak across the eyes. From three to four feet long. Native of India. One of the most beautiful of the serpent tribe, and perfectly innocent.

To exhibit even short definitions of the other species included in the genus *Coluber*, would extend this article to a disproportionate length. Of most of the omitted sorts, however, we may observe, that the history is either not particularly interesting, or too little known.

106 Hydrus.

Gen. 4 Hydrus, *Water-snake.*

107 Characters. Body slender in front, gradually thickening, scaled; tail compressed.—This is a genus of recent institution, comprising those species of serpents which naturally inhabit the water.

108 Colubrinus. *Colubrine Hydrus.*—Lead-coloured, with black surrounding bands. Ordinary length about two feet and a half. The fangs are very small in proportion to the size of the animal. It is the *coluber laticaudatus* (Lin.), and inhabits the American and Indian seas.

109 Fasciatus. *Fasciated Hydrus.*—Long and slender; black, longitudinally marked by yellowish white pointed bands; upwards of two feet in length, poisonous, and native of the Indian seas.

110 Spiralis. *Spiral Hydrus.*—Yellowish, with brown bands; body spirally twisted. A rare and elegant species, thus described by Dr Shaw.

"Its length is about two feet, and its habit slender; the body much compressed throughout; the back rising into a very sharp carina; the abdomen being also carinated, but having a flattened edge of scales somewhat wider than the rest, and measuring about the fifteenth of an inch in diameter; the head is small, and covered with large scales; the mouth wide; the scales on the whole animal moderately small, ovate, and slightly carinated; the ground colour is yellow, barred in a beautiful manner from head to tail with deep chesnut brown or blackish fasciæ, each widening on the abdomen, and thus forming a highly distinct and handsome pattern when viewed on each side, seeming to constitute so many large, round, yellow spots on a blackish ground: the back, at about the middle, is marked along its upper part with a row of rather large, round, blackish spots, situated between the fasciæ, and so placed as to be in some parts on one side, and in others on the opposite side of the dorsal carina, while some few are seated on the middle of the ridge itself: this variegation is continued to the tail, which is about an inch and three quarters long, black or deep brown, with a few yellow patches towards its beginning; it is remarkably broad for the size of the animal, and very thin on the edges, so as to be semitransparent on those parts. The most remarkable circumstance in this snake is the singular obliquity of its form, the body in different parts being alternately flatter on one side than the other, and the pattern completely expressed on the flattened side only; the other, or more convex side, being unmarked by the round spots, and lying as it were beneath, thus constituting several alternately spiral curves: this snake seems of an unusually stiff and elastic nature, and the carina on the back is so sharp as to surpass in this respect every other species of serpent. This specimen is in the British Museum; but its particular history seems to be unknown."

Black-backed Hydrus.—Head oblong, body black above, and yellowish beneath; tail spotted. *Anguis platma*, Lin. Native of the Indian seas, and common about the coasts of Otaheite, where it is used as an article of food. 111 Bicolor.

Great Hydrus.—Livid, with brown bands, and hexagonal scales abruptly carinated. Upwards of three feet long. Native of the Indian seas. Its habits little known. 112 Major.

The other *hydri* are, *caspius*, *gracilis*, *cœrulescens*, *curtus*, *atrocœruleus*, *cinereus*, *piscator*, and *palustris*.

Gen. 5. Langaya. 113 Langaya.

Abdominal plates, caudal rings, and terminal scales. 114 Characters.

There is only one species known, viz.

Snouted Langaya.—184 abdominal plates, 42 caudal rings; but these numbers are subject to vary. Length between two and three feet, and diameter about seven lines, in the thickest part of the body. Colour of the upper parts reddish, or violet, of the under parts pale or whitish. Teeth like those of the viper. Native of Madagascar, where it is much dreaded. 115 Nasuta.

Gen. 6. Acrochordus. 116 Acrochordus.

Body completely covered with warts. 117 Character.

Javan Acrochordus.—This reptile was discovered in 118 Javanicus.

a

Acrochordus. a pepper field, in the island of Java, in 1784. It measured eight feet in length, and 10 inches in diameter, in the thickest part of the body. It was blackish above, whitish beneath, and marked by dusk spots on the sides. Five young ones, full formed, and each nine inches long, were found in the belly. The Chinese esteem it as a food.

The *dubius* and *fasciatus* are so nearly allied to the preceding, that they may be regarded only as varieties.

119 ANGUIS.

Gen. 7. ANGUIS, *Slow-worm.*

120 Characters. Furnished with abdominal and subcaudal scales. Conformation resembling that of some of the lizard tribes, the body being composed of a series of moveable rings, which are easily broken and easily reproduced. A very harmless, and rather sluggish genus.

121 *Fragilis.* *Common Slow-worm*, *Blind-worm*, or *Long Cripple.*—135 abdominal, and the same number of subcaudal scales. Black, yellowish ash, or rufous gray; belly black, sides streaked with black and white, tail long and obtuse, scales small, soft, and compact. The colouring is subject to considerable variety. Length, from 10 to 12 inches, or more. Common in Europe and Siberia, frequenting hollow ways, woods, paths, rubbish, &c. Viviparous, subject to hybernation, living on worms and insects, and perfectly innoxious. It is observed of this species, as well as of some others, that, if struck with any degree of violence, the body not only breaks abruptly on the struck part, but even sometimes, at different places, and that the fragments will live a long while afterwards. Though of very gentle dispositions, the blind worm, like many of the family of serpents, refuses to eat in captivity, unless it be tamed. M. Daudin mentions that he kept one two months and a half, during all which time it constantly refused nourishment of every kind.—It is preyed on by various birds, hedgehogs, snakes, frogs, and tods.

According to Dr Shaw, the *Blue-bellied Snake*, or *Aberdeen Slow-worm* (*A. Eryx* Lin.) is only a variety of the *Fragilis.* It occurs in Scotland and North America.

122 *Scytale.* *Painted Slow-worm.*—240 abdominal, and 13 subcaudal scales. Varies much in colour, but is generally orange, with black blotches; sometimes black and white, sometimes pale rose and black, paler beneath, and elegantly fasciated with bars of deep black. Native of South America, particularly of Cayenne and Surinam. In preserved specimens, the orange hue is very apt to fade into white.

123 *Corallinus.* *Coral Slow-worm.*—Ground colour pale red, with coral-red variegations. A very beautiful species, native of Brazil.

124 *Ventralis.* *Glass Slow-worm.*—127 abdominal, 222 subcaudal scales. Blackish green, speckled with yellow, with a very short yellow abdomen, a deep furrow on each side of the body, from the corners of the mouth to the vent, and a tail more than twice the length of the abdomen. Native of North America, and not uncommon in Carolina, where it is called the *Glass Snake.* 'A small blow of a stick,' says Catesby, 'causes the body to separate, not only at the place struck, but at two or three other places, the muscles being articulated quite through the vertebræ.'

Snouted Slow-worm.—218 abdominal, and 12 subcaudal scales. Greenish black above, yellow beneath, snout elongated, tail terminating in a horny tip. Length about a foot. Native of Surinam.

Jamaica Slow-worm, or *Silver Snake.*—Pale brown, with a silvery gloss on the scales; the body, which rarely exceeds sixteen inches in length, gradually thickening, and the tail abruptly subacuminate.

The other species are, *meleagris*, *ater*, *maculata*, *leucomelas*, *rufa*, *reticulata* and *clivioca.*

Gen. 8. AMPHISBÆNA.

Body nearly cylindrical, with annular divisions round the body and tail. The skin divided in a longitudinal direction, by straight lines, forming with the wings so many square or parallelogrammic scales. A harmless and oviparous genus, native of the warmer regions of the new world, and not of Ceylon, as Seba has erroneously asserted.

White Amphisbæna.—223 abdominal, and 16 caudal scaly rings. Pale white, verging on yellowish, and unspotted. Two feet or more in length, and of a considerable proportionate thickness. Is found in woods, in Surinam, &c. where it preys chiefly on insects and worms.

Fuliginous Amphisbæna.—200 abdominal, and 30 caudal, scaly rings. Differs from the preceding chiefly by its black and white variegations. Common in Cayenne, Surinam, and Brazil; but Linnæus, and other naturalists, misled by Seba, have falsely represented it as a native of Libya, the island of Lemnos, &c.

Gen. 9. CÆCILIA.

Body cylindrical, wrinkles on the sides of the body and tail.

Eel-shaped Cæcilia.—Anguilliform, with distant wrinkles, and a very small cirrhus beneath each nostril. The skin of the whole body, when closely inspected, is found to be covered with very minute granules. About 18 inches long, native of South America, and destitute of poison fangs.

White-sided Cæcilia.—340 wrinkles on the body, 10 on the tail. Brown, with very close wrinkles, and a whitish lateral line. Native of South America.

Slender Cæcilia.—Brown, shaped like an earth-worm, nearly 14 inches long, and one fifth of an inch in diameter. The upper jaw is longer than the lower, and the teeth are so small, as not to be distinctly visible.

We cannot close our descriptive catalogue of the serpent tribe, without remarking, that the subject still requires elucidation; that the Linnæan characters are not always to be strictly interpreted; and that several species appear to have been overlooked, merely because the number of their scales could not be ascertained.

Miscellaneous Observations.

The formidable aspect of some serpents, and the poisonous qualities of others, have probably inspired mankind, in every age, with sentiments of terror and awe. In the rude periods of society, fear is akin to devotion, and Bartram informs us, that the rattle-snake is worshipped by several of the savage tribes in North America. On the

Miscellaneous Observations.

the Gold and Slave coasts, a stranger, on entering the cottages of the natives, is often surprised to see the roof swarming with serpents, that cling there without molesting, and unmolested by, the natives. But his surprise will increase as he advances farther southward, to the kingdom of Widah, when he finds that a serpent is the god of the country. This animal, which travellers describe as a huge overgrown creature, has its habitation, its temple, and its priests. These last impress the vulgar with an opinion of its virtues; and numbers are daily seen to offer, not only their goods, provisions, and prayers, but even their wives and daughters at the shrine of their hideous deity. The priests readily accept the proffered females, and after some days of *penance*, return them to their suppliants, much benefited by the serpent's supposed embraces.

137 Enchantment of serpents.

The ancients seem to have been aware, that certain species of serpents were attracted by musical sounds, and have celebrated the *Psylli* and *Marsi*,

Ad quorum cantus mites jacuêre cerastæ.

At this day, there are jugglers in India, who train snakes to move and gesticulate to the sound of the flute; and we have already mentioned, that they tame the *Cobra de Capello*, and exhibit it to the populace. When the snake-man first provokes the creature to attack him, he covers his hand with an earthen jar, which he uses as a shield, and thus hurts the animal's mouth, and knocks it backwards whenever it attempts to bite. He continues this exercise for an hour, or longer, taking care, however, not to fatigue the snake too much, nor to hurt it so as to deter it from returning to the attack. Thus, the animal is gradually taught to raise itself, on presenting a jar, a stick, or even the bare hand, the motions of which it follows with its head, without daring to bite, lest it should again wound its mouth. The juggler accompanies this exercise with singing, so that what is really a defensive war on the part of the serpent, has the appearance of a dance. To render this exhibition less dangerous, the fangs are sometimes removed; but more frequently the snake is deprived of its poison, by being daily irritated to bite on a piece of cloth, or any soft spongy subsance; nay, they have the address and courage to press its head, and thus provoke it, while biting, to make it seize the cloth with greater violence, and more effectually express its poison.

The Egyptian enchanters, however, appear to have recourse to more ingenious and mysterious artifices. "They take the most poisonous vipers," says Hasselquist, "with their bare hands, play with them, put them in their bosoms, and use a great many more tricks with them, as I have often seen. I have frequently seen them handle those that were three or four feet long, and of the most horrid sort. I inquired and examined if they had cut out the viper's poisonous teeth; but I have with my own eyes seen they do not. We may therefore conclude, that there are to this day Psylli in Egypt; but what art they use is not easily known. Some people are very superstitious, and the generality believe this to be done by some supernatural art which they obtain from invisible beings. I do not know whether their power is to be ascribed to good or evil; but I am persuaded that those who undertake it use many superstitions.

"The circumstances relating to the fascination of serpents in Egypt, related to me," he continues, "were principally, 1. That the art is only known to certain families, who propagate it to their offspring. 2. The person who knows how to fascinate serpents, never meddles with other poisonous animals, such as scorpions, lizards, &c. There are different persons who know how to fascinate these animals; and they again never meddle with serpents. 3. Those that fascinate serpents, eat them both raw and boiled, and even make broth of them, which they eat very commonly amongst them; but in particular, they eat such a dish when they go out to catch them. I have been told, that serpents fried or boiled are frequently eaten by the Arabians both in Egypt and Arabia, though they know not how to fascinate them, but catch them either alive or dead. 4. After they have eaten their soup, they procure a blessing from their scheik (priest or lawyer), who uses some superstitious ceremonies, and amongst others, spits on them several times with certain gestures. This manner of getting a blessing from the priest is pure superstition, and certainly cannot in the least help to fascinate serpents; but they believe, or at least persuade others, that the power of fascinating serpents depends upon this circumstance."

On this subject, the celebrated Mr Bruce, in his Travels to discover the Source of the Nile, is also minute and explicit. Among other passages, we shall be content to quote the following.

"I will not hesitate to aver, that I have seen at Cairo (and this may be seen daily without trouble or expence) a man who came from above the catacombs, where the pits of the mummy birds are kept, who has taken a cerastes with his naked hand from a number of others lying at the bottom of the tub, has put it upon his bare head, covered it with the common red cap he wears, then taken it out, put it in his breast, and tied it about his neck like a necklace; after which it has been applied to a hen, and bit it, which has died in a few minutes; and to complete the experiment, the man has taken it by the neck and beginning at his tail, has eaten it as one would do a carrot or a stock of celery, without any seeming repugnance."

"I can myself vouch, that all the black people in the kingdom of Sennaar, whether Funge or Nuba, are perfectly armed against the bite of either scorpion or viper. They take the cerastes in their hands at all times, put them in their bosoms, and throw them to one another as children do apples or balls, without having irritated them, by this usage, so much as to bite. The Arabs have not this secret naturally; but from their infancy they acquire an exemption from the mortal consequences, attending the bite of these animals, by chewing a certain root, and washing themselves (it is not anointing) with an infusion of certain plants in water."

The testimony of Savary is not less precise. At the feast of Sidi Ibrahim, he saw a troop of people, seemingly possessed, with naked arms and fierce looks, holding in their hands enormous serpents, which twined round their body, and endeavoured to escape. But these enchanters avoided the bite, by grasping the animals strongly by the neck, then tore them with their teeth, and ate them alive, while the blood streamed from their mouth.

Miscellaneous Observations

The circumstance of seizing them fast by the neck, accords with the concluding part of the ensuing relation of Denon.

"Having been always curious to observe the means by which some men command the opinions of others, I regretted that I was not at Rosetta, at the procession of the feast of Ibrahim, in which the convulsions of the Psylli form the most entertaining part, to the populace, of this religious ceremony. To make up for my loss, I addressed myself to the chief of the sect, who was keeper of the *Okel* or tavern of the Franks; I flattered him; and he promised to make me a spectator of the exaltation of one of the Psylli, as soon as he should have *inspired* him. From my curiosity he thought I was likely to become a proselyte, and he proposed to initiate me, which I accepted; but when I learned that in the ceremony of initiation, the grand master spits in the mouth of the neophyte, this circumstance cooled my ardour, and I found that I could not prevail on myself to submit to such a point of probation. I therefore gave my money to the chief, and the high priest promised to let me see one of the inspired.

"They had brought with them some serpents, which they let loose from a large leather sack in which they were kept, and by irritation made them erect their bodies, and hiss. I remarked that the light was the principal cause of their anger; for as soon as they were returned into the sack, their passion ceased, and they no longer endeavoured to bite. They had a particular quality, which was that when angry, the neck for six inches below the head was dilated to the size of one's hand. I soon saw, that I had no greater reason to dread the bite of these serpents than their masters had; for having well remarked that the Psylli, while they were threatening the animal with one hand, seized it on the back of the head with the other, I did the same with one of the serpents with equal success, though much to the indignation of these mysterious quacks."

We have likewise heard of people in Europe who allowed themselves to be bitten by vipers, with impunity, to the great astonishment of the spectators. They first made the animal eat of a prepared paste, which closed the apertures in the fangs, and thus precluded the discharge of the poison.

138 Serpentine poison.

Various and contradictory opinions, conjectures, and fictions, have been advanced relative to the nature, action, and cure of serpentine poison. Among the vulgar errors connected with this subject, we may reckon the *sting*, fixed in the serpent's tail, and the flowing of venom from the *black forked tongue*, and from the *teeth* in general.

Towards the end of the 17th century, Ferdinand II. Grand Duke of Tuscany, invited Steno, Redi, and some other eminent men of science, to his court, with a view to investigate the history of this important phenomenon in the animal economy. Redi, in particular, instituted a great variety of experiments, and arrived at some useful discoveries. When he either caused a living viper to bite a dog, or wounded the latter with the teeth of one newly dead, the event was the same. If the bite was repeated, its effect became weaker, and, at length was lost, the poison contained in the vesicle being exhausted. He observed, that when the teeth of serpents were extended to bite, they were moistened over with a certain liquor, and that when the vesicle at the base was pressed, a drop of poison flowed to the point of the fang. When the poison thus flowing from the vesicle was received in soft bread, or a sponge, an animal bitten by the serpent received no more harm from the wound than from the pinch of a needle, till after a few days, when the venom was secreted afresh; but when an animal was wounded with the point of a needle dipped in the poison, it was tormented with the same pains as if it had been bitten by the viper itself. Having preserved some of this poison in a glass, and totally evaporated the moisture in the sun, when the residuum was diluted with water, Redi found, to his great surprise, that it had the same effect as when recent. But the boldness of Jacob Sozzi, a viper charmer, excited the astonishment of the learned. As they happened in the prince's presence to talk of the certain death which would attend the swallowing of viperine poison, Sozzi, confiding in his art, drank a considerable portion of it without hesitation, and with the same safety as if he had drunk so much water. This result, which so much startled the grand duke and his philosophic associates, was not unknown to the ancients, as may be inferred from these lines in Lucan.

Noxia serpentum est admisto sanguine pestis:
Morsu virus habent et fatum dente minantur,
Pocula morte carent.

The ingenious and indefatigable Fontana made no fewer than 6000 experiments on this interesting subject. Of these, our limits will not permit us to enumerate the results. In consequence, however, of his multiplied and persevering researches, we are enabled to state, that this poison is not fatal to all animals; that it kills neither vipers, snakes, blind-worms, snails, nor leeches; that it acts very slightly on tortoises; that it is neither an acid nor an alkali; that it has no determined savour, and that it leaves in the mouth merely a sensation of astringency and stupor. It long retains its virulence in the cavity of the tooth, whether the latter be separated or not from its socket; but when dried and kept in an exposed situation, it loses its deleterious qualities in less than a year, Hence the propriety of caution in examining vipers that are stuffed or preserved in spirits, and in making use of clothes that have been bitten by them. Fontana has also proved that the poison of the viper is not uniformly fatal except to very small animals, and that it is more dangerous to the larger sorts, according to the quantity of virus secreted, the frequency of the bites, the different parts of the body on which they have been inflicted, and probably also, the higher temperature of the atmosphere. A sparrow dies in five or eight minutes, a pigeon in eight or twelve, a cat sometimes recovers, and a sheep very often; so that a man has little reason to dread the consequences of a single bite in the climate of Italy, and still less so in France or Great Britain. The hundredth part of a grain of poison applied to a muscle will kill a sparrow, whereas six times that quantity are required to kill a pigeon. According to this estimate, about three grains should prove fatal to a man, and 12 to an ox. But the vesicles of an ordinarily sized viper seldom contain more than two grains of poison, and even that quantity is not exhausted till after repeated bites. The poison is of a gummy consistency, and seems to act by destroying the irritability of the muscular fibre, Miscellaneous Observations. fibre, and introducing into the fluids a principle of putrefaction. It may be swallowed with impunity, provided there be no wound in the mouth; but if introduced into the blood, the most violent and convulsive agonies ensue, the sanguiferous system becoming coagulated, and the whole animal frame relaxed. Hence, powerful sudorifics, as the flesh of the viper itself, of snakes and lizards, which contain a large proportion of ammoniacal soap, the volatile alkali, and its various preparations, with numerous plants which excite copious perspiration, have been recommended, and often successfully used as antidotes, especially when their exhibition has been preceded by a tight ligature immediately above the wound, and by scarification and caustics.

On the effects and cure of the poison of snakes, some valuable observations and reflections occur in Dr Russell's splendid work on Indian serpents. The judicious author remarks, that when the poison is applied to brute animals, its progress is often so very rapid as hardly to leave time for the operation of medicine, or the application of any means whatever, with a probability of success. When the progress is slower, should the remedy be administered before unequivocal symptoms have removed all doubt of the poison having taken effect, recovery may be ascribed to the medicine given, whilst, in reality, no malady existed; and if deferred till doubts are removed, the remedy which, if applied in time might have proved efficacious, may be unjustly regarded as useless. Besides, it is well known that a bite of the most noxious snake does not constantly prove fatal, and that even some of the more tender animals, without the use of any remedy, recover in cases where the symptoms are apparently very formidable. These symptoms, in the bodies of different animals, are very much alike, and proceed nearly in the same order of progression, though with different degrees of rapidity.

The American Indians either suck the wound, or apply to it chewed tobacco, or make several incisions around it, which they fill with gunpowder, and then fire it off. During the progress of the cure they have likewise recourse to several pounded and bruised plants, as to some of the species of *lactuca*, the root of *prenanthes alba*, the stems and leaves of a species of *helianthus*, and in desperate cases the radical bark of the tulip-tree. In general they are partial to the use of the syngenesious plants, and to the bark of the trunk and roots of various trees.

The experiments of Bernard de Jussieu, Lebeau, Sonnini, and Bosc, seem to have established that, of all known remedies for the bite of the viper and the rattlesnake, the most efficacious are, the volatile alkali, or *eau de luce*, with suction and scarification of the recent wound.

In addition to these methods of cure, we shall quote the prescription of Dr Moseley, who spent 12 years in the West Indies.

"The bites and stings of all venomous animals are cured by the same local means, which are very simple if they were always at hand. The injured part must be instantly destroyed or cut out. Destroying it is the most safe, and equally certain; and the best application for that purpose is the *lapis infernalis*, or butter of antimony. These are preferable to a hot iron which the ancients used, because a hot iron forms a crust, which acts as a defence to the under parts instead of destroying them. The *lapis infernalis* is much better than any other, as it melts and penetrates during its application. The bitten part must be destroyed to the bottom, and where there is any doubt that the bottom of the wound is not sufficiently exposed, butter of antimony should be introduced to it on the following day, as deep as possible; and incisions should be made to lay every part open to the action of these applications. Besides destroying, burning, or cutting out the part, incisions should be made round the wound, to prevent the communication of the virus. The wound is to be dressed for some time with poultices, to assuage the inflammation caused by the caustics; and afterwards with acrid dressings and hot digestives to drain the injured parts.

"Where the above-mentioned caustics cannot be procured, corrosive sublimate, oil of vitriol, aquafortis, spirit of salt, common caustic, or a plaster made of quicklime and soap, may be applied to the wound. Gunpowder laid on the part and fired, has been used with success. When a person is bitten remote from any assistance, he should make a tight ligature above the part until proper application can be made. The Spanish writers say, that the *habilla de Carthagena*, or Carthagena bean, is a specific for poisonous bites taken inwardly.

Dr Moseley then proceeds to state the ample testimony of Ulloa in favour of this bean, which is found in great abundance in the West India islands, under the name of *antidote* or *cocoon antidote*. "I have been informed (adds he) by some intelligent Indians, that any of the red peppers, such as bird pepper or bell pepper, or what is called *Cayenne pepper*, powdered, and taken in a glass of rum, as much as the stomach can possibly bear, so as to cause and keep up for some time great heat and inflammation in the body, and a vigorous circulation, will stop the progress of the poison of serpents, even after its effects are visible; and that the bitten part only afterwards mortifies and separates, and that the patient, with bark, wine, and cordials, soon recovers."

139 Preservation of serpents. The naturalist who collects serpents for the purpose of preserving them in his cabinet, should have recourse to various precautions, which, though several of them are sufficiently obvious, are, at the same time, too often neglected. In general the hurtful sorts are caught with the greatest safety and dexterity by natives of the country in which they abound. The want of the head in many of the larger stuffed specimens from Guiana, &c. renders them of little value in a scientific point of view, and is the result of superfluous trouble to travellers who send them to Europe in this mutilated condition. Collectors, therefore, should carefully instruct their agents to preserve this part of the animal. As these larger specimens cannot easily be prepared without an incision in the skin, it will be of consequence to make this incision on the side, beginning at the termination of the plates, and not cutting across them, as is too often done, to the great prejudice of distinct classification. When the skin is once stripped, it may be carefully rolled up, and stuffed in the preparation room in the usual manner.

The smaller species of serpents may be kept in prepared spirits. Pure alcohol and spirituous liquors, especially when not reduced by water, frequently affect the most

Miscellaneous Observations.

most brilliant animal colours. Thus, in the ordinary cabinet liquors, the fine red of the hæmachate snake degenerates into a dark brown, scales of a bright green or blue become somewhat pale, yellow always whitens, and orange changes to red or pale. White, brown, black, purple, mother of pearl, and metal-coloured scales are not liable to change. The following is an approved recipe for preserving the various colours of serpents entire.

Take very pure spring water, saturate it with alum, then mix with it about one-fifth of its bulk of very limpid spirit of wine, pass the mixture through a paper strainer, and keep the liquor well corked up in bottles, in some cool and shady situation. Immerse the animal which you wish to preserve in a vessel filled with this liquor, and allow it to remain in it 24 hours. The vessel and its included liquor should be reserved for this preliminary process. Then remove the reptile into a cylindical vessel of fine glass, filled to three-fourths of its height with the liquor above described, and closed with a glass cover. Lute the latter with mastic and hogs grease; put the vessel on a shelf that is sheltered from heat and the solar rays; and at the end of two months, if the mastic be dry, and you wish the jar to remain closed, paint the luting with an oil colour; but if you intend to open it frequently, use only the hogs grease.

Reptiles may also be conveniently preserved according to the method indicated by Chaussier, in the *Bulletin des Sciences*, (for Prairial, year 10, N° 63.), without the previous trouble of preparing the skin. All that is required, is to stuff the cavities with cotton, and to immerse the body in distilled water, saturated with super-oxygenated muriate of mercury; and when it has sufficiently imbibed the saline solution in all its parts, to allow it to dry slowly in a well aired situation, screened from the sun and dust. All the parts of the animal harden, and are thus defended from the voracity of insects, and corruption of every kind.

Ophiomancy || Ophir.

OPHIOMANCY, in antiquity, the art of making predictions from serpents. Thus Calchas, on seeing a serpent devour eight sparrows with their dam, foretold the duration of the siege of Troy: and the seven coils of a serpent that was seen on Anchises's tomb, were interpreted to mean the seven years that Æneas wandered from place to place before he arrived at Latium.

OPHIORHIZA, a genus of plants belonging to the pentandria class, and in the natural method ranking under the 47th order, *Stellatæ*. See BOTANY *Index*.

OPHIOXYLON, a genus of plants belonging to the polygamia class, and in the natural method ranking with those of which the order is doubtful. See BOTANY *Index*.

1 Different hypotheses respecting the situation of Ophir.

OPHIR, a country mentioned in Scripture, from which Solomon had great quantities of gold brought home in ships which he sent out for that purpose; but where to fix its situation is the great difficulty, authors running into various opinions on that head. Some have gone to the West, others to the East Indies, and the eastern coast of Africa, in search of it.—Mr Bruce the celebrated Abyssinian traveller, has displayed much learning and ingenuity in settling this question of Biblical history. To the satisfaction of most of his readers, he has determined Ophir to be Sofala, a kingdom of Africa, on the coast of Mosambique, near Zanguebar (see SOFALA). His reasons for this determination are so generally known, that it would be improper to repeat them here at length; because such as are not already acquainted with them may consult his book, which has been long in the hands of the public. He justly observes, that in order to come to a certainty where this Ophir was, it will be necessary to examine what Scripture says of it, and to keep precisely to every thing like description which we can find there, without indulging our fancy farther. *1st*, Then, the trade to Ophir, was carried on from the Elanitic gulf through the Indian ocean. *2dly*, The returns were gold, silver, and ivory, but especially silver †. *3dly*, The time of the going and coming of the fleet was precisely three years ‡, at no period more or less.

2 Hypothesis of Mr Bruce.

† 1 Kings, x. 22.

‡ 1 Kings, x. 22. 2 Chron. ix. 21.

Now, if Solomon's fleet sailed from the Elanitic gulf to the Indian ocean, this voyage of necessity must have been made by monsoons, for no other winds reign in that ocean. And what certainly shows this was the case, is the precise term of three years in which the fleet went and came between Ophir and Ezion gaber.

These mines of Ophir were probably what furnished the East with gold in the earliest times: great traces of excavation must therefore have appeared.

Ophir.

But John dos Santos says, that he landed at Sofala in the year 1586; that he sailed up the great river Cuama as far as Tete, where, always desirous to be in the neighbourhood of gold, his order had placed their convent. Thence he penetrated for about two hundred leagues into the country, and saw the gold mines then working at a mountain called *Afura*. At a considerable distance from these are the silver mines of Chicoua; at both places there is a great appearance of ancient excavations; and at both places the houses of the kings are built with mud and straw, whilst there are large remains of massy buildings of stone and lime.

3 Arguments in support of it.

Every thing then conspires to fix the Ophir of Solomon in the kingdom of Sofala, provided it would necessarily require neither more nor less than three years to make a voyage from Ezion-gaber to that place and Tarshish and return. To establish this important fact, our author observes, that the fleet or ship for Sofala, parting in June from Ezion-gaber (see EZION-GABER), would run down before the northern monsoon to Mocha (see MOCHA). Here, not the monsoon, but the direction of the gulf, changes; and the violence of the south-westers, which then reign in the Indian ocean, make themselves at times felt even in Mocha roads. The vessel therefore comes to an anchor in the harbour of Mocha; and here she waits for moderate weather and a fair wind, which carries her out of the straits of Babelmandel, through the few leagues where the wind is variable.

Her course from this is nearly south-west, and she meets at Cape Guardafui, a strong south-wester that blows directly in her teeth. Being obliged to return into the gulf, she mistakes this for a trade-wind; because she is not able to make her voyage to Mocha but by the summer monsoon, which carries her no farther than the straits of Babelmandel, and then leaves her in the face of a contrary wind, a strong current to the northward, and violent swell.

The attempting this voyage with sails, in these circumstances, was absolutely impossible, as their vessels went only before the wind: if it was performed at all, it must have been by oars; and great havock and loss of men must have been the consequence of the several trials.

At last, philosophy and observation, together with the unwearied perseverance of man bent upon his own views and interests, removed these difficulties, and showed the mariners of the Arabian gulf, that these periodical winds,

Ophir.

winds, which in the beginning they looked upon as invincible barriers to the trading to Sofala, when once understood, were the very means of performing this voyage safely and expeditiously.

The vessel trading to Sofala sailed from the bottom of the Arabian gulf in summer, with the monsoon at north, which carried her to Mocha. There the monsoon failed her by the change of the direction of the gulf. The south-west winds, which blow without Cape Guardafui in the Indian ocean, force themselves round the cape so as to be felt in the road of Mocha, and make it uneasy riding there. But those soon changed, the weather became moderate, and the vessel, we suppose in the month of August, was safe at anchor under Cape Guardafui, where was the port which, many years afterwards, was called *Promontorium Aromatum*. Here the ship was obliged to stay all November, because all these summer months the wind south of the cape was a strong south-wester, as hath been before said, directly in the teeth of the voyage to Sofala. But this time was not lost; part of the goods bought to be ready for the return was ivory, frankincense, and myrrh; and the ship was then at the principal mart for these.

Our author supposes, that in November the vessel sailed with the wind at north-east, with which she would soon have made her voyage: but off the coast of Melinda, in the beginning of December, she there met an anomalous monsoon at south-west, in our days first observed by Dr Halley, which cut off her voyage to Sofala, and obliged her to put into the small harbour of Mocha, near Melinda, but nearer still to Tarshish, which we find here by accident, and which we think a strong corroboration that we are right as to the rest of the voyage. In the annals of Abyssinia, it is said that Amda Sion, making war upon that coast in the 14th century, in a list of the rebellious Moorish vassals, mentions the chief of Tarshish as one of them, in the very situation where we have now placed him.

Solomon's vessel, then, was obliged to stay at Tarshish till the month of April of the second year. In May, the wind set in at north-east, and probably carried her that same month to Sofala. All the time she spent at Tarshish was not lost, for part of her cargo was to be brought from that place; and she probably bought, bespoke, or left it there. From May of the second year, to the end of that monsoon in October, the vessel could not stir; the wind was north-east. But that time, far from being lost, was necessary to the traders for getting in their cargo, which we shall suppose was ready for them.

The ship sails on her return, in the month of November of the second year, with the monsoon south-west, which in a very few weeks would have carried her into the Arabian gulf. But off Mocha, near Melinda and Tarshish, she met the north-east monsoon, and was obliged to go into that port, and stay there till the end of that monsoon; after which a south-wester came to her relief in May of the third year. With the May monsoon she ran to Mocha within the straits, and was there confined by the summer monsoon blowing up the Arabian gulf from Suez, and meeting her. Here she lay till that monsoon which in summer blows northerly from Suez, changed to a south-east one in October or November, and that very easily brought her up into the Elanitic gulf, the middle or end of December of the third year. She had no need of more time to complete her voyage, and it was not possible she could do it in less.

Such is a very short and imperfect abstract of our author's reasons for placing Ophir in Sofala. If it excite the curiosity of our readers to consult his work, it will answer the purpose for which we have made it.

4 Another hypothesis.

We are now to give another ingenious conjecture concerning the situation of Ophir and Tarshish, with which we have been favoured by Dr Doig, the learned author of Letters on the Savage State, addressed to Lord Kames.

This respectable writer holds that Ophir was somewhere on the west coast of Africa, and that Tarshish was the ancient Bætica in Spain. His essay is not yet published; but he authorizes us to give the following abstract of it: "The first time that *Ophir*, or rather *Aufir*, occurs in Scripture, is in Gen. x. 29. where the sacred historian, enumerating the sons of Joktan, mentions Aufir as one of them." According to his account, the descendants of those 13 brothers settled all in a contiguous situation, from Mesha (the Mocha of the moderns) to Sepharah, a mountain of the east. Moses, as every one knows, denominates countries, and the inhabitants of countries, from the patriarch from whom those inhabitants descended. In describing the course of one of the branches of the river of paradise, the same Moses informs us that it encompassed the whole land of Havilah, &c. which abounded with fine gold, bdellium, and the onyx stone; and this land had its name from Havilah, the 12th son of the patriarch Joktan. *Ophir* or *Aufir* was Havilah's immediate elder brother; and of course the descendants of the former, in all probability, fixed their habitation in the neighbourhood of those of the latter. If, then, the land of Havilah abounded with gold and precious stones, the land of Ophir undoubtedly produced the very same articles.

5 The original Ophir not the Ophir of Solomon; of which

Here then we have the original Ophir; here was found the primary gold of Ophir; and here lay the Ophir mentioned in Job xi. 24. But as navigation was then in its infant state, the native land of gold mentioned by Job must have been much nearer home than that to which the fleets of Solomon and Hiram made their triennial voyages. That several countries on the south-east coast of Africa abounded with gold long after the era of Job, is evident from the testimony of Herodotus, Strabo, Diodorus Siculus, Ptolemy, Pomponius Mela, &c.; but that in these countries the Ophir of Solomon could not be situated, is plain, because his ships in the same voyage touched at Tarshish, which lay in a very different quarter.

The Abyssinian traveller has placed this *regio aurifera* in Sofala on the eastern coast of Africa, nearly opposite to the island of Madagascar. This hypothesis was current a hundred years before he was born; but I am persuaded (says our author) that it is not tenable. The Ophir of Solomon, in whatever part of Africa it lay, must have been well known, prior to his reign, both to the Phœnicians and the Edomites. These people navigated that monarch's fleet, and therefore could be no strangers to the port whither they were bound. That it

2

Ophir.

it was in Africa is certain; and that it was on the west coast of that immense peninsula, will appear more than probable, when we have ascertained the situation of Tarshish, and the usual course of Phoenician navigation. To these objects, therefore, we shall now direct our inquiries.

6 the situation must be ascertained by discovering that of Tarshish.

"Javan, the fourth son of the patriarch Japhet, had four sons, Elisha, *Tarshish*, Kittim, and Dodanim or Rodanim; among whose 'descendants were the isles of the Gentiles divided.' The city of *Tarsus* on the coast of Cilicia, at once ascertains the region colonized by the descendants of Tarshish. But as much depends upon determining the position of this country, I shall endeavour (says the Doctor) to fix it with all possible precision.

"In the first place, I must beg leave to observe, that there is not a single passage in any ancient author, sacred or profane, that so much as alludes to any city, district, canton, or country, of the name of Tarshish in the eastern parts of the world. The descendants of Javan, of whom Tarshish was one, are agreed on all hands to have extended their settlements towards the north-west, i. e. into Asia Minor, Italy, and Spain. The inhabitants of Tarshish are everywhere in Scripture said to be addicted to navigation and commerce, in which they seem to have been connected with the Tyrians and Phoenicians †, who were always said by the Jews to inhabit the isles of the sea. Indeed, in Hebrew geography, all the countries towards the north and west, which were divided from Judea by the sea, were called the isles of the sea‡. Thus Isaiah: 'The burden of Tyre. Howl ye ships of Tarshish, for it is laid waste, so that there is no house, no entering in: from the land of Chittim it is revealed unto them. Be still ye inhabitants of the isle, thou whom the merchants of Zidon, that pass over the sea, have replenished.' The land of Chittim was Macedonia, and often Greece, from which every one knows that the destruction of Tyre came; and that Tarshish was not an unconcerned spectator of that destruction, is obvious from the same prophet, who proceeds to say||: 'As at the report concerning Egypt, so shall they be sorely pierced at the report concerning Tyre. Pass over to Tarshish; howl ye inhabitants of the isle. Is this your joyous city?' It appears likewise from Ezekiel xxvii. 12. that Tarshish was the merchant with whom Tyre traded for silver, iron, tin, and lead, and that this trade was carried on in fairs.

† Ps. xlviii. 7. lxxii. 10.

‡ Gen. ii. 26.

|| Is. xxiii. *passim.*

7 The original Tarshish, where situated.

"From all these passages, it seems to be evident, that the descendants of Tarshish settled on the western coast of Asia Minor; that these people were addicted to navigation and commerce; that in the course of their traffic they were connected with the Tyrians and Phoenicians; that the commerce they carried on consisted of silver, iron, tin, and lead; that the people of Tarshish were connected with Kittim and the isles of the Gentiles, which are confessedly situated toward the north and west of Judea.

"But lest, after all, a fact so fully authenticated should still be called in question, I shall add one proof more, which will place the matter beyond the reach of doubt and controversy.

"When the prophet Jonah intended to flee from the presence of the Lord, in order to avoid preaching at Nineveh, let us see where the peevish deserter embarked (Jonah i. 3.). "And Jonah rose up to flee unto Tarshish, from the presence of the Lord, and went down to Joppa: and he found a ship going to Tarshish, and he paid the fare thereof, and went down into it, to go with them into Tarshish, from the presence of the Lord.' Every body knows that Joppa or Japhah stood upon the shore of the Mediterranean; of course the fugitive prophet had determined to go to some very distant region westward, and by that means to get as far from Nineveh as possible."

8 This not the Tarshish of Solomon.

Having thus proved to a demonstration, that the original Tarshish was a region on the western coast of Asia Minor, where either the patriarch of that name, or some of his immediate descendants, planted a colony, it remains to determine whether this was actually the country from which Solomon imported the vast quantities of silver mentioned by the sacred historian. That it was not, our author frankly acknowledges; and therefore, says he, we must look out for Solomon's Tarshish in some other quarter of the globe.

9 The name of one country transferred to another.

To pave the way for this discovery, he very justly observes, that it has at all times been a common practice to transfer the name of one country to another, in consequence of some analogy or resemblance between them. It has likewise often happened, that when a commodity was brought from a very distant country by a very distant people, the people to whom it was imported have taken it for granted that it was produced in the region from which it was immediately brought to them. Of the truth of this position no man acquainted with the Greek and Roman poets can for a moment entertain a doubt. Hence the *Assyrium amomum* of Virgil, and the *Assyrium malabathrum* of Horace, though these articles were the product not of Assyria but of India. The Jews, who were as little acquainted with foreign countries as the Greeks and Romans, had very probably the same notions with them respecting articles of commerce; and if so, they would undoubtedly suppose, that the silver sold by the merchants of Tarshish was the product of that country. When this mistake came to be discovered, they very naturally transferred the name *Tarshish* from the country of the merchants to that of the articles which they imported. Let us now, says our author, try if we cannot find out where that country was.

It has been already shown, by quotations from Isaiah and Ezekiel, that the merchants of Tarshish traded in the markets of Tyre with silver, iron, lead, and tin. To these authorities, we shall add another from Jeremiah: "Silver (says that prophet) spread into plates is brought from Tarshish." "But in Spain (continues our learned dissertator), all those commodities were found in the greatest abundance. All the ancient authors who describe that region dwell with rapture on its silver mines. This fact is too generally known to need to be supported by authorities. Spain was then the region which furnished Solomon's traders with the immense mass of silver he is said to have imported. This was, one might say, the modern Tarshish; and indeed both Josephus and Eusebius are positive that the posterity of Tarshish actually peopled that country. If this was an early opinion, as it certainly was, the Jews would of course denominate Spain from the patriarch in question.

I have shown above, that the inhabitants of Tarshish.

Ophir.

shish were strictly connected with the Kittim, or Grecians: I shall here produce an authority which will prove to a demonstration that the Kittim had extended their commerce into that part of Africa now called Barbary.

"The prophet Ezekiel, (xxvii. 6.) describing the splendour and magnificence of Tyre, tells us, 'that the company of the Ashurites made her benches of ivory, brought from the isles of Kittim.' In the first place, I must observe, that there is probably a small error in the orthography of the word Ashurim. This term is everywhere in Scripture translated Assyrians, which translation is certainly just. But how the Assyrians could export ivory from the isles of Kittim, and fashion it into benches for the Tyrian mariners, is, in my opinion, a problem of no easy solution. The fact is Ashurim should be Asherim, that is, the company of the men of Asher. The tribe of Asher obtained its inheritance in the neighbourhood of Tyre; (see Josh. xix. 28.). 'And Hebron, and Rehob, and Hammon and Canah, unto Zidon the great.' The companies of the tribe of the Asherites then, and not the Ashurim, were the people who manufactured the benches in question.

"Be that as it may, the ivory of which the implements were formed was imported from the isles of Kittim, that is, from Greece and its neighbourhood. These islands, it is certain, never produced ivory. They must therefore have imported it from some other country; but no other country, to which the Greeks and their neighbours could have extended their commerce, except the north of Africa, produced that commodity. The conclusion then is, that the maritime states of Asia Minor, Greece, and probably the Hetruscans on the west coast of Italy, carried on a gainful commerce with Spain and Barbary at a very early period.

"We have now seen that the original Tarshish on the coast of Asia Minor did not produce the metals imported by Solomon's fleet; that no Tarshish is to be found in the eastern parts of the globe; that the Tarshish we are in quest of was undoubtedly situated somewhere towards the west of Judea: we have shown that the mercantile people of Asia Minor, Greece, and probably of Italy, actually imported some of those articles from the coast of Africa; we have hazarded a conjecture, that Spain was the modern Tarshish, and that very country from which Solomon imported his silver, and the Tyrians their silver, iron, tin, and lead. Let us now make a trial whether we cannot exhibit some internal proofs in support of the hypothesis we have above adopted.

"The ancients divided Spain into three parts, Bætica, Lusitania, and Tarraconensis. Bætica is the modern Andalusia. It stretched along the Fretum Herculeum, or Straits of Gibraltar, to the mouth of the Guadalquiver. This region is thought by some to have been the Elysian fields of the poets. The river Bætis, which divides it, is called *Tartessus* by Aristotle, Stesichorus, Strabo, Pausanias, Steph. Byzant, and Avianus. Here too we have a city and a lake of the same name. But Tartessus is positively the very same with Tarshish. The Phœnicians, by changing *schin* into *thau*, made it Tartish. The Greeks manufactured the rest, by changing Tartish into Tartis, and in process of time into ταρτησσος. That the Phœnicians actually changed *schin* into *thau* is certain; for Plutarch tells us, in the life of Sylla, that in their language an ox was called *thor*, which is, no doubt, the same with the Hebrew *shor*.

"From this deduction, it appears highly probable at least, that the Spanish Bætica was originally called *Tarshish*. Indeed this similarity of names has operated so powerfully on the learned Bochart, and on some other moderns of no mean figure, that they have positively affirmed, as Josephus had done before them, that the patriarch Tarshish actually settled in that country. This I should think not altogether probable; but that his descendants who settled on the coast of Asia Minor colonized Bætica, and carried on an uninterrupted commerce to that country, along with the Phœnicians, for many centuries after it was peopled, and that from the circumstances above narrated, it was denominated *Tarshish*, are facts too palpable to admit of contradiction. 10 Tarshish Spanish Bætica.

"Let us now see whether this Bætica, where I have endeavoured to fix the situation of the Tarshish of the Scriptures, was actually furnished with those articles of commerce which are said to have been imported from that country. To enlarge on this topic would be altogether superfluous. Diodorus Siculus, Strabo, Polybius, Pliny, Solinus, and, in one word, all the Greek and Roman historians who have mentioned that region, have unanimously exhibited it as the native land of silver, iron, and tin: to these, contrary to the opinions of the celebrated modern traveller, they likewise add gold in very large quantities."

Our author having thus ascertained the situation of Tarshish, proceeds to prove, by a mass of evidence too large for our insertion, that the Edomites and Tyrians had doubled the Cape, and almost encompassed Africa, long before the era of Solomon. Then referring to 1 Kings, chap. ix. and x. 2 Chron. viii. ix. 2 Kings xxii. and 2 Chron. xx. he observes, that from these authorities it appears indubitable, that the fleets of Solomon and Hiram sailed from Eloth and Eziongeber; that the voyages to Ophir and Tarshish were exactly the same, performed at one and the same time, by the very same fleet; which must necessarily have encompassed the peninsula of Africa before it could arrive at the country of Tarshish. This being the case, the traders might easily enough collect the gold on the coast of Guinea, or on what is now vulgarly called the *Gold Coast*. The ivory they might readily enough procure on the Barbary coast, opposite to Tarshish. In Africa too, they might hunt apes, monkeys, baboons, &c.; and peacocks, or rather parrots, and parroquets, they might surprise in the forests which abounded on the coast. In Spain, silver, iron, lead, and tin, were, one may say, the native produce of the soil. Even at this early period, the Phœnician navigators had discovered the Cassiterides or Scilly islands, and Cornwall; and from that region, in company with the merchants, may have supplied them with that rare commodity.

"I have supposed that the navy of Solomon and Hiram collected their gold in the course of their voyage somewhere on the coast of Africa, beyond the Cape, for the following reasons: Had they found the golden fleece

Ophir.

fleece at Sofala (A), or any part of the coast of Africa, they would have chosen to return and unlade at Eloth or Ezion-geber, rather than pursue a long and dangerous course, quite round Africa, to Tarshish; to which last country they might have shaped their course much more commonly from Zidon, Tyre, Joppa, &c. But being obliged to double the cape in quest of some of those articles which they were enjoined to import, they pushed onward to Tarshish, and returned by the Pillars of Hercules to Tyre, or perhaps to Joppa, &c. Their next voyage commenced from one or other of these ports, from which they directed their course to Tarshish; and having taken in part of their lading there, they afterwards coasted round Africa, and so arrived once more at Eloth or Ezion-geber.

"Let us now attend to the space of time in which these voyages were performed. We are told expressly (2 Chron. ix. 21.) that once every three years came the ships of Tarshish, &c. This is exactly the time one would naturally imagine necessary to perform such a distant voyage, at a period when navigation was still in its infancy, and mariners seldom adventured to lose sight of the coast. Of this we have an irrefragable proof in the history of a voyage round the very same continent, undertaken and accomplished in the very same space of time, about two centuries after.

"We learn from Herodotus, lib. ii. cap. 149. that Nechus, one of the latter kings of Egypt, whom the Scripture calls *Pharaoh Necho*, built a great number of ships, both on the Red sea and the Mediterranean. The same historian, lib. iv. cap. 42. informs us, that this enterprising monarch projected a voyage round the continent of Africa, which was actually accomplished in the space of three years. In the conduct of this enterprise, he employed Phœnician mariners, as Solomon had done before him. These, we may suppose, were assisted in the course of this navigation by charts or journals, or at least by traditional accounts derived from their ancestors: 'These navigators (says the historian) took their departure from a port on the Red sea, and sailing from thence into the southern ocean, and, in the beginning of autumn, landing on the coast of Africa, there they sowed some grain which they had carried out with them on board their vessels. In this place they waited till the crop was ripened; and, having cut it down, they proceeded on their voyage. Having spent two years in this navigation, in the third they returned to Egypt, by the Pillars of Hercules. These mariners, adds the author, reported a fact, which, for his part, he could by no means believe to be true; namely, that in one part of their course their shadows fell on their right; a circumstance which gives considerable weight to the truth of the relation.'

"Let it now be observed that Phœnician mariners navigated the fleet of Solomon: the same people conducted that of Necho: the fleet of Necho spent three years in the course of its voyage; that of Solomon did the same in its course about two centuries before: the fleet of Necho sailed from a port on the Red sea; that of Solomon took its departure from Eloth or Ezion-geber, situated on the same sea: the fleet of the former returned by the Pillars of Hercules; that of the latter, according to the hypothesis, pursued the very same route. Such a coincidence of similar circumstances united with those adduced in the preceding part of this article, seem to prove almost to a demonstration, that the navy of Hiram and Solomon performed a voyage round Africa, in that age, in the same manner as that of Necho did two centuries after.

"Upon the whole, I conclude, that the original Ophir, which is really Aufir or Aufr, was situated on the south of Arabia Felix, between Sheba and Havilah, which last was encompassed by one of the branches of the river of Paradise: that the name Ophir, i. e. Aufr, was, in consequence of its resemblance, in process of time transferred to a region on the coast of Africa; and that from it first *Afer* and then Africa was denominated: that the primitive Tarshish was Cilicia, and that the Jews applied this name to all the commercial states on the coast of Asia Minor, and perhaps of Italy, there being strong presumptions that the Tyrrhenians were colonists from Tarshish; that Bætica, and perhaps some other regions of Spain, being planted with colonies from Tarshish, likewise acquired the name of Tarshish; that the Tyrians were strictly connected with the merchants of Tarshish in their commercial enterprises; that Tarshish was certainly situated westward from Judea, Phœnicia, &c.; that no other country in the western quarters produced the commodities imported by the two kings, except Spain and the opposite coasts; that this country, in those ages, produced not only silver, iron, tin, and lead, but likewise gold in great abundance; that the merchants of Kittim imported ivory, of which the Asherites made benches for the Tyrians; which commodity they must have purchased on the coast of Barbary, where the Jews and Phœnicians would find the same article; that Tarshish being situated in Spain, it was impossible for a fleet sailing from Eloth, or Ezion-geber, to arrive at that country without encompassing Africa; that of course the fleet in question did actually encompass that continent; that the Ophir of Solomon must have been situated somewhere on the coast of Africa, to the west of the Cape, because from it the course to Tarshish was more eligible than to return the same way back to Ezion-geber."

11
Ophir situated on the coast of Africa, west of the Cape.

Our author supports this conclusion by many other arguments and authorities, which the limits prescribed us will not permit us to detail; but perhaps the article might be deemed incomplete if we did not show how he obviates an objection that will readily occur to his theory. "If the original Ophir was seated on the coast of Arabia Felix, and the modern region of the same name on the west coast of Africa, it may be made a question, how the latter country came to be denominated from the former; Nothing (says our author) can be more easy than to answer this question. The practice of adapting the name of an ancient country to

12
An objection answered.

(A) That Sofala opposite to the island of Madagascar was Ophir, was an ancient conjecture. See Bochart, chan. l. ii. cap. 27. p. 160. 4to.

to a newly discovered one, resembling the other in appearance, in situation, in figure, in distance, in the nature of the climate, productions, &c. has ever been so common, that to produce instances would be altogether superfluous. The newly discovered region on the coast of Africa abounded with the same species of commodities by which the original one was distinguished; and of course, the name of the latter was annexed to the former.

Whether Mr Bruce's hypothesis, or Dr Doig's, respecting the long-disputed situation of Solomon's *Ophir*, be the true one, it is not for us to decide. Both are plausible, both are supported by much ingenuity and uncommon erudition; but we do not think that the arguments of either writer furnish a complete confutation of those adduced by the other. *Sub judice lis est.*

OPHIRA, a genus of plants belonging to the octandria class. See BOTANY *Index*.

OPHITES, in *Natural History*, an old term employed to denote a mineral, of a dusky green ground, sprinkled with spots of a lighter green, otherwise called *serpentine*. See MINERALOGY *Index*.

OPHITES, in church history, Christian heretics, so called both from the veneration they had for the serpent that tempted Eve, and the worship they paid to a real serpent: they pretended that the serpent was Jesus Christ, and that he taught men the knowledge of good and evil. They distinguished between *Jesus* and *Christ*: Jesus, they said, was born of the Virgin, but Christ came down from heaven to be united with him; Jesus was crucified, but Christ had left him to return to heaven. They distinguished the God of the Jews, whom they termed *Jaldabaoth*, from the supreme God: to the former they ascribed the body, to the latter the soul of man. They had a live serpent, which they kept in a kind of cage; at certain times they opened the cage door, and called the serpent: the animal came out, and mounting upon the table, twined itself about some loaves of bread; this bread they broke and distributed it to the company, who all kissed the serpent: this they called their *Eucharist*.

OPHRYS, TWYBLADE; a genus of plants belonging to the gynandria class; and in the natural method ranking under the 7th order, *Orchideæ*. See BOTANY *Index*.

OPHTHALMOSCOPY, a branch of physiognomy, which deduces the knowledge of a man's temper and character from the appearance of his eyes.

OPHTHALMIA, in *Medicine*, an inflammation of the eye or of the membranes which invest it; especially of the adnata, or albugineous coat. See MEDICINE, N° 174.

OPIATES, medicines which are administered to procure sleep, whether in the form of electuaries, drops, or pills.

OPINION is that judgment which the mind forms of any proposition, for the truth or falsehood of which there is not sufficient evidence to produce science or absolute belief.

That the three angles of a plane triangle are equal to two right angles, is not a matter of *opinion*, nor can it with propriety be called an object of the mathematician's *belief*: he does more than believe it; he *knows* it to be true. When two or three men, under no temptation to deceive, declare that they were witnesses of an uncommon, though not preternatural event, their testimony is complete evidence, and produces absolute *belief* in the minds of those to whom it is given; but it does not produce *science* like rigid demonstration. The fact is not doubted, but those who have it on report do not *know* it to be true, as they know the truth of propositions intuitively or demonstrably certain. When one or two men relate a story including many circumstances to a third person, and another comes who positively contradicts it either in whole or in part, he to whom those jarring testimonies are given, weighs all the circumstances in his own mind, balances the one against the other, and lends an assent, more or less wavering, to that side on which the evidence appears to preponderate. This assent is his *opinion* respecting the facts of which he has received such different accounts.

Opinions are often formed of events not yet in being. Were an officer from the combined armies, which are just now * besieging Valenciennes, to come into the room where we are writing, and tell us that those armies are in good health and high spirits; that every shot which they fire upon the fortress produces some effect; and that they have plenty of excellent provisions, whilst the besieged are perishing by hunger; we should absolutely *believe* every fact which he had told us upon the evidence of his testimony; but we could only be of *opinion* that the garrison must soon surrender. In forming opinions of this kind, upon which, in a great measure depends our success in any pursuit, every circumstance should be carefully attended to, and our judgments guided by former experience. Truth is a thing of such importance to man, that he should always pursue the best methods for attaining it; and when the object eludes all his researches, he should remedy the disappointment, by attaching himself to that which has the strongest resemblance to it; and that which most resembles truth is called *probability*, as the judgment which is formed of it is termed *opinion*. See PROBABILITY.

OPIUM, in the *Materia Medica*, is an inspissated juice, obtained from the capsule of the white poppy, partly of the resinous and partly of the gummy kind, and possessing also a narcotic principle. See MATERIA MEDICA, N° 612.

OPOBALSAMUM, in the *Materia Medica*, Opobalsum, or balm of Gilead, a resinous substance obtained from a species of AMYRIS. See CHEMISTRY, N° 2472, and MATERIA MEDICA, N° 507.

OPOCALPASUM, OPOCARBASUM, or APOCALPASUM; a gummy resinous substance, which has a strong resemblance to liquid myrrh, and which in the time of Galen was mixed with myrrh. It was difficult, according to this writer, to distinguish the one from the other unless by their effects, the former being of a poisonous nature, which frequently produced lethargy.

OPOPONAX, in the *Materia Medica*, is a gummy resinous substance brought from the East Indies. See MATERIA MEDICA, N° 455.

OPORTO, or PORTO, a flourishing city and seaport of Portugal, in the province of Entre-Douero-e-Minho, with a bishop's see. Nature has rendered it almost impregnable; and it is justly celebrated for the strength of its wines, large quantities of which are exported

ported to Britain, and on this account all red wines either from Spain or Portugal are denominated *port wines*. After the earthquake at Lisbon in the year 1755, the trade of this city increased rapidly, before which memorable period its population did not exceed 20,000; but it is now computed at upwards of 40,000. Oporto is situated on the declivity of a mountain, near the river Douero, which forms an excellent and commodious harbour; and is about 147 miles north by east of Lisbon. W. Long. 8. 21. N. Lat. 41. 10.

OPOSSUM, in *Zoology*, a species of didelphis. See DIDELPHIS.

OPOUN, one of the Navigators Islands, of which there are ten in number, first discovered by Bougainville, and so called by him, because the inhabitants do not pass from one village to another but in canoes. This and the other islands lie in 14° south latitude, and from 171° to 173° longitude west from Paris, according to Perouse. Here the sugar cane is to be met with growing spontaneously; but it is said to contain less of the saccharine substance than what is produced in the West Indies. The men are possessed of uncommon strength, and tatow their bodies in such a manner, that, although almost naked, they have the appearance at a little distance of being clothed. Ferocity and treachery are characteristic marks of this people, of which the unfortunate Perouse had but too soon a melancholy proof, 11 out of 60 of his crew having been murdered by them, although received at first with an air of good humour. This ought to serve as a caution to future navigators, not to place implicit confidence in the apparent kindness of these savages, which is frequently the dismal prelude of ruin and destruction. Among these fell the celebrated naturalist Lamanon; see LAMANON.

OPPENHEIM, a town of Germany, in the lower palatinate of the Rhine, and capital of a bailiwick of the same name; seated on the declivity of a hill near the Rhine. E. Long. 8. 20. N. Lat. 49. 48.

OPPIANUS, a poet and grammarian of Anazarba in Cilicia, in the second century. He composed a poem of hunting, and another of fishing, for which Antoninus Caracalla gave him as many golden crowns as there were verses in his poems; they were hence called *Oppian's golden verses*. He died in the 30th year of his age.

OPPILATION, in *Medicine*, the act of obstructing or stopping up the passage of the body, by redundant or peccant humours. This word is used chiefly for obstructions in the lower belly.

OPTATIVE MOOD, in *Grammar*, that which serves to express an ardent desire or wish for something.

In most languages, except the Greek, the optative is only expressed by prefixing to the subjunctive an adverb of wishing; as *utinam*, in Latin: *plut à Dieu*, in French; and *would to God*, in English.

OPTIC ANGLE, the angle which the optic axes of both eyes make with one another, as they tend to meet at some distance before the eyes.

OPTIC Axis, the axis of the eye, or a line going through the middle of the pupil and the centre of the eye.

OPTICS.

History.

1 Definition. OPTICS, from ὀπτομαι, *to see*, is that science which considers the nature, the composition, and the motion of light;—the changes which it suffers from the action of bodies;—the phenomena of vision, and the instruments in which light is the chief agent.

HISTORY.

SECT. I. *Discoveries concerning the Refraction of Light.*

2 Refraction known to the ancients;

THOUGH the ancients made few optical experiments, they nevertheless knew, that when light passed through media of different densities, it did not move in a straight line, but was bent or *refracted* out of its original direction. This was probably suggested to them by the appearance of a straight rod partly immersed in water; and accordingly we find many questions concerning this and other optical appearances in the works of Aristotle. Archimedes is said to have written a treatise on the appearance of a ring or circle under water, and therefore could not have been ignorant of the common phenomena of refraction. The ancients, however, were not only acquainted with these more ordinary appearances, but also with the production of colours by refraction. Seneca says, that if the light of the sun shines through an angular piece of glass, it will show all the colours of the rainbow. These colours, he says, are false, such as are seen in a pigeon's neck when it changes its position; and of the same nature, he says, is a speculum, which, without having any colour of its own, assumes that of any other body. It appears, also, that the ancients were not ignorant of the magnifying power of glass globes filled with water, though they do not seem to have been acquainted with its cause; and the ancient engravers are supposed to have used a glass globe filled with water to magnify their figures. This indeed seems evident, from their lenticular and spherical gems of rock crystal which are still preserved, the effect of which, in magnifying at least, could scarcely have escaped the notice of those who had often occasion to handle them; if indeed, in the spherical or lenticular form, they were not solely intended for the purposes of burning. One of these, of the spherical kind, of about an inch and a half diameter, is preserved among the fossils presented by Dr Woodward to the university of Cambridge.

3 and the magnifying power of glass globes.

The first treatise of any consequence written on the subject of optics, was by the celebrated Ptolemy. The treatise is now lost; but from the accounts of others, we find that he treated of astronomical refractions. The first astronomers were not aware that the intervals between stars appear less near the horizon than near the meridian; but it is evident that Ptolemy was aware of this circumstance, by the caution which he gives to allow something

4 Refraction first treated scientifically by Ptolemy.

History.

something for it, upon every recourse to ancient observations.

5 His hypothesis concerning the horizontal sun and moon.

Ptolemy also advances a very sensible hypothesis to account for the greater apparent size of the sun and moon when seen near the horizon. The mind, he says, judges of the size of objects by means of a preconceived idea of their distance from us: and this distance is fancied to be greater when a number of objects intervene; which is the case when we see the heavenly bodies near the horizon. In his Almagest, however, he ascribes this appearance to a refraction of the rays by vapours, which actually enlarge the angle subtended by the luminaries.

6 Discoveries of Alhazen.

The nature of refraction was afterwards considered by Alhazen an Arabian writer; insomuch that, having made experiments upon it at the common surface between air and water, air and glass, water and glass; and, being prepossessed with the ancient opinion of crystalline orbs in the regions above the atmosphere, he even suspected a refraction there also, and fancied he could prove it by astronomical observations. Hence this author concludes, that refraction increases the altitudes of all objects in the heavens; and he first advanced, that the stars are sometimes seen above the horizon by means of refraction, when they are really below it. This observation was confirmed by Vitellio, B. Waltherus, and by the excellent observations of Tycho Brahe. Alhazen observed, that refraction contracts the vertical diameters and distances of the heavenly bodies, and that it is the cause of the twinkling of the stars. But we do not find that either he, or his follower Vitellio, subjected it to mensuration. Indeed it is too small to be determined except by very accurate instruments, and therefore we hear little more of it till about the year 1500, when great attention was paid to the subject by Bernard Walther, Mæstlin, and Tycho Brahe.

Alhazen supposed that the refraction of the atmosphere did not depend upon the vapours, but on the different transparency; by which, as Montucla conjectures, he meant the density of the gross air contiguous to the earth, and the ether or subtile air that lies beyond it. We judge of distance, he says, by comparing the angle under which objects appear, with their supposed distance; so that if these angles be nearly equal, and the distance of one object be conceived greater than that of the other, it will be imagined to be larger. He also observes, that the sky near the horizon is always imagined to be farther from us than any other part of the concave surface. Roger Bacon ascribes this account of the horizontal moon to Ptolemy; and as such it is examined, and objected to by B. Porta.

In the writings of Roger Bacon, we find the first distinct account of the magnifying power of glasses; and it is not improbable, that what he wrote upon this subject gave rise to the useful invention of spectacles. He says, that if an object be applied close to the base of the larger segment of a sphere of glass, it will appear magnified. He also treats of the appearance of an object through a globe, and says that he was the first who observed the refraction of rays into it.

7 Of Vitellio. 1270.

Vitellio, a native of Poland, published a treatise of optics, containing all that was valuable in Alhazen. He observes, that light is always lost by refraction; but he does not pretend to estimate the quantity of this loss. He reduced into a table the result of his experiments on the refractive powers of air, water, and glass, corresponding to different angles of incidence. In his account of the horizontal moon he agrees exactly with Alhazen. He ascribes the twinkling of the stars to the motion of the air in which the light is refracted; and to illustrate this hypothesis, he observes, that they twinkle still more when viewed in water put in motion. He also shows, that refraction is necessary as well as reflection, to form the rainbow; because the body which the rays fall upon is a transparent substance, at the surface of which one part of the light is always reflected and another refracted. But he seems to consider refraction as serving only to condense the light, thereby enabling it to make a stronger impression upon the eye. This writer also makes many attempts to ascertain the law of refraction. He likewise considers the foci of glass spheres, and the apparent size of objects seen through them: though upon these subjects his observations are inaccurate. It is sufficient indeed to show the state of knowledge, at that time, to observe, that both Vitellio, and his master Alhazen, account for objects appearing larger when seen under water, by the circular figure of its surface; since, being fluid, it conforms to the figure of the earth.

8 Of Roger Bacon.

Contemporary with Vitellio was Roger Bacon, a man of extensive genius, who wrote upon almost every branch of science; yet in optics he does not seem to have made any considerable advances. Even some of the most absurd of the opinions of the ancients have had the sanction of his authority. He believed that visual rays proceed from the eye; because every thing in nature is qualified to discharge its proper functions by its own powers, in the same manner as the sun and other celestial bodies. In his *Specula Mathematica*, he added some observations of little importance on the refraction of the light of the stars; the apparent size of objects; the enlargement of the sun and moon in the horizon. In his *Opus Majus* he demonstrates, what Alhazen had done before, that if a transparent body interposed between the eye and an object, be convex towards the eye, the object will appear magnified.

9 Of Maurolycus. 1575.

From this time, to that of the revival of learning in Europe, we have no treatise on optics. One of the first who distinguished himself in this way was Maurolycus, teacher of mathematics at Messina. In two works, entitled *Theoremata Lucis et Umbræ*, and *Diaphanorum Partes*, &c. he demonstrates that the crystalline humour of the eye is a lens that collects the rays of light issuing from the object, and throws them upon the retina, where is the focus of each pencil. From this principle he discovered the reason why some people were short-sighted and others long-sighted; and why the former are relieved by concave, and the others by convex, glasses.

10 Discoveries of B. Porta. Born 1445. Died 1515.

While Maurolycus made such advances towards the discovery of the nature of vision, Baptista Porta of Naples invented the *camera obscura*, which throws still more light on the same subject. His house was resorted to by all the ingenious persons at Naples, whom he formed into *an academy of secrets*; each member being obliged to contribute something useful and not generally known. By this means he was furnished with materials for his *Magia Naturalis*, which contains his account of the *camera obscura*, and which was published, as he informs us, when he was not quite 15 years old. He also gave

History.

gave the first hint of the magic lantern; which Kircher afterwards improved. His experiments with the *camera obscura* convinced him, that vision, as Aristotle supposed, is performed by the intromission of something into the eye, and not by visual rays proceeding from the eye, as had been formerly imagined by Empedocles; and he was the first who fully satisfied himself and others upon this subject. The resemblance indeed between experiments with the *camera obscura* and the manner in which vision is performed in the eye, was too striking to escape the observation of a less ingenious person. But when he says that the eye is a *camera obscura*, and the pupil the hole in the window shutter, he was so far mistaken as to suppose that it was the crystalline humour that corresponds to the wall which receives the images; nor was it discovered till the year 1604, that this office is performed by the retina. He makes a variety of just observations on vision; and explains several cases in which we imagine things to be without the eye, when the appearances are occasioned by some affection of the organ itself, or some motion within it. He remarks also, that, in certain circumstances, vision will be assisted by convex or concave glasses; and he seems also to have made some small advances towards the discovery of telescopes. He observes, that a round and flat surface plunged into water, will appear hollow as well as magnified to an eye above it; and he explains by a figure the manner in which this effect is produced.

11 The law of refraction discovered. 1637.

The great problem concerning the measure of refractions was still unsolved. Alhazen and Vitellio, indeed, had attempted it; but failed, by trying to measure the angle instead of its sine. At last it was discovered by Snellius, professor of mathematics at Leyden. This philosopher, however, did not perfectly understand his own discovery, nor did he live to publish any account of it. It was afterwards explained by Professor Hortensius before it appeared in the writings of Descartes, who published it under a different form, without making any acknowledgement of his obligations to Snellius, whose papers Huygens assures us, were seen by Descartes. Before this time Kepler had published a New Table of Angles of Refraction, determined by his own experiments, for every degree of incidence. Kircher had done the same, and attempted a theory of refraction, on principles, which, if conducted with precision, would have led him to the law discovered by Snellius.

12 Opinions of Descartes and Leibnitz on this subject.

Descartes undertook to explain the cause of refraction by the resolution of forces. Hence he was obliged to suppose that light passes with more ease through a dense medium, than through a rare one. The truth of this explanation was first questioned by M. Fermat, who asserted, contrary to the opinion of Descartes, that light suffers more resistance in water than air, and more in glass than in water; and maintained, that the resistance of different media with respect to light is in proportion to their densities. M. Leibnitz adopted the same general idea, upon the principle that nature accomplishes her ends by the shortest methods, and that light therefore ought to pass from one point to another, either by the shortest road, or that in which the least time is required.

At a meeting of the Royal Society, Aug. 31. 1664, it was found, with a new instrument prepared for that purpose, that the angle of incidence being 40 degrees, that of refraction is 30. About this time also we find the first mention of media not refracting the light in an exact proportion to their densities. For Mr Boyle, in a letter to Mr Oldenburgh, dated Nov. 3. 1664, observes, that in spirit of wine, the proportion of the sines of the angles of incidence to the sines of the angles of refraction was nearly the same as 4 to 3; and that, as spirit of wine occasions a greater refraction than common water, so oil of turpentine, which is lighter than spirit of wine, produces not only a greater refraction than common water, but a much greater than salt water. And at a meeting held November 9. the same year, Dr Hooke mentioned, that pure and clear salad oil produced a much greater refraction than any liquor which he had tried; the angle of refraction that answered to an angle of incidence of 30° being no less than 40° 30′, and the angle of refraction that answered to an angle of incidence of 20° being 29° 47′.—M. de la Hire also made several experiments to ascertain the refractive power of oil, and found the sine of the angle of incidence to that of refraction as 60 to 42; which, he observes, is a little nearer to that of glass than to that of water, though oil is much lighter than water, and glass much heavier.

13 Discoveries concerning the refraction of different substances.

The members of the Royal Society finding that the refraction of salt water exceeded that of fresh, pursued the experiment farther with aqueous solutions of vitriol, saltpetre, and alum. They found the refraction of the solution of vitriol and saltpetre a little more, but that of alum a little less, than common water.

Dr Hooke made an experiment before the Royal Society, Feb. 11. 1663, which clearly proves that ice refracts the light less than water. M. de la Hire also took a good deal of pains to determine whether the refractive power of ice and water were the same; and he found, as Dr Hooke had done before, that ice refracts less than water.

By a most accurate experiment made in 1698, in which a ray of light was transmitted through a Torricellian vacuum, Mr Lowthorp found, that the refractive power of air is to that of water as 36 to 34.400. He observes, that the refractive power of bodies is not proportioned to the density, at least not to the specific gravity, of the refracting medium. For the refractive power of glass to that of water is as 55 to 34, whereas its specific gravity is as 87 to 34; that is, the squares of their refractive powers are very nearly as their respective gravities. And there are some fluids, which, though they are lighter than water, yet have a greater power of refraction. Thus the refractive power of spirit of wine, according to Dr Hooke's experiment, is to that of water as 36 to 33, and its gravity reciprocally as 33 to 36, or $36\frac{1}{7}$. But the refractive powers of air and water seem to observe the simple direct proportion of their gravities.

The Royal Academy of Sciences at Paris endeavoured to repeat this experiment in 1700; but they did not succeed.—For, as they said, beams of light passed through the vacuum without suffering any refraction. The Royal Society being informed of this, ordered Mr Hawksbee to make an instrument for the purpose, under the direction of Dr Halley, for the purpose of repeating the experiment. It consisted of a strong brass prism, two sides of which had sockets to receive two plane glasses,

History.

glasses, whereby the air in the prism might either be exhausted or condensed. The prism had also a mercurial gage fixed to it, to discover the density of the contained air; and turned upon its axis, in order to make the refractions equal on each side when it was fixed to the end of a telescope. The refracting angle was near 64°; and the length of the telescope, having a fine hair in its focus, was about 10 feet. The event of this accurate experiment was as follows:—Having chosen a proper object, whose distance was 2588 feet, June 15. O. S. 1708, in the morning, the barometer being then at $29.7\frac{1}{7}$, and the thermometer at 60, they first exhausted the prism, and then applying it to the telescope, the horizontal hair in the focus covered a mark on the object distinctly seen through the vacuum, the two glasses being equally inclined to the visual ray. Then admitting the air into the prism, the object was seen to rise above the hair gradually as the air entered, and when the prism was full, the hair was observed to hide a mark $10\frac{1}{4}$ inches below the former mark.

After this they applied the condensing engine to the prism; and having forced in another atmosphere, so that the density of the included air was double to that of the outward, they again placed it before the telescope, and, letting out the air, the object, which before seemed to rise, appeared gradually to descend, and the hair at length rested on an object higher than before by the same interval of $10\frac{1}{4}$ inches They then forced in another atmosphere; and upon discharging the condensed air, the object was seen near 21 inches lower than before.

Now the radius in this case being 2588 feet, $10\frac{1}{4}$ inches will subtend an angle of 1′ 8″, and the angle of incidence of the visual ray being 32 degrees (because the angle of the glass planes was 64°), it follows from the known laws of refraction, that as the sine of 39° is to that of 31° 59′ 26″, differing from 32° by 34″ the half of 1′ 8″; so is the sine of any other angle of incidence, to the sine of its angle of refraction; and so is radius, or 1000000, to 999736; which, therefore, is the proportion between the sine of incidence *in vacuo* and the sine of refraction from thence into common air.

14
Refractive power of the air determined.

It appears, by these experiments, that the refractive power of the air is proportional to its density. And since the density of the atmosphere is as its weight directly, and its temperature inversely, the ratio of its density, at any given time, may be had by comparing the heights of the barometer and thermometer; and thence he concludes that this will also be the ratio of the refraction of the air. But Dr Smith observes, that before we can depend upon the accuracy of this conclusion, we ought to examine whether heat and cold alone may not alter the refractive power of air, while its density continues the same.

The French academicians, being informed of the result of the above-mentioned experiment, employed M. De l'Isle the younger to repeat the former experiment with more care: He presently found, that the operators had never made any vacuum at all, there being chinks in their instrument, through which the air had insinuated itself. He therefore annexed a gage to his instrument, by which means he was sure of his vacuum; and then the result of the experiment was the same with that of the Royal Society. The refraction was always proportional to the density of the air, excepting when the mercury was very low, and consequently the air very rare; in which case the whole quantity being very small, he could not perceive much difference in them. Comparing, however, the refractive power of the atmosphere, observed at Paris, with the result of his experiment, he found, that the best vacuum he could make was far short of that of the regions above the atmosphere.

Dr Hooke first suggested the idea of making allowance for the effect of the refraction of light, in passing from the rarer to the denser regions of the atmosphere, in the computed height of mountains. To this he ascribes the different opinions of authors concerning the height of several very high hills. He could not account for the appearance of very high mountains, at so great a distance as that at which they are actually seen, but upon the supposition of the curvature of the visual ray, that is made by its passing obliquely through a medium of such different density, from the top of them to the eye, very far distant in the horizon. All calculations of the height of mountains that are made upon the supposition that the rays of light come from the tops of them, to our eyes, in straight lines, he considers very erroneous.

Dr Hooke ascribes the twinkling of the stars to the irregular and unequal refraction of the rays of light, which is also the reason why the limbs of the sun, moon, and planets, appear to wave or dance. That there is such an unequal distribution of the atmosphere, he says, will be evident by looking upon distant objects, over a piece of hot glass, which cannot be supposed to throw out any kind of exhalation from itself, as well as through ascending steams of water.

About this time Grimaldi first observed that the coloured image of the sun refracted through a prism is always oblong, and that colours proceed from refraction. —The way in which he first discovered this was by Vitellio's experiment already mentioned, in which a piece of white paper placed at the bottom of a glass vessel filled with water, and exposed to the light of the sun, appears coloured. However, he observed, that in case the two surfaces of the refracted medium were exactly parallel to each other, no colours were produced. But of the true cause of those colours, he had not the least suspicion. This discovery was reserved for Sir Isaac Newton. Having procured a triangular glass prism to satisfy himself concerning the phenomena of colours; he was surprised at the oblong figure of the coloured spectrum, and the great disproportion betwixt its length and breadth; the former being about five times the measure of the latter. After various conjectures respecting the causes of these appearances, he suspected that the colours might arise from the light being dilated by some unevenness in the glass, or some other accidental irregularity; and to try this, he took another prism like the former, and placed in such a manner, that the light, passing through them both, might be refracted in opposite directions, and thus be returned by the latter into the same course from which it had been diverted by the former. In this manner he thought that the regular effects of the first prism would be augmented by the multiplicity of refractions. The event was, that the light, diffused by the first prism into an oblong form, was by by the second reduced into a circular one, with as much regularity as if it had not passed through either of them. He then hit upon what he calls the *experimentum crucis*, and found that light is not similar, or homogeneous; but that it consists of rays, some of which are more refrangible than others: so that, without any difference in their incidence on the same medium, some of them shall be more refracted than others; and therefore, that, according to their particular degrees of refrangibility, they will be transmitted through the prism to different parts of the opposite wall.

Since it appears from these experiments that different rays of light have different degrees of refrangibility, it follows, that the rules laid down by preceding philosophers concerning the refractive power of water, glass, &c. must be limited to the mean rays of the spectrum. Sir Isaac, however, proves, both geometrically and by experiment, that the sine of the incidence of every kind of light, considered apart, is to its sine of refraction in a given ratio.

17 Mr Dollond's discovery of the method of correcting the errors of refracting telescopes.

The most important discovery concerning refraction since the time of Sir Isaac Newton is that of Mr Dollond, who found out a method of remedying the defects of refracting telescopes arising from the different refrangibility of light. Sir Isaac Newton imagined that the different rays were refracted in the same proportion by every medium, so that the refrangibility of the extreme rays might be determined if that of the mean ones were given. From this it followed, as Mr Dollond observes, that equal and contrary refractions must not only destroy each other, but that the divergency of the colours from one refraction would likewise be corrected by the other, and that there could be no possibility of producing any such thing as refraction without colour. Hence it was natural to infer, that all object glasses of telescopes must be equally affected by the different refrangibility of light, in proportion to their apertures, of whatever materials they may be formed.

For this reason, philosophers despaired of bringing refracting telescopes to perfection. They therefore applied themselves chiefly to the improvement of the reflecting telescope; till 1747, when M. Euler, improving upon a hint of Sir Isaac Newton's, proposed to make object glasses of water and glass; hoping, that by their difference of refractive powers, the refractions would balance one another, and thereby prevent the dispersion of the rays that is occasioned by their difference of refrangibility. This memoir of M. Euler excited the attention of Mr Dollond. He went over all M. Euler's calculations, substituting for his hypothetical laws of refraction those which had been ascertained by Newton; and found, that it followed from Euler's own principles, that there could be no union of the foci of all kinds of colours, but in a lens infinitely large.

Euler did not mean to controvert the experiments of Newton: but asserted, that, if they were admitted in all their extent, it would be impossible to correct the difference of refrangibility occasioned by the transmission of the rays from one medium into another of different density; a correction which he thought was very possible, since he supposed it to be effected in the eye, which he considered as an achromatic instrument. To this reasoning Mr Dollond made no reply, but by appealing to the experiments of Newton, and the circumspection with which it was known that he conducted all his inquiries.

This paper of Euler's was particularly noticed by M. Klingenstierna of Sweden, who found that, from Newton's own principles, the result of his 8th experiment could not answer his description of it. Newton found, that when light passes out of air through several media, and thence goes out again into air, whether the refracting surfaces be parallel or inclined to one another, this light, as often as by contrary refractions it is so corrected as to emerge in lines parallel to those in which it was incident, continues ever after to be white; but if the emergent rays be inclined to the incident, the whiteness of the emerging light will, by degrees, become tinged at its edges with colours. This he tried by refracting light with prisms of glass, placed within a prismatic vessel of water.

By theorems deduced from this experiment he infers, that the refractions of the rays of *every* sort, made out of any medium into air, are known by having the refraction of the rays of *any one* sort; and also that the refraction out of one medium into another is found as often as we have the refractions out of them both into any third medium.

On the contrary, the Swedish philosopher observes, that, in this experiment, the rays of light, after passing through the water and the glass, though they come out parallel to the incident rays, will be coloured; but that the smaller the glass prism is, the nearer will the result of it approach to Newton's description.

This paper of M. Klingenstierna being communicated to Dollond, made him entertain doubts concerning Newton's report, and induced him to have recourse to experiment.

He therefore cemented together two plates of glass at their edges, so as to form a prismatic vessel, when stopped at the ends; and the edge being turned downwards, he placed in it a glass prism, with one of its edges upwards, and filled up the vacancy with clear water; so that the refraction of the prism was contrary to that of the water, in order that a ray of light, transmitted through both these refracting media, might be affected by the difference only between the two refractions. As he found the water to refract more or less than the glass prism, he diminished or increased the angle between the glass plates, till he found the two contrary refractions to be equal; which he discovered by viewing an object through this double prism. For when it appeared neither raised or depressed, he was satisfied that the refractions were equal, and that the emergent and incident rays were parallel.

But according to the prevailing opinion, the object should have appeared of its natural colour; for if the difference of refrangibility had been equal in the two equal refractions, they would have rectified each other. This experiment, therefore, fully proved the fallacy of the received opinion, by showing the divergency of the light by the glass prism to be almost double of that by the water; for the image of the object was as much infected with the prismatic colours, as if it had been seen through a glass wedge only, whose refracting angle was near 30 degrees.

Mr Dollond was convinced that if the refracting angle of the water vessel could have admitted of a sufficient increase, the divergency of the coloured rays would have been greatly diminished, or entirely rectified; and that there would have been a very great refraction without

out colour; but the inconvenience of so large an angle as that of the prismatic vessel must have been, to bring the light to an equal divergency with that of the glass prism whose angle was about 60 degrees, made it necessary to try some experiments of the same kind with smaller angles.

He, therefore, got a wedge of plate glass, the angle of which was only nine degrees; and using it in the same circumstances, he increased the angle of the water wedge, in which it was placed, till the divergency of the light by the water was equal to that by the glass; that is, till the image of the object, though considerably refracted by the excess of the refraction of the water, appeared quite free from any colours proceeding from the different refrangibility of the light; and as near as he could then measure, the refraction by the water was about $\frac{1}{4}$ of that by the glass.

As these experiments proved, that different substances caused the light to diverge very differently in proportion to their general refractive power, Mr Dollond began to suspect that such a variety might possibly be found in different kinds of glass.

His next object, therefore, was to grind wedges of different kinds of glass, and apply them together; so that the refractions might be made in contrary directions, in order to discover whether the refraction and the divergency of the colours would vanish together.

From these experiments, which were not made till 1757, he discovered a difference far beyond his hopes in the refractive qualities of different kinds of glass, with respect to the divergency of colours. The yellow or straw coloured kind, commonly called *Venice glass*, and the *English crown glass*, proved to be nearly alike in that respect; though, in general, the crown glass seemed to make light diverge less than the other. The common English plate glass made the light diverge more; and the white crystal, or English flint glass, most of all.

He then examined the particular qualities of every kind of glass that he could obtain, to fix upon two kinds in which the difference of their dispersive powers should be the greatest; and he soon found these to be the crown glass and the white flint glass. He therefore ground one wedge of white flint, of about 25 degrees; and another of crown glass, of about 29 degrees; which refracted very nearly alike, but their power of making the colours diverge was very different. He then ground several others of crown glass to different angles, till he got one which was equal, with respect to the divergency of the light, to that in the white flint glass; for when they were put together so as to refract in contrary directions, the refracted light was entirely free from colours. Then measuring the refraction of each wedge with these different angles, he found that of the white glass to be to that of the crown glass nearly as two to three: so that any two wedges made in this proportion, and applied together, that they might refract in a contrary direction, would transmit the light without any dispersion of the rays. He found also, that the sine of incidence in crown glass is to that of its general refraction as 1 to 1.53, and in flint glass as 1 to 1.583.

In order to apply these discoveries to the construction of telescopes, Mr Dollond considered, that in order to make two spherical glasses that should refract the light in contrary directions, the one must be concave and the other convex; and as the rays are to converge to a real focus, the excess of refraction must be in the convex lens. Also, as the convex glass is to refract the most, it appeared from his experiments, that it must be made of crown glass, and the concave of white flint glass. Farther, As the refractions of spherical glasses are in the inverse ratio of their focal distances, it follows, that the focal distances of the two glasses shall be inversely as the ratios of the refractions of the wedges; for being thus proportioned, every ray of light that passes through this combined glass, at whatever distance it may pass from its axis, will constantly be refracted, by the difference between two contrary refractions, in the proportion required; and therefore the different refrangibility of the light will be entirely removed.

The difficulties which occurred in the application of this reasoning to practice, arose from the following circumstances. In the first place, The focal distances, as well as the particular surfaces, must be very nicely proportioned to the densities or refracting powers of the glasses, which are very apt to vary in the same sort of glass made at different times. Secondly, The centres of the two glasses must be placed truly in the common axis of the telescope, otherwise the desired effect will be in a great measure destroyed. And, thirdly, The difficulty of forming the four surfaces of the lenses exactly spherical. At length, however, after numerous trials, he was able to construct refracting telescopes, with such apertures and magnifying powers, under limited lengths, as far exceeded any thing that had been produced before, representing objects with great distinctness, and in their natural colours.

As Mr Dollond did not explain the method by which he determined the curvatures of his lenses, the celebrated M. Clairaut, who had begun to investigate this subject, endeavoured to reduce it to a complete theory, from which rules might be deduced, for the benefit of the practical optician.

With this view, therefore, he endeavoured to ascertain the refractive power of different kinds of glass, and also their property of dispersing the rays of light. For this purpose he made use of two prisms, as Mr Dollond had done: but, instead of looking through them, he placed them in a dark room; and when the transmitted image of the sun was perfectly white, he concluded that the different refrangibility of the rays was corrected.

In order to ascertain more easily the true angles that prisms ought to have in order to destroy the effect of the difference of refrangibility, he constructed a prism which had one of its surfaces cylindrical, with several degrees of amplitude. By this means, without changing his prisms, he had the choice of an infinity of angles; among which, by examining the point of the curve surface, which, receiving the solar ray, gave a white image, he could easily find the true one. He also ascertained the proportion in which different kinds of glass separated the rays of light, by measuring, with proper precautions, the oblong image of the sun made by transmitting through them a beam of light.

In these experiments M. Clairaut was assisted by M. de Tournieres, and the results agreed with Mr Dollond's in general; but whereas Mr Dollond had made the dispersion of the rays in glass and in water to be as five

five to four (acknowledging, however, that he did not pretend to do it with exactness), these gentlemen, who took more pains, found it to be as three to two. For the theorems and problems deduced by M. Clairaut from these new principles of optics, with a view to the perfection of telescopes, we must refer the reader to *Mem. Acad. Par.* 1756, 1757.

The subject of achromatic telescopes was also investigated by the illustrious D'Alembert. This excellent mathematician proposed a variety of new constructions, the advantages and disadvantages of which he distinctly notes; at the same time that he points out several methods of correcting the errors to which these telescopes are liable: as by placing the object glasses, in some cases, at a small distance from one another, and sometimes by using eye glasses of different refractive powers; which is an expedient that does not seem to have occurred to any person before him. He even shows, that telescopes may be made to advantage, consisting of only one object glass, and an eye glass of a different refractive power. Some of his constructions have two or more eye glasses of different kinds of glass. This subject he considered at large in one of the volumes of his *Opuscules Mathematiques*. We have also three memoirs of M. D'Alembert upon this subject, among those of the French Academy; in the years 1764, 1765, and 1767.

The investigations of Clairaut and D'Alembert do not seem to have assisted the exertions of foreign artists. The telescopes made in England, according to no exact rule, as foreigners supposed, were greatly superior to any that could be made elsewhere, though under the immediate direction of those able calculators.

M. Euler who first gave occasion to this inquiry, having persuaded himself, both by reasoning and calculation, that Mr Dollond had discovered no new principle in optics, and yet not being able to controvert Mr Short's testimony in favour of the achromatic telescopes, concluded that this extraordinary effect was partly owing to the crown glass not transmitting all the red light, which would have otherwise come to a different focus, and have distorted the image; but principally to his giving a just curvature to his glass, which he did not doubt would have produced the same effect if the lenses had all been made of the same kind of glass. At another time he imagined that the goodness of Mr Dollond's telescopes might be owing to the eye glass. If my theory, says he, be true, this disagreeable consequence follows, that Mr Dollond's object glasses cannot be exempt from the dispersion of colours: yet a regard to so respectable a testimony embarrasses me extremely, it being as difficult to question such express authority, as to abandon a theory which appears to me well founded, and to embrace an opinion which is as contrary to all the established laws of nature as it is strange and seemingly absurd. He even appeals to experiments made in a darkened room; in which he says, he is confident that Mr Dollond's object-glasses would appear to have the same defects to which others are subject.

Not doubting, however, but that Mr Dollond had made some improvement in the construction of telescopes, by the combination of glasses, he abandoned his former project, in which he had recourse to different media, and confined his attention to the correction of the errors which arise from the curvature of lenses. But while he was proceeding, as he imagined, upon the true principles of optics, he could not help expressing his surprise that Mr Dollond should have been led to so important a discovery by reasoning in a manner quite contrary to the nature of things. At length, however, M. Euler was convinced of the reality and importance of Mr Dollond's discoveries; and frankly acknowledges, that perhaps he should never have been brought to assent to it, had he not been assured by his friend M. Clairaut that the experiments of the English optician might be depended upon. The experiments of M. Zeiher, however, gave him the most complete satisfaction with respect to this subject. This gentleman demonstrated, that it is the lead in the composition of glass which produces the variation in its dispersive power; and, by increasing the quantity of lead in the mixture, he produced a kind of glass, which occasioned a much greater separation of the extreme rays than the flint glass which Mr Dollond had made use of.

From these new principles M. Euler deduces theorems concerning the combination of the lenses, and, in a manner similar to M. Clairaut and D'Alembert, points out methods of constructing achromatic telescopes. 18

Different compositions of glass for the purpose of correcting the imperfection of telescopes.

While he was employed upon this subject, he informs us, that he received a letter from M. Zeiher, dated Petersburgh, 30th of January 1764, in which he gives him a particular account of the success of his experiments on the composition of glass; and that, having mixed minium and sand in different proportions, the result of the mean refraction and the dispersion of the rays varied according to the following table.

	Proportion of minium to flint.	Ratio of the mean refraction from air into glass.	Dispersion of the rays in comparison of crown glass.
I.	— 3 : 1	2028 : 1000	4800 : 1000
II.	— 2 : 1	1830 : 1000	3550 : 1000
III.	— 1 : 1	1787 : 1000	3259 : 1000
IV.	— $\frac{3}{4}$: 1	1732 : 1000	2207 : 1000
V.	— $\frac{1}{2}$: 1	1724 : 1000	1800 : 1000
VI.	— $\frac{1}{4}$: 1	1664 : 1000	1354 : 1000

From this table it is evident, that a greater quantity of lead not only produces a greater dispersion of the rays, but also increases the mean refraction. The first of these kinds of glass, which contains three times as much minium as flint, will appear very extraordinary; since, hitherto, no transparent substance has been known, whose refractive power exceeded the ratio of two to one, and since the dispersion occasioned by this glass is almost five times as great as that of crown glass, which could scarcely be believed by those who entertained any doubt concerning the same property in flint glass, the effect of which is three times as great as crown glass.

Here, however, M. Euler announces to us another discovery of M. Zeiher, no less surprising than the former, and which disconcerted all his schemes for reconciling the above-mentioned phenomena. As the six kinds of glass mentioned in the preceding table were composed of nothing but minium and flint, M. Zeiher happened to think of mixing alkaline salts with them, in order to give the glass a consistence more proper for dioptric uses: This mixture, however, greatly diminished the mean refraction, almost without making any change in the dispersion. After many trials, he is said to have obtained a kind of glass, which occasioned three times as great a dispersion of the rays as the common glass, at the same time that the mean refraction was only as 1.61 to 1.; though we have not heard that this kind of glass was ever used in the construction of telescopes.

Mr Dollond was not the only optician who had the merit of discovering the achromatic telescope, as this instrument appears to have been constructed by a private gentleman—Mr Chester More Hall. He observed that prisms of flint glass gave larger spectra than prisms of water, when the mean refraction was the same in both. He tried prisms of other glass, and found similar differences; and he applied this discovery to the same purposes as Mr Dollond. These facts came out in a process raised at the instance of Watkins optician, as also in a publication of Mr Ramsden. There is, however, no evidence that Dollond stole the idea from Mr Hall, or that they had not both claims to the discovery.

The best refracting telescopes, constructed on the principles of Mr Dollond, are still defective, on account of that colour which, by the aberration of the rays, they give to objects viewed through them, unless the object glass be of small diameter. This defect philosophers have endeavoured to remove by various contrivances, and Boscovich has, in his attempts for this purpose, displayed much ingenuity; but the philosopher whose exertions have been crowned with most success, and who has perhaps made the most important discovery in this science, is Dr Robert Blair professor of practical astronomy in the college of Edinburgh.

19 Discovery of Dr Robert Blair for this purpose.

By a judicious set of experiments, he has proved, that the quality of dispersing the rays in a greater degree than crown glass, is not confined to a few media, but is possessed by a great variety of fluids, and by some of these in a most extraordinary degree. He has shown, that though the greater refrangibility of the violet rays than of the red rays, when light passes from any medium whatever into a vacuum, may be considered as a law of nature; yet in the passage of light from one medium into another, it depends entirely on the qualities of the media which of these rays shall be the most refrangible, or whether there shall be any difference in their refrangibility. In order to correct the aberration arising from difference of refrangibility among the rays of light, he instituted a set of experiments, by which he detected a very singular and important quality in the muriatic acid. In all the dispersive media hitherto examined, the green rays, which are the mean refrangible in crown glass, were found among the less refrangible; but in the muriatic acid, these same rays were found to make a part of the more refrangible. This discovery led to complete success in removing the great defect of optical instruments, viz. that dissipation or aberration of the rays which arises from their unequal refrangibility, and has hitherto rendered it impossible to converge all of them to one point either by single or opposite refractions. A fluid, in which the particles of marine acid and metalline particles hold a due proportion, at the same time that it separates the extreme rays of the spectrum much more than crown glass, refracts all the orders of the rays in the same proportion that glass does: and hence rays of all colours, made to diverge by the refraction of the glass, may either be rendered parallel by a subsequent refraction in the confine of the glass and this fluid; or, by weakening the refractive density of the fluid, the refraction which takes place in the confine of it and glass may be rendered as regular as reflection, without the least colour whatever. The doctor has a telescope, not exceeding 15 inches in length, with a compound object glass of this kind, which equals in all respects, if it does not surpass, the best of Dollond's 42 inches long. See Phil. Trans. Edin. vol. iii.

20 Of the refraction of the atmosphere.

We shall conclude the history of the discoveries concerning refraction, with some account of the refraction of the atmosphere.—Tables of refraction have been calculated by Mr Lambert, with a view to correct inaccuracies in determining the altitudes of mountains geometrically. The observations of Mr Lambert go upon the supposition that the refractive power of the atmosphere is invariable: But as this is by no means the case, his rules must be considered as true only for the mean state of the air.

Dr Nettleton observed a remarkable variety in the refractive power of the atmosphere, which demonstrates how little we can depend upon the calculated heights of mountains, when the observations are made with an instrument, and when the refractive power of the air is to be taken into the account. Being desirous to learn, by observation, how far the mercury would descend in the barometer at any given elevation, he proposed to measure the height of some of their highest hills; but when he attempted it, he found his observation so much disturbed by refraction, that he could obtain no certain result. Having measured one hill of a considerable height, in a clear day, and observed the mercury at the bottom and at the top, he found, that about 19 feet or more were required to make the mercury fall $\frac{1}{10}$th of an inch; but afterwards, repeating the experiment, when the air was rather gross and hazy, he found the small angles so much increased by refraction as to make the hill much higher than before. He afterwards frequently made observations at his own house, by pointing a quadrant to the tops of some neighbouring hills, and observed that they would appear higher in the morning before sunrise, and also late in the evening, than at noon in a clear day, by several minutes. In one case the elevations of the same hill differed more than 30 minutes.

M. Euler considered the refractive power of the atmosphere, as affected by different degrees of heat and elasticity; in which he shows that its refractive power, to a considerable distance from the zenith, is sufficiently near the proportion of the tangent of that distance, and that the law of refraction follows the direct ratio of the difference marked by the thermometer; but when stars are in the horizon, the changes are in a ratio somewhat greater than this, more especially on account of the variation in the heat.

21 La Place resolves the problem of astronomical refraction.

As the density of the atmosphere varies with its altitude, and as the irregular curvature of the earth causes a constant change in the inclination of the strata through which any ray of light passes to the eye, the refraction cannot be obtained from the density of the atmosphere, and the angular direction of the refracted ray. By comparing astronomical with meteorological observations, however, the celebrated M. La Place has given

History.

given a complete solution of this very important problem.

22 Phenomena of irregular refractions.

The phenomena known by the names of *mirage*, *looming*, and *fata morgana*, have been traced to irregularities of refractions arising from accidental changes in the temperature of the atmosphere. From the rarefaction of the air near the surface of water, buildings, or the earth itself, a distant object seen through this rarefied air sometimes appears depressed instead of raised by refraction; at other times it appears both elevated and depressed, so that the object seems double, and sometimes triple, one of the images being in an inverted position. This subject is much indebted to the researches of the ingenious Dr Wollaston, who has imitated these natural phenomena by viewing objects through the rarefied air contiguous to a red-hot poker, or through a saline or saccharine solution with water and spirit of wine floating upon its surface. This branch of optics has also been well illustrated by Mr Vince and Mr Huddart.

SECT. II. *Discoveries concerning the Reflection of Light.*

23 Discoveries of the ancients.

The followers of Plato were acquainted with the equality between the angles of incidence and reflection; and it is probable that they discovered this, by observing a ray of the sun reflected from standing water, or some other polished body; or from attending to the images of objects reflected by such surfaces. If philosophers paid any attention to this phenomenon, they could not but perceive, that, if the ray fell nearly perpendicular upon such a surface, it was reflected near the perpendicular; and if it fell obliquely, it was reflected obliquely: and observations upon these angles, the most rude and imperfect, could not fail to convince them of their equality, and that the incident and reflected rays were in the same plane.

Aristotle was sensible that it is the reflection of light from the atmosphere which prevents total darkness after the sun sets, and in places where he does not shine in the day-time. He was also of opinion, that rainbows, halos, and mock suns, were occasioned by the reflection of the sunbeams in different circumstances, by which an imperfect image of his body was produced, the colour only being exhibited, and not his proper figure. The image, he says, is not single, as in a mirror; for each drop of rain is too small to reflect a visible image, but the conjunction of all the images is visible.

24 Treatise of optics by Euclid.

Without inquiring any farther into the nature of light or vision, the ancient geometers contented themselves with deducing a system of optics from two facts, the rectilineal progress of light, and the equality of the angles of incidence and reflection. The treatise of optics ascribed to Euclid is employed in determining the apparent size and figure of objects, from the angle which they subtend at the eye, and the apparent place of the image of an object reflected from a polished miror. This place he fixes at the point where the reflected ray meets a perpendicular to the mirror drawn through the object. But this work is so imperfect and inaccurate, that it does not seem to be the production of Euclid.

25 Burning glasses of the ancients.

It appears from Pliny and Lactantius, that burning glasses were known to the ancients. In one of the plays of Aristophanes, indeed, a person is introduced who proposes to destroy his adversary's papers by means of this instrument; and there is reason to believe that the Romans had a method of lighting their sacred fire by means of a concave speculum. It seems indeed to have been known A. C. 433, that there is an increase of heat in the place where the rays of light meet, after reflection from a concave mirror. The burning power of concave mirrors is noticed by the author of the work ascribed to Euclid. If we give any credit to what some ancient historians are said to have written concerning the exploits of Archimedes, we shall be induced to think that he constructed some very powerful burning mirrors; but nothing being said of other persons making use of his inventions, the whole account is very doubtful. It is allowed, however, that this eminent geometer did write a treatise on the subject of burning mirrors, which has not descended to our times.

B. Porta supposes that the burning mirrors of the ancients were parabolic and made of metal. It follows from the properties of this curve, that all the rays which fall upon it, parallel to its axis, will meet in the same point at the focus. Consequently, if the vertex of the parabola be cut off, as in fig. 1. it will make a convenient burning mirror. In some drawings of this instrument the frustum is so small, as to look like a ring. With an instrument of this kind, it is thought, that the Romans lighted their sacred fire, and that with a similar mirror Archimedes burnt the Roman fleet; using a lens, to throw the rays parallel, when they had been brought to a focus; or applying a smaller parabolic mirror for this purpose, as is represented fig. 2.

Plate CCCLXXV. Fig. 1.

Fig. 2.

26 Of seeing images in the air.

The nature of reflection was, however, very far from being understood. Even Lord Bacon, who made much greater advances in physics than his predecessors, supposed it possible to see the image reflected from a looking glass, without seeing the glass itself; and to this purpose he quotes a story of Friar Bacon, who is reported to have apparently walked in the air between two steeples, and which was thought to have been effected by reflection from glasses while he walked upon the ground.

Vitellio had endeavoured to show that it is possible, by means of a cylindrical convex speculum, to see the images of objects in the air, out of the speculum, when the objects themselves cannot be seen. But from his description of the apparatus, it will be seen that the eye was to be directed towards the speculum placed within a room, while the object and the spectator were without it. But as no such effect can be produced by a convex mirror, Vitellio must have been under some deception with respect to his experiment.

B. Porta says, that this effect may be produced by a plain mirror only; and also by the combination of a plain and a concave mirror.

Kircher also speaks of the possibility of exhibiting these pendulous images, and supposes that they are reflected from the dense air: But the most perfect and pleasing deception, depending upon the images in the air, is one of which this writer gives a particular account in his *Ars Magna Lucis et Umbræ*, p. 783. In this case the image is placed at the bottom of a hollow polished cylinder, by which means it appears like a real solid substance, suspended within the mouth of the vessel.

27 Discoveries of Kepler.

It was Kepler who first discovered, that the apparent places of objects seen by reflecting mirrors depended upon

History.

upon the angle which the rays of light, issuing from the extreme part of an object, make with one another after reflection.

28 Discoveries of Mr Boyle.

Mr Boyle made some curious observations concerning the reflecting powers of differently coloured substances. In order to shew that snow shines by a *borrowed* and not by a *native* light, he placed a quantity of it in a room, from which all foreign light was excluded, and found that it was completely invisible. To try whether white bodies reflect more light than others, he held a sheet of white paper in a sunbeam admitted into a darkened room; and observed that it reflected much more light than a paper of any other colour, a considerable part of the room being enlightened by it. To show that white bodies reflect the rays outwards, he adds, that common burning glasses require a long time to burn or discolour white paper; that the image of the sun was not so well defined upon white paper as upon black; that when he put ink upon the paper, the moisture would be quickly dried up, and the paper, which he could not burn before, would presently take fire;—and that by exposing his hand to the sun, with a thin black glove upon it, it would be suddenly and more considerably heated, than if he held his naked hand to the rays, or put on a glove of thin white leather.

To prove that black is the reverse of white, with respect to its property of reflecting the rays of the sun, he procured a large piece of black marble, ground into the form of a large concave speculum, and found that the image of the sun reflected from it was far from offending or dazzling his eyes, as it would have done from another speculum; and though this was large, he could not for a long time set a piece of wood on fire with it; though a far less speculum, of the same form, and of a more reflecting substance, would presently have made it flame.

To satisfy himself still farther with respect to this subject, he took a tile; and having made one half of its surface white and the other black, he exposed it to the summer sun. Having let it lie there some time, he found, that while the whitened part remained cool, the black part was very hot. He sometimes left part of the tile of its native red; and, after exposing the whole to the sun, observed that this part grew hotter than the white, but not so hot as the black part.

29 Of the infusion of lignum nephriticum.

A remarkable property of lignum nephriticum (a species of guilandina) was first observed by Kircher. Mr Boyle has described this lignum nephriticum as a whitish kind of wood, which was brought from Mexico, and which had been thought to tinge water of a green colour only; but he says that he found it to communicate all kinds of colours. If an infusion of this wood be put into a glass globe, and exposed to a strong light, it will be as colourless as pure water; but if it be carried into a place a little shaded, it will be a beautiful green. In a place still more shaded, it will incline to red; and in a very shady place, or in an opaque vessel, it will be green again.

Mr Boyle first distinctly noted the two very different colours which this remarkable tincture exhibits by transmitted and reflected light. If it be held directly between the light and the eye, it will appear tinged (excepting the very top of it, where a sky-coloured circle sometimes appears) almost of a golden colour, except the infusion be too strong; in which case it will be dark or reddish, and requires to be diluted with water. But if it be held from the light, so that the eye be between the light and the phial, it will appear of a deep lively blue colour, as will also the drops, if any lie on the outside of the glass.

When a little of this tincture was poured upon a sheet of white paper, and placed in a window where the sun shone upon it, he observed, that if he turned his back upon the sun, the shadow of any body projected upon the liquor would not be all dark, like other shadows; but that part of it would be curiously coloured, the edge of it next the body being almost of a lively golden colour, and the more remote part blue.

Observing that this tincture, if it were too deep, was not tinged in so beautiful a manner, and that the impregnating virtue of the wood did, by frequent infusion in fresh water, gradually decay, he conjectured that the tincture contained much of the essential salt of the wood; and to try whether the subtle parts, on which the colour depended, were volatile enough to be distilled, without dissolving their texture, he applied some of it to the gentle heat of a lamp furnace; but he found all that came over was as limpid and colourless as rock water, while that which remained behind was of so deep a blue, that it was only in a very strong light that it appeared of any colour.

Having sometimes brought a round long-necked phial, filled with this tincture, into a darkened room, into which a beam of the sun was admitted by a small aperture; and holding the phial sometimes near the sunbeams, and sometimes partly in them and partly out of them, changing also the position of the glass, and viewing it from several parts of the room, it exhibited a much greater variety of colours than it did in an enlightened room. Besides the usual colours, it was red in some places and green in others, and within were intermediate colours produced by the different mixtures of light and shade.

It was not only in this tincture of lignum nephriticum that Mr Boyle perceived the difference between reflected and transmitted light. He observed it even in gold, though no person explained the cause of these appearances before Sir Isaac Newton. He took a piece of leaf gold, and holding it betwixt his eye and the light, observed, that it did not appear of a golden colour, but of a greenish blue. He also observed the same change of colour by candle light; but the experiment did not succeed with a leaf of silver.

The constitution of the atmosphere and of the sea, we shall find, by more recent observations, to be similar to that of this infusion; for the blue rays, and others of a faint colour, do not penetrate so far into them as the red, and others of a stronger colour.

The first distinct account of the colours exhibited by thin plates of various substances is to be found among the observations of Mr Boyle. To show that colours may be made to appear or vanish, where there is no accession or change either of the sulphureous, the saline, or the mercurial principle of bodies, he observes, that all chemical essential oils, as also good spirit of wine, being shaken till they rise in bubbles, appear of various colours; which immediately vanish when the bubbles burst, so that a colourless liquor may be immediately made to exhibit a variety of colours, and lose them in a moment,

History.

moment, without any change in its essential principles. He then mentions the colours that appear in bubbles of soap and water, and also in those of turpentine. He sometimes got glass blown so thin as to exhibit similar colours; and observes, that a feather, and also a black ribbon, held at a proper distance, between his eye and the sun, showed a variety of little rainbows, with very vivid colours, none of which were constantly to be seen in the same objects.

31
Dr Hooke's account of these colours.

This subject was more carefully investigated by Dr Hooke, who promised, at a meeting of the society on the 7th of March 1672, to exhibit, at their next meeting, something which had neither reflection nor refraction, and yet was diaphanous. Accordingly he produced the famous coloured bubble of soap and water of which such use was afterwards made by Sir Isaac Newton, but which Dr Hooke and his contemporaries seem to have overlooked in Mr Boyle's treatise on colours, though it was published nine years before. It is no wonder that so curious an appearance excited the attention of that inquisitive body, and that they should desire him to bring an account of it in writing at their next meeting.

By the help of a small glass pipe, there were blown several small bubbles, out of a mixture of soap and water. At first, they appeared white and clear; but, after some time, the film of water growing thinner, there appeared upon it all the colours of the rainbow: First, a pale yellow; then orange, red, purple, blue, green, &c. with the same series of colours repeated; in which it was farther observable, that the first and last series were very faint, and that the middlemost series was very bright. After these colours had passed through the changes above mentioned, the film of the bubble began to appear white again; and presently, in several parts of this second white film, there were seen several holes, which by degrees grew very large, several of them running into one another.

Dr Hooke was the first who observed the beautiful colours that appear in thin plates of Muscovy glass. With a microscope he could perceive that these colours were ranged in rings surrounding the white specks or flaws in this thin substance, that the order of the colours was the very same as in the rainbow, and that they were often repeated ten times. But the colours were disposed as in the outer rainbow. Some of them also were much brighter than others, and some of them very much broader. He also observed, that if there was a part where the colours were very broad, and conspicuous to the naked eye, they might be made, by pressing the part with the finger, to change places, and move from one part to another. Lastly, He observed, that if great care be used, this substance may split into plates of one-eighth or one-sixth of an inch in diameter, each of which will appear through a microscope to be uniformly adorned with some one vivid colour, and that these plates will be found upon examination to be of the same thickness throughout.

A phenomenon similar to this was noticed by Lord Brereton, who at a meeting of the Royal Society in 1666, produced some pieces of glass taken out of a church window, both on the north and on the south side of it; they were all eaten in by the air, but the piece taken from the south side had some colours like those of the rainbow upon it, which the others on the north side had not. It cannot be doubted, but that in all these cases, the glass is divided into thin plates, which exhibit colours, upon the same principle with those which Dr Hooke observed in the bubble of soap and water, and in the thin plate of glass, which we shall find more fully explained by Sir Isaac Newton.

The inquiries of M. Bouguer concerning the reflection of light are worthy of particular notice. They are fully detailed in his *Traité d'Optique*, a posthumous work published by La Caille in 1760.

32
Discoveries of M. Bouguer.

In order to compare different degrees of light, he always contrived to place the radiant bodies or other bodies illuminated by them, in such a manner that he could view them distinctly at the same time; and he either varied the distances of these bodies, or modified their light in some other way, till he could perceive no difference between them. Then, considering their different distances, or the other circumstances by which their light was affected, he calculated the proportion which they would have borne to each other at the same distance, or in the same circumstances.

Plate CCCLXXV. fig. 3.

To ascertain the quantity of light lost by reflection, he placed the mirror, or reflecting surface, B, on which the experiment was to be made, truly upright; and having taken two tablets, of precisely the same colour, or of an equal degree of whiteness, he placed them exactly parallel to one another at E and D, and threw light upon them by means of a lamp or candle, P, placed in a right line between them. He then placed himself so, that with his eye at A he could see the tablet E, and the image of the tablet D, reflected from the mirror B, at the same time; making them as it were, to touch one another. He then moved the candle along the line ED, so as to throw more or less light upon either of them, till he could perceive no difference in the strength of the two lights that came to his eye. After this, he had nothing more to do than to measure the distances EP and DP, and then the intensity of the lights was as EP^2 to $\overline{DP}^2$.

Fig. 4.

To find how much light is lost by oblique reflection, he took two equally polished plates, D and E, and caused them to be enlightened by the candle P. While one of them, D, was seen at A, by reflection from B, placed in a position oblique to the eye, the other, E, was so placed, as to appear contiguous to it; and removing the plate E, till the light which it reflected was no stronger than that which came from the image D, seen by reflection at B, he estimated the quantity of light that was lost by this oblique reflection, by the squares of the distances of the two objects from the candle.

Fig. 5.

In order to ascertain the quantity of light lost by reflection with the greatest exactness, M. Bouguer introduced two beams of light into a darkened room, as by the apertures P and Q; which he had so contrived, that he could place them higher and lower, and enlarge or contract them at pleasure; and the reflecting surface (as that of a fluid contained in a vessel) was placed horizontally at O, from which the light coming through the hole P, was reflected to R upon the screen GH, where it was compared with another beam of light that fell upon S, through the hole Q; which he made so much less than P, as that the spaces S and R were equally illuminated; and by the proportion that the apertures P and Q bore to each other, he calculated what quantity of light was lost by the reflection at O.

It

It was necessary, he observes, that the two beams of light PO and QS (which he usually made 7 or 8 feet long) should be exactly parallel, that they might come from two points of the sky of the same altitude, and having precisely the same intensity of light. It was also necessary that the hole Q should be a little higher than P, in order that the two images should be at the same height, and near one another. It is no less necessary, he says, that the screen GH be exactly vertical, in order that the direct and reflected beams may fall upon it, with the same inclination; since, otherwise, though the two lights were perfectly equal, they would not illuminate the screen equally. This disposition, he says, serves to answer another important condition in these experiments; for the direct ray QS must be of the same length with the sum of the incident and reflected rays, PO and OR, in order that the quantity of light introduced into the room may be sensibly proportional to the sizes of the apertures.

Before we proceed to detail the other experiments of Bouguer, we shall notice some which were made previous to them by Buffon on the diminution of light by reflection, and the transmission of it to considerable distances through the air.

33
Experiment of M. Buffon.

By receiving the light of the sun in a dark room, and comparing it with the same light of the sun reflected by a mirror, he found that at small distances, as four or five feet, about one half was lost by reflection.

When the distances were 100, 200, and 300 feet, he could hardly perceive that it lost any of its intensity by being transmitted through such a space of air.

He afterwards made the same experiments with candles, in the following manner: He placed himself opposite to a looking glass, with a book in his hand, in a dark room; and having one candle lighted in the next room, at the distance of about 40 feet, he had it brought nearer to him by degrees, till he could just distinguish the letters of the book, which was then 24 feet from the candle. He then received the light of the candle, reflected by the looking glass, upon his book, carefully excluding all the light that was reflected from any thing else; and he found that the distance of the book from the candle, including the distance from the book to the looking glass (which was only half a foot) was in all 15 feet. He repeated the experiment several times, with nearly the same result; and therefore concluded, that the quantity of direct is to that of reflected light as 576 to 225; so that the light of five candles reflected from a plain mirror is about equal to that of two candles.

From these experiments it appeared, that more light was lost by reflection of the candles than of the sun, which M. Buffon thought was owing to this circumstance, that the light issuing from the candle diverges, and therefore falls more obliquely upon the mirror than the light of the sun, the rays of which are nearly parallel.

These experiments and observations of M. Buffon, though curious, are inferior to those of M. Bouguer, both in extent and accuracy.

34
M. Bouguer's discoveries concerning the reflection of glass and polished metal.

In order to ascertain the difference in the quantity of light reflected by glass and polished metal, he used a smooth piece of glass one line in thickness, and found that when it was placed at an angle of 15 degrees with the incident rays, it reflected 628 parts of 1000 which fell upon it; at the same time that a metallic mirror, which he tried in the same circumstances, reflected only 561 of them. At a less angle of incidence much more light was reflected: so that at an angle of three degrees the glass reflected 700 parts, and the metal something less, as in the former case.

In the case of unpolished bodies, he found that a piece of white plaster, placed at an angle of 75°, with the incident rays, reflected $\frac{1}{210}$ part of the light that is received from a candle nine inches from it. White paper, in the same circumstances, reflected in the same proportion; but at the distance of three inches, they both reflected 150 parts out of 1000.

Proceeding to make further observations on the subject of reflected light, he premises the two following theorems, which he demonstrates geometrically. 1. When the luminous body is at an infinite distance, and its light is received by a globe, the surface of which has a perfect polish, and absorbs no light, it reflects the light equally in all directions, provided it be received at a considerable distance. He excepts the place where the shadow of the globe falls: because this is no more than a single point, with respect to the immensity of the spherical surface which receives the light.

2. The quantity of light reflected in one certain direction will always be exactly the same, whether it be reflected by a very great number of small polished hemispheres, by a less number of large hemispheres, or by a single hemisphere, provided they occupy the same base, or cover the same ground plan.

The use he proposes to make of these theorems is to assist him in distinguishing whether the light reflected from bodies be owing to the extinction of it within them, or whether the eminences which cover them have not the same effect as the small polished hemispheres above mentioned.

He begins with observing, that of the light reflected from mercury, one fourth at least is lost, and that probably no substances reflect more than this. The rays were received at an angle of $11\frac{1}{4}$ degrees of incidence, that is measured from the surface of the reflecting body, and not from the perpendicular, which, he says, is what we are from this place to understand whenever he mentions the angle of incidence.

35
Great differences in the reflective power of substances according to the angle of incidence.

With regard to the quantities of light reflected at different angles of incidence, M. Bouguer found in general, that reflection is stronger at small angles of incidence, and weaker at large ones. The difference is excessive when the rays strike the surface of transparent substances, with different degrees of obliquity; but it is almost as great in some opaque substances, and it was always more or less so in every thing that he tried. He found the greatest inequality in black marble, which, though not perfectly polished, yet with an angle of 3° 35′ of incidence, it reflected almost as well as quicksilver. Of 1000 rays which it received, it returned 600: but when the angle of incidence was 14°, it reflected only 156; when it was 30°, it reflected 51; and when it was 80°, it reflected only 23.

Similar experiments made with metallic mirrors always gave the differences much less considerable. The greatest was hardly ever an eighth or a ninth part of it, but they were always in the same way.

The great difference between the quantity of light reflected from the surface of water, at different angles of incidence, is truly surprising. M. Bouguer sometimes suspected, that, when the angles of incidence were very

History.

very small, the reflection from water was even greater than from quicksilver; though he rather thought that it was scarcely so great. In very small angles, he says, that water reflects nearly $\frac{3}{4}$ of the direct light.

The light reflected from a lake is sometimes $\frac{1}{3}$ or $\frac{1}{4}$, or even a greater proportion, of the light that comes directly from the sun, which is an addition to the direct rays of the sun that cannot fail to be very sensible. The direct light of the sun diminishes gradually as it approaches the horizon, while the reflected light at the same time grows stronger: so that there is a certain altitude of the sun, in which the united force of the direct and reflected light will be the greatest possible, and this he says is 12 or 13 degrees.

The light reflected from water at great angles of incidence is extremely small. M. Bouguer was assured, that, when the light was perpendicular, it reflected no more than the 37th part that quicksilver does in the same circumstances; for it did not appear that water reflects more than the 60th, or rather the 55th, part of perpendicular light. When the angle of incidence was 50°, the light reflected from the surface of water was about the 32d part of that which mercury reflected; and as the reflection from water increases as the angle of incidence diminishes, it was twice as strong in proportion at 30°; for it was then the 16th part of the quantity reflected from mercury.

In order to procure a common standard by which to measure the proportion of light reflected from various fluid substances, he selected water as the most commodious; and partly by observation and calculation he drew up the following table of the quantity of light reflected from its surface at different angles of incidence.

Angles of incidence.	Rays reflected of 1000.	Angles of incidence.	Rays reflected of 1000.
$\frac{1}{2}$	721	$17\frac{1}{2}$	178
1	692	20	145
$1\frac{1}{2}$	669	25	97
2	639	30	65
$2\frac{1}{2}$	614	40	34
5	501	50	22
$7\frac{1}{2}$	409	60	19
10	333	70	18
$12\frac{1}{2}$	271	80	18
15	211	90	18

In the same manner, he constructed the following table containing the quantity of light reflected from the looking-glass not quicksilvered.

Angles of incidence.	Rays reflected of 1000.	Angles of incidence.	Rays reflected of 1000.
$2\frac{1}{2}$	584	30	112
5	543	40	57
$7\frac{1}{2}$	474	50	34
10	412	60	27
$12\frac{1}{2}$	356	70	25
15	299	80	25
20	222	90	25
25	157		

When water floats upon mercury there will be two images of any object seen by reflection from them, one at the surface of the water, and the other at that of the quicksilver. In the largest angles of incidence, the image at the surface of the water will disappear, which will happen when it is about a 60th or an 80th part less luminous than the image at the surface of the quicksilver. Depressing the eye, the image on the water will grow stronger, and that on the quicksilver weaker in proportion; till at last, the latter will be incomparably weaker than the former, and at an angle of about 10 degrees they will be equally luminous. According to the table, $\frac{333}{1000}$ of the incident rays are reflected from the water at this angle of 10 degrees. At the surface of the mercury they were reduced to 500; and of these, part being reflected back upon it from the under surface of the water, only 333 remained to make the image from the mercury.

36
Reflection of images by the air.

It has been frequently observed, that there is a remarkably strong reflection into water, with respect to rays issuing from the water; and persons under water have seen images of things in the air in a manner peculiarly distinct and beautiful. In order to account for these facts, M. Bouguer observes that from the smallest angles of incidence, to a certain number of degrees, the greatest part of the rays are reflected, perhaps, in as great a proportion as at the surface of metallic mirrors, or of quicksilver; while the other part, which does not escape into the air, is extinguished or absorbed; so that the surface of the transparent body appears opaque on the inside. If the angle of incidence be increased only a few degrees, the strong reflection ceases altogether, a great number of rays escape into the air, and very few are absorbed. As the angle of incidence is farther increased, the quantity of the light reflected becomes less and less; and when it is near 90 degrees, almost all the rays escape out of the transparent body, its surface losing almost all its power of reflection, and becoming nearly as transparent as when the light falls upon it from without.

37
Extinction of the rays of light at the surface of transparent bodies.

This property belonging to the surfaces of transparent bodies, of absorbing the rays of light, is truly remarkable, and, as there is reason to believe, had not been noticed by any person before Bouguer.

38
Strong reflection by a prism.

That all the light is reflected at certain angles of incidence from air into denser substances, had frequently been noticed, especially in glass prisms; so that Newton made use of one of them, instead of a mirror, in the construction of his reflecting telescope. If a beam of light fall upon the air from within these prisms, at an angle of 10, 20, or 30 degrees, the effect will be nearly the same as at the surface of quicksilver, one-fourth or one-third of the rays being extinguished, and two-thirds or three-fourths reflected. This property retains its full force as far as an angle of 49° 49′, (the proportion of the sines of the refraction being 31 and 20); but if the angle of incidence be increased but one degree, the quantity of light reflected inwards suddenly decreases, and a great part of the rays escape out of the glass, so that the surface becomes suddenly transparent.

All transparent bodies have the same property, with this difference, that the angle of incidence at which the strong reflection ceases, and at which the light which is not reflected is extinguished, is greater in some than in others. In water this angle is about 41° 32′; and in every medium it depends so much on the invariable

proportion

History.

proportion of the sine of the angle of refraction to the sine of the angle of incidence, that this law alone is sufficient to determine all the phenomena of this new circumstance, at least as to this accidental opacity of the surface.

When M. Bouguer proceeded to measure the quantity of light reflected by these internal surfaces at great angles of incidence, he had to struggle with many difficulties; but by using a plate of crystal, he found, that at an angle of 75 degrees, this internal reflection diminished the light 27 or 28 times; and as the external reflection at the same angle diminished the light only 26 times, it follows that the internal reflection is a little stronger than the other.

Repeating these experiments with the same and different pieces of crystal, he sometimes found the two reflections to be equally strong; but, in general, the internal was the stronger.

39 Of the quantity of light reflected by different substances

Resuming his observations on the diminution of light, occasioned by the reflection of opaque bodies obliquely situated, he compared it with the appearances of similar substances which reflected the light perpendicularly. Using pieces of silver made very white, he found, that when one of them was placed at an angle of 75 degrees with respect to the light, it reflected only 640 parts out of 1000. He then varied the angle, and also used white plaster and fine Dutch paper, and drew up the following table of the proportion of the light reflected from each of those substances at certain angles.

Angles of incidence.	Quantity of Light reflected from Silver.	Plaster.	Dutch Paper.
90	1000	1000	1000
75	802	762	971
60	640	640	743
45	455	529	507
30	319	352	332
15	209	194	203

Supposing the asperities of opaque bodies to consist of very small planes, it appears from these observations, that there are fewer of them in those bodies which reflect the light at small angles of incidence than at greater. None of them had their roughness equivalent to small hemispheres, which would have dispersed the light equally in all directions; and, from the *data* in the preceding table, he deduces mathematically the number of the planes that compose those surfaces, and that are inclined to the general surface at the angles above mentioned, supposing that the whole surface contains 1000 of them that are parallel to itself, so as to reflect the light perpendicularly, when the luminous body is situated at right angles with respect to it. His conclusions reduced to a table, corresponding to the preceding, are as follow:

Inclinations of the small surfaces with respect to the large one.	The distribution of the small planes that constitute the asperities of the opaque surface in the Silver.	Plaster.	Paper.
0	1000	1000	1000
15	777	736	937
30	554	554	545
45	333	374	358
60	161	176	166
75	53	50	52

These variations in the number of little planes, he expresses in the form of a curve; and afterwards shows, geometrically, what would be the effect if the bodies were enlightened in one direction, and viewed in another. Upon this subject he has several curious theorems and problems; but for these we must refer to the work itself.

Since the planets are more luminous at their edges than at their centres, he concludes, that the bodies which form them are constituted in a manner different from ours; particularly that their opaque surfaces consist of small planes, more of which are inclined to the general surface than they are in terrestrial substances; and that there are in them an infinity of points, which have exactly the same splendour.

M. Bouguer next proceeds to ascertain the quantity of surface occupied by the small planes of each particular inclination, from considering the quantity of light reflected by each, allowing those that have a greater inclination to the common surface to take up proportionably less space than those which are parallel to it. And comparing the quantity of light that would be reflected by small planes thus disposed, with the quantity of light that was actually reflected by the three substances above mentioned, he found that plaster, notwithstanding its extreme whiteness, absorbs much light; for that, of 1000 rays falling upon it, of which 166 or 167 ought to be reflected at an angle of 77°, only 67 are in fact returned; so that 100 out of 167 were extinguished, that is, about three-fifths.

With respect to the planets, Bouguer concludes, that of 300,000 rays which the moon receives, 172,000, or perhaps 204,100, are absorbed.

Having considered the surfaces of bodies as consisting of planes only, he observes that each small surface, separately taken, is extremely irregular, some of them really concave, and others convex; but, in reducing them to a middle state, they are to be regarded as planes. Nevertheless he considers them as planes only with respect to the reception of the rays; for as they are almost all curves, and as, besides this, many of those whose situation is different from others contribute to the same effects, the rays always issue from an actual or imaginary focus, and after reflection always diverge from another.

The experiments of Lambert, related in his *Photometria*, have laid open to us many curious observations concerning the natural history of light. He was the first who determined that a radiating surface emits its light with nearly the same intensity in all directions, so that

History.

that every portion of it appears equally bright to an observer placed in any direction.

42
Mr Melville's observations on the manner in which bodies are heated by light.

We are obliged to Mr Melville for some ingenious observations on the manner in which bodies are heated by light. He observes, that, as each colorific particle of an opaque body must be somewhat moved by the reflection of the particles of light, when it is reflected backwards and forwards between the same particles, it is manifest that they must likewise be agitated with a vibratory motion, and the time of a vibration will be equal to that which light takes up in moving from one particle of a body to another adjoining. This distance, in the most solid opaque bodies, cannot be supposed greater than $\frac{1}{12500}$th of an inch, which space light describes in the $\frac{1}{125000000000000}$th of a second. With so rapid a motion, therefore, may the internal parts of bodies be agitated by the influence of light, as to perform 125,000,000,000,000 vibrations, or more, in a second of time.

The arrival of different particles of light at the surface of the same colorific particle, in the same or different rays, may disturb the regularity of its vibrations, but will evidently increase their frequency, or raise still smaller vibrations among the parts which compose those particles; whence the intestine motion will become more subtle, and more thoroughly diffused. If the quantity of light admitted into the body be increased, the vibrations of the particles must likewise increase in magnitude and velocity, till at last they may be so violent, as to make all the component particles dash one another to pieces by their mutual collision; in which case, the colour and texture of the body must be destroyed.

Since there is no reflection of light but at the surface of a medium, the same gentleman observes, that the greatest quantity of rays, though crowded into the smallest space, will not of themselves produce any heat. Hence it follows, that the portion of air which lies in the focus of the most potent speculum, is not at all affected by the passage of light through it, but continues of the same temperature with the ambient air; though any opaque body, or even any transparent body denser than air, when put in the same place, would, in an instant, be intensely heated.

The easiest way to be satisfied of this truth experimentally is, to hold a hair, or a piece of down, immediately above the focus of a lens or speculum, or to blow a stream of smoke from a pipe horizontally over it; for if the air in the focus were hotter than the surrounding fluid, it would continually ascend on account of its rarefaction, and thereby sensibly agitate those slender bodies. Or a lens may be so placed as to form its focus within a body of water, or some other transparent substance, the heat of which may be examined from time to time with a thermometer; but care must be taken, in this experiment, to hold the lens as near as possible to the transparent body, lest the rays, by falling closer than ordinary on its surface, should warm it more than the common sunbeams. See Priestley on Vision.

43
Abbé Nollet's experiments with burning glasses.

The attempts of the Abbé Nollet to fire inflammable substances by the concentration of the solar rays, have a near relation to the present subject. He attempted to fire liquid substances, but he was not able to do it either with spirit of wine, olive oil, oil of turpentine, or ether; and though he could fire sulphur, yet he could not succeed with Spanish wax, rosin, black pitch, or suet. He both threw the focus of these mirrors upon the substances themselves, and also upon the fumes that rose from them; but the only effect was, that the liquor boiled, and was dispersed in vapour or very small drops. When linen rags, and other solid substances, were moistened with any of these inflammable liquids, they would not take fire till the liquid was dispersed in a copious fume; so that the rags thus prepared were longer in burning than those that were dry.

44
M. Beaume's experiments.

M. Beaume, who assisted M. Nollet in some of these experiments, observed farther, that the same substances which were easily fired by the flame of burning bodies, could not be set on fire by the contact of the hottest bodies that did not actually flame. Neither ether nor spirit of wine could be fired with a hot coal, or even red-hot iron, unless they were of a white heat.

45
Bodies which seem to touch one another are not in actual contact.

By the help of optical principles, and especially by observations on the reflection of light, Mr Melville demonstrated that bodies which seem to touch one another are not always in actual contact. Upon examining the volubility and lustre of drops of rain that lie on the leaves of colewort, and some other vegetables, he found that the lustre of the drop is produced by a copious reflection of light from the flattened part of its surface contiguous to the plant. He found also, that, when the drop rolls along a part which has been wetted, it immediately loses all its lustre, the green plant being then seen clearly through it; whereas, in the other case, it is hardly to be discerned.

From these two observations, he concluded, that the drop does not really touch the plant, when it has the mercurial appearance, but is suspended in the air at some distance from it by a repulsive force. For there could not be any copious reflection of white light from its under surface, unless there were a real interval between it and the surface of the plant.

If that surface were perfectly smooth, the under surface of the drop would be so likewise, and would therefore show an image of the illuminating body by reflection, like a piece of polished silver; but as it is considerably rough, the under surface becomes rough likewise, and thus by reflecting the light copiously in different directions, assumes the brilliant hue of unpolished silver.

It being thus proved by an optical argument, that the drop is not really in contact with the leaf, it may easily be conceived whence its volubility arises, and why it leaves no moisture where it rolls.

46
Two curious miscellaneous observations.

Before we conclude the history of the observations concerning the reflection of light, we must not omit to take notice of two singular miscellaneous observations. Baron Alexander Funk, visiting some silver mines in Sweden, observed, that, in a clear day, it was as dark as pitch below ground, in the eye of a pit, at 60 or 70 fathoms deep; whereas, in a cloudy or rainy day, he could even see to read at the depth of 106 fathoms. He imagined that it arose from this circumstance, that when the atmosphere is full of clouds, light is reflected from them into the pit in all directions, and that thereby a considerable proportion of the rays is reflected perpendicularly upon the earth; whereas, when the atmosphere is clear, there are no opaque bodies to reflect the light in this manner, at least in a sufficient quantity; and rays from the sun itself can never fall perpendicularly in that country.

History.

The other observation was that of the ingenious Mr Grey. He took a piece of stiff brown paper, and pricking a small hole in it, he held it at a little distance before him; when, applying a needle to his eye, he was surprised to see the point of it inverted. The nearer the needle was to the hole, the more it was magnified, but the less distinct; and if it was so held, that its image was near the edge of the hole, its point seemed crooked. From these appearances he concluded, that these small holes, or something in them, produce the effects of concave speculums; and from this circumstance he took the liberty to call them *aërial speculums.*

This method of accounting for the inverted image of the pin is evidently erroneous; for the same effect is produced, when the small aperture is formed of two semi-apertures at different distances from the eye, or when a small opening is made in the pigment on a piece of smoked glass. We have found indeed that the same phenomenon will appear, if, instead of looking at a hole in a piece of paper, we view a small luminous point so that it is expanded by indistinct vision into a circular image of light. The pin always increases in magnitude in proportion to its distance from the luminous point.

SECT. III. *Discoveries concerning the Inflection of Light.*

This property of light was not discovered till about the middle of the 17th century. The person who first made the discovery was Father Grimaldi; at least he first published an account of it in his treatise *De lumine, coloribus, et iride*, printed in 1666. Dr Hooke, however, laid claim to the same discovery, though he did not make his observations public till six years after Grimaldi.

47 Dr Hooke's discoveries. Dr Hooke having darkened his room, admitted a beam of the sun's light through a very small hole in a brass plate. This beam spreading itself, formed a cone, the vertex of which was in the hole, and the base was on a paper, so placed as to receive it at some distance. In the image of the sun, thus painted on the paper, he observed that the middle was much brighter than the edges, and that there was a kind of dark penumbra about it, of about a 16th part of the diameter of the circle; which he ascribed to a property of light, that he promised to explain.—Having observed this, at the distance of about two inches from the former he let in another cone of light; and receiving the bases of them, at such a distance from the holes that the circles intersected each other, he observed that there was not only a darker ring, encompassing the lighter circle, but a manifest dark line, or circle, as in fig. 6. which appeared even where the limb of the one interfered with that of the other.

Plate CCLXXV Fig. 6.

Fig. 7.

In the light thus admitted, he held an opaque body BB, fig. 7. so as to intercept the light that entered at a hole in the window shutter O, and was received on the screen AP. In these circumstances, he observed, that the shadow of the opaque body (which was a round piece of wood, not bright or polished) was all over somewhat enlightened, but more especially towards the edge. In order to show that this light was not produced by reflection, he admitted the light through a hole burnt in a piece of pasteboard, and intercepted it with a razor which had a very sharp edge; but still the appearances were the very same as before; so that he concluded that they were occasioned by some new property of light.

He diversified this experiment, by placing the razor so as to divide the cone of light into two parts, and placing the paper so that none of the enlightened part of the circle fell upon it, but only the shadow of the razor; and, to his great surprise, he observed what he calls a *very brisk and visible radiation* striking down upon the paper, of the same breadth with the diameter of the lucid circle. This radiation always struck perpendicularly from the line of shadow, and, like the tail of a comet, extended more than 10 times the breadth of the remaining part of the circle. He found, wherever there was a part of the interposed body higher than the rest, that, opposite to it, the radiation of light into the shadow was brighter, as in the figure; and wherever there was a notch or gap in it, there would be a dark stroke in the half-enlightened shadow. From all these appearances, he concluded, that there is a deflection of light, differing both from reflection and refraction, and seeming to depend on the unequal density of the constituent parts of the ray, whereby the light is dispersed from the place of condensation, and rarefied, or gradually diverged into a quadrant; that this deflection is made towards the superficies of the opaque body perpendicularly; that those parts of the diverged radiations which are deflected by the greatest angle from the straight or direct radiations are the faintest, and those that are deflected by the least angles are the strongest; that rays cutting each other in one common aperture do not make the angles at the vertex equal; that colours may be made without refraction; that the diameter of the sun cannot be truly taken with common sights; that the same rays of light, falling upon the same point of an object, will turn into all sorts of colours, by the various inclinations of the object; and that colours begin to appear when two pulses of light are blended so well, and so near together, that the sense takes them for one.

We shall now proceed to give an account of the discoveries of Father Grimaldi. Having introduced a ray of light, through a very small hole, AE, fig. 8. into a darkened room, he observed that the light was diffused in the form of a cone, the base of which was CD; and that if any opaque body, FE, was placed in this cone of light, at a considerable distance from the hole, and the shadow received upon a piece of white paper, the boundaries of it were not confined within GH, or the penumbra IL, occasioned by the light proceeding from different parts of the aperture, and of the disk of the sun, but extended to MN: At this he was very much surprised, as he found that it was broader than it ought to have been made by rays passing in right lines by the edges of the object. 48 Grimaldi's discoveries. Fig. 8.

But the most remarkable circumstance in this appearance was, that upon the lucid part of the base, CM and ND, streaks of coloured light were plainly distinguished, each being terminated by blue on the side next the shadow, and by red on the other; and though these coloured streaks depended, in some measure on the size of the aperture AB, because they could not be made to appear if it was large, yet he found that they were not limited either by it, or by the diameter of the sun's disk.

He farther observed, that these coloured streaks were

History. were not all of the same breadth, but grew narrower as they receded from the shadow, and were each of them broader the farther the shadow was received from the opaque body, and also the more obliquely the paper on which they were received was held with respect to it. He never observed more than three of these streaks.

Fig. 9. To give a clearer idea of these coloured streaks, he drew the representation of them, exhibited in fig. 9. in which NMO represents the largest and most luminous streak, next to the dark shadow X. In the space in which M is placed there was no distinction of colour, but the space NN was blue, and the space OO on the other side of it was red. The second streak QPR was narrower than the former; and of the three parts of which it consisted, the space P had no particular colour, but QQ was a faint blue, and RR a faint red. The third streak, TSV, was exactly similar to the two others, but narrower than either of them, and the colour still fainter.

These coloured streaks he observed to lie parallel to the shadow of the opaque body; but when it was of an angular form, they did not make the same acute angles, but were bent into a curve, the outermost being rounder than those that were next the shadow, as is represented in fig. 10. If it was an inward angle, as DCH, the coloured streaks, parallel to each other of the two sides crossed without obliterating one another; only the colours were thus rendered either more intense or mixed.

Fig. 10.

Within the shadow itself, Grimaldi sometimes perceived coloured streaks, similar to those above mentioned on the outside of the shadow. Sometimes he saw more of them, and sometimes fewer; but for this purpose it was necessary to have strong light, and to make the opaque body long and moderately broad. A hair, for instance, or a fine needle, did not answer so well as a thin and narrow plate: and the streaks were most distinguishable when the shadow was taken at the greatest distance; though the light grew fainter in the same proportion.

The numbers of these streaks increased with the breadth of the plate. They were at least two, and sometimes four, if a thicker plate were made use of. But, with the same plate, more or fewer streaks appeared, in proportion to the distance at which the shadow was received; but they were broader when they were few, and narrower when there were more of them; and they were all much more distinct when the paper was held obliquely.

Fig. 11. These coloured streaks, like those on the outside of the shadow, were bent in an arch, round the acute angles of the shadow, as they are represented in fig 11. At this angle also, as at D, other shorter lucid streaks were visible, bent in the form of a plume, as they are drawn betwixt D and C, each bending round and meeting again in D. These angular streaks appeared, though the plate or rod was not wholly immersed in the beam of light, but the angle of it only; and they increased in number with the breadth of the plate. If the plate was very thin, the coloured streaks bent round from the opposite sides, and met one another as at B.

In order to obtain a more satisfactory proof, that rays of light really bend, in passing by the edges of bodies, he admitted a beam of light into a dark room, as before; and, at a great distance from it, he fixed a plate EF, (fig. 12.) with a small aperture GH, which admitted only a part of the beam of light, and found, that when the light transmitted through this plate was received at some distance upon a white paper, the base IK was considerably larger than it could possibly have been made by rays issuing in right lines through the two apertures. Grimaldi generally made the aperture CD $\frac{4}{100}$ or $\frac{5}{100}$ part of a foot, and the second aperture, GH, $\frac{25}{100}$ or $\frac{10}{100}$; and the distances, DG and GN, were at least 12 feet. The observation was made about midday in the summer time, when the atmosphere was free from all vapours.

Fig. 12.

Grimaldi also made the same experiment that has been recited from Dr Hooke, in which two beams of light, entering a dark room by two small apertures near one another, projected cones of light, which, at a certain distance, in part coincided; and he particularly observed, that the dark boundaries of each of them were visible within the lucid ground of the other.

49 Observation of Dechales.

To these discoveries of Grimaldi, we shall subjoin an additional observation of Dechales; who found, that if a piece of polished metal, with small scratches in it, be exposed to the beams of the sun in a darkened room, it will reflect the rays streaked with colours in the direction of the scratches; as will appear, if the reflected light be received upon a piece of white paper. That these colours are not produced by refraction, he says, is manifest; for if the scratches be made upon glass, the effect will be the same; and in this case, if the light had been refracted at the surface of the glass, it would have been transmitted through it. From these and many other observations, he concluded, that colour does not depend upon the refraction of light only, nor upon a variety of other circumstances which he particularly enumerates, but upon the intensity of the light only.

50 Of M. de la Hire.

We shall here give an account of the phenomenon of vision observed by M. de la Hire, as being connected with the subject of this section. When we look at a candle, or any luminous body, with our eyes nearly shut, rays of light are extended from it, in several directions, to a considerable distance, like the tails of comets. This appearance exercised the sagacity of Descartes and Rohault, as well as of De la Hire; but all these philosophers seem to have been mistaken with regard to its cause. Descartes ascribed this effect to certain wrinkles in the surface of the humours of the eyes Rohault says, that when the eye-lids are nearly closed, the edges of them act like convex lenses. But De la Hire observes, that the moisture on the surface of the eye, adhering partly to the eye itself, and partly to the edge of the eye-lid, makes a concave mirror, and so disperses the rays at their entrance into the eye. The true account of the phenomenon, however, is this. There are three different kinds of radiations distinctly visible; the most brilliant, which diverge directly from the candle, are formed by the *refraction* of the light of the candle through the moisture that lubricates the eye, and which is brought opposite the pupil by one of the eye-lids. Another kind of radiation, which appears at a distance from the candle in the form of small luminous specks, is produced by *reflection* from the part of the eye-lid in which the lashes are

are inserted. The third kind of radiation is horizontal, and is caused by the *inflection* of the light in passing between the eye-lashes.

51
Sir Isaac Newton's discoveries.

The experiments of Grimaldi and Hooke were repeated and extended by Sir Isaac Newton, and were in some measure explained by that distinguished philosopher.

He made in a piece of lead a small hole the 42d part of an inch in diameter. Through this hole he let into his dark chamber a beam of the sun's light; and found, that the shadows of hairs, and other slender substances, placed in it, were considerably broader than they would have been if the rays of light had passed by those bodies in right lines. He therefore concluded, that they must have passed as they are represented in fig. 1. in which X represents a section of the hair, and AD, BE, &c. rays of light passing by at different distances, and then falling upon the wall GQ. Since, when the paper which receives the rays is at a great distance from the hair, the shadow is broad, it must follow, that the hair acts upon the rays at some considerable distance from it, the action being strongest on those rays which are at the least distance, and growing weaker and weaker on those which are farther off, as is represented in this figure; and hence it comes to pass that the shadow of the hair is much broader in proportion to the distance of the paper from the hair when it is nearer than when it is at a greater distance.

Plate CCLXXVI. fig. 1.

By wetting a polished plate of glass, and laying the hair in the water upon the glass, and then laying another polished plate of glass upon it, so that the water might fill up the space between the glasses, he found that the shadow at the same distance was as big as before, so that this breadth of shadow must proceed from some other cause than the refraction of the air.

The shadows of all bodies placed in this light were bordered with three parallel fringes of coloured light, of which that which was nearest to the shadow was the broadest and most luminous, while that which was farthest from it was the narrowest, and so faint as to be scarcely visible. It was difficult to distinguish these colours, unless when the light fell very obliquely upon some smooth white body, so as to make them appear much broader than they would otherwise have done; but in these circumstances the colours were plainly visible, and in the following order. The first or innermost fringe was violet, and deep blue next the shadow, light blue, green, and yellow in the middle, and red without.

The second fringe was almost contiguous to the first, and the third to the second; and both were blue within, and yellow and red without; but their colours were very faint, especially those of the third. The colours, therefore, proceeded in the following order from the shadow; violet, indigo, pale blue, green, yellow, red; blue, yellow, red; pale blue, pale yellow, and red. The shadows, made by scratches and bubbles in polished plates of glass, were bordered with the like fringes of coloured light.

Measuring these fringes and their intervals with the greatest accuracy, he found the former to be in the progression of the numbers 1, $\sqrt{\frac{1}{3}}$, $\sqrt{\frac{1}{5}}$, and their intervals to be in the same progression with them, that is, the fringes and their intervals together to be nearly in continual progression of the numbers 1, $\sqrt{\frac{1}{2}}$, $\sqrt{\frac{1}{3}}$, $\sqrt{\frac{1}{4}}$, $\sqrt{\frac{1}{5}}$.

Having made the aperture $\frac{1}{4}$ of an inch in diameter, and admitted the light as formerly, Sir Isaac placed, at the distance of two or three feet from the hole, a sheet of pasteboard, black on both sides; and in the middle of it he made a hole about $\frac{1}{4}$ of an inch square, and behind the hole he fastened to the pasteboard the blade of a sharp knife, to intercept some part of the light which passed through the hole. The planes of the pasteboard and blade of the knife were parallel to each other, and perpendicular to the rays; and when they were so placed that none of the light fell on the pasteboard, but all of it passed through the hole to the knife, and there part of it fell upon the blade of the knife, and part of it passed by its edge, he let that part of the light which passed fall on a white paper, 2 or 3 feet beyond the knife, and there he saw two streams of faint light shoot out both ways from the beam of light into the shadow. But because the sun's direct light, by its brightness upon the paper, obscured these faint streams, so that he could scarcely see them, he made a little hole in the midst of the paper for that light to pass through and fall on a black cloth behind it; and then he saw the two streams plainly. They were similar to one another, and pretty nearly equal in length, breadth, and quantity of light. Their light, at that end which was next to the sun's direct light, was pretty strong for the space of about $\frac{1}{4}$ of an inch, or $\frac{1}{2}$ of an inch, and gradually decreased till it became insensible.

The whole length of either of these streams, measured upon the paper, at the distance of 3 feet from the knife, was about 6 or 8 inches; so that it subtended an angle, at the edge of the knife, of about 10 or 12, or at most 14, degrees. Yet sometimes he thought he saw it shoot 3 or 4 degrees farther; but with a light so very faint, that he could hardly perceive it. This light he suspected might, in part at least, arise from some other cause than the two streams. For, placing his eye in that light, beyond the end of that stream which was behind the knife, and looking towards the knife, he could see a line of light upon its edge; and that not only when his eye was in the line of the streams, but also when it was out of that line, either towards the point of the knife, or towards the handle. This line of light appeared contiguous to the edge of the knife, and was narrower than the light of the innermost fringe, and narrowest when his eye was farthest from the direct light; and therefore seemed to pass between the light of that fringe and the edge of the knife; and that which passed nearest the edge seemed to be most bent.

He then placed another knife by the former, so that their edges might be parallel, and look towards one another, and that the beam of light might fall upon both the knives, and some part of it pass between their edges. In this situation he observed, that when the distance of their edges was about the 400th of an inch, the stream divided in the middle, and left a shadow between the two parts. This shadow was so dark, that all the light which passed between the knives seemed to be bent to the one hand or the other; and as the knives still approached each other, the shadow grew broader and the streams shorter next to it, till, upon the contact of the knives, all the light vanished.

Hence Sir Isaac concluded, that the light which is least bent, and which goes to the inward ends of the streams, passes by the edges of the knives at the greatest distance;

distance; and this distance, when the shadow began to appear between the streams, was about the 800th of an inch; and the light which passed by the edges of the knives at distances still less and less, was more and more faint, and went to those parts of the streams which were farther from the direct light; because, when the knives approached one another till they touched, those parts of the stream vanished last which were farthest from the direct line.

In the experiment of one knife only, the coloured fringes did not appear; but, on account of the breadth of the hole in the window, became so broad as to run into one another, and, by joining, to make one continual light in the beginning of the streams; but in the last experiment, as the knives approached one another, a little before the shadow appeared between the two streams, the fringes began to appear on the inner ends of the streams, on either side of the direct light; three on one side, made by the edge of one knife, and three on the other side, made by the edge of the other knife. They were the most distinct when the knives were placed at the greatest distance from the hole in the window, and became still more distinct by making the hole less; so that he could sometimes see a faint trace of a fourth fringe beyond the three above mentioned: and as the knives approached one another the fringes grew more distinct and larger, till they vanished; the outermost vanishing first, and the innermost last. After they were all vanished, and the line of light in the middle between them was grown very broad, extending itself on both sides into the streams of light described before, the above mentioned shadow began to appear in the middle of this line, and to divide it along the middle into two lines of light, and increased till all the light vanished. This enlargement of the fringes was so great, that the rays which went to the innermost fringe seemed to be bent about 20 times more when the fringe was ready to vanish, than when one of the knives was taken away.

From both these experiments Newton concluded, that the light of the first fringe passed by the edge of the knife at a distance greater than the 800th of an inch; that the light of the second fringe passed by the edge of the knife at a greater distance than the light of the first fringe, and that of the third at a greater distance than that of the second; and that the light of which the streams above mentioned consisted, passed by the edges of the knives at less distances than that of any of the fringes.

He then got the edges of two knives ground straight, and fixed their points into a board, so that their edges might contain a rectilinear angle. The distance of the edges of the knives from one another, at four inches from the angular point, was the 8th of an inch; so that the angle contained by their edges was about 1° 54′. The knives being thus fixed, he placed them in a beam of the sun's light let into his darkened chamber, through a hole the 42d of an inch wide, at the distance of 10 or 13 feet from the hole; and he let the light which passed between their edges fall very obliquely on a smooth white ruler, at the distance of ½ inch, or an inch, from the knives; and there he saw the fringes made by the two edges of the knives run along the edges of the shadows of the knives, in lines parallel to those edges, without growing sensibly broader, till they met in angles equal to the angle contained by the edges of the knives; and where they met and joined, they ended, without crossing one another. But if the ruler was held at a much greater distance from the knives, the fringes, where they were farther from the place of their meeting, were a little narrower, and they became something broader as they approached nearer to one another, and after they met they crossed one another, and then became much broader than before.

From these observations he concluded, that the distances at which the light composing the fringes passed by the knives were not increased, or altered by the approach; and that the knife which was nearest to any ray determined which way the ray should be bent, but that the other knife increased the bending.

When the rays fell very obliquely upon the ruler, at the distance of ⅓ of an inch from the knives, the dark line between the first and second fringes of the shadow of one knife, and the dark line between the first and second fringe of the shadow of the other knife, met one another, at the distance of ⅕ of an inch from the end of the light which passed between the knives, where their edges met; so that the distance of the edges of the knives, at the meeting of the dark lines, was the 160th of an inch; and one half of that light passed by the edge of one knife, at a distance not greater than the 320th part of an inch, and, falling upon the paper, made the fringes of the shadow of that knife; while the other half passed by the edge of the other knife, at a distance not greater than the 320th part of an inch, and, falling upon the paper, made the fringes of the shadow of the other knife. But if the paper was held at a distance from the knives greater than ⅓ of an inch, the dark lines above mentioned met at a greater distance than ⅕ of an inch from the end of the light which passed between the knives, at the meeting of their edges; so that the light which fell upon the paper where those dark lines met passed between the knives, where their edges were farther distant than the 160th of an inch. For at another time, when the two knives were 8 feet 5 inches from the little hole in the window, the light which fell upon the paper where the above mentioned dark lines met passed between the knives, where the distance between their edges was, as in the following table, at the distances from the paper noted.

Distance of the paper from the knives in inches.	Distance between the edges of the knives in thousandth parts of an inch.
1½	0,012
3⅓	0,020
8⅗	0,034
32	0,057
96	0,081
131	0,087

From these observations he concluded, that the light which forms the fringes upon the paper is not the same light at all distances of the paper from the knives; but that when the paper is held near the knives, the fringes are made by light which passes by the

the edges of the knives at a less distance, and is more bent than when the paper is held at a greater distance from the knives.

When the fringes of the shadows of the knives fell perpendicularly upon the paper, at a great distance from the knives, they were in the form of hyperbolas, of the following dimensions Let CA, CB, (fig. 2.) represent lines drawn upon the paper, parallel to the edges of the knives; and between which all the light would fall if it suffered no inflection. DE is a right line drawn through C, making the angles ACD, BCE, equal to one another, and terminating all the light which falls upon the paper, from the point where the edges of the knives meet, Then *e i s*, *f k t*, and *g l v*, will be three hyperbolic lines, representing the boundaries of the shadow of one of the knives, the dark line between the first and second fringes of that shadow, and the dark line between the second and third fringes of the same shadow. Also *x i p*, *y k q*, and *z l r*, will be three other hyperbolic lines, representing the boundaries of the shadow of the other knife, the dark line between the first and second fringes of that shadow, and the dark line between the second and third fringes of the same shadow. These three hyperbolas, which are similar, and equal to the former, cross them in the points *i*, *k*, and *l*; so that the shadows of the knives are terminated, and distinguished from the first luminous fringes, by the lines *e i s*, and *x i p*, till the meeting and crossing of the fringes; and then those lines cross the fringes in the form of dark lines terminating the first luminous fringes on the inside, and distinguishing them from another light, which begins to appear at *i*, and illuminates all the triangular space *i p* DE *s*, comprehended by these dark lines and the right line DE. Of these hyperbolas one asymptote is the line DE, and the other asymptotes are parallel to the lines CA and CB.

Plate CCLXXVI fig. 2.

Before the small hole in the window Newton placed a prism, to form on the opposite wall the coloured image of the sun; and he found that the shadows of all bodies held in the coloured light, were bordered with fringes of the colour of the light in which they were held; and he found that those made in the red light were the largest, those made in the violet the least, and those made in the green of a middle bigness. The fringes with which the shadow of a man's hair were surrounded, being measured across the shadow, at the distance of six inches from the hair, the distance between the middle and most luminous part of the first or innermost fringe on one side of the shadow, and that of the like fringe on the other side of the shadow, was, in the full red light $\frac{1}{37\cdot5}$ of an inch, and in the full violet $\frac{1}{46}$. The like distance between the middle and most luminous parts of the second fringes, on either side of the shadow, was in the full red light $\frac{1}{22}$, and in the violet $\frac{1}{27}$ of an inch; and these distances of the fringes held the same proportion at all distances from the hair, without any sensible variation.

From these observations it was evident, that the rays which formed the fringes in the red light, passed by the hair at a greater distance than those which made the like fringes, in the violet; so that the hair, in causing these fringes, acted alike upon the red light or least refrangible rays at a greater distance, and upon the violet or most refrangible rays at a less distance; and thereby occasioned fringes of different sizes, without any change in the colour of any sort of light.

It may therefore be concluded, that when the hair was held in the white beam of light, and cast a shadow bordered with three coloured fringes, those colours arose not from any new modifications impressed upon the rays of light by the hair, but only from the various inflections by which the several sorts of rays were separated from one another, which before separation, by the mixture of all their colours, composed the white beam of the sun's light; but, when separated, composed lights of the several colours which they are originally disposed to exhibit.

52 Maraldi's discoveries.

The person who first made any experiments similar to those of Newton on inflected light is M. Maraldi. His observations chiefly respect the inflection of light towards other bodies, whereby their shadows are partially illuminated.

53 Experiments concerning the shadows of cylinders.

He exposed in the light of the sun a cylinder of wood three feet long, and $6\frac{1}{2}$ lines in diameter, when its shadow was everywhere equally black and well defined, even at the distance of 23 inches from it. At a greater distance the shadow appeared of two different densities; for its two extremities, in the direction of the length of the cylinder, were terminated by two dark strokes, a little more than a line in breadth. Within these dark lines there was a faint light, equally dispersed through the shadow, which formed an uniform penumbra, much lighter than the dark strokes at the extremity, or than the shadow received near the cylinder. This appearance is represented in Plate CCCLXXVI. fig. 3. Fig. 5.

As the cylinder was removed to a greater distance from the paper, the two black lines continued to be nearly of the same breadth, and the same degree of obscurity; but the penumbra in the middle grew lighter, and its breadth diminished, so that the two dark lines at the extremity of the shadow approached one another, till at the distance of 60 inches, they coincided, and the penumbra in the middle entirely vanished. At a still greater distance a faint penumbra was visible; but it was ill defined, and grew broader as the cylinder was removed farther off, but was sensible at a very great distance.

Besides the black and dark shadow which the cylinder formed near the opaque body, a narrow and faint penumbra was seen on the outside of the dark shadow. And on the outside of this there was a tract more strongly illuminated than the rest of the paper.

The breadth of the external penumbra increased with the distance of the shadow from the cylinder, and the breadth of the tract of light on the outside of it was also enlarged; but its splendour diminished with the distance.

He repeated these experiments with three other cylinders of different dimensions; and from all of them he inferred, that every opaque cylindrical body, exposed to the light of the sun, makes a shadow which is black and dark to the distance of 38 to 45 diameters of the cylinder which forms it; and that, at a greater distance, the middle part begins to be illuminated in the manner described above.

In explaining these appearances, Maraldi supposes that

History.

that the light which diluted the middle part of the shadow was occasioned by the inflection of the rays, which, bending inwards on their near approach to the body, did at a certain distance enlighten all the shadow, except the edges, which were left undisturbed. At the same time other rays were deflected from the body, and formed a strong light on the outside of the shadow, and which might at the same time contribute to dilute the outer shadow, though he supposed that penumbra to be occasioned principally by that part of the paper not being enlightened, except by a part of the sun's disk only, according to the known principles of optics.

54 Concerning those of globes.

The same experiments he made with globes of several diameters; but he found, that the shadows of the globes were not visible beyond 15 of their diameters; which he thought was owing to the light being inflected on every side of a globe, and consequently in such a quantity as to disperse the shadows sooner than in the case of the cylinders.

In repeating the experiments of Grimaldi and Newton, he observed that, besides the enlarged shadow of a hair, a fine needle, &c. the bright gleam of light that bordered it, and the three coloured fringes next to this enlightened part, when the shadow was at a considerable distance from the hair, the dark central shadow was divided in the middle by a mixture of light; and that it was not of the same density, except when it was very near the hair.

A bristle, at the distance of nine feet from the hole, made a shadow, which, being received at five or six feet from the object, he observed to consist of several streaks of light and shade. The middle part was a faint shadow, or rather a kind of penumbra, bordered by a darker shadow, and after that by a narrower penumbra; next to which was a light streak broader than the dark part, and next to the streak of light, the red, violet, and blue colours were seen as in the shadow of the hair.

55 Experiments concerning the shadows of plates.

A plate, two inches long, and about half a line broad, being fixed perpendicularly to the rays, at the distance of nine feet from the hole, a faint light was seen uniformly dispersed over the shadow, when it was received perpendicularly to it, and very near. The shadow of the same plate, received at the distance of two feet and a half, was divided into four narrow black streaks, separated by small lighter intervals equal to them. The boundaries of this shadow on each side had a penumbra, which was terminated by a very strong light, next to which were the coloured streaks of red, violet, and blue, as before. This is represented in Plate CCLXXVI. fig. 4. Fig. 4.

The shadow of the same plate, at $4\frac{1}{2}$ feet distance from it, was divided into two black streaks only, the two outermost having disappeared, as in fig. 5.; but these two black streaks which remained were broader than before, and separated by a lighter shade, twice as broad as one of the former black streaks, when the shadow was taken at $2\frac{1}{2}$ feet. This penumbra in the middle had a tinge of red. After the two black streaks there appeared a pretty strong penumbra, terminated by the two streaks of light, which were now broad and splendid, after which followed the coloured streaks. Fig. 5.

A second plate, 2 inches long and a line broad, being placed 14 feet from the hole, its shadow was received perpendicularly very near the plate, and was found to be illuminated by a faint light, equally dispersed, as in the case of the preceding plate. But being received at the distance of 13 feet from the plate, six small black streaks began to be visible, as in fig. 6. At 17 feet the black streaks were broader, more distinct, and more separated from the streaks that were less dark. At 42 feet, only two black streaks were seen in the middle of the penumbra, as in fig. 7. This middle penumbra between the two black streaks was tinged with red. Next to the black streaks there always appeared the streaks of light, which were broad, and the coloured streaks next to them. At the distance of 72 feet, the appearances were the same as in the former situation, except that the two black streaks were broader, and the interval between them, occupied by the penumbra, was broader also, and tinged with a deeper red. With plates from $\frac{1}{4}$ line to 2 lines broad, he could not observe any of the streaks of light, though the shadows were in some cases 56 feet from them. Fig. 6. Fig. 7.

The extraordinary size of the shadows of small substances M. Maraldi thought to be occasioned by the shadow from the enlightened part of the sky, added to that which was made by the light of the sun, and also to a vortex occasioned by the circulation of the inflected light behind the object.

Maraldi having made the preceding experiments upon single long substances, placed two of them so as to cross one another in a beam of the sun's light. The shadows of two hairs placed in this manner, and received at some distance from them, appeared to be painted reciprocally one upon the other, so that the obscure part of one of them was visible upon the obscure part of the other. The streaks of light also crossed one another, and the coloured streaks did the same.

He also placed in the rays of the sun a bristle and a plate of iron a line thick, so that they crossed one another obliquely; and when their shadows were received at the same distance, the light and dark streaks of the shadow of the bristle were visible so far as the middle of the shadow of the plate on the side of the acute angle, but not on the side of the obtuse angle, whether the bristle or the plate were placed next to the rays. The plate made a shadow sufficiently dark, divided into six black streaks; and these were again divided by as many light ones equal to them; and yet all the streaks belonging to the shadow of the bristle were visible upon it, as in fig. 8. To explain this appearance, he supposed that the rays of the sun glided a little along the bristle, so as to enlighten part of that which was behind the plate. But this seems to be an arbitrary and improbable supposition. Fig. 8.

M. Maraldi also placed small globes in the solar light, admitted through a small aperture, and compared their shadows with those of the long substances, as he had done in the day light, and the appearances were still similar. It was evident, that there was much more light in the shadows of the globes than in those of the cylinders, not only when they were both of an equal diameter, but when that of the globe was larger than that of the cylinder, and the shadows of both the bodies were received at the same distance. He also observed, that he could perceive no difference of light in the shadows of

History.

of the plates which were a little more than one line broad, though they were received at the distance of 72 feet; but he could observe a difference of shades in those of the globes, taken at the same distance, though they were $2\frac{1}{4}$ lines in diameter.

In order to explain the colours at the edges of these shadows, he threw some of the shadows upon others.

56 Experiments with a mixture of coloured shadows.

He threw the gleam of light, which always intervened between the colours and the darker part of the shadow, upon different parts of other shadows; and observed, that, when it fell upon the exterior penumbra made by another needle, it produced a beautiful sky blue colour, almost like that which was produced by two blue colours thrown together. When the same gleam of light fell upon the deeper shadow in the middle, it produced a red colour.

He placed two plates of iron, each three or four lines broad, at a very small distance: and having placed them in the rays of the sun, and received their shadows at the distance of 15 or 20 feet from them, he saw no light between them but a continued shadow, in the middle of which were some parallel streaks of a lively purple, separated by other black streaks; but between them there were other streaks, both of a very faint green, and also of a pale yellow.

57 M. Mairan's theory.

The subject of inflection was next investigated by M. Mairan: but he only endeavoured to explain the facts which were known, by the hypothesis of an atmosphere surrounding all bodies; and consequently making two reflections and refractions of the light that falls upon them, one at the surface of the atmosphere, and the other at that of the body. This atmosphere he supposed to be of a variable density and refractive power, like the atmosphere.

58 Discoveries of M. Du Tour.

M. Du Tour thought the variable atmosphere superfluous, and attempted to account for all the phenomena by an atmosphere of an uniform density, and of a less refractive power than the air surrounding all bodies.

Only three fringes had been observed by preceding authors, but M. Du Tour was accidentally led to observe a greater number of them, and adopted from Grimaldi the following ingenious method of making them all appear very distinct.

Plate CCCLXXVI. fig. 9.

He took a circular board ABED, (fig. 9.) 13 inches in diameter, the surface of which was black, except at the edge, where there was a ring of white paper about three lines broad, in order to trace the circumference of a circle, divided into 360 degrees, beginning at the point A, and reckoning 180 degrees on each hand to the point E; B and D being each of them placed at 90 degrees. A slip of parchment 3 inches broad, and disposed in the form of a hoop, was fastened round the board, and pierced at the point E with a square hole, each side being 4 or 5 lines, in order to introduce a ray of the sun's light; and in the centre of the board C, he fixed a perpendicular pin about $\frac{1}{5}$ of a line in diameter.

This hoop being so placed, that a ray of light entering the chamber, through a vertical cleft of $2\frac{1}{3}$ lines in length, and about as wide as the diameter of the pin, went through the hole at E, and passing parallel to the plane of the board, projected the image of the sun and the shadow of the pin at A. In these circumstances he observed, 1. That quite round the concave surface of this hoop, there were a multitude of coloured streaks; but that the space m A n, of about 18 degrees, the middle of which was occupied by the image of the sun, was covered with a faint light only. 2. The order of the colours in these streaks was generally such that the most refrangible rays were the nearest to the incident ray ECA; so that, beginning from the point A, the violet was the first and the red the last colour in each of the streaks. In some of them, however, the colours were disposed in a contrary order. 3. The image of the sun, projected on each side of the point A, was divided by the shadow of the pin, which was bordered by two luminous streaks. 4. The coloured streaks were narrower in some parts of the hoop than others, and generally decreased in breadth in receding from the point A. 5. Among these coloured streaks, there were sometimes others which were white, 1 or $1\frac{1}{2}$ lines in breadth, which were generally bordered on both sides by a streak of orange colour.

From this experiment he thought it evident, that the rays which passed beyond the pin were not the only ones that were decomposed, for that those which were reflected from the pin were decomposed also, whence he concluded that they must have undergone some refraction. He also imagined that those which went beyond the pin suffered a reflection, so that they were all affected in a similar manner.

In order to give some idea of his hypothesis, M. Du Tour shows that the ray a b, fig. 10. after being refracted at b, reflected at r and u, and again refracted at s and t, will be divided into its proper colours; the least refrangible or the red rays issuing at x, and the most refrangible or violet at y. Those streaks in which the colours appear in a contrary order he thinks are to be ascribed to inequalities in the surface of the pin.

The coloured streaks nearest the shadow of the pin, he supposes to be formed by those rays which, entering the atmosphere, do not fall upon the pin; and, without any reflection, are only refracted at their entering and leaving the atmosphere, as at b and r u, fig. 11. In this case, the red or least refrangible rays will issue at r, and the violet at u.

To distinguish the rays which fell upon the hoop in any particular direction, from those that came in any other, he made an opening in the hoop, as at P, fig. 9. by which means he could, with advantage, and at any distance from the centre, observe those rays unmixed with any other.

To account for the coloured streaks being larger next the shadow of the pin, and growing narrower to the place where the light was admitted, he shows, by fig. 12. that the rays a b are farther separated by both the refractions than the rays c d.

Sometimes M. Du Tour observed, that the broader streaks were not disposed in this regular order; but then he found, that by turning the pin they changed their places, so that this circumstance must have been an accidental irregularity in the surface of the pin.

The white streaks mixed with the coloured ones he ascribes to small cavities in the surface of the pin; for they also changed their places when the pin was turned upon its axis.

He also found, that bodies of various kinds, and of different sizes, always produced fringes of the same dimensions.

Exposing two pieces of paper in the beam of light, so that part of it passed between two planes formed by them,

History.

them, M. du Tour observed, that the edges of this light were bordered with two orange streaks. To account for them, he supposes, that the more refrangible of the rays which enter at *b* are so refracted, that they do not reach the surface of the body at R: so that the red and orange light may be reflected from thence in the direction *d* M, where the orange streaks will be formed; and, for the same reason, another streak of orange will be formed at *m*, by the rays which enter the atmosphere on the other side of the chink. In a similar manner he accounts for the orange fringes at the borders of the white streaks, in the experiment of the hoop. He supposes, that the blue rays, which are not reflected at R, pass on to I; and that these rays form the blue tinge observable in the shadows of some bodies. This, however, is mere trifling.

Fig. 13.

60
This hypothesis useless and ill-founded.

We may here make a general observation, applicable to all the attempts of philosophers to explain these phenomena by atmospheres. These attempts gave no explanation whatever of the physical cause of the phenomena. A phenomenon is some individual fact or event in nature. We are said to explain it, when we point out the general fact in which it is comprehended, and show the manner in which it is so comprehended, or the particular modification of the general fact. Philosophy resembles natural history, having for its subject the *events* of nature; and its investigations are nothing but the classification of these events, or the arrangement of them under the general facts of which they are individual instances. In the present instance there is no general fact referred to. The atmosphere is a mere gratuitous supposition; and all that is done is to show a resemblance between the phenomena of inflection of light to what would be the phenomena were bodies surrounded with such atmospheres; and even in this point of view, the discussions of Marian and Du Tour are extremely deficient. They have been satisfied with very vague resemblances to a fact observed in one single instance, namely, the refraction of light through the atmosphere of this globe.

The attempt is to explain how light is turned out of its direction by passing near the surface of bodies. This indicates the action of forces in a direction transverse to that of the light. Newton took the right road of investigation, by taking the phenomenon in its original simplicity, and attending merely to this, that the rays are deflected from their former course; and the sole aim of his investigation was to discover the laws, or the more general facts in this deflection. He deduced from the phenomena, that some rays are more deflected than others, and endeavoured to determine in what rays the deflections are most remarkable: and no experiment of M. du Tour has shown that he was mistaken in his modified assertion, that those rays are most inflected which pass nearest to the body. We say modified assertion; for Newton points out with great sagacity many instances of alternate fits of inflection and deflection; and takes it for granted, that the law of continuity is observed in these phenomena, and that the change of inflection into deflection is gradual.

But these analogical discussions are eminently deficient in another respect: They are held out as mechanical explanations of the changes of motion observed in rays of light. When it shall be shewn, that these are precisely such as are observed in refracting atmospheres, nothing is done towards deciding the original question; for the action of refracting atmospheres presents it in all its difficulties, and we must still ask how do these atmospheres produce this effect? No advance whatever is gained in science by thrusting in this hypothetical atmosphere; and Newton did wisely in attaching himself to the simple fact: and he thus gives us another step in science, by showing us a fact unknown before, viz. that the action of bodies on light is not confined to transparent bodies. He adds another general fact to our former stock, *that light as well as other matter is acted on at a distance;* and thus he made a very important deduction, *that reflection, refraction, and inflection, are probably brought about by the same forces.*

61
Reflection, refraction, and inflection probably produced by the same forces.

62
Objects sometimes magnified by inflection.

M. Le Cat has well explained a phenomenon of vision depending upon the inflection of light, which shows, that, in some cases objects by this means appear magnified. Looking at a distant steeple, when a wire, of a less diameter than the pupil of his eye, was held near to it, and drawing it several times betwixt his eye and that object, he found, that, every time the wire passed before his pupil, the steeple seemed to change its place, and some hills beyond the steeple appeared to have the same motion, just as if a lens had been drawn betwixt his eye and them. He found also, that there was a position of the wire in which the steeple seemed not to have any motion, when the wire was passed before his eye; and in this case the steeple appeared less distinct and magnified. He then placed his eye in such a manner with respect to the steeple, that the rays of light by which he saw it must come very close to the edge of a window; where he had placed himself to make his observations; and passing the wire before his eyes, he observed, that when it was in the visual axis, the steeple appeared nearer to the window, on whichever side the wire was made to approach. He repeated this experiment, and always, with the same result, the object being by this means magnified, and nearly doubled.

Plate CCCLXXVI. fig. 14.

This phenomenon he explains by fig. 14. in which B represents the eye, A the steeple, and C a section of the wire. The black lines express the cone of light by which the natural image of the steeple A is formed, and which is much narrower than the diameter of the wire C; but the dotted lines include not only that cone of light, stopped and turned out of its course by the wire, but also more distant rays inflected by the wire, and thereby thrown more converging into the pupil; just as would have been the effect of the interposition of a lens between the eye and the object.

Sect. IV. *Discoveries concerning Vision.*

63
Discoveries of Maurolycus, Kepler, &c. concerning vision.

Maurolycus was the first who demonstrated that the crystalline humour of the eye is a lens which collects the light issuing from external objects, and converges them upon the retina. He did not, however, seem to be aware that an image of every visible object was thus formed upon the retina, though this seems hardly to have been a step beyond the discovery he had made. Montucla conjectures, that he was prevented from mentioning this part of the discovery by the difficulty of accounting for the upright appearance of objects. This discovery was made by Kepler; but he, too, was much puzzled with the inversion of the image upon the retina.

History.

na. The rectification of these images, he says, is the business of the mind; which, when it perceives an impression on the lower part of the retina, considers it as made by rays proceeding from the higher parts of objects; tracing the rays back to the pupil, where they cross one another. This is the true explanation of the difficulty, and is exactly the same as that which was lately given by Dr Reid.

64 Discoveries of Scheiner.

These discoveries concerning vision were completed by Scheiner. For, in cutting away the coats of the back part of the eyes of sheep and oxen, and presenting several objects before them, he saw their images distinctly painted upon the retina. He did the same with the human eye, and exhibited this experiment at Rome in 1625.

Scheiner took a good deal of pains to ascertain the density and refractive power of all the humours of the eye, by comparing their magnifying power with that of water or glass in the same form and circumstances. The result of his inquiries was, that the aqueous humour does not differ much from water in this respect, nor the crystalline from glass; and that the vitreous humour is a medium between both. He also traces the progress of the rays of light through all the humours; and after discussing every possible hypothesis concerning the seat of vision, he demonstrates that it is in the retina, and shows that this was the opinion of Alhazen, Vitellio, Kepler, and all the most eminent philosophers. He advances many reasons for this hypothesis; answers many objections to it; and, by a variety of arguments, refutes the opinion that the seat of vision is in the crystalline lens.

65 Discoveries of Descartes.

The subject of vision occupied the attention of Descartes. He explains the methods of judging of the magnitudes, situations, and distances, of objects, by the direction of the optic axes; comparing it to a blind man's judging of the size and distance of an object, by feeling it with two sticks of a known length, when the hands in which he holds them are at a known distance from each other. He also remarks, that having been accustomed to judge of the situation of objects by their images falling on a particular part of the eye; if by any distortion of the eye they fall on a different place, we are apt to mistake their situation, or imagine one object to be two, in the same way as we imagine one stick to be two, when it is placed between two contiguous fingers laid across one another. The direction of the optic axes, he says, will not serve us beyond 15 or 20 feet, and the change of form of the crystalline not more than three or four feet. For he imagined that the eye conforms itself to different distances by a change in the curvature of the crystalline, which he supposed to be a muscle, the tendons of it being the ciliary processes. In another place, he says, that the change in the conformation of the eye is of no use to us for the purpose of judging of distances beyond four or five feet, and the angle of the optic axes not more than 100 or 200 feet: for this reason, he says, that the sun and moon are conceived to be much more nearly of the same size than they are in reality. White and luminous objects, he observes, appear larger than others, and also the parts contiguous to those on which the rays actually impinge; and for the same reason, if the objects be small, and placed at a great distance, they will always appear round, the figure of the angles disappearing.

66 Berkeley's theory of vision.

The celebrated Dr Berkeley, bishop of Cloyne, published, in 1709, An Essay towards a New Theory of Vision, in which he solves many difficulties. He does not admit that it is by means of those lines and angles, which are useful in explaining the theory of optics, that different distances are estimated by the sense of sight; neither does he think that the mere direction of the optic axes, or the greater or less divergency of the rays of light, are sufficient for this purpose. "I appeal (says he) to experience, whether any one computes distance by the bigness of the angle made by the meeting of the two *optic axes*; or whether he ever thinks of the greater or less divergency of the rays which arrive from any point to his pupil: Nay, whether it be not perfectly impossible for him to perceive, by sense, the various angles wherewith the rays according to their greater or lesser divergency fell upon his eye." That there is a necessary connexion between these various angles, &c. and different degrees of distance, and that this connexion is known to every person skilled in optics, he readily acknowledges; but "in vain (he observes) shall mathematicians tell me, that I *perceive* certain *lines* and *angles*, which introduce into my mind the various notions of *distance*, so long as I am conscious of no such thing." He maintains that distance, magnitude, and even figure, are the objects of immediate perception only by the sense of touch; and that when we judge of them by sight, it is from different sensations felt in the eye, which experience has taught us to be the consequence of viewing objects of greater or less magnitude, of different figures, and at different distances. These sensations, with the respective distances, figures, and magnitudes by which they are occasioned, become so closely associated in the mind long before the period of distinct recollection, that the presence of the one instantly suggests the other; and we attribute to the sense of sight those notions which are acquired by the sense of touch, and of which certain *visual* sensations are merely the signs or symbols, just as words are the symbols of ideas. Upon these principles he accounts for single and erect vision. Subsequent writers have made considerable discoveries in the theory of vision; and among them there is hardly any one to whom this branch of science is so much indebted as to Dr Reid, and Dr Wells, whose reasonings we shall afterwards have occasion to detail.

Sect. V. *Of Optical Instruments.*

67 Invention of spectacles.

Glass globes, and specula, seem to have been the only optical instruments known to the ancients. Alhazen gave the first hint of the invention of spectacles. From the writings of this author, together with the observations of Roger Bacon, it is not improbable that some monks gradually hit upon the construction of spectacles; to which Bacon's lesser segment was a nearer approach than Alhazen's larger one.

It is certain that spectacles were well known in the 13th century, and not long before. It is said that Alexander Spina, a native of Pisa, who died in 1313, happened to see a pair of spectacles in the hands of a person who would not explain them to him; but that he succeeded in making a pair for himself, and immediately made the construction public. It is also inscribed on the tomb of Salvinus Armatus, a nobleman of Florence, who died 1317, that he was the inventor of spectacles.

Though

History.

68 Descartes's account of the invention of telescopes.

Though both convex and concave lenses were sufficiently common, yet no attempt was made to combine them into a telescope till the end of the 16th century. Descartes considers James Metius as the first constructor of the telescope: and says, that as he was amusing himself with mirrors and burning glasses, he thought of looking through two of his lenses at a time; and that happening to take one that was convex and another that was concave, and happening also to hit upon a pretty good adjustment of them, he found, that by looking through them, distant objects appeared very large and distinct. In fact, without knowing it, he had made a telescope.

69 Other accounts.

Other persons say, that this great discovery was first made by John Lippersheim, a spectacle-maker at Middleburgh, or rather by his children; who were diverting themselves with looking through two glasses at a time, and placing them at different distances from one another. But Borellus, the author of a book entitled *De vero telescopii inventore*, gives this honour to Zacharius Joannides, i. e. Jansen, another spectacle-maker at the same place, who made the first telescope in 1590.

This ingenious mechanic had no sooner found the arrangement of glasses that magnified distant objects, than he enclosed them in a tube, and ran with his instrument to Prince Maurice; who, immediately conceiving that it might be useful in his wars, desired the author to keep it a secret. But this was found impossible; and several persons in that city immediately applied themselves to the making and selling of telescopes. One of the most distinguished of these was Hans Laprey, called *Lippersheim* by Sirturus. Some person in Holland being very early supplied by him with a telescope, he passed with many for the inventor; but both Metius above mentioned, and Cornelius Drebell of Alcmaar, in Holland, applied to the inventor himself in 1620; as also did Galileo, and many others. The first telescope made by Jansen did not exceed 15 or 16 inches in length; but Sirturus, who says that he had seen it, and made use of it, thought it the best that he had ever examined.

70 The first telescope an exceedingly good one.

Jansen directing his telescope to celestial objects, distinctly viewed the spots on the surface of the moon; and discovered many new stars, particularly seven pretty considerable ones in the Great Bear. His son, Joannes Zacharias, observed the lucid circle near the limb of the moon, from whence several bright rays seem to dart in different directions: and he says, that the full moon, viewed through this instrument, did not appear flat, but was evidently globular. Jupiter appeared round, and rather spherical; and sometimes he perceived two, sometimes three, and at other times even four small stars, a little above or below him; and, as far as he could observe, they performed revolutions round him.

71 A telescope made by Galileo without seeing one.

There are some who say that Galileo was the inventor of telescopes; but he himself acknowledges, that he first heard of the instrument from a German; but, that being informed of nothing more than the effects of it, first by common report, and a few days after by a French nobleman, J. Badovere, at Paris, he himself discovered the construction, by considering the nature of refraction: and thus he had much more real merit than the inventor himself.

About April or May, in 1609, it was reported at Venice, where Galileo (who was professor of mathematics in the university of Padua) then happened to be, that a Dutchman had presented to Count Maurice of Nassau, a certain optical instrument, by means of which, distant objects appeared as if they were near; but no farther account of the discovery had reached that place, though this was near 20 years after the first discovery of the telescope. Struck, however, with this account, Galileo returned to Padua, considering what kind of an instrument this must be. The night following, the construction occurred to him; and the day after, putting the parts of the instrument together, as he had previously conceived it; and notwithstanding the imperfection of the glasses that he could then procure, the effect answered his expectations, as he presently acquainted his friends at Venice, where, from several eminences, he showed to some of the principal senators of that republic a variety of distant objects, to their very great astonishment. When he had made farther improvements in the instrument, he made a present of one of them to the Doge, Leonardo Donati, and at the same time to all the senate of Venice; giving along with it a written paper, in which he explained the structure and wonderful uses that might be made of the instrument both by land and sea. In return for so noble an entertainment, the republic, on the 25th of August, in the same year, more than tripled his salary as professor.

History.

72 Account of his discoveries.

Galileo having amused himself for some time with the view of terrestrial objects, at length directed his tube towards the heavens; and found, that the surface of the moon was diversified with hills and valleys, like the earth. He found that the milky way and *nebulæ* consisted of a collection of fixed stars, which on account either of their vast distance, or extreme smallness, were invisible to the naked eye. He also discovered innumerable fixed stars dispersed over the face of the heavens, which had been unknown to the ancients; and examining Jupiter, he found him attended by four stars, which, at certain periods, performed revolutions round him.

This discovery he made in January 1610, new style; and continuing his observations the whole of February following, he published, in the beginning of March, an account of all his discoveries, in his *Nuncius Sidereus*, printed at Venice.

The extraordinary discoveries contained in the Nuncius Sidereus, which was immediately reprinted both in Germany and France, were the cause of much debate among the philosophers of that time; many of whom could not give any credit to Galileo's account, while others endeavoured to decry his discoveries as nothing more than mere illusions.

In the beginning of July, 1610, Galileo being still at Padua, and getting an imperfect view of Saturn's ring, imagined that that planet consisted of three parts; and therefore, in the account which he gave of this discovery to his friends, he calls it *planetam tergeminam*.

Whilst he was still at Padua, he observed some spots on the face of the sun: but he did not choose, at that time, to publish his discovery; partly for fear of incurring more of the hatred of many obstinate Peripatetics; and partly in order to make more exact observations on this remarkable phenomenon, as well as to form some conjecture concerning the probable cause of it. He therefore contented himself with communicating his observations to some of his friends at Padua and Venice,

among

among whom we find the name of Father Paul. This delay, however, was the cause of this discovery being contested with him by the famous Scheiner, who likewise made the same observation in October 1611, and we suppose had anticipated Galileo in the publication of it.

In November following Galileo was satisfied, that, from the September preceding, Venus had been continually increasing in bulk, and that she changed her phases like the moon. About the end of March 1611, he went to Rome, where he gratified the cardinals, and all the principal nobility, with a view of the new wonders which he had discovered in the heavens.

Twenty-nine years Galileo enjoyed the use of his telescope, continually enriching astronomy with his observations: but by too close an application to that instrument, and the detriment he received from the nocturnal air, his eyes grew gradually weaker, till in 1639 he became totally blind; a calamity which, however, neither broke his spirits, nor interrupted the course of his studies.

73 Account of his telescopes.

The first telescope that Galileo constructed magnified only three times; but presently after, he made another which magnified 18 times; and afterwards with great trouble and expence, he constructed one that magnified 33 times; and with this it was that he discovered the satellites of Jupiter and the spots of the sun.

74 The *rationale* of the instrument first discovered by Kepler.

The honour of explaining the rationale of the telescope is due to the celebrated Kepler. He made several discoveries relating to the nature of vision; and not only explained the theory of the telescope which he found in use, but also pointed out methods of constructing others of superior powers and more commodious application.

It was Kepler who first gave a clear explication of the effects of lenses, in converging and diverging the rays of a pencil of light. He showed, that a plano-convex lens makes rays that were parallel to its axis, to meet at the distance of the diameter of the sphere of convexity; but that if both sides of the lens be equally convex, the rays will have their focus at the distance of the radius of the circle, corresponding to that degree of convexity. He did not, however, investigate any rule for the foci of lenses unequally convex. He only says, in general, that they will fall somewhere in the middle, between the foci belonging to the two different degrees of convexity. We owe this investigation to Cavalieri, who laid down the following rule: As the sum of both the diameters is to one of them, so is the other to the distance of the focus.

75 General reason of the effects of telescopes.

The principal effects of telescopes depend upon these simple principles, viz. That objects appear larger in proportion to the angles which they subtend at the eye; and the effect is the same whether the pencils of rays, by which objects are visible to us, come directly from the objects themselves, or from any place nearer to the eye, where they may have been converged so as to form an image of the object; because they issue again from those points where there is no real substance, in certain directions, in the same manner as they did from the corresponding points in the objects themselves.

In fact, therefore, all that is effected by a telescope is, first, to make such an image of a distant object, by means of a lens or mirror; and then to give the eye some assistance for viewing that image as near as possible: so that the angle which it shall subtend at the eye, may be very large, compared with the angle which the object itself would subtend in the same situation. This is done by means of an eye-glass, which so refracts the pencils of rays, that they may afterwards be brought to their several foci by the humours of the eye. But if the eye was so formed as to be able to see the image with sufficient distinctness at the same distance without any eye-glass, it would appear to him as much magnified as it does to another person who makes use of a glass for that purpose, though he would not in all cases have so large a field of view.

If, instead of an eye-glass, an object be looked at through a small hole in a thin plate or piece of paper, held close to the eye, it may be viewed very near to the eye, and, at the same distance, the apparent magnitude of the object will be the same in both cases. For if the hole be so small as to admit but a single ray from every point of the object, these rays will fall upon the retina in as many other points, and make a distinct image. They are only pencils of rays, which have a sensible base, as the breadth of the pupil, that are capable, by their spreading on the retina, of producing an indistinct image. As very few rays, however, can be admitted through a small hole, there will seldom be light sufficient to view any object to advantage in this manner.

If no image be formed by the foci of the pencils without the eye, yet if, by the help of a concave eye-glass, the pencils of rays shall enter the pupil, just as they would have done from any place without the eye, the visual angle will be the same as if an image had actually been formed in that place. Objects will not appear inverted through this telescope, because the pencils which form the images of them, only cross one another once, viz at the object glass, as in natural vision they do in the pupil of the eye.

Such is the telescope that was first discovered and used by philosophers. The great inconvenience attending it is, that the field of view is exceedingly small. For since the pencils of rays enter the eye very much diverging from one another, but few of them can be intercepted by the pupil. This inconvenience increases with the magnifying power of the telescope; so that it is a matter of surprise how, with such an instrument, Galileo and others could have made such discoveries. No other telescope, however, than this, was so much as thought of for many years after the discovery. Descartes, who wrote 30 years after, mentions no others as actually constructed.

76 Galilean telescope more difficult of construction than others.

It is to the celebrated Kepler that we are indebted for the construction of what we now call the *astronomical telescope*. The *rationale* of this instrument is explained, and the advantages of it are clearly pointed out, by this philosopher, in his Catoptrics; but, what is very surprising, he never actually reduced his theory into practice. Montucla conjectures, that the reason why he did not make trial of this new construction was, his not being aware of the great increase of the field of view; so that being engaged in other pursuits, he might not think it of much consequence to take any pains about the construction of an instrument, which could do little more than answer the same purpose with those which he already possessed. He must also have foreseen, that the length,

77 Telescopes improved by Kepler.

History.

length of this telescope must have been greater in proportion to its magnifying power, so that it might appear to him to be upon the whole not quite so good a construction as the former.

78 His method first put in practice by Scheiner.

The first person who actually made an instrument of Kepler's construction was Father Scheiner, who has given a description of it in his *Rosa Ursina*, published in 1630. If, says he, you insert two similar lenses in a tube, and place your eye at a convenient distance, you will see all terrestrial objects, inverted, indeed, but magnified, and very distinct, with a considerable extent of view. He afterwards subjoins an account of a telescope of a different construction, with two convex eye-glasses, which again reverses the images, and makes them appear in their natural position. This disposition of the lenses had also been pointed out by Kepler, but had not been reduced to practice. This construction, however, answered the end very imperfectly; and Father Rheita presently after discovered a better construction, using three eye-glasses instead of two.

The only difference between the Galilean and the astronomical telescope is, that the pencils by which the extremities of any object are seen in this case, enter the eye diverging; whereas, in the other they enter it converging; but if the sphere of concavity in the eye-glass of the Galilean telescope be equal to the sphere of convexity in the eye-glass of another telescope, their magnifying power will be the same. The concave eye-glass, however, being placed between the object-glass and its focus, the Galilean telescope will be shorter than the other, by twice the focal length of the eye-glass. Consequently, if the length of the telescopes be the same, the Galilean will have the greater magnifying power.

79 Huygens improves the telescopes of Scheiner and Rheita.

Huygens was particularly eminent for his systematic knowledge of optics, and is the author of the chief improvements which have been made on all the dioptrical instruments till the discovery of the achromatic telescope. He was well acquainted with the theory of aberration arising from the spherical figure of the glasses, and has shown several ingenious methods of diminishing them by proper constructions of the eye-pieces. He first pointed out the advantages of two eye glasses in the astronomical telescope and double microscope, and gave rules for this construction, which both enlarges the field and shortens the instrument. Mr Dollond adapted his construction to the terrestrial telescope of De Rheita; and his five eye-glasses are nothing but the Huygenian eye-piece doubled. This construction has been too hastily given up by the artists of the present day for another, also of Mr Dollond's, of four glasses.

80 Binocular telescope.

The same Father Rheita, to whom we are indebted for the construction of a telescope for land objects, invented a binocular telescope, which Father Cherubin, of Orleans, afterwards endeavoured to bring into use. It consists of two telescopes fastened together, pointed to the same object. When this instrument is well fixed, the object appears larger, and nearer to the eye, when it is seen through both the telescopes, than through one of them only, though they have the very same magnifying power. But this is only an illusion, occasioned by the stronger impression made upon the eye, by two equal images, equally illuminated. This advantage, however, is counterbalanced by the inconvenience attending the use of it.

81 Telescopes of Campani and Divini.

The first who distinguished themselves in grinding telescopic glasses were two Italians, Eustachio Divini at Rome, and Campani at Bologna, whose fame was much superior to that of Divini, or that of any other person of his time; though Divini himself pretended, that, in all the trials that were made with their glasses, his, of a greater focal length, performed better than those of Campani, and that his rival was not willing to try them with equal eye-glasses. It is generally supposed, however, that Campani really excelled Divini, both in the goodness and the focal length of his object-glasses. It was with telescopes made by Campani that Cassini discovered the nearest satellites of Saturn. They were made by the express order of Louis XIV. and were of 86, 100, and 136 Paris feet in focal length.

Campani sold his lenses for a great price, and took every possible method to keep his art of making them secret. His laboratory was inaccessible, till after his death; when it was purchased by Pope Benedict XIV. who presented it to the academy called the *Institute*, established in that city; and by the account which M. Fougeroux has given of what he could discover from it, we learn, that (except a machine, which M. Campani constructed, to work the basons on which he ground his glasses) the goodness of his lenses depended upon the clearness of his glass, his Venetian tripoli, the paper with which he polished them, and his great skill and address as a workman. It was also the general opinion that he owed much of his reputation to the secrecy and air of mystery which he affected; and that he made a great number of object-glasses which he rejected, showing only those that were very good. He made few lenses of a very great focal distance; and having the misfortune to break one of 141 feet in two pieces, he took incredible pains to join the two parts together, which he did at length so effectually, that it was used as if it had been entire; but it is not probable that he would have taken so much pains about it, if, as he pretended, he could very easily have made another as good.

Sir Paul Neille, Dr Hooke says, made telescopes of 36 feet, pretty good, and one of 50, but not of proportional goodness. Afterwards Mr Reive, and then Mr Cox, who were the most celebrated in England as grinders of optic glasses, made some good instruments of 50 and 60 feet focal length, and Mr Cox made one of 100.

82. Extraordinary object-glass made by M. Auzout.

These, and all other telescopes, were far exceeded by an object glass of 600 feet focus made by M. Auzout; but he was never able to manage it. Hartsocker is even said to have made some of a still greater focal length; but this ingenious mechanic, finding it impossible to make use of object-glasses the focal distance of which was much less than this, when they were enclosed in a tube, contrived a method of using them without a tube, by fixing them at the top of a tree, a high wall, or the roof of a house.

83. Telescopes used without tubes.

Mr Huygens, who was also an excellent mechanic, made considerable improvements on this contrivance of Hartsocker's. He placed the object-glass at the top of a long pole, have previously enclosed it in a short tube, which was made to turn in all directions by means of a ball and socket. The axis of this tube he could command with a fine silken string, so as to bring it into a line with the axis of another short tube which he held in his hand, and which contained the eye-glass. In this method he could make use of object-glasses of the greatest

History. greatest magnifying power, at whatever altitude his object was, and even in the zenith, provided his pole was as long as his telescope; and to adapt it to the view of objects of different altitudes, he had a contrivance, by which he could raise or depress at pleasure, a stage that supported his object-glass.

M. de la Hire made some improvements in this method of managing the object-glass, by fixing it in the centre of a board, and not in a tube; but as it is not probable that this method will ever be made use of, since the discovery of both reflecting and achromatic telescopes, which are now brought to great perfection, and have even micrometers adapted to them, we shall not describe the apparatus minutely, but shall only give a drawing of M. Huygen's pole, with a short explanation. In fig. 1. *a* represents a pulley, by the help of which a stage *c*, *d*, *e*, *f*, (that supports the object-glass *k*, and the apparatus belonging to it), may be raised higher or lower at pleasure, the whole being counterpoised by the weight *h*, fastened to a string *g*. *n*, is a weight, by means of which the centre of gravity of the apparatus belonging to the object-glass is kept in the ball and socket, so that it may be easily managed by the string *l u*, and its axis brought into a line with the eye-glass at *o*. When it was very dark, M. Huygens was obliged to make his object-glass visible by a lantern, *y*, so constructed as to throw up to it the rays of light in a parallel direction.

Plate CCCLXXVII. fig. 1.

84
Of the apertures of refracting telescopes.

Before leaving this subject, it must be observed, that M. Auzout, in a paper delivered to the Royal Society, observed, that the apertures which the object-glasses of refracting telescopes can bear with distinctness, are in the subduplicate ratio of their lengths; and upon this supposition he drew up a table of the apertures of object-glasses of a great variety of focal lengths, from 4 inches to 400 feet. Upon this occasion, however, Dr Hooke observed, that the same glass will bear a greater or less aperture, according to the less or greater light of the object.

But all these improvements were diminished in value by the discovery of the *reflecting telescope*. For a refracting telescope, even of 1000 feet focus, supposing it possible to be made use of, could not be made to magnify with distinctness more than 1000 times; whereas a reflecting telescope, not exceeding 9 or 10 feet will magnify 1200 times.

85
History of the reflecting telescope.

"It must be acknowledged, says Dr Smith, that Mr James Gregory of Aberdeen was the first inventor of the reflecting telescope; but his construction is quite different from Sir Isaac Newton's, and not nearly so advantageous."

According to Dr Pringle, Mersennus was the man who entertained the first thought of a reflector. He certainly proposed a telescope with specula to the celebrated Descartes many years before Gregory's invention, though indeed in a manner so very unsatisfactory, that Descartes was so far from approving the proposal, that he endeavoured to convince Mersennus of its fallacy. Dr Smith, it appears, had never perused the two letters of Descartes to Mersennus which relate to that subject.

Gregory, a young man of uncommon genius, was led to the invention, in trying to correct two imperfections of the common telescope: the first was its too great length, which made it less manageable; the second, the incorrectness of the image. Mathematicians had demonstrated, that a pencil of rays could not be collected in a single point by a spherical lens; and also, that the image transmitted by such a lens would be in some degree incurvated. These inconveniences he believed would be obviated by substituting for the object-glass a metallic speculum, of a parabolic figure, to receive the incident rays, and to reflect them towards a small speculum of the same metal; this again was to return the image to an eye-glass placed behind the great speculum, which for that purpose was to be perforated in its centre. This construction he published in 1663, in his *Optica Promota*. But as Gregory, by his own account, was endowed with no mechanical dexterity, nor could find any workman capable of constructing his instrument, he was obliged to give up the pursuit: and probably, had not some new discoveries been made in light and colours, a reflecting telescope would never more have been thought of.

At an early period of life, Newton had applied himself to the improvement of the telescope; but imagining that Gregory's specula were neither very necessary, nor likely to be executed, he began with prosecuting the views of Descartes, who aimed at making a more perfect image of an object, by grinding lenses, not to the figure of a sphere, but to that of one of the conic sections. Whilst he was thus employed, three years after Gregory's publication, he happened to examine the colours, formed by a prism, and having by means of that simple instrument discovered the different refrangibility of the rays of light, he then perceived that the errors of telescopes arising from that cause alone, were some hundred times greater than those which were occasioned by the spherical figure of lenses. This circumstance forced, as it were, Newton to fall into Gregory's track, and to turn his thoughts to reflectors. "The different refrangibility of the rays of light (says he in a letter to Mr Oldenburg, secretary to the Royal Society, dated Feb. 1672) made me take reflections into consideration; and finding them regular, so that the angle of reflection of all sorts of rays was equal to the angle of incidence, I understood that by their mediation optic instruments might be brought to any degree of perfection imaginable, providing a reflecting substance could be found which would polish as finely as glass, and reflect as much light as glass transmits, and the art of communicating to it a parabolical figure be also obtained. Amidst these thoughts I was forced from Cambridge by the intervening plague, and it was more than two years before I proceeded further."

It was towards the end of 1668, or in the beginning of the following year, when Newton being obliged to have recourse to reflectors, and not relying on any artificer for making his specula, set about the work himself, and early in the year 1672 completed two small reflecting telescopes. In these he ground the great speculum into the concave portion of a sphere; not but that he approved of the parabolic form proposed by Gregory, though he found himself unable to accomplish it. In the letter that accompanied one of these instruments which he presented to the Society, he writes, "that though he then despaired of performing that work (to wit, the parabolic figure of the great speculum) by geometrical rules, yet he doubted not but that the thing might in some measure be accomplished by mechanical devices."

Not less did the difficulty appear to find a metallic substance

substance that would be of a proper hardness, have the fewest pores, and receive the smoothest polish; a difficulty which he deemed almost unsurmountable, when he considered, that every irregularity in a reflecting surface would make the rays of light stray five or six times more out of their due course, than similar irregularities in a refracting one. In another letter, written soon after, he informs the secretary, "that he was very sensible that metal reflects less light than glass transmits; but as he had found some metallic substances more strongly reflective than others, to polish better, and to be freer from tarnishing than others, so he hoped that there might in time be found out some substances much freer from these inconveniences than any yet known." Newton therefore laboured till he found a composition that answered in some degree, and left it to those who should come after him to find a better. Huygens, one of the greatest geniuses of the age, and a distinguished improver of the refracting telescope, no sooner was informed by Mr Oldenburg of the discovery, than he wrote in answer, "that it was an admirable telescope; and that Mr Newton had well considered the advantage which a concave speculum had over convex glasses in collecting the parallel rays, which, according to his own calculation, was very great: Hence that Mr Newton could give a far greater aperture to that speculum than to an object glass of the same focal length, and consequently produce a much greater magnifying power than by an ordinary telescope. Besides, that by the reflector he avoided an inconvenience inseparable from object glasses, which was the obliquity of both their surfaces, which vitiated the refraction of the rays that pass towards the side of the glass: Again, That by the mere reflection of the metalline speculum there were not so many rays lost as in glasses, which reflected a considerable quantity by each of their surfaces, and besides intercepted many of them by the obscurity of their substance: That the main business would be to find a substance for this speculum that would bear as good a polish as glass. Lastly, He believed that Mr Newton had not omitted to consider the advantage which a parabolic speculum would have over a spherical one in this construction; but had despaired, as he himself had done, of working other surfaces than spherical ones with exactness." Huygens was not satisfied with thus expressing to the society his high approbation of the invention; but drew up a favourable account of the new telescope, which he published in the *Journal des Sçavans* for 1672, by which channel it was soon known over Europe.

Excepting an unsuccessful attempt which the society made, by employing an artificer to imitate the Newtonian construction, but upon a larger scale, and a disguised Gregorian telescope, set up by Cassegrain abroad as a rival to Newton's, no reflector was heard of for nearly half a century after. But when that period was elapsed, a reflecting telescope of the Newtonian form was at last produced by Mr Hadley, the inventor of the reflecting quadrant. The two telescopes which Newton had made were but six inches long; they were held in the hand for viewing objects, and in power were compared to a six feet refractor; whereas Hadley's was about five feet long, was provided with a well-contrived apparatus for managing it, and equalled in performance the famous aërial telescope of Huygens of 123 feet in length. Excepting the manner of making the specula, we have, in the Philosophical Transactions of 1723, a complete description, with a figure of this telescope, together with that of the machine for moving it; but, by a strange omission, Newton's name is not once mentioned in that paper, so that any person not acquainted with the history of the invention, and reading that account only, might be apt to conclude that Hadley had been the sole inventor.

The same celebrated artist, after finishing two telescopes of the Newtonian construction, accomplished a third of the Gregorian form; but, it would seem, less successfully. Mr Hadley spared no pains to instruct Mr Molyneux and the Reverend Dr Bradley; and when those gentlemen had made a sufficient proficiency in the art, being desirous that these telescopes should become more public, they liberally communicated to some of the principal instrument-makers of London the knowledge they had acquired from him.

Mr James Short, as early as the year 1734, had signalized himself at Edinburgh by the excellence of his telescopes. Mr Maclaurin wrote that year to Dr Jurin, "that Mr Short, who had begun with making glass specula, was then applying himself to improve the metallic; and that by taking care of the figure, he was enabled to give them larger apertures than others had done; and that upon the whole they surpassed in perfection all that he had seen of other workmen." He added, "that Mr Short's telescopes were all of the Gregorian construction; and that he had much improved that excellent invention." This character of excellence Mr Short maintained to the last; and with the more facility, as he was well acquainted with the theory of optics. It was supposed that he had fallen upon a method of giving the parabolic figure to his great speculum; a point of perfection that Gregory and Newton had despaired of attaining; and that Hadley had never, as far as we know, attempted. Mr Short indeed affirmed, that he had acquired that faculty, but never would tell by what peculiar means he effected it; so that the secret of working that configuration, whatever it was, died with that ingenious artist. Mr Mudge, however, has lately realized the expectation of Sir Isaac Newton, who, above 100 years ago, presaged that the public would one day possess a parabolic speculum, not accomplished by mathematical rules, but by mechanical devices.

This was a *desideratum*, but it was not the only want supplied by this gentleman: he has taught us likewise a better composition of metals for the specula, how to grind them better, and how to give them a finer polish; and this last part (namely the polish), he remarks, was the most difficult and essential of the whole operation. "In a word (says Sir John Pringle), I am of opinion, there is no optician in this great city (which hath been so long, and so justly renowned for ingenious and dexterous makers of every kind of mathematical instruments) so partial to his own abilities as not to acknowledge, that Mr Mudge has opened to them all some new and important lights, and has greatly improved the art of making reflecting telescopes."

86 Mr Edwards's improvements of the reflecting telescope.

The late reverend and ingenious John Edwards devoted much of his time to the improvement of reflecting telescopes, and brought them to such perfection, History. fection, that Dr Maskelyne, the astronomer royal, found telescopes constructed by him to surpass in brightness, and other respects, those of the same size made by the best artists in London. The chief excellence of his telescopes arises from the composition, which, from various trials on metals and semimetals, he discovered for the specula, and from the true parabolic figure, which, by long practice, he had found a method of giving them, preferable to any that was known before him. His directions for the composition of specula, and for casting, grinding, and polishing them, were published, by order of the commissioners of longitude, at the end of the Nautical Almanack for the year 1787. To the same almanack is also annexed his account of the cause and cure of the tremors which particularly affect reflecting telescopes more than refracting ones, together with remarks on these tremors by Dr Maskelyne.

87 Herschel's improvements.

But in constructing reflecting telescopes of extraordinary magnifying powers, Dr Herschel has displayed skill and ingenuity surpassing all his predecessors in this department of mechanics. He has made them from 7, 10, 20, to even 40 feet in length; and with instruments of these dimensions he is now employed in making discoveries in astronomy. Of the construction, magnifying powers, and the curious collection of machinery by which his 40 feet telescope is supported and moved from one part of the heavens to another, accounts will be given under the word TELESCOPE.

The greatest improvement in *refracting* telescopes hitherto made public is that of Mr Dollond, of which an account has already been given in a preceding section, in which his discoveries in the science of Optics were explained. But, besides the obligation we are under to him for correcting the aberration of the rays of light in the focus of object-glasses, he made another considerable improvement in telescopes, viz. by correcting, in a great measure, both this kind of aberration, and also that which arises from the spherical form of lenses, by an expedient of a very different nature, viz. increasing the number of eye-glasses.

88 Account of Mr Dollond's improvements.

If any person, says he, would have the visual angle of a telescope to contain 20 degrees, the extreme pencils of the field must be bent or refracted in an angle of 10 degrees; which, if it be performed by one eye-glass, will cause an aberration from the figure, in proportion to the cube of that angle; but if two glasses be so proportioned and situated, as that the refraction may be equally divided between them, they will each of them produce a refraction equal to half the required angle; and therefore, the aberration being proportional to the cube of half the angle taken twice over, will be but a fourth part of that which is in proportion to the cube of the whole angle; because twice the cube of one is but $\frac{1}{4}$ of the cube of 2; so the aberration from the figure, where two eye-glasses are rightly proportioned, is but a fourth of what it must unavoidably be, where the whole is performed by a single eye-glass. By the same way of reasoning, when the refraction is divided between three glasses, the aberration will be found to be but the ninth part of what would be produced from a single glass; because three times the cube of 1 is but one-ninth of the cube of 3. Whence it appears, that by increasing the number of eye-glasses, the indistinctness which is observed near the borders of the field of a telescope may be very much diminished.

The method of correcting the errors arising from the different refrangibility of light is of a different consideration from the former. For, whereas the errors from the figure can only be diminished in a certain proportion according to the number of glasses, in this they may be entirely corrected by the addition of only one glass. Also in the day-telescope, where no more than two eye-glasses are absolutely necessary for erecting the object, we find, that by the addition of a third, rightly situated, the colours, which would otherwise make the image confused, are entirely removed. This, however, is to be understood with some limitation: for though the different colours into which the extreme pencils must necessarily be divided by the edges of the eye-glasses, may in this manner be brought to the eye in a direction parallel to each other, so as to be made to converge to a point on the retina; yet, if the glasses exceed a certain length, the colours may be spread too wide to be capable of being admitted through the pupil or aperture of the eye; which is the reason, that in long telescopes, constructed in the common manner, with three eye-glasses, the field is always very much contracted.

These considerations first set Mr Dolload on contriving how to enlarge the field, by increasing the number of eye-glasses without affecting the distinctness or brightness of the image; and though others had been about the same work before, yet, observing that some five-glass telescopes which were then made would admit of farther improvement, he endeavoured to construct one with the same number of glasses in a better manner; which so far answered his expectations, as to be allowed by the best judges to be a considerable improvement on the former.

Encouraged by this success, he resolved to try if he could not make some farther enlargement of the field, by the addition of another glass, and by placing and proportioning the glasses in such a manner as to correct the aberrations as much as possible, without injuring the distinctness; and at last he obtained as large a field as is convenient or necessary, and that even in the longest telescopes that can be made.

These telescopes with six glasses having been well received, and some of them being carried into foreign countries, it seemed a proper time to the author to settle the date of his invention; on which account he drew up a letter, which he addressed to Mr Short, and which was read at the Royal Society, March 1. 1753.

Equatorial telescope, or portable observatory.

To Mr Short we are indebted for the excellent contrivance of an equatorial telescope, or, as he likewise called it, a *portable observatory*; for with it pretty accurate observations may be made with very little trouble, by those who have no building adapted to the purpose. The instrument consists of a piece of machinery, by which a telescope mounted upon it may be directed to any degree of right ascension or declination, so that the place of any of the heavenly bodies being known, they may be found without any trouble, even in the day-time. As it is made to turn parallel to the equator, any object is easily kept in view, or recovered, without moving the eye from its situation. By this instrument most of the stars of the first and second magnitude have been seen even at mid-day, when the sun was shining bright; as also

History. also Mercury, Venus, and Jupiter. Saturn and Mars are not so easy to be seen, on account of the faintness of their light, except when the sun is but a few hours above the horizon. This particular effect depends upon the telescope excluding almost all the light, except what comes from the object itself, and which might otherwise efface the impression made by its weaker light upon the eye. Any telescope of the same magnifying power would have the same effect, could we be sure of pointing it right. Mr Ramsden invented a *portable* or *equatorial telescope*, which may perhaps supersede the use of Mr Short's.

90 How to observe the stars in the day-time.

In order to see the fixed stars in the day-time, it is necessary to exclude the extraneous light as much as possible. For this reason the greater the magnifying power of any telescope is, the more easily a fixed star will be distinguished in the day-time; the light of the star remaining the same in all magnifying powers of the same telescope, but the ground upon which it is seen becoming darker by increasing the magnifying power; and the visibility of a star depends very much upon the difference between its own light and that of the ground upon which it is observed. A fixed star will be very nearly equally visible with telescopes of very different apertures, provided the magnifying power remains the same.

91 M. Epinus's proposal for bending the tubes of telescopes.

M. Æpinus proposes to bend the tubes of long telescopes at right angles, fixing a plane mirror in the angular point, in order to make them more commodious for viewing objects near the zenith; and he gives particular instructions how to make them in this form, especially when they are furnished with micrometers. We are also informed that a little plane speculum is sometimes placed betwixt the last eye-glass and the eye in the reflecting telescopes, at an angle of 45°, for the same purpose.

92 History of microscopes.

The invention of MICROSCOPES was not much later than that of telescopes; and, according to Borellus, we are indebted for them to the same author, at least to Zacharias Jansen, in conjunction with his son.

The Jansens, however, have not always enjoyed, undisturbed, that share of reputation to which they seem to be entitled, with respect either to the telescope or the microscope. The discovery of the latter, in particular, has generally been considered as more uncertain than that of the former. All that many writers say we can depend upon is, that microscopes were first used in Germany about the year 1621. Others say positively, that this instrument was the contrivance of Cornelius Drebell, a man of ingenuity, who also invented the thermometer.

According to Borellus, Zacharias Jansen and his son presented the first microscopes they had constructed to Prince Maurice, and Albert archduke of Austria. William Borell, who gives this account in a letter to his brother Peter, says, that when he was ambassador in England, in 1619, Cornelius Drebell, with whom he was intimately acquainted, showed him a microscope, which he said was the same that the archduke had given him, and had been made by Jansen himself. This instrument was not so short as they are generally made at present, but was six feet long, consisting of a tube of gilt copper, an inch in diameter, supported by three brass pillars in the shape of dolphins, on a base of ebony, on which the small objects were placed.

93 Microscope made by Jansen.

This microscope was evidently a compound one, or rather something betwixt a telescope and a microscope, so that it is possible that single microscopes might have been known, and in use, some time before: but perhaps nobody thought of giving that name to single lenses; though, from the first use of lenses, they could not but have been used for the purpose of magnifying small objects. In this sense we have seen, that even the ancients were in possession of microscopes; and it appears from Jamblicus and Plutarch, quoted by Dr Rogers, that they gave such instruments as they used for this purpose the name of *dioptra*. At what time lenses were made so small as we now generally use them for magnifying in single microscopes, we have not found. But as this must necessarily have been done gradually, the only proper object of inquiry is the invention of the double microscope; and this is clearly given, by the evidence of Borellus above mentioned, to Z. Jansen, or his son.

The invention of compound microscopes is claimed by the same Fontana who arrogated to himself the discovery of telescopes; and though he did not publish any account of this invention till the year 1646 (notwithstanding he pretended to have made the discovery in 1618), Montucla, from not attending perhaps to the testimony of Borellus, is willing to allow his claim, as he thought there was no other person who seemed to have any better title to it.

Eustachio Divini made microscopes with two common object-glasses, and two plano-convex eye-glasses joined together on their convex sides so as to meet in a point. The tube in which they were inclosed was very large, and the eye-glasses almost as broad as the palm of a man's hand. Mr Oldenburg, secretary to the Royal Society, received an account of this instrument from Rome, and read it at one of their meetings, August 6. 1668. 94 By Divini.

It was about this time that Hartsocker improved single microscopes, by using small globules of glass, made by melting them in the flame of a candle, instead of the lenses which had before been made use of for that purpose. By this means he first discovered the *animalcula in semine masculino*, which gave rise to a new system of generation. A microscope of this kind, consisting of a globule of $\frac{1}{10}$th of an inch in diameter, M. Huygens demonstrated to magnify 100 times; and since it is easy to make them of less than half a line in diameter, they may be made to magnify 300 times. 95 By Hartsocker.

But no man distinguished himself so much by microscopical discoveries as the famous M. Leeuwenhoek, though he used only single lenses with short foci, preferring distinctness of vision to a large magnifying power. 96 By Leeuwenhoek.

M. Leeuwenhoek's microscopes were all single ones, each of them consisting of a small double convex glass, set in a socket between two silver plates rivetted together, and pierced with a small hole; and the object was fixed on the point of a needle, which could be placed at any distance from the lens. If the objects were solid, he fastened them with glue; and if they were fluid, or required to be spread upon glass, he placed them on a small piece of Muscovy talc, or thin glass; which he afterwards glued to his needle. He had, however, a different apparatus for viewing the circulation of the blood, which he could attach to the same microscopes.

History.

M. Leeuwenhoek bequeathed the greatest part of his microscopes to the Royal Society. They were placed in a small Indian cabinet, in the drawers of which were 13 little boxes, each of which contained two microscopes, neatly fitted up in silver.

The glass of all these lenses is exceedingly clear, but none of them magnifies so much as those globules which are frequently used in other microscopes. Mr Folkes, who examined them, thought that they showed objects with much greater distinctness, a circumstance which M. Leeuwenhoek principally valued. His discoveries, however, are to be ascribed not so much to the goodness of his glasses, as to his great experience in using them.

Mr Baker, who also examined these microscopes, and reported concerning them to the Royal Society, found that the greatest magnifier enlarged the diameter of an object about 160 times, but that all the rest fell much short of that power. He therefore concluded that M. Leeuwenhoek must have had other microscopes of a much greater magnifying power for many of his discoveries.

It appears from M. Leeuwenhoek's writings, that he was not unacquainted with the method of viewing opaque objects by means of a small concave reflecting mirror, which was afterwards improved by M. Lieberkhun. For, after describing his apparatus for viewing eels in glass tubes, he adds, that he had an instrument to which he screwed a microscope set in brass, upon which microscope he fastened a little dish of brass, probably that his eye might be thereby assisted to see objects better; for he says he had filed the brass which was round his microscope as bright as he could, that the light, while he was viewing objects, might be reflected from it as much as possible. This microscope, with its dish, is constructed upon principles so similar to those which are the foundation of our single microscope by reflection (see MICROSCOPE,) that it may well be supposed to have given the hint to the ingenious inventor of it.

97 Wilson's microscope.

In 1702, Mr Wilson made several ingenious improvements in the method of using single magnifiers for the purpose of viewing transparent objects; and his microscope, which is also a necessary part of the solar microscope, is in very general use at this day. (See MICROSCOPE, sect. 1.)

98 Adams's method of making globules for large magnifiers.

In 1710, Mr Adams gave to the Royal Society the following account of his method of making small globules for large magnifiers. He took a piece of fine window-glass, and cut it with a diamond into several slips, not exceeding $\frac{1}{8}$ of an inch in breadth; then, holding one of them between the fore-finger and thumb of each hand over a very fine flame, till the glass began to soften, he drew it out till it was as fine as a hair, and broke; then putting each of the ends into the purest part of the flame, he had two globules, which he could increase or diminish at pleasure. If they were held a long time in the flame, they would have spots on them, so that he drew them out immediately after they became round. He broke off the stem as near to the globule as he could, and lodging the remainder between the plates, in which holes were drilled exactly round, the microscope, he says, performed to admiration. Through these magnifiers the same thread of very fine muslin appeared three or four times bigger than it did in the largest of Mr Wilson's magnifiers.

99 Temporary microscopes by Mr Grey.

The ingenious Mr Grey hit upon a very easy expedient to make very good temporary microscopes, at a very little expence. They consist of nothing but small drops of water taken up with the point of a pin, and put into a small hole made in a piece of metal. These globules of water do not, indeed, magnify so much as those which are made of glass of the same size, because the refractive power of water is not so great; but the same purpose will be answered nearly as well by making them somewhat smaller.

The same ingenious person, observing that small heterogeneous particles inclosed in the glass of which microscopes are made, were much magnified when those glasses were looked through, thought of making his microscopes of water that contained living animalcula, to see how they would look in this new situation; and he found his scheme to answer beyond his expectation, so that he could not even account for their being magnified so much as they were: for it was much more than they would have been magnified if they had been placed beyond the globule, in the proper place for viewing objects. But Montucla observes, that, when any object is inclosed within this small transparent globule, the hinder part of it acts like a concave mirror, provided they be situated between that surface and the focus; and that, by this means, they are magnified above $3\frac{1}{3}$ times more than they would have been in the usual way.

100 Microscopes of turpentine varnish by Dr Brewster.

Temporary microscopes of a different kind have been constructed by Dr Brewster. They were composed of turpentine varnish, which was formed into a plano-convex lens, by laying a drop of it upon a piece of plain glass: the under surface of the glass was then smoked, and the black pigment removed immediately below the fluid lens. These lens lasted for a long time, and shewed objects distinctly, even when combined into a compound microscope. See *Appendix to Ferguson's Lectures*, vol. ii. and MICROSCOPE, p. 19.

101 Reflecting microscope, by Dr Barker.

After the successful construction of the reflecting telescope, it was natural to expect that attempts would also be made to render a similar service to microscopes. Accordingly we find two plans of this kind. The first was that of Dr Robert Barker. His instrument differs in nothing from the reflecting telescope, excepting the distance of the two speculums, in order to adapt it to those pencils of rays which enter the microscope diverging; whereas they come to the telescope from very distant objects nearly parallel to each other.

This microscope is not so easy to manage as those of the common kind. For vision by reflection, as it is much more perfect, so it is far more difficult than that by refraction. Nor is this microscope so useful for any but very small or transparent objects. For the object, being between the speculum and image, would, if it were large and opaque, prevent a due reflection.

102 Dr Smith's reflecting microscope superior to all others.

Dr Smith invented a double reflecting microscope, of which a theoretical and practical account is given in his remarks at the end of the second volume of his System of Optics. As it is constructed on principles different from all others, and in the opinion of some, superior to them all, the reader will not be displeased with the following practical description.

Plate CCCLXXVII. fig. 2.

A section of this microscope is shewn in fig. 2. where ABC and *a b c* are two specula, the former concave, and the latter convex, inclosed within the tube DEFG. The speculum ABC is perforated, and the object to be viewed

History. viewed is so placed between the centre and principal focus of that speculum, that the rays flowing from it to ABC are reflected towards an image *p q*. But before that image is formed, they are intercepted by the convex speculum *a b c*, and thence reflected through the hole BC in the vertex of the concave to a second image *π x*, to be viewed through an eye-glass *l*. The object may either be situated between the two specula, or, which is perhaps better, between the principal focus and vertex *c* of the convex speculum *a b c*, a small hole being made in its vertex for the transmission of the incident rays. When the microscope is used, let the object be included between two little round plates of Muscovy-glass, fixed in a hole of an oblong brass plate *u m*, intended to slide close to the back side of the convex speculum: which must therefore be ground flat on that side, and so thin that the object may come precisely to its computed distance from the vertex of the speculum. The slider must be kept tight to the back of the metal by a gentle spring. The distance of the object being thus determined, distinct vision to different eyes, and through different eye-glasses, must be procured by a gentle motion of the little tubes that contain these glasses. These tubes must be made in the usual form of those that belong to Sir Isaac Newton's reflecting telescope, having a small hole in the middle of each plate, at the ends of the tube, situated exactly in each focus of the glass: The use of these holes and plates is to limit the visible area, and prevent any straggling rays from entering the eye. To the tube of the eye-glass is fastened the arm *g*, on which the adjusting screw turns. A similar arm *u* is attached to the fixed tube X, in which the neck of the screw turns; and by turning the button *y*, the eye-tube is moved farther from or nearer to the object, by which means different sorts of eyes obtain distinct vision.

The rays which flow from the object directly through the hole in the concave speculum and through the eye-glass, by mixing with the reflected rays, would dilute the image on the retina, and therefore must be intercepted. This is done by a very simple contrivance. The little hole in the convex speculum is ground conical as in the figure; and a conical solid P, of which the base is larger than the orifice in the back of the convex speculum, supported on the slender pillar PQ, is so placed as to intercept all the *direct* rays from the eye-glass. The tubes are strongly blacked on their insides, and likewise the conical solid, to hinder all reflection of rays upon the convex speculum. The little base, too, of the solid should be made concave, that whatever light it may still reflect, may be thrown back upon the object; and its back-side being conical and blacked all over, will either absorb or laterally disperse any straggling rays which the concave speculum may scatter upon it, and so prevent their coming to the eye-glass.

Notwithstanding the interposition of this conical solid, yet when the eye-glass is taken out, distant objects may be distinctly seen through the microscope, by rays reflected from the metals, and diverging upon the eye from an image behind the convex speculum. But this mixture of foreign rays with those of the object, which is common to all kinds of microscopes in viewing transparent objects, is usually prevented by placing before the object a thick double convex lens *l*, to collect the sky light exactly upon the object. This lens should be just so broad as to subtend the opposite angle to that which the concave speculum subtends at the object. The annular frame of the lens must be very narrow, and connected with the microscope by two or three slender wires or blades, whose planes produced may pass through the object, and intercept from it as little sky light as possible. History.

This is not the place for explaining the principles of this microscope, or demonstrating its superiority over most others; nor are such explanation and demonstration necessary. Its excellence, as well as the principles upon which it is constructed, will be perceived by the reader, when he has made himself master of the laws of refraction and reflection as laid down in the sequel of this article. 103

Solar microscope, and that for opaque objects.

M. Lieberkuhn, in 1738 or 1739, made two capital improvements in microscopes, by the invention of the *solar microscope*, and the *microscope for opaque objects*. When he was in England in the winter of 1739, he showed an apparatus for each of these purposes, made by himself, to several gentlemen of the Royal Society, as well as to some opticians.

The microscope for opaque objects remedies the inconvenience of having the dark side of an object next the eye. For by means of a concave speculum of silver, highly polished, in the centre of which a magnifying lens is placed, the object is so strongly illuminated that it may be examined with all imaginable ease and pleasure. A convenient apparatus of this kind, with four different specula and magnifiers of different powers, was brought to perfection by Mr Cuff in Fleet-street. M. Lieberkuhn made considerable improvements in his solar microscope, particularly in adapting it to the view of opaque objects; but in what manner this was effected, M. Æpinus, who was highly entertained with the performance, and who mentions the fact, was not able to recollect; and the death of the ingenious inventor prevented his publishing any account of it himself. M. Æpinus invites those who came into the possession of M. Lieberkuhn's apparatus to publish an account of this instrument; but it does not appear that his method was ever published.

This improvement of M. Lieberkuhn's induced M. Æpinus himself to attend to the subject; and he thus produced a very valuable improvement in this instrument. For by throwing the light upon the foreside of any object by means of a mirror, before it is transmitted through the object lens, all kinds of objects are equally well represented by it. 104

Reflected light introduced into the microscope and magic lantern.

M. Euler proposed to introduce vision by reflected light into the magic lantern and solar microscope, by which many inconveniences to which those instruments are subject might be avoided. For this purpose, he says, that nothing is necessary but a large concave mirror, perforated as for a telescope; and the light should be so situated, that none of it may pass directly through the perforation, so as to fall on the images of the objects upon the screen. He proposes to have four different machines, for objects of different sizes; the first for those of six feet long, the second for those of one foot, the third for those of two inches, and the fourth for those of two lines; but it is needless to be particular in the description

History. scription of these, as more perfect instruments are described under the article MICROSCOPE.

Several improvements were made in the apparatus to the solar microscope, as adapted to view opaque objects, by M. Zeiher, who made one construction for the larger kind of objects, and another for the small ones.

105 Mr Martin's improvement in the solar microscope.

Mr Martin having constructed a solar microscope of a larger size than common, for his own use, the illuminating lens being $4\frac{1}{2}$ inches in diameter, and all the other parts of the instrument in proportion, found, that by the help of an additional part, which he does not describe, he could see even opaque objects very well. If he had made the lens any larger, he was aware that the heat produced at the focus would have been too great for most objects to bear. The expence of this instrument, he says, does not much exceed the price of the common solar microscope.

106 Di Torre's extraordinary magnifying microscope.

The smallest globules, and consequently the greatest magnifiers, for microscopes, that have yet been executed, were made by T. Di Torre of Naples, who, in 1765, sent four of them to the Royal Society. The largest of them was only two Paris points in diameter, and it was said to magnify the diameter of an object 640 times. The second was the size of one Paris point, and the third was no more than half of a Paris point, or the 144th part of an inch in diameter, and was said to magnify the diameter of an object 2560 times. One

107 Could not be used by Mr Baker.

of these globules was wanting when they came into the hands of Mr Baker, to whose examination they were submitted by the Royal Society. This gentleman, however, was not able to make any use of these. With that which magnifies the least, he was not able to see any object with satisfaction; and he concludes his account with expressing his hopes only, that, as his eyes had been much used to microscopes, they were not injured by the attention he had given to them, though he believed there were few persons who would not have been blinded by it.

The construction of a telescope with six eye-glasses led M. Euler to a similar construction of microscopes, by introducing into them six lenses, one of which admits of so small an aperture, as to serve, instead of a diaphragm, to exclude all foreign light, though, as he says, it neither lessens the field of view, nor the brightness of objects.

108 Difficulties attending the construction of dioptric instruments.

The improvement of all dioptric instruments is greatly impeded by inequalities in the substance of the glass of which they are formed; but though many attempts have been made to make glass without that imperfection, none of them have been hitherto quite effectual. M. A. D. Merklein, having found some glass which had been melted when a building was on fire, and which proved to make excellent object-glasses for telescopes, concluded that its peculiar goodness arose from its not having been disturbed when it was in a fluid state; and therefore he proposed to take the metal out of the furnace in iron vessels, of the same form that was wanted for the glass; and after it had been perfectly fluid in those vessels, to let it stand to cool, without any disturbance. This, however, is not always found to answer.

PART I. THEORY OF OPTICS.

THE science of optics is commonly divided into three parts, *Dioptrics*, which treats of the laws of refraction, and the phenomena depending upon them; *Catoptrics*, which treats of the laws of reflection, and the phenomena connected with them; and, lastly, *Chromatics*, which treats of the phenomena of colour. But this division is of no use in a treatise of Optics, as most of the phenomena depend both on refraction and reflection, colour itself not excepted. For this reason, though we have given detached articles under the words DIOPTRICS, CATOPTRICS, and CHROMATICS; we have reserved for this place the explanation of the laws of reflection and refraction, by which all optical phenomena may be explained.

CHAP. I. *On Light.*

UNDER the article LIGHT we have given some account of the controversies concerning its nature. The opinions of philosophers may, in general, be arranged under these two: 1. That light is produced by the undulations of an elastic fluid, nearly in the same manner as sound is produced by the undulations of the air.

109 Different opinions concerning the nature of light.

This opinion was first offered to the public by Des Cartes, and afterwards by Mr Huygens. It was revived by Euler, and has lately found an able and ingenious defender in Dr Thomas Young.—2d, That the phenomena of vision are produced by the motion and action of matter emitted from the shining body with immense velocity, moving uniformly in straight lines, and acted on by other bodies; so as to be reflected, refracted, or inflected, in various ways, by means of forces which act on it in the same manner as on other inert matter. Sir Isaac Newton has ably shown the dissimilarity between the phenomena of vision and the legitimate consequences of the undulations of an elastic fluid. All M. Euler's ingenious and laborious discussions have not removed Newton's objections in the smallest degree. Sir Isaac adopts the vulgar opinion, therefore, because the difficulties attending this opinion are not inconsistent with the established principles of mechanics, and are merely difficulties of conception to limited faculties like ours. We need not despair of being able to decide, by experiment, which of these opinions is nearest to the truth; because there are phenomena where the result should be sensibly different in the two hypotheses. At present, we shall content ourselves with giving some account of the legitimate consequences of the vulgar opinion, as modified by Sir Isaac Newton, viz. that light consists of small particles emitted with very great velocity, and attracted or repelled by other bodies at very small distances.

110 Light is emitted in straight lines from each point of a surface.

Every visible body emits or reflects inconceivably small particles of matter from each point of its surface, which issue from it continually, not unlike sparks from a coal, in straight lines and in all directions. These particles

Refraction. particles entering the eye, and striking upon the retina (an expansion of the optic nerve over the back part of the eye to receive their impulses), excite in our minds the idea of light. And according as they differ in substance, density, velocity, or magnitude, they produce in us the ideas of different colours; as will be explained in its proper place.

That the particles which constitute light are exceedingly small, appears from this, that if a hole be made through a piece of paper with a needle, rays of light from every object on the farther side of it are capable of being transmitted through it at once without the least confusion; for any one of those objects may as clearly be seen through it, as if no rays passed through it from any of the rest. Besides, if a candle is lighted, and there be no obstacle in the way to obstruct the progress of its rays, it will fill all the space within some miles of it every way with luminous particles, before it has lost the least sensible part of its substance in consequence of this copious emission.

It is evident that these particles proceed from every point of the surface of a visible body, and in all directions, because wherever a spectator is placed with regard to the body, every point of that part of the surface which is turned towards him is visible. That they proceed from the body in right lines, we are assured, because just so many and no more will be intercepted in their passage to any place by an interposed object, as that object ought to intercept, supposing them to come in such lines.

The velocity with which they proceed from the surface of the visible body is no less surprising than their minuteness: the method by which philosophers estimate their velocity, is by observations made on the eclipses of Jupiter's satellites; which eclipses appear to us about seven minutes sooner than they ought to do by calculation, when the earth is placed between the sun and him, that is, when we are nearest to him; and as much later, when the sun is between him and us, at which time we are farthest from him. Hence it is concluded, that they require about seven minutes to pass over a space equal to the distance of the earth from the sun.

A stream of these particles issuing from the surface of a visible body in one and the same direction, is called a *ray of light*.

As rays proceed from a visible body in all directions, they necessarily become thinner and thinner, continually spreading themselves as they pass along into a larger space, and that in proportion to the squares of their distances from the body; that is, at the distance of two spaces, they are four times thinner than they are at one; at the distance of three spaces, nine times thinner, and so on.

Chap. II. *On Refraction.*

111 Refraction defined.

Light, when proceeding from a luminous body, is invariably found to proceed in straight lines, without the least deviation. But, if it happens to pass obliquely from one medium to another, it always leaves the direction it had before, and assumes a new one; and this change of course is called its *refraction*. After having taken this new direction, it then proceeds invariably in a straight line till it meets with a different medium, when it is again turned out of its course. It must be observed, however, that though by this means we may cause the rays of light to make any number of angles in their course, it is impossible to make them describe a curve, except in one single case, namely, where they pass through a medium, the density of which uniformly either increases or decreases. This is the case with the light of the celestial bodies, which passes downwards through our atmosphere, and likewise with that which is reflected upwards through it by terrestrial objects. In both these cases, it describes a curve of the hyperbolic kind; but at all other times it proceeds in straight lines, or in what may be taken for straight lines, without any sensible error.

Cause of Refraction.

Sect. I. *On the cause of Refraction, and the Law by which it is performed.*

112 Phenomena of refraction solved by an attractive power in the medium.

The phenomena of refraction are explained by an attractive power in the medium through which light passes, in the following manner. All bodies being endowed with an attractive force, which is extended to some distance beyond their surfaces; when a ray of light passes out of a rarer into a denser medium (if this latter has a greater attractive force than the former, as is commonly the case), the ray, just before its entrance, will begin to be attracted towards the denser medium; and this attraction will continue to act upon it, till some time after it has entered the medium; and therefore, if a ray approaches a denser medium in a direction perpendicular to its surface, its velocity will be continually accelerated during its passage through the space in which that attraction exerts itself; and therefore, after it has passed that space, it will move on, till it arrive at the opposite side of the medium, with a greater degree of velocity than it had before it entered. So that in this case its velocity only will be altered. Whereas, if a ray enters a denser medium obliquely, it will not only have its velocity augmented thereby, but its direction will become less oblique to the surface. Just as when a stone is thrown downwards obliquely from a precipice, it falls to the surface of the ground in a direction nearer to a perpendicular one, than that with which it was thrown from the hand. Hence we see a ray of light, in passing out of a rarer into a denser medium, is refracted towards the perpendicular; that is, supposing a line drawn perpendicularly to the surface of the medium, through the point where the ray enters, and extended both ways, the ray in passing through the surface is refracted or bent towards the perpendicular line; or, which is the same thing, the line which it describes by its motion after it has passed through the surface, makes a less angle with the perpendicular, than the line which is described before. These positions may be illustrated in the following manner.

Plate CCCLXXVII Fig. 3.

Let us suppose first, that the ray passes out of a vacuum into the denser medium ABCD (fig. 3.), and that the attractive force of each particle in the medium is extended from its respective centre to a distance equal to that which is between the lines AB and EF, or AB and GH; and let KL be the path described by a ray of light in its progress towards the denser medium. This ray, when it arrives at L, will enter the sphere of attraction of those particles which lie in AB the surface of the denser medium, and will therefore cease to proceed any longer in the right line KLM, but will be diverted from its course by being attracted towards

Cause of Refraction.

wards the line AB, and will begin to describe the curve LN, passing through the surface AB in some new direction, as OQ; making a less angle with a line PR, drawn perpendicularly through the point N, than it would have done had it proceeded in its first direction KLM.

As we have supposed the attractive force of each particle to be extended through a space equal to the distance between AB and EF, it is evident that the ray, after it has entered the surface, will still be attracted downwards, till it has arrived at the line EF; for, till then, there will not be so many particles above it which will attract it upwards, as below, that will attract it downwards. So that after it has entered the surface at N, in the direction OQ, it will not proceed in that direction, but will continue to describe a curve, as NS; after which it will proceed straight on towards the opposite side of the medium, being attracted equally every way; and therefore will at last proceed in the direction XST, still nearer the perpendicular PR than before.

If we suppose ABZY not to be a vacuum, but a rarer medium than the other, the case will still be the same; but the ray will not be so much refracted from its rectilineal course, because the attraction of the particles of the upper medium being in a contrary direction to that of the attraction of those in the lower one, the attraction of the denser medium will in some measure be destroyed by that of the rarer.

When a ray, on the contrary, passes out of a denser into a rarer medium, if its direction be perpendicular to the surface of the medium, it will only lose somewhat of its velocity, in passing through the spaces of attraction of that medium (that is, the space wherein it is attracted more one way than it is another). If its direction be oblique, it will continually recede from the perpendicular during its passage, and by that means, have its obliquity increased, just as a stone thrown up obliquely from the surface of the earth increases its obliquity all the time it rises. Thus, supposing the ray TS passing out of the denser medium ABCD into the rarer ABZY, when it arrives at S it will begin to be attracted downwards, and so will describe the curve SNL, and then proceed in the right line LK; making a larger angle with the perpendicular PR, than the line TSX in which it proceeded during its passage through the other medium.

We may here make a general observation on the forces which produce this deviation of the rays of light from their original path. They arise from the joint action of all the particles of the body which are sufficiently near the particle of light; that is, whose distance from it is not greater than the line AE or GA; and therefore the whole force which acts on a particle in its different situations between the planes GH and EF, follows a very different law from the force exerted by one particle of the medium.

The space through which the attraction of cohesion of the particles of matter is extended is so very small, that in considering the progress of a ray of light out of one medium into another, the curvature it describes in passing through the space of attraction is generally neglected; and its path is supposed to be bent or refracted, only in the point where it enters the denser medium.

Law of Refraction.

Now the line which a ray describes before it enters a denser or a rarer medium, is called the *incident ray*; and that which it describes after it has entered, is the *refracted ray*.

The angle comprehended between the incident ray and the perpendicular, is the *angle of incidence*; and that between the refracted ray and the perpendicular, is the *angle of refraction*.

There is a certain and immutable law, by which refraction is always performed; which is this: Whatever inclination a ray of light has to the surface of any medium before it enters it, the degree of refraction will always be such, that the sine of the angle of incidence and that of the angle of refraction, will always have a constant ratio to one another in that medium.

Plate CCCLXXVII fig. 4.

To illustrate this: Let us suppose ABCD (fig. 4.) to represent a rarer, and ABEF a denser medium: let GH be a ray of light passing through the first and entering the second at H, and let HI be the refracted ray: then supposing the perpendicular PR drawn through the point H, on the centre H, and with any radius, describe the circle ABPR; and from G and I, where the incident and refracted rays cut the circle, let fall the lines GK and IL perpendicularly upon the line PR; the former of these will be the sine of the angle of incidence, the latter of refraction. Now if in this case the ray GH is so refracted at H, that GK is double or triple, &c. of IL, then, whatever other inclination the ray GH might have had, the sine of its angle of incidence would have been double or triple, &c. to that of its angle of refraction. For instance, had the ray passed in the line MH before refraction, it would have passed in some line as HN afterwards, so situated that MO should have been double or triple, &c. of NQ.

The following table contains the refractive densities of several bodies.

Diamond, -	2.500
Flint glass, -	1.585
Plate glass, -	1.502
Crown glass, -	1.525
Sulphuric acid, -	1.435
Solution of potash,	1.390
Olive oil, -	1.469
Alcohol, -	1.370
Atmospheric air,	1.000276
Ice, - -	1.31
Water, - -	1.336

This relation of the sine of the angle of incidence to that of refraction, which is a proposition of the most extensive use in explaining the optical phenomena on physical or mechanical principles, may be demonstrated in the following easy and familiar manner.

Lemma I.

The augmentations or diminutions of the squares of the velocities produced by the uniform action of accelerating or retarding forces, are proportional to the forces, and to the spaces along which they act, jointly; or are proportional to the products of the forces multiplied by the spaces.

Let two bodies be uniformly accelerated from a state of rest in the points A a, along the spaces AB, ab, fig. 5. by Fig. 5.

Law of Refraction.

by the accelerating forces F f, and let AC, $a\,c$, be spaces described in equal times; it is evident, from what has been said under the articles GRAVITY and ACCELERATION, that because these spaces are described with motions uniformly accelerated, AC and $a\,c$ are respectively the halves of the spaces which would be uniformly described during the same time with the velocities acquired at C and c, and are therefore measures of these velocities. And as these velocities are uniformly acquired in equal times, they are measures of the accelerating forces. Therefore, AC : ac=F : f. Also, from the nature of uniformly accelerated motion, the spaces are proportional to the squares of the acquired velocities. Therefore, (using the symbols $\surd^2$C, $\surd^2 c$, &c. to express the squares of the velocities at C c, &c.) we have

Fig. 5.

$$\surd^2 B : \surd^2 C = AB : AC$$
$$\surd^2 C : \surd^2 c = AC^2 : a\,c^2$$
$$\surd^2 c : \surd^2 b = a\,c : a\,b$$

Therefore, by equality of compound ratios

$\surd^2 B : \surd^2 b = AB \times AC : ab \times ac, = AB \times F : ab \times f$.
And in like manner $\surd^2 D : \surd^2 d \surd AD \times F : ad \times f$;
and $\surd^2 B - \surd^2 D : \surd^2 b - \surd^2 d = BD \times F : bd \times f$.
Q. E. D.

COROLLARY. If the forces are as the spaces inversely, the augmentations or diminutions of the squares of the velocities are equal.

Remark. If D B, $d\,b$, be taken extremely small, the products BD $\times$ F and $b\,d \times f$ may be called the momentary actions of the forces, or the momentary increments of the squares of the velocities. It is usually expressed, by the writers on the higher mechanics, by the symbol $f\dot{s}$, or $f\,d\,s$, where f means the accelerating force, and $\dot{s}$ or $d\,s$ means the indefinitely small space along which it is uniformly exerted. And the proposition is expressed by the fluxionary equation $f\dot{s} = v\dot{v}$ because $v\dot{v}$ is half the increment of v^2, as is well known.

LEMMA II.

Plate CCCLXXVII. fig. 6.

If a particle of matter, moving with any velocity along the line AC, be impelled by an accelerating or retarding force, acting in the same or in the opposite direction, and if the intensity of the force in the different points B, F, H, C, &c. be as the ordinates BD, FG, &c. to the line DGE, the areas BFGD, BHKD, &c. will be as the changes made on the square of the velocity, at B, when the particle arrives at the points F, H, &c.

For let BC be divided into innumerable small portions, of which let FH be one, and let the force be supposed to act uniformly, or to be of invariable intensity during the motion along FH; draw GI perpendicular to HK: It is evident that the rectangle FHIG will be as the product of the accelerating force by the space along which it acts, and will therefore express the momentary increment of the square of the velocity. (Lemma I.). The same may be said of every such rectangle. And if the number of the portions, such as FH, be increased, and their magnitude diminished without end, the rectangles will ultimately occupy the whole curvilineal area, and the force will therefore be as the finite changes made on the square of the velocity, and the proposition is demonstrated.

Law of Refraction.

COROLLARY. The whole change made on the square of the velocity, is equal to the square of that velocity which the accelerating force would communicate to the particle by impelling it along BC from a state of rest in B. For the area BCED will still express the square of this velocity, and it equally expresses the change made on the square of *any* velocity wherewith the particle may pass through the point B, and is independent on the magnitude of that velocity.

Remark. The figure is adapted to the case where the forces all conspire with the initial motion of the particle, or all oppose it, and the area expresses an augmentation or a diminution of the square of the initial velocity. But the reasoning would have been the same, although, in some parts of the line B C, the forces had conspired with the initial motion, and in other parts had opposed it. In such a case, the ordinates which express the intensity of the forces must lie on different sides of the abscissa BC, and that part of the area which lies on one side must be considered as negative with respect to the other, and be subtracted from it. Thus, if the forces be represented by the ordinates of the dotted curve line DH e, which crosses the abscissa in H, the figure will correspond to the motion of a particle, which, after moving uniformly along AB, is subjected to the action of a variable accelerating force during its motion along BH, and the square of its initial velocity is increased by the quantity BHD; after which it is retarded during its motion along HC, and the square of its velocity in H is diminished by a quantity HC e. Therefore the square of the initial velocity is changed by a quantity BHB—HC e, or HC e—BHD.

This proposition, which is the 39th of the 1st book of the Principia, is perhaps the most important in the whole science of mechanics, being the foundation of every application of mechanical theory to the explanation of natural phenomena. No traces of it are to be found in the writings of philosophers before the publication of Newton's Principia, though it is assumed by John Bernoulli and other foreign mathematicians, as an elementary truth, without any acknowledgment of their obligations to its author. It is usually expressed by the equation $f\dot{s} = v\dot{v}$ and $\int f\dot{s} = v^2$, i. e. *the sum of the momentary actions is equal to the whole or finite increment of the square of the velocity.*

PROPOSITION.

When light passes obliquely into or out of a transparent substance, it is refracted so that the sine of the angle of incidence is to the sine of the angle of refraction in the constant ratio of the velocity of the refracted light to that of the incident light.

113 The ratio of the sine of incidence to the sine of refraction.

Plate CCCLXXVII. fig. 7.

LET ST, KR, represent two planes (parallel to, and equidistant from, the refracting surface XY) which bound the space in which the light, during its passage, is acted on by the refracting forces.

The intensity of the refracting forces being supposed equal at equal distances from the bounding planes, though anyhow different at different distances from them, may be represented by the ordinates T a, $n\,q$, $p\,r$, c R, &c. of the curve $a\,b\,n\,p\,c$, of which the form must be

Law of Refraction

be determined from observation, and may remain for ever unknown. The phenomena of inflected light show us that it is attracted by the refracting substance at some distances, and repelled at others.

Let the light, moving uniformly in the direction AB, enter the refracting stratum at B. It will not proceed in that direction, but its path will be incurvated upwards, while acted on by a repulsive force, and downwards, while impelled by an attractive force. It will describe some curvilineal path B d o CDE, which AB touches in B, and will finally emerge from the refracting stratum at E, and move uniformly in a straight line EF, which touches the curve in E. If, through b, the intersection of the curve of forces with its abscissa, we draw b o, cutting the path of the light in o, it is evident that this path will be concave upwards between B and o, and concave downwards between o and E. Also, if the initial velocity of the light has been sufficiently small, its path may be so much bent upwards, that in some point d its direction may be parallel to the bounding planes. In this case it is evident, that being under the influence of a repulsive force, it will be more bent upwards, and it will describe d f, equal and similar to d B, and emerge in an angle g f s, equal to ABG. In this case it is reflected, making the angle of reflection equal to that of incidence. By which it appears how reflection, refraction, and inflection, are produced by the same forces and performed by the same laws.

But let the velocity be supposed sufficiently great to enable the light to penetrate through the refracting stratum, and emerge from it in the direction EF; let AB and EF be supposed to be described in equal times: They will be proportional to the initial and final velocities of the light. Now, because the refracting forces *must* act in a direction perpendicular to the refracting surface (since they arise from the joint action of all the particles of a homogeneous substance which are within the sphere of mutual action), they cannot affect the motion of the light estimated in the direction of the refracting surface. If, therefore, AG be drawn perpendicular to ST, and FK to KR, the lines GB, EK, must be equal, because they are the motions AB, EF, estimated in the direction of the planes. Draw now EL parallel to AB. It is also equal to it. Therefore, EL, EF, are as the initial and final velocities of the light. But EF is to EL as the sine of the angle ELK to the sine of the angle EFK; that is, as the sine of the angle ABH to the sine of the angle FEI; that is, as the sine of the angle of incidence to the sine of the angle of refraction.

By the same reasoning it will appear that light, moving in the direction and with the velocity FE, will describe the path EDB, and will emerge in the direction and with the velocity BA.

Let another ray enter the refracting stratum perpendicularly at B, and emerge at Q. Take two points N, P, in the line BQ, extremely near to each other, so that the refracting forces may be supposed to act uniformly along the space NP: draw NC, PD, parallel to ST, CM perpendicular to DP, and MO perpendicular to CD, which may be taken for a straight line. Then, because the forces at C and N are equal, by supposition they may be represented by the equal lines CM and NP. The force NP is wholly employed in accelerating the light along NP; but the force CM being transverse to the motion BD, is but partly so employed, and may be conceived as arising from the joint action of the forces CO, OM, of which CO only is employed in accelerating the motion of the light, while OM is employed in incurvating its path. Now it is evident, from the similarity of the triangles DCM, MCO, that DC : CM = CM : CO, and that $DC \times CO = CM \times CM = NP \times NP$. But $DC \times CO$ and $NP \times NP$ are as the products of the spaces by the accelerating forces, and express the momentary increments of the squares of the velocities at C and N. (Lemma 1.). These increments, therefore, are equal. And as this must be said of every portion of the paths BCE and BNQ, it follows that the whole increment of the square of the initial velocity produced in the motion along BCE, is equal to the increment produced in the motion along BNQ. And, because the initial velocities were equal in both paths, their squares were equal. Therefore the squares of the final velocities are also equal in both paths, and the final velocities themselves are equal. The initial and final velocities are therefore in a constant ratio, whatever are the directions; and the ratio of the sines of the angles of incidence and refraction being the ratio of the velocities of the refracted and incident light, by the former case of Prop. 1. is also constant.

Remark. The augmentation of the square of the initial velocity is equal to the square of the velocity which a particle of light would have acquired, if impelled from a state of rest at B along the line BQ. (Corol. of the Lemma 2.), and is therefore independent on the initial velocity. As this augmentation is expressed by the curvilineal area a T b n p c R, it depends both on the intensity of the refracting forces, expressed by the ordinates, and on the space through which they act, viz. TR. These circumstances arise from the nature of the transparent substance, and are characteristic of that substance. Therefore, to abbreviate language, we shall call this the *specific velocity.*

This specific velocity is easily determined for any substance in which the refraction is observed, by drawing L i perpendicular to EL, meeting in i the circle described with the radius EF. For E i being equal to EF, will represent the velocity of the refracted light, and EL represent the velocity of the incident light, and $\mathrm{E}i^2 = \mathrm{EL}^2 + \mathrm{L}i^2$, and therefore $\mathrm{L}i^2$ is the augmentation of the square of the initial velocity, and L i is the specific velocity.

It will now be proper to deduce some corollaries from these propositions, tending to explain the chief phenomena of refraction.

11[illegible] The [illegible] of light [illegible] known or [illegible] by refraction.

Cor. 1. When light is refracted towards the perpendicular to the refracting surface it is accelerated; and it is retarded when it is refracted from the perpendicular. In the first case, therefore, it must be considered as having been acted on by forces conspiring (in part at least) with its motion, and *vice versa.* Therefore, because we see that it is always refracted towards the perpendicular, when passing from a void into any transparent substance, we must conclude that it is, on the whole, attracted by that substance. We must draw the same conclusion from observing, that it is refracted from the perpendicular in its passage out of any transparent substance whatever into a void. It has been attracted backwards by that substance.

This

Law of Refraction.

This acceleration of light in refraction is contrary to the opinion of those philosophers who maintain that illumination is produced by the undulation of an elastic medium. Euler attempts to prove, by mechanical laws, that the velocities of the incident and refracted light, are proportional to the sines of incidence and refraction, while our principles make them in this ratio inversely. Boscovich proposed a fine experiment for deciding this question. The aberration of the fixed stars arises from the combination of the motion of light with the motion of the telescope by which it is observed. Therefore this aberration should be greater or less when observed by means of a telescope filled with water, according as light moves slower or swifter through water than through air. He was mistaken in the manner in which the conclusion should be drawn from the observation made in the form prescribed by him: and the experiment has not yet been made in a convincing manner; because no fluid has been found of sufficient transparency to admit of the necessary magnifying power. It is an experiment of the greatest importance to optical science.

Plate CCCXXVII. fig. 8.

Cor. 2. If the light be moving within the transparent substance, and if its velocity (estimated in a direction perpendicular to the surface) do not exceed the specific velocity of that substance, it will not emerge from it, but will be reflected backwards in an angle equal to that of its incidence. For it must be observed, that in the figure of last proposition, the excess of the square of EF above the square of EL, is the same with the excess of the square of KF above the square of KL. Therefore the square of the specific velocity is equal to the augmentation or diminution of the square of the perpendicular velocity. If therefore the initial perpendicular velocity FK be precisely equal to the specific velocity, the light will just reach the farther side of the attracting stratum, as at B, where its perpendicular velocity will be completely extinguished, and its motion will be in the direction BT. But it is here under the influence of forces tending towards the plane KR, and its motion will therefore be still incurvated towards it; and it will describe a curve BD equal and similar to EB, and finally emerge back from the refracting stratum into the transparent substance in an angle RDA equal to KEF.

If the direction of the light be still more oblique, so that its perpendicular velocity is less than the specific velocity, it will not reach the plane ST, but be reflected as soon as it has penetrated so far that the specific velocity of the part penetrated (estimated by the compounding part of the area of forces) is equal to its perpendicular velocity. Thus the ray f E will describe the path E d D a penetrating to b d, so that the corresponding area of forces $a\ b\ c\ e$ is equal to the square of $f\,k$, its perpendicular velocity.

The extreme brilliancy of dew drops and of jewels had often excited the attention of philosophers, and it always appeared a difficulty how light was reflected at all from the posterior surface of transparent bodies. It afforded Sir Isaac Newton his strongest argument against the usual theory of reflection, viz. that it was produced by impact on solid elastic matter. He was the first who took notice of the total reflection in great obliquities; and very properly asked how it can be said that there is any impact in this case, or that the reflecting impact should cease at a particular obliquity?

115 Rays at a certain obliquity are wholly reflected by transparent substances.

It must be acknowledged that it is a very curious circumstance, that a body which is perfectly transparent should cease to be so at a certain obliquity; that a great obliquity should not hinder light from passing from a void into a piece of glass; but that the same obliquity should prevent it from passing from the glass into a void. The finest experiment for illustrating the fact is, to take two pieces of mirror-glass, not silvered, and put them together with a piece of paper between them, forming a narrow margin all round to keep them apart. Plunge this apparatus into water. When it is held nearly parallel to the surface of the water, every thing at the bottom of the vessel will be seen clearly through the glasses; but when they are turned so as to be inclined about 50 degrees, they will intercept the light as much as if they were plates of iron. It will be proper to soak the paper in varnish, to prevent water from getting between the glasses.

116 The brilliant cut in diamonds produces total reflection.

What is called the brilliant cut in diamonds, is such a disposition of the posterior facets of the diamond, that the light is made to fall upon them so obliquely that none of it can go through, but all is reflected. To produce this effect in the greatest possible degree is a matter of calculation, and merits the attention of the lapidary. When diamonds are too thin to admit of this form, they are cut in what is called the rose fashion. This has a plain back, and the facets are all on the front, and so disposed as to refract the rays into sufficient obliquities, to be strongly reflected from the posterior plane. Doublets are made by cutting one thin diamond rose fashion, and another similar one is put behind it, with their plane surfaces joined. Or, more frequently, the outside diamond has the anterior facets of the brilliant, and the inner has the form of the inner part of a brilliant. If they be joined with very pure and strongly refracting varnish, little light is reflected from the separating plane, and their brilliancy is very considerable, though still inferior to a true and deep brilliant. If no varnish be used, much of the light is reflected from the flat side, and the effect of the posterior facets is much diminished. But doublets might be constructed, by making the touching surfaces of a spherical form (of which the curvature should have a due proportion to the size of the stone), that would produce an effect nearly equal to that of the most perfect brilliant.

117 Refraction diminishes as the incident velocity increases.

Cor. 3. Since the change made on the square of the velocity of the incident light is a constant quantity, it follows, that the refraction will diminish as the velocity of the incident light increases. For if L i in fig. 7. be a constant quantity, and EL be increased, it is evident that the ratio of E i, or its equal EF, to EL will be diminished, and the angle LEF, which constitutes the refraction, will be diminished. The physical cause of this is easily seen: When the velocity of the incident light is increased, it employs less time in passing through the refracting stratum or space between the planes ST and KR, and is therefore less influenced by the refracting forces. A similar effect would follow if the transparent body were moving with great velocity towards the luminous body.

Some naturalists have accounted for the different refrangibility

frangibility of the differently coloured rays, by supposing that the red rays move with the greatest rapidity, and they have determined the difference of original velocity which would produce the observed difference of refraction. But this difference would be observed in the eclipses of Jupiter's satellites. They should be ruddy at their immersions, and be some seconds before they attain their pure whiteness; and they should become bluish immediately before they vanish in emersions. This is not observed. Besides, the difference in refrangibility is much greater in flint glass than in crown glass, and this would require a proportionally greater difference in the original velocities. The explanation therefore must be given up.

118

The refraction of a star greater in the evening than in the morning.

It should follow, that the refraction of a star which is in our meridian at six o'clock in the evening should be greater than that of a star which comes on the meridian at six in the morning; because we are moving away from the first, and approaching to the last. But the difference is but $\frac{1}{3000}$ of the whole, and cannot be observed with sufficient accuracy in any way yet practised. A form of observation has been proposed by Dr Blair, professor of practical astronomy in the university of Edinburgh, which promises a very sensible difference of refraction. It is also to be expected, that a difference will be observed in the refraction of the light from the east and western ends of Saturn's ring. Its diameter is about 26 times that of the earth, and it revolves in 10h. 32′; so that the velocity of its edge is about $\frac{1}{10000}$ of the velocity of the sun's light. If therefore the light be reflected from it according to the laws of perfect elasticity, or in the manner here explained, that which comes to us from the western extremity will move more slowly than that which comes from the eastern extremity in the proportion of 2500 to 2501. And if Saturn can be seen distinctly after a refraction of 30° through a prism, the diameter of the ring will be increased one half in one position of the telescope, and will be as much diminished by turning the telescope half round its axis; and an intermediate position will exhibit the ring of a distorted shape. This experiment is one of the most interesting to optical science, as its result will be a severe touchstone of the theories which have been attempted for explaining the phenomena on mechanical principles.

If the tail of a comet be impelled by the rays of the sun, as is supposed by Euler and others, the light by which its extreme parts are seen by us must have its velocity greatly diminished, being reflected by particles which are moving away from the sun with immense rapidity. This may perhaps be discovered by its greater aberration and refrangibility.

119

All light subject to the same laws.

As common day light is nothing but the sun's light reflected from terrestrial bodies, it is reasonable to expect that it will suffer the same refraction. But nothing but observation could assure us that this would be the case with the light of the stars; and it is rather surprising that the velocity of their light is the same with that of the sun's light. It is a circumstance of connexion between the solar system and the rest of the universe. It was as little to be looked for on the light of terrestrial luminaries. If light be conceived as small particles of matter emitted from bodies by the action of accelerating forces of any kind, the vast diversity which we observe in the constitution of sublunary bodies should make us expect differences in this particular. Yet it is found, that the light of a candle, of a glow-worm, &c. suffers the same refraction, and consists of the same colours. This circumstance is adduced as an argument against the theory of emission. It is thought more probable that this sameness of velocity is owing to the nature of the medium, which determines the frequency of its undulations and the velocity of their propagation.

120

Law of refraction when light passes out of one transparent body into another contiguous to it.

Cor. 4. When two transparent bodies are contiguous, the light in its passage out of the one into the other will be refracted towards or from the perpendicular, according as the refracting forces of the second are greater or less than those of the first, or rather according as the area expressing the square of the specific velocity is greater or less. And as the difference of these areas is a determined quantity, the difference between the velocity in the medium of incidence and the velocity in the medium of refraction, will also be a determined quantity. Therefore the sine of the angle of incidence will be in a constant ratio to the sine of the angle of refraction; and this ratio will be compounded of the ratio of the sine of incidence in the first medium to the sine of refraction in a void; and the ratio of the sine of incidence in a void to the sine of refraction in the second medium. If therefore a ray of light, moving through a void in any direction, shall pass through any number of media bounded by parallel planes, its direction in the last medium will be the same as if it had come into it from a void.

Cor. 5. It also follows from these propositions, that if the obliquity of incidence on the posterior surface of a transparent body be such, that the light should be reflected back again, the placing a mass of the same or of another medium in contact with this surface, will cause it to be transmitted, and this the more completely, as the added medium is more dense or more refractive; and the reflection from the separating surface will be the more vivid in proportion as the posterior substance is less dense or of a smaller refractive power. It is not even necessary that the other body be in contact; it is enough if it be so near, that those parts of the refracting strata which are beyond the bodies interfere with or coincide with each other.

All these consequences are agreeable to experience. The brilliant reflection from a dew-drop ceases when it touches the leaf on which it rests: The brilliancy of a diamond is greatly damaged by moisture getting behind it: The opacity of the combined mirror plates, mentioned in Cor. 2. is removed by letting water get between them: A piece of glass is distinctly or clearly seen in air, more faintly when immersed in water, still more faintly amidst oil of olives, and it is hardly perceived in spirits of turpentine. These phenomena are incompatible with the notion that reflection is occasioned by impact on solid matter, whether of the transparent body, or of any ether or other fancied fluid behind it; and their perfect coincidence with the legitimate consequences of the assumed principles, is a strong argument in favour of the truth of those principles.

121

An objection to the Newtonian theory of refraction.

It is worth while to mention here a fact taken notice of by Mr Beguelin, and proposed as a great difficulty in the Newtonian theory of refraction. In order to get the greatest possible refraction, and the simplest measure of the refracting power at the anterior surface of any transparent

Law of Refraction.

transparent substance, Sir Isaac Newton enjoins us to employ a ray of light falling on the surface *quam obliquissimè*. But Mr Beguelin found, that when the obliquity of incidence in glass was about 89° 50′, no light was refracted, but that it was wholly reflected. He also observed, that when he gradually increased the obliquity of incidence on the superior surface of the glass, the light which emerged last of all did not skim along the surface, making an angle of 90° with the perpendicular, as it should do by the Newtonian theory, but made an angle of more than ten minutes with the posterior surface. Also, when he began with very great obliquities, so that all the light was reflected back into the glass, and gradually diminished the obliquity of incidence, the first ray of light which emerged did not skim along the surface, but was raised about 10 or 15 minutes.

122 Shown to be the necessary consequence of that theory, and of course a confirmation of it.

But all these phenomena are necessary consequences of our principles, combined with what observation teaches us concerning the forces which bodies exert on the rays of light. It is evident, from the experiments of Grimaldi and Newton, that light is both attracted and repelled by solid bodies. Newton's sagacious analysis of these experiments discovered several alternations of actual inflection and deflection; and he gives us the precise distance from the body when some of these attractions end and repulsion commences; and the most remote action to be observed in his experiments is repulsion. Let us suppose this to be the case, although it be not absolutely necessary. Let us suppose that the forces are represented by the ordinates of a curve *a b n p c* which crosses the abscissa in *b*. Draw *b o* parallel to the refracting surface. When the obliquity of incidence of the ray AB has become so great, that its path in the glass, or in the refracting stratum, does not cut, but only touches the line *o b*, it can penetrate no further, but is totally reflected; and this must happen in all greater obliquities. On the other hand, when the ray LE, moving within the glass, has but a very small perpendicular velocity, it will penetrate the refracting stratum no further than till this perpendicular velocity is extinguished, and its path becomes parallel to the surface, and it will be reflected back. As the perpendicular velocity increases by diminishing the obliquity of incidence, it will penetrate farther; and the last reflection will happen when it penetrates so far that its path touches the line *o b*. Now diminish the obliquity by a single second; the light will get over the line *o b*, will describe an arch *o d* B concave upwards, and will emerge in a direction BA, which does not skim the surface, but is sensibly raised above it. And thus the facts observed by M. Beguelin, instead of being an objection against this theory, afford an argument in its favour.

Plate CCCLXXVII. fig. 7.

123 Euler's theory of undulation contrary to fact;

Cor. 6. Those philosophers who maintain the theory of undulation, are under the necessity of connecting the dispersive powers of bodies with their mean refractive powers. M. Euler has attempted to deduce a necessary difference in the velocity of the rays of different colours from the different frequency of the undulations, which he assigns as the cause of their different colorific powers. His reasoning on this subject is of the most delicate nature, and unintelligible to such as are not completely master of the infinitesimal calculus of partial differences, and is unsatisfactory to such as are able to go through its intricacies. It is contradicted by fact. He says, that musical sounds which differ greatly in acuteness are propagated through the air with different velocities: but one of the smallest bells in the chimes of St Giles's church in Edinburgh was struck against the rim of the very deep-toned bell on which the hours are struck. When the sound was listened to by a nice observer at the distance of more than two miles, no interval whatever could be observed. A similar experiment was exhibited to M. Euler himself, by means of a curious instrument used at St Petersburg, and which may be heard at three or four miles distance. But the experiment with the bells is unexceptionable, as the two sounds were produced in the very same instant. This connection between the refrangibility in general and the velocity must be admitted, in its full extent, in every attempt to explain refraction by undulation; and Euler was forced by it to adopt a certain consequence which made a necessary connection between the mean refraction and the dispersion of heterogeneous rays. Confident of his analysis, he gave a deaf ear to all that was told him of Mr Dollond's improvements on telescopes, and asserted, that they could not be such as were related; for an increase of mean refraction must always be accompanied with a *determined* increase of dispersion. Newton had said the same thing, being misled by a limited view of his own principles; but the dispersion assigned by him was different from that assigned by Euler. The dispute between Euler and Dollond was confined to the decision of this question only; and when some glasses made by a German chemist at Petersburg convinced Euler that his determination was erroneous, he did not give up the principle which had forced him to this determination of the dispersion, but immediately introduced a new theory of the achromatic telescopes of Dollond; a theory which took the artists out of the track marked out by mathematicians, and in which they had made considerable advances, and led them into another path, proposing *maxims* of construction hitherto untried, and inconsistent with real improvements which they had already made. The leading principle in this theory is to arrange the different ultimate images of a point which arise either from the errors of a spherical figure or different refrangibility, in a straight line passing through the centre of the eye. The theory itself is specious; and it requires great mathematical skill to accomplish this point, and hardly less to decide on the propriety of the construction which it recommends. It is therefore but little known. But that it is a false theory, is evident from one simple consideration. In the most indistinct vision arising from the worst construction, this rectilineal arrangement of the images obtains completely in that pencil which is situated in the axis, and yet the vision is indistinct. But, what is to our present purpose, this new theory is purely mathematical, suiting any observed dispersive power, and has no connection with the physical theory of undulations, or indeed with any mechanical principles whatever. But, by admitting any dispersive power, whatever may be the mean refraction, all the physical doctrines in his *Nova Theoria Lucis et Colorum* are overlooked, and therefore never once mentioned, although the effects of M. Zeiher's glass are taken notice of as inconsistent with that mechanical proposition of Newton's which occasioned the whole dispute between Euler and Dollond.

124 and misleads artists.

They are indeed inconsistent with the universality of

 that

Law of Refraction.

that proposition. Newton advances it in his Optics merely as a mathematical proposition highly probable, but says that it will be corrected if *he shall find it* false. The ground on which he *seems* (for he does not expressly say so) to rest its probability, is a limited view of his own principle, the action of bodies on light. He (not knowing any cause to the contrary) supposed that the action of all bodies was similar on the different kinds of light, that is, that the specific velocities of the differently coloured rays had a determined proportion to each other. This was gratuitous; and it might have been doubted by him who had observed the analogy between the chemical actions of bodies by elective attractions and repulsions, and the similar actions on light. Not only have different menstrua unequal actions on their solids, but the order of their affinities is also different. In like manner, we might expect not only that some bodies would attract light in general more than others, but also might differ in the proportion of their actions on the different kinds of light, and this so much, that some might even attract the red more than the violet. The late discoveries in chemistry show us some very distinct proofs, that light is not exempted from the laws of chemical action, and that it is susceptible of chemical combination. The changes produced by the sun's light on vegetable colours, show the necessity of illumination to produce the green fecula; and the aromatic oils of plants, the irritability of their leaves by the action of light, the curious effects of it on the mineral acids, on manganese, and the calces of bismuth and lead, and the imbibition and subsequent emission of it by phosphorescent bodies, are strong proofs of its chemical affinities, and are quite inexplicable on the theory of undulations.

All these considerations taken together, had they been known to Sir Isaac Newton, would have made him expect differences quite anomalous in the dispersive powers of different transparent bodies; at the same time that they would have afforded to his sagacious mind the strongest arguments for the actual emission of light from the luminous body.

Having in this manner established the observed law of refraction on mechanical principles, showing it to be a necessary consequence of the known action of bodies on light, we proceed to trace its mathematical consequences through the various cases in which it may be exhibited to our observation. These constitute that part of the mathematical branch of optical science which is called *dioptrics*.

125
The variation of the intensity of attractions and repulsions unknown.

We are quite unacquainted with the law of action of bodies on light, that is, with the variation of the intensity of the attractions and repulsions exerted at different distances. All that we can say is, that from the experiments and observations of Grimaldi, Newton, and others, light is deflected towards a body, or is attracted by it, at some distances, and repelled at others, and this with a variable intensity. The action may be extremely different, both in extent and force, in different bodies, and change by a very different law with the same change of distance. But, amidst all this variety, there is a certain similarity arising from the joint action of many particles, which should be noticed, because it tends both to explain the similarity observed in the refractions of light, and also its connexion with the phenomena of reflection.

126
The law of variation in the action of many particles different from that of one.
Plate CCCLXXVII. fig. 9.

The law of variation in the joint action of many particles adjoining to the surface of a refracting medium, is extremely different from that of a single particle; but when this last is known, the other may be found out. We shall illustrate this matter by a very simple case. Let DE be the surface of a medium, and let us suppose that the action of a particle of the medium on a particle of light extends to the distance EA, and that it is proportional to the ordinates ED, Ff, Gg, Hh, &c. of the line AhCgfD; that is, that the action of the particle E of the medium on a particle of light in F, is to its action on a particle in H as Ff to Hh, and that it is attracted at F but repelled at H, as expressed by the situation of the ordinates with respect to the abscissa. In the line AE produced to B, make EB, Eχ, E$\varkappa$, Eγ, Eφ, &c. respectively equal to EA, EH, EC, EG, EF, &c.

It is evident that a particle of the medium at B will exert no action on the particle of light in E, and that the particles of the medium in $\varkappa\gamma\varphi$E, will exert on it actions proportional to Hh, Gg, Ff, ED. Therefore, supposing the matter of the medium continuous, the whole action exerted by the row of particles EB will be represented by the area AhCDE; and the action of the particles between B and φ will be represented by the area AhCfF, and that of the particles between E and φ by the area FfDE.

Now let the particle of light be in F, and take Fo =AE. It is no less evident that the particle of light in F will be acted on by the particles in Eo alone, and that it will be acted on in the same manner as a particle in E is acted on by the particles in φB. Therefore the action of the whole row of particles EB on a particle in F will be represented by the area AhCfF. And thus the action on a particle of light in any point of AE will be represented by the area which lies beyond it.

But let us suppose the particles of light to be within the medium, as at φ, and make φd=AE. It is again evident that it is acted on by the particles of the medium between φ and d with a force represented by the area AhCDE, and in the opposite direction by the particles in Eφ with a force represented by the area FfDE. This balances an equal quantity of action, and there remains an action expressed by the area AhCfF. Therefore, if an equal and similar line to AhCDE be described on the abscissa EB, the action of the medium on a particle of light in φ will be represented by the area $\varphi f \varkappa h$B, lying beyond it.

If we now draw a line AKLMRNPB, whose ordinates CK, FQ, φR, &c. are as the areas of the other curve, estimated from A and B; these ordinates will represent the whole forces which are exerted by the particles in EB, on a particle of light moving from A to B. This curve will cut the axis in points L, N such, that the ordinates drawn through them intercept areas of the first curve, which are equal on each side of the axis; and in these points the particle of light sustains no action from the medium. These points are very different from the similar points of the curve expressing the action of a single particle. These last are in the very places where the light sustains the greatest repulsive action

Refraction by Plane Surfaces.

tion of the whole row of particles. In the same manner may a curve be constructed, whose ordinates express the united action of the whole medium.

From these observations we learn in general, that a particle of light within the space of action is acted on with equal forces, and in the same direction, when at equal distances on each side of the surface of the medium.

Sect. II. *Of the focal distance of rays refracted by passing out of one medium into another of different density and through a plane surface.*

Lemma.

The indefinitely small variation of the angle of incidence is to the simultaneous variation of the angle of refraction, as the tangent of incidence is to the tangent of refraction; or, the cotemporaneous variations of the angles of incidence and refraction are proportional to the tangents of these angles.

Plate cclxxvii. fig. 10.

127 Laws of refraction in plane surfaces.

Let RVF, or r V f (fig. 10.) be the progress of the rays refracted at V (the angle r VR being considered in its nascent or evanescent state), and VC perpendicular to the refracting surface VA. From C draw CD, CB perpendicular to the incident and refracted rays RV, VF, cutting r V, V f in δ and β, and let C d, C b be perpendicular to r V, V f.

Because the sines of incidence and refraction are in a constant ratio, their simultaneous variations are in the same constant ratio. Now the angle RV r is to the angle FVf in the ratio of $\frac{B\beta}{BV}$ to $\frac{D\delta}{DV}$; that is, of $\frac{BC}{BV}$ to $\frac{DC}{DV}$; that is, of $\frac{\text{sin. incid.}}{\text{cos. incid.}}$ to $\frac{\text{sin. refr.}}{\text{cos. refr.}}$; that is, of *tan. incid.* to *tan. refr.*

Corollary. The difference of these variations is to the greatest or least of them as the difference of the tangents to the greatest or least tangent.

Problem.

Plate cclxxviii. figs. 1, 2, 3, 4.

Let two rays RV, RP diverge from, or converge to, a point R, and pass through the plane surface PV, separating two refracting mediums AB, of which let B be the most refracting, and let RV be perpendicular to the surface. It is required to determine the point of dispersion or convergence, F, of the refracted rays VD, PE.

Make VR to VG as the sine of refraction to the sine of incidence, and draw GIK parallel to the surface, cutting the incident ray in I. About the centre P, with the radius PI, describe an arch of a circle IF, cutting VR in F; draw PE tending from or towards F. We say PE is the refracted ray, and F the point of dispersion or convergence of the rays RV, RP, or the conjugate focus to R.

For since GI and PV are parallel, and PF equal to PI, we have PF : PR=PI : PR,=VG : VR,=sin. incid. : sin. refr. But PF : PR=sin. PRV : sin. PFV, and RRV is equal to the angle of incidence at P; therefore PFV is the corresponding angle of refraction; FPE is the refracted ray, and F the conjugate focus to R.

Cor. 1. If diverging or converging rays fall on the surface of a more refracting medium, they will diverge or converge less after refraction, F being farther from the surface than R. The contrary must happen when the diverging or converging rays fall on the surface of a less refracting medium, because, in this case, F is nearer to the surface than R.

Cor. 2. Let Rp be another ray, more oblique than RP, the refracting point p being farther from V, and let f p e be the refracted ray, determined by the same construction. Because the arches FI, fi, are perpendicular to their radii, it is evident that they will converge to some point within the angle RIK, and therefore will not cross each other between F and I; therefore R f will be greater than RF, as RF is greater than RG, for similar reasons. Hence it follows, that all the rays which tended from or towards R, and were incident on the whole of VP p, will not diverge from or converge to F, but will be diffused over the line GFf. This diffusion is called aberration from the focus, and is so much greater as the rays are more oblique. No rays flowing from or towards R will have the point of concourse with RV nearer to R than F is: But if the obliquity be inconsiderable, so that the ratio of RP to FP does not differ sensibly from that of RV to FV, the point of concourse will not be sensibly removed from G. G is therefore usually called the *conjugate focus* to R. It is the conjugate focus of an indefinitely slender pencil of rays falling perpendicularly on the surface. The conjugate focus of an oblique pencil, or even of two oblique rays, whose dispersion on the surface is considerable, is of more difficult investigation. See *Gravesande's Natural Philosophy* for a very neat and elementary determination (B).

In a work of this kind, it is enough to have pointed out, in an easy and familiar manner, the nature of optical aberration. But as this is the chief cause of the imperfection of optical instruments, and as the only method of removing this imperfection is to diminish this aberration, or correct it by a subsequent aberration in the opposite direction, we shall here give a fundamental and very simple proposition, which will (with obvious alterations) apply to all important cases. This is the determination of the focus of an infinitely slender pencil of oblique rays RP, Rp.

" Retaining the former construction for the ray PF, (fig. 1.)

(B) We refer to Gravesande, because we consider it of importance to make such a work as ours serve as a general index to science and literature. At the same time we take the liberty to observe, that the focus in question is virtually determined by the construction which we have given: for the points P, F of the line PF are determined, and therefore its position is also determined. The same is true of the position of pf, and therefore the intersection φ of the two lines is likewise determined.

(fig. 1) suppose the other ray R p infinitely near to RP. Draw PS perpendicular to PV, and R r perpendicular to RP, and make P r : PS=VR : VF. On P r describe the semicircle r RP, and on PS the semicircle S ϕ P, cutting the refracted ray PF in ϕ; draw $p\,r$, p S, $p\,\phi$." It follows from the lemma, that if ϕ be the focus of refracted rays, the variation P ϕ p of the angle of refraction is to the corresponding variation PR p of the angle of incidence as the tangent of the angle of refraction VFP to the tangent of the angle of incidence VRP. Now P p may be considered as coinciding with the arch of the semicircles. Therefore the angles PR p, P r p are equal, as also the angles P ϕp, PS p. But PS p is to P r p as P r to PS; that is, as VR to VF; that is, as the cotangent of the angle of incidence to the cotangent of the angle of refraction; that is, as the tangent of the angle of refraction to the tangent of the angle of incidence. Therefore the point ϕ is the focus.

Sect. III. *Of Refraction by Spherical Surfaces.*

Problem.

To find the focus of refracted rays, the focus of incident rays being given.

Plate cccxxviii. figs. 5, 6, &c.

Let PV π (figs. 5, 6, 7, 8, 9, 10, 11, 12, 13, 14,) be a spherical surface whose centre is C, and let the incident light diverge from or converge to R. Draw the ray RC through the centre, cutting the surface in the point V, which we shall denominate the *vertex*, while RC is called the *axis*. This ray passes on without refraction, because it coincides with the perpendicular to the surface.

128 The focus of rays refracted by spherical surfaces ascertained.

Let RP be another incident ray, which is refracted at P; draw the radius PC. In RP make RE to RP as the sine of incidence m to the sine of refraction n; and about the centre R, with the distance RE, describe the circle EK, cutting PC in K; draw RK and RF parallel to it, cutting the axis in F. PF is the refracted ray, and F is the focus.

For the triangles PCF, KCR are similar, and the angles at P and K are equal. Also RK is equal to RE, and RPD is the angle of incidence. Now $m:n$=RK : RP, =sin. DPR : sin. RKP, =sin. DPR : sin. CPF. Therefore CPF is the angle of refraction corresponding to the angle of incidence RPD, and PF is the refracted ray, and F the focus. Q. E. D.

Cor. 1. CK : CP=CR : CF, and $\text{CF}=\dfrac{\text{CP}\times\text{CR}}{\text{CK}}$.

Now CP$\times$CR is a constant quantity; and therefore CF is reciprocally as CK, which evidently varies with a variation of the arch VP. Hence it follows, that all the rays flowing from R are not collected at the conjugate focus F. The ultimate situation of the point F, as the point P gradually approaches to, and at last coincides with, V, is called *the conjugate focus of central rays*, and the distance between this focus and the focus of a lateral ray is called *the aberration* of that ray, arising from the spherical figure.

There are, however, two situations of the point R such, that all the rays which flow from it are made to diverge from one point. One of those is C (fig. 5.), because they all pass through without refraction, and therefore still diverge from C; the other is when rays in the rare medium with a convex surface flow from a point R, so situated beyond the centre that CV is to CR as the sine of incidence in the rare medium is to the sine of refraction in the denser, or when rays in the rare medium fall on the convex surface of the denser, converging to F, so situated that CF : CV= $m:n$. In this case they will all be dispersed from F, so situated that CV : CF=$n:m$,=CR : CV for sine RPC : sine PKC=$n:m$, =CR : CP, =sine RPC : sine PRC. Therefore the angle PRC is equal to PKC, or to FPC (by construction of the problem), and the angle C is common to the triangles PRC, FPC; they are therefore similar, and the angles PRC, FPC are equal, and $n:m$= CP : CF, =CK : CR, =CR : CP; therefore CP : CK= CP^2 : CR^2 : but CP and CR are constant quantities, and therefore CK is a constant quantity, and (by the corollary) CF is a constant quantity, and all the rays flowing from R are dispersed from F by refraction. In like manner rays converging to F will by refraction converge to R. This was first observed by Huygens.

Cor. 2. If the incident ray R'P is parallel to the axis KC, we have PO to CO as the sine of incidence to the sine of refraction. For the triangles R'PK'PCO are similar, and PO : CO=R'K' : R'P, =$m:n$. Fig. 5.

Cor. 3. In this case, too, we have the focal distance of central parallel rays reckoned from the vertex = $\dfrac{n}{m-n}\times$VC. For since PO is ultimately VO, we have $m:n$=VO : CO, and $m-n:m$=VO—CO : VO, = VC : VO, and VO=$\dfrac{m}{m-n}\times$VC. This is called the principal focal distance, or focal distance of parallel rays. Also CO, the principal focal distance reckoned from the centre, =$\dfrac{n}{m-n}\times$VC.

N. B. When m is less than n, $m-n$ is a negative quantity.—Also observe, that in applying symbols to this computation of the focal distances, those lines are to be accounted positive which lie from their beginnings, that is, from the vertex, or the centre, or the radiant point, in the direction of the incident rays. Thus when rays diverge from R on the convex surface of a medium, VR is accounted negative and VC positive. If the light passes out of air into glass, m is greater than n; but if it passes out of glass into air, m is less than n. If, therefore, parallel rays fall on the convex surface of glass out of air, in which case $m:n=3:2$ very nearly, we have for the principal focal distance $\dfrac{3}{2-3}$VC, or $+3$ VC. But if it pass out of glass into the convex surface of air, we have VO=$\dfrac{2}{2-3}$VC, or -2 VC; that is, the focus O will be in the same side of the surface with the incident light. In like manner, we shall have for these two cases CO=$+2$VC, and -3VC.

Cor. 4. By construction we have RK : RP=$m:n$

by similarity of triangles	PF : RK=CF : CR
therefore	PF : PR=mCF : nCR
and	mPR$\times$CF=nCR$\times$PF
therefore	mPR : nCR=PF : CF
and	mPR—nCR : mPR=PF—CF : PF
ultimately	mVR—nCR : mVR=VC : VF

This is a very general optical theorem, and affords an easy method for computing the focal distance of refracted rays.

For

Refraction by Spherical Surfaces.

For this purpose let VR, the distance of the radiant point, be expressed by the symbol r, the distance of the focus of refracted rays by the symbol f, and the radius of the spherical surface by a; we have

$$mr - n\overline{r-a} : mr = a : f, \text{ and}$$

$$f = \frac{mar}{mr - n\overline{r-a}}, = \frac{mar}{\overline{m-n}\,r + nd}.$$

In its application due attention must be paid to the qualities of r and a, whether they be positive or negative, according to the conditions of last corollary.

Plate cccLXXVIII. Fig. 8.

Cor. 5. If Q be the focus of parallel rays coming from the opposite side, we shall have RQ : QC=RV : VF. For draw Cq parallel to PF, cutting RP in q; then Rq : qC=RP : PF. Now q is the focus of the parallel rays FP, Cq. And when the point P ultimately coincides with the point V, q must coincide with Q, and we have RQ : QC=RV : VF.

This is the most general optical theorem, and is equally applicable to lenses, or even to a combination of them, as to simple surfaces. It is also applicable to reflections, with this difference, that Q is to be assumed the focus of parallel rays coming the *same* way with the incident rays. It affords us the most compendious methods of computing symbolically and arithmetically the focal distances in all cases.

Cor. 6. We have also Rq : RP=RV : RF, and ultimately for central rays RQ : RV=RV : RF, and RF$=\frac{RV^2}{RQ}$. This proposition is true in lenses and mirrors, but not in single refracting surfaces.

Cor. 7. Also Rq : RC=RP : RF, and ultimately RQ : RV=RC : RF, and RF$=\frac{RV \times RC}{RQ}$. *N.B.* These four points Q, V, C, F, either lie all one way from P, or two of them forward and two backward.

Cor. 8. Also making O the principal focus of rays coming the same way, we have Rq : qC=Co : oF, and ultimately RQ : Qc=cO : OF, and OF$=\frac{QC \times CO}{RQ}$, and therefore reciprocally proportional to RQ, because QC$\times co$ is a constant quantity.

These corollaries or theorems give us a variety of methods for finding the focus of refracted rays, or the other points related to them; and each formula contains four points, of which any three being given, the fourth may be found. Perhaps the last is the most simple, as the quantity $oc+c$Q is always negative, because o and Q are on different sides.

Cor. 9. From this construction we may also derive a very easy and expeditious method of drawing many refracted rays. Draw through the centre C (fig. 15. 16.) a line to the point of incidence P, and a line CA parallel to the incident ray RP. Take VO to VC as the sine of incidence to the sine of refraction, and about A, with the radius VO, describe an arch of a circle cutting PC produced in B. Join AB; and PF parallel to AB is the refracted ray. When the incident light is parallel to RC, the point A coincides with V, and a circle described round V with the distance VO will cut the lines PC, pC, &c. in the points B b. The demonstration is evident.

Having thus determined the focal distance of refracted rays, it will be proper to point out a little more particularly its relation to its conjugate focus of incident rays. We shall consider the four cases of light incident on the convex or concave surface of a denser or a rarer medium.

Fig. 5. to fig. 14.

1. Let light moving in air fall on the convex surface of glass. Let us suppose it tending to a point beyond the glass infinitely distant. It will be collected to its principal focus o beyond the vertex V. Now let the incident light converge a little, so that R is at a great distance beyond the surface. The focus of refracted rays F will be a little within O or nearer to V. As the incident rays are made to converge more and more, the point R comes nearer to V, and the point F also approaches it, but with a much slower motion, being always situated between O and C till it is overtaken by R at the centre C, when the incident light is perpendicular to the surface in every point, and therefore suffers no refraction. As R has overtaken F at C, it now passes it, and is again overtaken by it at V. Now the point R is on the side from which the light comes, that is, the rays diverge from R. After refraction they will diverge from F a little without R; and as R recedes farther from V, F recedes still farther, and with an accelerated motion, till, when R comes to Q, F has gone to an infinite distance, or the refracted rays are parallel. When R still recedes, F now appears on the other side, or beyond V; and as R recedes back to an infinite distance, F has come to O: and this completes the series of variations, the motion of F during the whole changes of situation being in the same direction with the motion of R.

2. Let the light moving in air fall on the concave surface of glass; and let us begin with parallel incident rays, conceiving, as before, R to lie beyond the glass at an infinite distance. The refracted rays will move as if they came from the principal focus O, lying on that side of the glass from which the light comes. As the incident rays are made gradually more converging, and the point of convergence R comes toward the glass, the conjugate focus F moves backward from O; the refracted rays growing less and less diverging, till the point R comes to Q, the principal focus on the other side. The refracted rays growing parallel, or F has retreated to an infinite distance. The incident light converging still more, or R coming between Q and V, F will appear on the other side, or beyond the surface, or within the glass, and will approach it with a retarded motion, and finally overtake R at the surface of the glass. Let R continue its motion backwards (for it has all the while been moving backwards, or in a direction contrary to that of the light); that is, let R now be a radiant point, moving backwards from the surface of the glass. F will at first be without it, but will be overtaken by it at the centre C, when the rays will suffer no refraction. R still receding will get without F; and while R recedes to an infinite distance, F will recede to O, and the series will be completed.

3. Let the light moving in glass fall on the convex surface of air; that is, let it come out of the concave surface of glass, and let the incident rays be parallel, or tending to R, infinitely distant: they will be dispersed by refraction from the principal focus O, within the glass. As they are made more converging, R comes

On Lenses. comes nearer, and F retreats backward, till R comes to Q, the principal focus without the glass; when F is now at an infinite distance within the glass, and the refracted rays are parallel. R still coming nearer, F now appears before the glass, overtakes R at the centre C, and is again overtaken by it at N. R now becoming a radiant point within the glass, F follows it backwards, and arrives at O, when R has receded to an infinite distance, and the series is completed.

4. Let the incident light, moving in glass, fall on the concave surface of air, or come out of the convex surface of glass. Let it tend to a point R at an infinite distance without the glass. The refracted rays will converge to O, the principal focus without the glass. As the incident light is made more converging, R comes towards the glass, while F, setting out from *v*, also approaches the glass, and R overtakes it at the surface V. R now becomes a radiant point within the glass, receding backwards from the surface. F recedes slower at first, but overtakes R at the centre C, and passes it with an accelerated motion to an infinite distance; while R retreats to Q, the principal focus within the glass. R still retreating, F appears before the glass; and while R retreats to an infinite distance, F comes to V, and the series is completed.

Sect. IV. *On Lenses.*

129
Lenses, how many. Lenses for optical purposes may be ground into nine different shapes. Lenses cut into five of those shapes, together with their axes, are described in vol. vi. page 33. (See Dioptrics). The other four are,

Plate CCCLXXIX. figs. 1. 2.

1. A *plane glass*, which is flat on both sides, and of equal thickness in all its parts, as EF, fig. 1.
2. A *flat plano-convex*, whose convex side is ground into several little flat surfaces as A, fig. 2.
3. A *prism*, which has three flat sides, and when viewed endwise appears like an equilateral triangle, as B.
4. A *concavo-convex* glass, or *meniscus*, as C, which is seldom made use of in optical instruments.

Fig. 1.

A ray of light G*h* falling perpendicularly on a plane glass EF, will pass through the glass in the same direction *hi*, and go out of it into the air in the same straight line *i* H.

A ray of light AB falling obliquely on a plane glass, will go out of the glass in the same direction, but not in the same straight line: for in touching the glass, it will be refracted into the line BC; and in leaving the glass, it will be refracted in the line CD.

Lemma.

Fig. 3. to 6. There is a certain point E within every double convex or double concave lens, through which every ray that passes will have its incident and emergent parts QA, *a q* parallel to each other: but in a plano-convex or plano-concave lens, that point E is removed to the vertex of the concave or convex surface; and in a meniscus, and in that other concavo-convex lens, it is removed a little way out of them, and lies next to the surface which has the greatest curvature.

For let RE*r* be the axis of the lens joining the centres B, *r* of its surfaces A, *a*. Draw any two of their semidiameters RA, *r a* parallel to each other, and join the point, A, *a*, and the line A *a* will cut the axis in the point E above described. For the triangles REA, *r* E *r* being equiangular, RE will be to E *r* in the given ratio of the semidiameters RA, *ra;* and consequently the point E is invariable in the same lens. Now supposing a ray to pass both ways along the line A *a*, it being equally inclined to the perpendiculars to the surfaces, will be equally bent, and contrariwise in going out of the lens; so that its emergent part AQ *aq* will be parallel. Now any of these lenses will become plano-convex or plano-concave, by conceiving one of the semidiameters RA, *r a* to become infinite, and consequently to become parallel to the axis of the lens, and then the other semidiameter will coincide with the axis; and so the points A, E or *a*, E will coincide. Q. E. D.

Corol. Hence when a pencil of rays falls almost perpendicularly upon any lens, whose thickness is inconsiderable, the course of the ray which passes through E, above described, may be taken for a straight line passing through the centre of the lens without sensible error in sensible things. For it is manifest from the length of A *a*, and from the quantity of the refractions at its extremities, that the perpendicular distance of AQ, *a q*, when produced, will be diminished both as the thickness of the lens and the obliquity of the ray is diminished.

Prop. I.

To find the focus of parallel rays falling almost perpendicularly upon any given lens.

Let E be the centre of the lens, and *r* the centres of its surfaces, R *r* its axis, *g* EG a line parallel to the incident rays upon the surface B, whose centre is R. Parallel to *g* E draw a semidiameter BR, in which produced let V be the focus of the rays after their first refraction at the surface B, and joining *r* let it cut *g* E produced in G, and G will be the focus of the rays that emerge from the lens.

Fig. 7. to 12.

130
The focus of parallel rays falling perpendicularly upon any lens.

For since V is also the focus of the rays incident upon the second surface A, the emergent rays must have their focus in some point of that ray which passes straight through this surface; that is, in the line V *r*, drawn through its centre *r*: and since the whole course of another ray is reckoned a straight line *g* EG †, its intersection G with V *r* determines the focus of them all. Q. E. D.

† Corol. from Lemma.

Corol. 1. When the incident rays are parallel to the axis *r* R, the focal distance EF is equal to EG. For let the incident rays that were parallel to *g* E be gradually more inclined to the axis till they become parallel to it; and their first and second foci V and G will describe circular arches NT and GF whose centres are R and E. For the line RV is invariable; being in proportion to RB in a given ratio of the lesser of the sines of incidence and refraction to their difference (by a former proposition); consequently the line EG is also invariable, being in proportion to the given line RV in the given ratio of *r* E to *r* R, because the triangles EG *r*, RV *r* are equiangular.

Corol. 2. The last proportion gives the following rule for finding the focal distance of any thin lens. As R *r*, the interval between the centres of the surfaces, is

Of Lenses. is to r E, the semidiameter of the second surface, so is RV or RT, the continuation of the first semidiameter to the first focus, to EG or EF the focal distance of the lens; which, according as the lens is thicker or thinner in the middle than at its edges, must lie on the same side as the emergent rays, or on the opposite side.

Corol. 3. Hence when rays fall parallel on both sides of any lens, the focal distances EF, Ef are equal. For let rt be the continuation of the semidiameter Er to the first focus t of rays falling parallel upon the surface A; and the same rule that gave rR : rE = RT : EF, gives also rR : RE = rt : Ef. Whence Ef = EF, because the rectangles rE × RT = RE × rt. For rE is to rt and also RE to RT in the same given ratio.

Corol. 4. Hence in particular in a double convex or double concave lens made of glass, it is as the sum of their semidiameters (or in a meniscus as their difference) to either of them, so is double the other, to the focal distance of the glass. For the continuations RT, rt are severally double their semidiameters: because in glass ET : TR and also Et : tr = 3 : 2.

Corol. 5. Hence if the semidiameters of the surfaces of the glass be equal, its focal distance is equal to one of them; and is equal to the focal distance of a plano-convex or plano-concave glass whose semidiameter is as short again. For considering the plane surface as having an infinite semidiameter, the first ratio of the last-mentioned proportion may be reckoned a ratio of equality.

Prop. II.

131 The focus of emergent rays found. Plate CCLXXX. fig. 1. to 6.

The focus of incident rays upon a single surface, sphere, or lens, being given, it is required to find the focus of the emergent rays.

Let any point Q be the focus of incident rays upon a spherical surface, lens, or sphere, whose centre is E; and let other rays come parallel to the line QEq the contrary way to the given rays, and after refraction let them belong to a focus F; then taking Ef equal to EF the lens or sphere, but equal to FC in the single surface, say as QF to FE so Ef to fq; and placing fq the contrary way from f to that of FQ from F, the point q will be the focus of the refracted rays, without sensible error; provided the point Q be not so remote from the axis, nor the surfaces so broad, as to cause any of the rays to fall too obliquely upon them.

For with the centre E and semidiameters EF and Ef describe two arches FG, fg cutting any ray QAaq in G and g, and draw EG and Eg. Then supposing G to be a focus of incident rays (as GA), the emergent rays (as agq) will be parallel to GE*; and on the other hand supposing g another focus of incident rays (as ga), the emergent rays (as AGQ) will be parallel to gE. Therefore the triangles QGE, Egq are equiangular, and consequently QG : GE = Eg : gq; that is, when the ray QAaq is the nearest to QEq, QF : FE = Ef : fg. Now when Q accedes to F and coincides with it, the emergent rays become parallel, that is, q recedes to an infinite distance; and consequently when Q passes to the other side of F, the focus q will also pass through an infinite space from one side of f to the other side of it. Q. E. D.

* By Cor. I. from former Prop.

Corol. 1. In a sphere or lens the focus q may be found by this rule: QF : QE = QE : Qq, to be placed the same way from Q as QF lies from Q.—For let the incident and emergent rays QA, qa be produced till they meet in e; and the triangles QGE, Qeq being equiangular, we have QG : QE = Qe : Qq; and when the angles of these triangles are vanishing, the point e will coincide with E; because in the sphere the triangle Aea is equiangular at the base Aa, and consequently Ae and ae will at last become semidiameters of the sphere. In a lens the thickness Aa is inconsiderable.

The focus may also be found by this rule;—QF : FE = QE : Eq, for QG : GE = QA : Aq.—And then the rule formerly demonstrated for single surfaces holds good for the lenses.

Corol. 2. In all cases the distance fq varies reciprocally as FQ does; and they lie contrariwise from f and F; because the rectangle or the square under EF and Ef, the middle terms in the foregoing proportions, is invariable.

The principal focal distance of a lens may not only be found by collecting the rays coming from the sun, considered as parallel, but also (by means of this proposition) it may be found by the light of a candle or window. For, because Qq : qA = QE : EG, we have (when A coincides with E) Qq : qE = QE : EF; that is, the distance observed between the radiant object and its picture in the focus is to the distance of the lens from the focus as the distance of the lens from the radiant is to its principal focal distance. Multiply therefore the distances of the lens from the radiant and focus, and divide the product by their sum.

Corol. 3. Convex lenses of different shapes that have equal focal distance when put into each others places, have equal powers upon any pencil of rays to refract them to the same focus. Because the rules above mentioned depend only upon the focal distance of the lens, and not upon the proportion of the semidiameters of its surfaces.

Corol. 4. The rule that was given for a sphere of an uniform density, will serve also for finding the focus of a pencil of rays refracted through any number of concentric surfaces, which separate uniform mediums of any different densities. For when rays come parallel to any line drawn through the common centre of these mediums, and are refracted through them all, the distance of their focus from that centre is invariable, as in an uniform sphere.

Corol. 5. When the focuses Q, q lie on the same side of the refracting surfaces, if the incident rays flow from Q, the refracted rays will also flow from q; and if the incident rays flow towards Q, the refracted will also flow towards q: and the contrary will happen when Q and q are on contrary sides of the refracting surfaces. Because the rays are continually going forwards.

From this proposition we also derive an easy method of drawing the progress of rays through any number of lenses ranged on a common axis.

Let A, B, C, be the lenses, and RA a ray incident on the first of them. Let α, β, κ, be their foci for parallel rays coming in the opposite direction; draw the perpendicular αd, cutting the incident ray in d, and draw da through the centre of the lens: AB parallel Fig. 7.

to $d\,a$ will be the ray refracted by the first lens. Through the focus of the second lens draw the perpendicular $\beta\,e$, cutting AB in e; and draw $e\,b$ through the centre of the second lens. BD parallel to $b\,e$ will be the next refracted ray. Through the focus $\varkappa$ of the third lens draw the perpendicular $\varkappa f$, cutting BD in f, and draw $f\,c$ through the centre of the third lens. CE parallel to $f\,c$, will be the refracted ray; and so on.

Sect. V. *On Vision.*

Having described how the rays of light, flowing from objects, and passing through convex glasses, are collected into points, and form the images of external objects; it will be easy to understand how the rays are refracted by the humours of the eye, and are thereby collected into innumerable points on the retina, on which they form the images of the objects from which they flow. For the different humours of the eye, and particularly the crystalline, are to be considered as a convex glass; and the rays in passing through them as affected in the same manner in the one as in the other. A description of the coats and humours, &c. has been given in Anatomy; but it will be proper to repeat as much of the description as will be sufficient for our present purpose.

Plate CCLXXX. fig. 3.

132

Description of the eye.

The eye is nearly globular, and consists of three coats and three humours. The part DHHG of the outer coat, is called the *sclerotica;* the rest, DEFG, the *cornea.* Next within this coat is that called the *choroides*, which serves as it were for a lining to the other, and joins with the iris, $m\,n$, $m\,n$. The iris is composed of two sets of muscular fibres; the one of a circular form, which contracts the hole in the middle called the *pupil*, when the light would otherwise be too strong for the eye; and the other of radical fibres, tending everywhere from the circumference of the iris towards the middle of the pupil; which fibres, by their contraction, dilate and enlarge the pupil when the light is weak, in order to let in a greater quantity of it. The third coat is only a fine expansion of the optic nerve L, which spreads like net work all over the inside of the choroides, and is therefore called the *retina;* upon which are thrown the images of all visible objects.

Under the cornea is a fine transparent fluid like water, thence called the *aqueous humour*. It gives a protuberant figure to the cornea, fills the two cavities $m\,m$ and $n\,n$, which communicate by the pupil P; and has the same limpidity, specific gravity, and refracting power, as water. At the back of this lies the crystalline humour II, which is shaped like a double convex glass; and is a little more convex on the back than the fore part. It converges the rays, which pass through it from every visible object to its focus at the bottom of the eye. This humour is transparent like crystal, is of the consistence of hard jelly, and is to the specific gravity of water as 11 to 10. It is enclosed in a fine transparent membrane, called the capsule of the crystalline lens, from which proceed radial fibres $o\,o$, called the *ciliary ligaments*, all around its edge, and join to the circumference of the iris.

At the back of the crystalline, lies the *vitreous* humour KK, which is transparent like glass, and is largest of all in quantity, filling the whole orb of the eye, and giving it a globular shape. It is much of a consistence with the white of an egg, and very little exceeds the specific gravity and refractive power of water.

133

The objects on the retina of the eye are inverted.

As every point of an object ABC, sends out rays in all directions, some rays, from every point on the side next the eye, will fall upon the cornea between E and F; and by passing on through the pupil and humours of the eye, they will be converged to as many points on the retina or bottom of the eye, and will form upon it a distinct inverted picture $c\,b\,a$, of the object. Thus, the pencil of rays $q\,r\,s$ that flows from the point A of the object, will be converged to the point a on the retina; those from the point B will be converged to the point b; those from the point C will be converged to the point c; and so of all the intermediate points: by which means the whole image $a\,b\,c$ is formed, and the object made visible; though it must be owned, that the method by which this sensation is conveyed by the optic nerve from the eye to the brain, and there discerned, is above the reach of our comprehension. Fig. 8.

That vision is effected in this manner, may be demonstrated experimentally. Take a bullock's eye whilst it is fresh; and having cut off the three coats from the back part, quite to the vitreous humour, put a piece of white paper over that part, and hold the eye towards any bright object, and you will see an inverted picture of the object upon the paper, or the same thing may be better accomplished by paring the sclerotic coat so thin that it becomes a little transparent, and retains the vitreous humour.

134

Why they are seen upright.

Since the image is inverted, many have wondered why the object appears upright. But we are to consider, 1. That *inverted* is only a relative term: and, 2. That there is a very great difference between the real object and the image by which we perceive it. When all the parts of a distant prospect are painted upon the retina, they are all right with respect to one another, as well as the parts of the prospect itself; and we can only judge of an object's being inverted, when it is turned reverse to its natural position with respect to other objects which we see and compare it with.—If we lay hold of an upright stick in the dark, we can tell which is the upper or lower part of it, by moving our hand downward and upward; and know very well that we cannot feel the upper end by moving our hand downward. In the same manner we find by experience, that upon directing our eyes towards a tall object, we cannot see its top by turning our eyes downward, nor its foot by turning our eyes upward; but must trace the object the same way by the eye to see it from head to foot, as we do by the hand to feel it; and as the judgment is informed by the motion of the hand in one case, so it is also by the motion of the eye in the other.

In fig. 9. is exhibited the manner of seeing the same object ABC, by both the eyes D and E at once. Fig. 9.

135

An object when viewed with both eyes does not appear double, because the optic nerve is insensible of light.

When any part of the image $c\,b\,a$ falls upon the optic nerve L, the corresponding part of the object becomes invisible. On this account, the optic nerve is wisely placed, not in the middle of the bottom of the eye, but towards the side next the nose; so that whatever part of the image falls upon the optic nerve of one eye, may not fall upon the optic nerve of the other. Thus the point a of the image $c\,b\,a$ falls upon the optic nerve of the eye D, but not of the eye E; and the point

c

Of Vision. *c* falls upon the optic nerve of the eye E, but not of the eye D; and therefore to both eyes taken together, the whole object ABC is visible.

The nearer that any object is to the eye, the larger is the angle under which it is seen, and the magnitude of which it appears. Thus to the eye D, the object ABC is seen under the angle APC; and its image *c b a* is very large upon the retina: but to the eye E, at a double distance, the same object is seen under the angle A*p*C, which is equal only to half the angle APC, as is evident by the figure. The image *c b a* is likewise twice as large in the eye D, as the other image *c b a* is in the eye E. In both these representations, a part of the image falls on the optic nerve, and the object in the corresponding parts is invisible.

Plate CCCLXXXI. fig. 1.

As the sense of seeing is allowed to be occasioned by the impulse of the rays from the visible object upon the retina, and thus forming the image of the object upon it, and that the retina is only the expansion of the optic nerve all over the choroides; it should seem surprising, that the part of the image which falls on the optic nerve should render the like part of the object invisible; especially as that nerve is allowed to be the instrument by which the impulse and image are conveyed to the common sensory in the brain.

136 Proved by experiment. Fig. 2.

That part of the image which falls upon the middle of the optic nerve is lost, and consequently the corresponding part of the object is rendered invisible, is plain by experiment. For if a person fixes three patches, A, B, C, (fig. 2.) upon a white wall, at the height of the eye, and at the distance of about a foot from each other, and places himself before them, shutting the right eye, and directing the left towards the patch C, he will see the patches A and C, but the middle patch B will disappear. Or, if he shuts his left eye, and directs the right towards A, he will see both A and C, but B will disappear; and if he directs his eye towards B, he will see both B and A, but not C. For whatever patch is directly opposite to the optic nerve N, vanishes. This requires a little practice; after which he will find it easy to direct his eye so as to lose the sight of whatever patch he pleases.

137 Dispute concerning the seat of vision.

This experiment, first tried by M. Marriotte, occasioned a new hypothesis concerning the seat of vision, which he supposed not to be in the retina, but in the choroides. An improvement on the experiment was afterwards made by M. Picard, who contrived that an object should disappear when both the eyes were kept open. He fastened upon a wall a round white paper, an inch or two in diameter; and by the side of it he fixed two marks, one on the right hand, and the other on the left, each at about two feet distance from the paper, and somewhat higher. He then placed himself directly before the paper, at the distance of nine or ten feet, and putting the end of his finger over against both his eyes, so that the left-hand mark might be hid from the right eye, and the right-hand mark from the left eye. Remaining firm in this posture, and looking steadily, with both eyes, on the end of his finger, the paper which was not at all covered by it would totally disappear. This, he says, is the more surprising, because, without this particular encounter of the optic nerves, where no vision is made, the paper will appear double, as is the case when the finger is not rightly placed.

M. Marriotte observes, that this improvement on his experiment, by M. Picard, is ingenious, but difficult to execute, since the eyes must be considerably strained in looking at any object so near as four inches; and proposes another not less surprising, and more easy. Place, says he, on a dark ground, two round pieces of white paper, at the same height, and three feet from one another; then stand opposite to them, at the distance of 12 or 13 feet, and hold your thumb before your eyes, at the distance of about eight inches, so that it may conceal from the right eye the paper that is to the left hand, and from the left eye the paper to the right hand. Then, if you look at your thumb steadily with both eyes, you will lose sight of both the papers; the eyes being so disposed, that each of them receives the image of one of the papers upon the base of the optic nerve, while the other is intercepted by the thumb. Of Vision.

M. Le Cat pursued this curious experiment a little farther than M. Marriotte. In the place of the second paper, he fixed a large white board, and observed, that at a proper distance he lost sight of a circular space in the centre of it. He also observed the size of the paper which is thus concealed from the sight, corresponding to several distances, which enabled him to ascertain several circumstances relating to this part of the structure of the eye more exactly than had been done before.

The following is the manner in which this curious experiment is now generally made. Let three pieces of paper be fastened upon the side of a room, about two feet asunder; and let a person place himself opposite to the middle paper, and, beginning near to it, retire gradually backwards, all the while keeping one of his eyes shut, and the other turned obliquely towards that outside paper which is towards the covered eye, and he will find a situation (which is generally at about five times the distance at which the papers are placed from one another), when the middle paper will entirely disappear, while the two outermost continue plainly visible; because the rays which come from the middle paper will fall upon the retina where the optic nerve is inserted.

It is not surprising that M. Marriotte was led, by this remarkable observation, to suspect that the retina was the seat of vision. He not only did so; but, in consequence of attentively considering the subject, a variety of other arguments in favour of the choroides occurred to him, particularly his observation, that the retina is transparent, as well as the crystalline and other humours of the eye, which he thought could only enable it to transmit the rays farther; and he could not persuade himself that any substance could be considered as being the termination of the pencils and the proper seat of vision, at which the rays are not stopped in their progress.

He was farther confirmed in his opinion of the small degree of sensibility in the retina, and of the greater sensibility of the choroides, by observing that the pupil dilates itself in the shade, and contracts itself in a great light; which involuntary motion, he thought, was a clear proof that the fibres of the iris are extremely sensible to the action of light; and this part of the eye is only a continuation of the choroides. He also thought that the dark colour of the choroid coat was intended to make it more susceptible of the impression of light.

Of Vision.

M. Pecquet, in answer to M. Marriotte's observation concerning the transparency of the retina, says, that it is very imperfectly so, resembling only oiled paper, or the horn that is used for lanterns; and besides, that its whiteness demonstrates it to be sufficiently opaque for stopping the rays of light, as much as is necessary for the purpose of vision; whereas, if vision be performed by means of those rays which are transmitted through such a substance as the retina, it must be very indistinct. The retina resembles very much the thin white film which intervenes between the white of an egg and its shell.

As to the blackness of the choroides, which M. Marriotte thought to be necessary for the purpose of vision, M. Pecquet observes, that it is not the same in all eyes, and that there are very different shades of it among the individuals of mankind, as also among birds, and some other animals, whose choroides is generally black; and that in the eyes of lions, camels, bears, oxen, stags, sheep, dogs, cats, and many other animals, that part of the choroides which is the most exposed to light, very often exhibits colours as vivid as those of mother-of-pearl, or of the iris. He admits that there is a defect of vision at the insertion of the optic nerve; but he thought that it was owing to the blood-vessels of the retina, the trunks of which are so large in that place as to obstruct all vision.

To M. Pecquet's objection, founded on the opacity of the retina, M. Marriotte replies, that there must be a great difference betwixt the state of that substance in living and dead subjects; and as a further proof of the transparency of the retina, and the power of the choroides beyond it to reflect light, he says, that if a lighted candle be held near to a person's eyes, and a dog, at the distance of eight or ten steps, be made to look at him, he would see a bright light in the dog's eyes, which he thought to proceed from the reflection of the light of the candle from the choroides of the dog, since the same appearance cannot be produced in the eyes of men, or other animals, whose choroides is black.

M. Marriotte observes, in opposition to Pecquet's remark concerning the blood-vessels of the retina, that they are not large enough to prevent vision in every part of the base of the nerve, since the diameter of each of the two vessels occupies no more than $\frac{1}{5}$th part of it. Besides, if this were the cause of this want of vision, it would vanish gradually, and the space to which it is confined would not be so exactly terminated as it appears to be.

We must add, that M. Pecquet also observed, that notwithstanding the insensibility of the retina at the insertion of the optic nerve when the light is only moderate; yet luminous objects, such as a bright candle placed at the distance of four or five paces, do not absolutely disappear, in the same circumstances in which a white paper would; for this strong light may be perceived though the picture fall on the base of the nerve.

Dr Priestley, however, found that a large candle made no impression on that part of his eye, though by no means able to bear a strong light.

The common opinion was also favoured by the anatomical description of several animals by the members of the French academy, and particularly their account of the sea calf and porcupine; in both of which the optic nerve is inserted in the very axis of the eye, exactly opposite to the pupil, which was thought to leave no room to doubt, but that in these animals the retina is perfectly sensible to the impression of light at the insertion of the nerve.

M. De la Hire took part with M. Pecquet, arguing in favour of the retina from the analogy of the senses, in all of which the nerves are the proper seat of sensation. This philosopher, however, supposed that the choroid coat receives the impressions of images, in order to transmit them to the retina.

M. Perrault also took the part of M. Pecquet against M. Marriotte, and in M. Perrault's works we have several letters that passed between these two gentlemen upon this subject.

This dispute was revived by an experiment of M. Mery, recorded in the memoirs of the French Academy for 1704. He plunged a cat in water, and exposing her eye to the strong light of the sun, observed that the pupil was not at all contracted by it; whence he concluded, that the contraction of the iris is not produced by the action of the light. For he contended that the eye receives more light in this situation than in the open air. At the same time he thought he observed that the retina of the cat's eye was transparent, and that he could see the opaque choroides beyond it; from which he concludes, that the choroides is the substance intended to receive the rays of light, and to be the chief instrument of vision. But M. De la Hire, in opposition to this argument of M. Mery, endeavours to show that fewer rays enter the eye under water, and that in those circumstances it is not so liable to be affected by them. Besides, it is obvious, that the cat must be in great terror in this situation; and being an animal that has a very great voluntary power over the muscles of the iris, and being now extremely attentive to every thing about her, she might keep her eye open notwithstanding the action of the light upon it, and though it might be very painful to her. We are informed, that when a cat is placed in a window through which the sun is shining, and consequently her iris nearly closed, if she hear a rustling, like that which is made by a mouse, on the outside of the window, she will immediately open her eyes to their greatest extent, without in the least turning her face from the light.

M. Le Cat took the side of M. Marriotte in this controversy, it being peculiarly agreeable to his general hypothesis, viz. that the pia mater, of which the choroides is a production, and not the nerves themselves, is the proper instrument of sensation. He thought that the change which takes place in the eyes of old people (the choroides growing less black with age) favoured his hypothesis, as they do not see with the same distinctness as young persons. M. Le Cat supposed that the retina answers a purpose similar to that of the scarf-skin, covering the papillæ pyramidales, which are the immediate organs of feeling, or that of the porous membrane which covers the glandulous papillæ of the tongue. The retina, he says, receives the impression of light, moderates it, and prepares it for its proper organ, but is not itself sensible of it.

It must be observed, that M. Le Cat had discovered that the pia mater, after closely embracing the optic nerve, at its entrance into the eye, divides into two branches, one of which closely lines the cornea, and at length is lost in it, while the second branch forms what is

Of Vision.

is called the *choroides*, or *uvea*. He also showed that the sclerotic coat is an expansion of the dura mater: and he sent dissections of the eye to the Royal Academy of Sciences in 1739, to prove these assertions, and several others contrary to the opinions of the celebrated Winslow, which he had advanced in his *Traité de Sens*.

To these arguments in favour of the choroides, we may add the following given by Mr Michell.

In order that vision be distinct, the pencils of rays which issue from the several points of any object, must be collected either accurately, or at least very nearly, to corresponding points in the eye, which can only be done upon some uniform surface. But the retina being of a considerable thickness, and the whole of it being uniformly nervous, and at least nearly, if not perfectly, transparent, presents no particular surface; so that, in whatever part of it the pencils be supposed to have their foci, the rays belonging to them will be separated from one another, either before or after they arrive there, and consequently vision would be confused.

If we suppose the seat of vision to be at the interior surface of the retina, and the images of objects to be formed by direct rays, a considerable degree of confusion could not but arise from the light reflected by the choroides, in those animals in which it is white, or coloured. On the other hand, it would be impossible that vision should be performed at this place by light reflected from the choroides, because in many animals it is perfectly black; and yet such animals see even more distinctly than others.

If the seat of vision be at the farther surface of the retina, and if vision be performed by direct rays, a white choroid coat could be of no use; and if it were by reflected rays, a black one could not answer the purpose.

It is likewise an argument in favour of the choroides being the organ of vision, that it is a substance which receives a more distinct impression from the rays of light than any other membrane in any part of the animal system, excepting, perhaps, that white cuticle which lies under the scales of fishes: whereas the retina is a substance on which the light makes an exceedingly faint impression, and perhaps no impression at all; since light in passing out of one transparent medium into another immediately contiguous to it, suffers no refraction or reflection, nor are any of the rays absorbed unless there is some difference in the refracting power of the two media, which probably is not the case between the retina and the vitreous humour which is in contact with it: And wherever the light is not affected by the medium on which it falls, we can hardly suppose the medium to receive any impression from the light, the action being probably always mutual and reciprocal.

Besides, the retina is so situated, as to be exposed to many rays besides those which terminate in it, and which, therefore, cannot be subservient to vision, if it be performed there. Now this is not the case with the choroides, which is in no shape transparent, and has no reflecting substance beyond it.

It is, besides, peculiarly favourable to the opinion of Marriotte, that we can then see a sufficient reason for the diversity of its colour in different animals, according as they are circumstanced with respect to vision. In all terrestrial animals, which use their eyes by night, the choroides is either of a bright white, or of some very vivid colour, which reflects the light very strongly. On this account vision may be performed with less light, but it cannot be with great distinctness, the reflection of the rays doubling their effect, since it must extend over some space, all reflection being made at a distance from the reflecting body. Besides, the choroides in brutes is not in general perfectly white, but inclined to blue; and is therefore, probably, better adapted to see by the fainter coloured light, which chiefly prevails in the night; and we would add, is on the same account more liable to be strongly impressed by the colours to which they are chiefly exposed.

On the other hand, the choroides of birds in general, especially eagles, hawks, and other birds of prey, is black; by which means they are able to see with the greatest distinctness, but only in bright day light. The owl, however, seeking her food by night, has the choroides white like that of a cat. In the eyes of man, which are adapted to various uses, the choroides is neither so black as that of birds, nor so white as that of those animals who make the greatest use of their eyes in the night.

As to a third hypothesis, which is in effect that of M. de la Hire, and which makes both the retina and the choroides equally necessary to vision, and supposes it to be performed by the impression of light on the choroides communicated to the retina; Mr Michell observes, that the perceptions can hardly be supposed to be so acute, when the nerves do not receive the impressions immediately, but only after they have been communicated to another substance. Besides, it must be more natural to suppose, that, when the principal impression is made upon the choroides, it is communicated to the brain by its own nerves, which are sufficient for the purpose.

138 Dimensions of the spot in the eye where there is no vision. Plate CCCLXXXII. fig. 3.

The dimensions and precise form of the spot in the eye in which there is no vision, were more accurately calculated by Daniel Bernouilli, in the following manner. He placed a piece of money, O, upon the floor; and then shutting one of his eyes, and making a pendulum to swing, so that the extremity of it might be nearly in the line AO, he observed at what place C it began to be invisible, and where it again emerged into view at A. Raising the pendulum higher and lower, he found other points, as H, N, P, G, B, at which it began to be invisible; and others, as M, L, E, A, at which it began to be visible again; and drawing a curve through them, he found that it was elliptical; and, with respect to his own eye, the dimensions of it were as follow; OC was 23, AC 10, BD 3, DH 13, and EG 14; so that the centre being at F, the greater axis was to the less as 8 to 7.

From these *data* the plane on which the figure was drawn being obliquely situated with respect to the eye, he found, that the place in the eye that corresponded to it was a circle, the diameter of which was a seventh part of the diameter of the eye, the centre of it being 27 parts of the diameter from the point opposite to the pupil, a little above the middle. In order, therefore, that this space in which there is no vision may be as small as possible, it is necessary that the nerve should enter the eye perpendicularly, and that both this end, and also its entering the eye at a distance from its axis, are gained by the particular manner in which the two optic nerves

Of Vision. nerves unite and become separate again, by crossing one another.

In support of one of the observations of Mr Michell, Dr Priestley observes, that Aquapendente mentions the case of a person at Pisa, who could see very well in the night, but very little or none at all in the day time. This is also said to be the case with those white people among the blacks of Africa, and the inhabitants of the isthmus of America, who, from this circumstance, are called *moon-eyed*. Dr Priestley thinks it probable that their choroides is not of a dark colour, as it is in others of the human species; but white or light-coloured, as in those animals which have most occasion for their eyes in the night.

139
Arguments for the retina's being the seat of vision.

Dr Porterfield observes, that the reason why there is no vision at the entrance of the optic nerve into the eye, may be its want of that softness and delicacy which it has when it is expanded upon the choroides; and that, in those animals in which that nerve is inserted in the axis of the eye, it is observed to be equally delicate, and therefore probably equally sensible, in that place as in any other part of the retina. In general, the nerves, when embraced by their coats, have but little sensibility in comparison of what they are endued with when they are divested of them, and unfolded in a soft and pulpy substance.

Haller observes, that the choroides cannot be universally the seat of vision, because, sometimes in men and birds, but especially in fishes, it is covered internally with a black mucus, through which the rays cannot penetrate. This writer speaks of a fibrous membrane in the retina distinct from its pulpy substance. On these fibres, he conjectures, that the images of objects are painted.

M. De la Hire's argument in favour of the retina, from the analogy of the senses, is much strengthened by considering that the retina is a large nervous apparatus, immediately exposed to the impression of light; whereas the choroides receives but a slender supply of nerves, in common with the sclerotica, the conjunctiva, and the eyelids, and that its nerves are much less exposed to the light than the naked fibres of the optic nerve.

That the optic nerve is of principal use in vision, is farther probable from several phenomena attending some of the diseases of the eye. When an amaurosis has affected one eye only, the optic nerve of that eye has been found manifestly altered from its sound state. Dr Priestley was present when Mr Hey examined the brain of a young girl, who had been blind of one eye, and saw that the optic nerve belonging to it was considerably smaller than the other; and he informed him, that upon cutting into it, it was much harder, and cineritious. Morgagni mentions two cases, in one of which he found the optic nerves smaller than usual, and of a cineritious colour, when, upon inquiry, he was informed that the person had not been blind, though there might have been some defect in the sight of one of the eyes. In the other case, only one of the optic nerves was affected in that manner, and the eye itself was in other respects very perfect. Here, also, he was expressly told, that the person was not blind of that eye.

Besides, as the optic nerve is solely spent in forming the retina, so no function of the eye not immediately subservient to vision, is affected by an amaurosis. On the contrary, those nerves which go to the choroides are found to retain, in this disease, their natural influence. The iris will contract in a recent gutta serena of one eye, if the other remains sound, and is suddenly exposed to a strong light. The sclerotica, conjunctiva, and eyelids, which receive their nerves from the same branches as the choroides, retain their sensibility in this disorder.

The manner in which persons recover from an amaurosis, favours the supposition of the seat of vision being in the retina: since those parts which are the most distant from the insertion of the nerve, recover their sensibility the soonest, being in those places the most pulpy and soft; whereas there is no reason to think that there is any difference in this respect in the different parts of the choroides. Mr Hey has been repeatedly informed, by persons labouring under an imperfect amaurosis, or gutta serena, that they could not, when looking at any object with one eye, see it so distinctly when it was placed in the axis of the eye, as when it was situated out of the axis. And those persons whom he had known to recover from a perfect amaurosis, first discovered the objects whose images fell upon that part of the retina which is at the greatest distance from the optic nerve.

We shall conclude these remarks with observing, that if the retina be as transparent as it is generally represented to be, so that the termination of the pencils must necessarily be either upon the choroides, or some other opaque substance interposed between it and the retina, the action and reaction occasioned by the rays of light being at the common surface of this body and the retina, both these mediums (supposing them to be equally sensible to light) may be equally affected; but the retina, being naturally much more sensible to this kind of impression, may be the only instrument by which the sensation is conveyed to the brain, though the choroides, or the black substance with which it is sometimes lined, may also be absolutely necessary to vision. This is not far from the hypothesis of M. de la Hire, and will completely account for the entire defect of vision at the insertion of the optic nerve. 140

Of bright and obscure, distinct and indistinct vision.

Vision is distinguished into *bright* and *obscure*, *distinct* and *indistinct*.—It is said to be *bright*, when a sufficient number of rays enter the pupil at the same time; *obscure*, when too few. It is *distinct* when each pencil of rays is collected into a focus exactly upon the retina; *indistinct*, when they meet before they come at it, or when they would pass it before they meet; for, in either of these last cases, the rays flowing from different parts of the object will fall upon the same part of the retina, which must necessarily render the image indistinct.—Now, that objects may appear with a due brightness, whether more or fewer rays proceed from them, we have a power of contracting or dilating the pupil, by means of the muscular fibre of the iris, in order to take in a greater or smaller number of rays. But this power has its limits. In some animals it is much greater than in others; particularly in such as are obliged to seek their food by night as well as by day, as in cats, &c. 141

Of distinct vision at different distances.

In order that the rays be collected into points exactly upon the retina, that is, in order that objects may appear *distinct*, whether they be nearer or farther off, i. e. whether the rays proceeding from them diverge more or less

less, some change must necessarily take place in the eye. The nature of this change has been a subject of great dispute among philosophers. While some have maintained, that the eye accommodates itself to different distances, by the muscular power of the ciliary ligament, which makes the crystalline lens approach to, or recede from, the retina; others are of opinion, that the form of the crystalline is altered by the ciliary ligament, or by the muscular power of the laminæ of which it is composed. M. de la Hire supposes, that the eye is adapted to various distances by the contraction and dilatation of the pupil; and Dr Monro imagines, that its effect is produced by the pressure of the orbicular muscles upon the upper and under parts of the cornea, or by the action of the recti muscles, which elongate the axis of the eye, by pressing chiefly upon the sides of the eyeballs.—This subject has lately been accurately examined by Mr Ramsden, and Mr Everard Home, who found, that the adjustment of the eye is effected by three changes in the organ: 1. By an increase of curvature in the cornea, occasioned by the action of the recti muscles, which produces $\frac{1}{3}$ of the effect. 2. By an elongation of the eyeball; and, 3. By a motion of the crystalline lens.

142 **Of short-sighted and long-sighted people.**

In those eyes where the cornea is very protuberant, the rays of light suffer a considerable refraction at their entrance into the aqueous humour, and are therefore collected into a focus before they fall upon the retina, unless the object be placed very near, so that the rays which enter the eye may have a considerable degree of divergency. People that have such eyes are said to be *purblind*. Now, since the nearer an object is to the eye, the greater is its image, these people can see much smaller objects than others, as they see much nearer ones with the same distinctness; and their sight continues good longer than that of other people, because the cornea, as they grow old, becomes less protuberant, from the want of that redundancy of humours with which they were filled before. On the contrary, old men having the cornea of their eyes too flat, for want of a sufficient quantity of the aqueous humour, if the rays diverge too much before they enter the eye, they cannot be brought to a focus when they reach the retina: on which account those people cannot see distinctly, unless the object be situated at a greater distance from the eye than is required for those whose eyes are of a due form. The latter require the assistance of convex glasses to make them see objects distinctly; the former of concave ones. For if either the cornea *a b c*, (fig. 4). or crystalline humour *e*, or both of them, be too flat, as in the eye A, their focus will not be on the retina as at A, where it ought to be, in order to render vision distinct; but beyond the eye, as at *f*. This is remedied by placing a convex glass *g h* before the eye, which makes the rays converge sooner, and forms the image exactly on the retina at *d*. Again, If either the cornea, or crystalline humour, or both of them, be too convex, as in the eye B, the rays that enter it from the object C will be converged to a focus in the vitreous humour, as at *f*; and by diverging from thence to the retina, will form a very confused image upon it; so that the observer will have as confused a view of the object as if his eye had been too flat. This inconvenience is remedied by placing a concave glass *g h* before the eye; which glass, by causing the rays to diverge between it and the eye, lengthens the focal distance, and makes the rays unite at the retina, and form a distinct image of the object.

Plate CCCLXXXI. fig. 4.

143 **Of the least angle of vision.**

Such eyes as are of a proper convexity, cannot see any object distinctly at less distance than six inches; and there are numberless objects too small to be seen at that distance, because they cannot appear under any sensible angle.—Concerning the least angle under which any object is visible, there was a debate between Dr Hooke and Hevelius. The former asserted that no object could well be seen if it subtended an angle less than one minute; and, if the object be round as a black circular spot upon a white ground, or a white circle upon a black ground, it follows, from an experiment made by Dr Smith, that this is near the truth; and from this he calculates, that the diameter of the picture of such least visible point upon the retina is the 8000th part of an inch; which he therefore calls a *sensible point of the retina*. On the other hand, Mr Courtivron found, by experiment, that the smallest angle of vision was 40 seconds. According to Dr Jurin, there are cases in which a much smaller angle than one minute can be discerned by the eye; and he observes, that in order to our perceiving any impression upon our senses, it must either be of a certain degree of force, or of a certain degree of magnitude. For this reason, a star, which appears only as a lucid point through a telescope subtending not so much as an angle of one second, is visible to the eye;

144 **Lines can be seen under smaller angles than spots, and why.**

though a white or black spot of 25 or seconds, is not perceptible. Also a line of the same breadth with the circular spot will be visible at such a distance as the spot is not to be perceived at: because the quantity of impression from the line is much greater than that from the spot; and a longer line is visible at a greater distance than a shorter one of the same breadth. He found by experience, that a silver wire could be seen when it subtended an angle of three seconds and a half; and that a silk thread could be seen when it subtended an angle of two seconds and a half.

This greater visibility of a line than of a spot seems to arise only from the greater quantity of the impression; but without the limits of perfect vision, Dr Jurin observes, that another cause concurs, whereby the difference of visibility between the spot and the line is rendered much more considerable. For the impression upon the retina made by the line is then not only much greater, but also much stronger, than that of the spot; because the faint image, or penumbra, of any one point of the line, when the hole is placed beyond the limits of distinct vision, will fall within the faint image of the next point, and thereby much increase the light that comes from it.

In some cases Dr Jurin found the cause of indistinct vision to be the unsteadiness of the eye; as our being able to see a single black line upon a white ground or a single white line upon a black ground, and not a white line between two black ones on a white ground. In viewing either of the former objects, if the eye be imperceptibly moved, all the effect will be, that the object will be painted upon a different part of the retina; but wherever it is painted, there will be but one picture, single and uncompounded with any other. But in viewing the other, if the eye fluctuate ever so little, the image of one or other of the black lines will be so shifted to that part of the retina which was before possessed by

Of Vision.

by the white line; and this must occasion such a dazzling in the eye, that the white line cannot be distinctly perceived, and distinguished from the black lines; which by a continual fluctuation, will alternately occupy the space of the white line, whence must arise an appearance of one broad dark line, without any manifest separation.

By trying this experiment with two pins of known diameter, set in a window against the sky light, with a space between them equal in breadth to one of the pins, he found that the distance between the pins could hardly be distinguished when it subtended an angle of less than 40 seconds, though one of the pins alone could be distinguished when it subtended a much less angle. But though a space between two pins cannot be distinguished by the eye when it subtends an angle less than 40 seconds, it does not follow that the eye must necessarily commit an error of 40 seconds in estimating the distance between two pins when they are much farther from one another. For if the space between them subtend an angle of one minute, and each of the pins subtend an angle of four seconds, which is greater than the least angle the eye can distinguish, it is manifest that the eye may judge of the place of each pin within two seconds at the most; and consequently the error committed in taking the angle between them cannot at the most exceed four seconds, provided the instrument be sufficiently exact. And yet, says he, upon the like mistake was founded the principal objection of Dr Hooke against the accuracy of the celestial observations of Hevelius.

A black spot upon a white ground, or a white spot upon a black ground, he says, can hardly be perceived by the generality of eyes when it subtends a less angle than one minute. And if two black spots be made upon white paper, with a space between them equal in breadth to one of their diameters, that space is not to be distinguished, even within the limits of perfect vision, under so small an angle as a single spot of the same size. To see the two spots distinctly, therefore, the breadth of the space between them must subtend an angle of more than a minute. It would be difficult, he says, to make this experiment accurately, within the limits of perfect vision; because the objects must be extremely small: but by a rude trial, made with square bits of white paper, placed upon a black ground, he judged, that the least angle under which the interval of two objects could be perceived, was at least a fourth part greater than the least angle under which a single object can be perceived. So that an eye which cannot perceive a single object under a smaller angle than one minute, will not perceive the interval between two such objects under a less angle than 75 seconds.

Without the limits of perfect vision, the distance at which a single object ceases to be perceptible will be much greater in proportion than the distance at which a space of equal breadth between two such objects ceases to be perceptible. For, without these limits, the image of each of the objects will be attended with a penumbra, and the penumbra of the two near objects will take up part of the space between them, and thus render it less perceptible; but the penumbra will add to the breadth of the single object, and will thereby make it more perceptible, unless its image be very faint. Upon the same principles he likewise accounts for the radiation of the stars, whereby the light seems to project from them different ways at the same time.

Mr Mayer made many experiments in order to ascertain the smallest angle of vision in a variety of respects. He began with observing at what distance a black spot was visible on white paper; and found, that when it could barely be distinguished, it subtended an angle of about 34 seconds. When black lines were disposed with intervals broader than themselves, they were distinguished at a greater distance than they could be when the objects and the intervals were equal in breadth. In all these cases it made no difference whether the objects were placed in the shade or in the light of the sun; but when the degrees of light were small, their differences had a considerable effect, though by no means in proportion to the differences of the light. For if an object was illuminated to such a degree as to be just visible at the distance of nine feet, it would be visible at the distance of four feet, though the light was diminished above 160 times. It appeared in the course of these experiments, that common daylight is, at a medium, equal to that of 25 candles placed at the distance of one foot from the object.

145 Of single vision with two eyes.

As an image of every visible object is painted on the retina of each of our eyes, it thence becomes a natural question, Why we do not see every thing double? It was the opinion of Sir Isaac Newton and others, that objects appear single, because the two optic nerves unite before they reach the brain. But Dr Porterfield shows, from the observation of several anatomists, that the optic nerves do not mix, or confound their substance, being only united by a close cohesion; and objects have appeared single where the optic nerves were found to be disjoined.

146 Solutions of this difficulty by Dr Briggs.

Dr Briggs supposed that single vision was owing to the equal tension of the corresponding parts of the optic nerves, whereby they vibrated in a synchronous manner. But, besides several improbable circumstances in this account, Dr Porterfield shows that facts do by no means favour it.

To account for this phenomenon, this ingenious writer supposes, that by an original law in our natures, we imagine objects to be situated somewhere in a right line drawn from the picture of it upon the retina, through the centre of the pupil. Consequently, the same object appearing to both eyes to be in the same place, the mind cannot distinguish it into two. In answer to an objection to this hypothesis, from objects appearing double when one eye is distorted, he says the mind mistakes the position of the eye, imagining that it had moved in a manner corresponding to the other, in which case the conclusion would have been just.

147 Dr Porterfield.

This principle, however, has been thought sufficient to account for this appearance. Originally, every object, making two pictures, is imagined to be double; but by degrees, we find, that when two corresponding parts of the retina are impressed, the object is but one; but if those corresponding parts be changed, by the distortion of one of the eyes, the object must again appear double as at the first. This has been thought verified by Mr Cheselden; who informs us, that a gentleman, who from a blow on his head had one eye distorted, found every object to appear double; but by degrees the

Of Vision. the most familiar ones came to appear single again, and in time all objects did so, without any amendment of the distortion.

148 Dr Reid, and

On the other hand, Dr Reid is of opinion, that the correspondence of the centres of the two eyes, on which single vision depends, does not arise from custom, but from some natural constitution of the eye and of the mind. He makes several just objections to the case of Mr Forster, recited by Dr Smith and others; and thinks that the case of the young man couched by Cheselden, who saw singly with both eyes immediately upon receiving his sight, is nearly decisive in proof of his supposition. He also found that three young gentlemen, whom he endeavoured to cure of squinting, saw objects singly, as soon as ever they were brought to direct the centres of both their eyes to the same object, though they had never been used to do so from their infancy; and he observes, that there are cases, in which, notwithstanding the fullest conviction of an object being single, no practice of looking at it will ever make it appear so, as when it is seen through a multiplying glass.

To all these solutions of the difficulty respecting single vision by both eyes, objections have been lately made which seem insurmountable. By judicious experiments, Dr Wells has shown, that it is neither by custom alone, nor by the original property of the eyes alone, that objects appear single; and having demolished the theories of others, he thus endeavours to account for the phenomenon.

149 Dr Wells.

"The visible place of an object being composed of its visible distance and visible direction, to show how it may appear the same to both eyes, it will be necessary (says he*) to explain in what manner the distance and direction, which are perceived by one eye, may coincide with those which are perceived by the other." With respect to visible distance, the author's opinion seems not to differ from that which we have stated elsewhere (see Metaphysics, N° 49, 50.); and therefore we have to attend only to what he says of visible direction.

* *Essay on Single Vision, &c.*

When a small object is so placed with respect to either eye, as to be seen more distinctly than in any other situation, our author says that it is then in the *optic axis*, or the axis of that eye. When the two optic axes are directed to a small object not very distant, they may be conceived to form two sides of a triangle, of which the base is the interval between the points of the corners where the axis enter the eyes. This base he called the *visual base;* and a line drawn from the middle of it to the point of intersection of the optic axis he calls the *common axis*. He then proceeds to show, that objects *really situated* in the *optic* axis do not *appear* to be in that line, but in the *common axis*.

Every person (he observes) knows, that if an object be viewed through two small holes, one applied to each eye, the two holes appear but as one. The theories hitherto invented afford two explanations of this fact. According to Aguilonius, Dechales, Dr Porterfield, and Dr Smith, the two holes, or rather their borders, will be seen in the same place as the object viewed through them, and will consequently appear united, for the same reason that the object itself is seen single. But whoever makes the experiment will distinctly perceive, that the united hole is much nearer to him than the object; not to mention, that any fallacy on this head might be corrected by the information from the sense of touch, that the card or other substance in which the holes have been made is within an inch or less of our face. The other explanation is that furnished by the theory of Dr Reid. According to it, the centres of the retinas, which in this experiment receive the pictures of the holes, will, by an original property, represent but one. This theory, however, though it makes the two holes to appear one, does not determine where this one is to be seen. It cannot be seen in only one of the perpendiculars to the images upon the retinas, for no reason can be given why this law, of visible direction, which Dr Reid thinks established beyond dispute, if it operates at all, should not operate upon both eyes at the same time; and if it be seen by both eyes in such lines, it must appear where those lines cross each other, that is, in the same place with the object viewed through the holes, which, as I have already mentioned, is contrary to experience. Nor is it seen in any direction, the consequence of a law affecting both eyes considered as one organ, but suspended when each eye is used separately. For when the two holes appear one, if we pay attention to its situation, and then close one eye, the truly single hole will be seen by the eye remaining open in exactly the same direction as the apparently single hole was by both eyes.

"Hitherto I have supposed the holes almost touching the face. But they have the same unity of appearance, in whatever parts of the optic axes they are placed; whether both be at the same distance from the eyes, or one be close to the eye in the axis of which it is, and the other almost contiguous to the object seen through them. If a line, therefore, be drawn from the object to one of the eyes, it will represent all the real or tangible positions of the hole, which allow the object to be seen by that eye, and the whole of it will coincide with the optic axis. Let a similar line be drawn to the other eye, and the two must appear but as one line; for if they do not, the two holes in the optic axes will not, at every distance, appear one, whereas experiments prove that they do. This united line will therefore represent the visible direction of every object situated in either of the optic axes. But the end of it, which is towards the face, is seen by the right eye to the left, and by the left eye as much to the right. It must be seen then in the middle between the two, and consequently in the common axis. And as its other extremity coincides with the point where the optic axes intersect each other, the whole of it must lie in the common axis. Hence the truth of the proposition is evident, that objects situated in the optic axis, do not appear to be in that line, but in the common axis."

He then proves by experiments, that objects situated in the common axis did not *appear* to be in that line, but in the axis of the eye by which they are not seen: that is, an object situated in the common axis appears to the right eye in the axis of the left, and *vice versa*. His next proposition, proved likewise by experiments, is, that "objects, situated in any line drawn through the mutual intersection of the optic axes to the visual base, do not appear to be in that line, but in another drawn through the same intersection, to a point in the visual base distant half this base from the similar extremity of the former line towards the left, if the objects be seen

Of Vision.

seen by the right eye, but towards the right if seen by the left eye."

From these propositions he thus accounts for single vision by both eyes. "If the question be concerning an object at the concourse of the optic axes, it is seen single, because its two similar appearances, in regard to size, shape, and colour, are seen by both eyes in one and the same direction, or if you will, in two directions, which coincide with each other through the whole of their extent. It therefore matters not whether the distance be truly or falsely estimated; whether the object be thought to touch our eyes, or to be infinitely remote. And hence we have a reason, which no other theory or visible direction affords, why objects appeared single to the young gentleman mentioned by Mr Cheselden, immediately after his being couched, and before he could have learned to judge of distance by sight.

"When two similar objects are placed in the optic axes, one in each, at equal distances from the eyes, they will appear in the same place, and therefore one, for the same reason that a truly single object, in the concourse of the optic axes, is seen single.

"To finish this part of my subject, it seems only necessary to determine, whether the dependence of visible direction upon the actions of the muscles of the eyes be established by nature, or by custom. But facts are here wanting. As far as they go, however, they serve to prove that it arises from an original principle of our constitution. For Mr Cheselden's patient saw objects single, and consequently in the same directions with both eyes, immediately after he was couched; and persons affected with squinting from their earliest infancy see objects in the same directions with the eye they have never been accustomed to employ, as they do with the other they have constantly used."

150
Objects seen with both eyes appear brighter than when seen with one.

We are indebted to Dr Jurin for the following curious experiments, to determine whether an object seen by both eyes appears brighter than when seen with one only.

He laid a slip of clean white paper directly before him on a table, and applying the side of a book close to his right temple, so that the book was advanced considerably farther forward than his face, he held it in such a manner, as to hide from his right eye that half of the paper which lay to his left hand, while the left half of the paper was seen by both eyes, without any impediment.

Then looking at the paper with both eyes, he observed it to be divided, from the top to the bottom, by a dark line, and the part which was seen with one eye only was manifestly darker than that which was seen with both eyes; and, applying the book to his left temple, he found, by the result of the experiment, that both his eyes were of equal goodness.

He then endeavoured to determine the excess of this brightness; and comparing it with the appearance of an object illuminated partly by one candle and partly by two, he was surprised to find that an object seen with two eyes is by no means twice as luminous as when it is seen with one; and after a number of trials, he found, that when one paper was illuminated by a candle placed at the distance of three feet, and another paper by the same candle at the same distance, and by another candle at the distance of 11 feet, the former seen by both eyes and the latter with one eye only, appeared to be of equal whiteness; so that an object seen with both eyes appears brighter than when it is seen with one only by about a 13th part.

He then proceeded to inquire, whether an object seen with both eyes appears larger than when seen with one; but he concluded that it did not, except on account of some particular circumstances, as in the case of the binocular telescope and the concave speculum.

M. du Tour maintains, that the mind attends to no more than the image made in one eye at a time, and produces several curious experiments in favour of this hypothesis, which had also been maintained by Kepler and almost all the first opticians. But, as M. Buffon observes, it is a sufficient answer to this hypothesis, however ingeniously it may be supported, that we see more distinctly with two eyes than with one; and that when a round object is near us, we see more of the surface in one case than in the other.

With respect to single vision with two eyes, Dr Hartley observes, that it deserves particular attention, that the optic nerves of men, and such other animals as look the same way with both eyes, unite in the *cella turcica* in a ganglion, or little brain, as one may call it, peculiar to themselves; and that the associations between synchronous impressions on the two retinas must be made sooner and cemented stronger on this account: also that they ought to have a much greater power over one another's images, than in any other part of the body. And thus an impression made on the right eye alone, by a single object, may propagate itself into the left, and there raise up an image almost equal in vividness to itself; and consequently when we see with one eye only, we may, however, have pictures in both eyes.

A curious deception in vision, arising from the use of both eyes, was observed and accounted for by Dr Smith. It is a common observation, he says, that objects seen with both eyes appear more vivid and stronger than they do to a single eye; especially when both of them are equally good. A person not short-sighted may soon be convinced of this fact, by looking attentively at objects that are pretty remote, first with one eye, and then with both. This observation gave occasion to the construction of the binocular telescope, in the use of which the phenomenon is still more striking.

Besides this, Dr Smith observes, that there is another phenomenon observable with this instrument, which is very remarkable. In the foci of the two telescopes there are two equal rings, as usual, which terminate the pictures of the objects there formed, and consequently the visible area of the objects themselves. These equal rings, by reason of the equal eye-glasses, appear equal and equidistant when seen separately by each eye; but when they are seen with both eyes, they appear much larger, and more distant also; and the objects seen through them also appear much larger, though circumscribed by their united rings, in the same places as when they were seen separately.

He observes that the phenomenon of the enlarged circle of the visible area in the binocular telescope, may be seen very plainly in looking at distant objects through a pair of spectacles, removed from the eyes about four or five inches, and held steady at that distance. The two innermost of the four apparent rings, which hold the glasses, will then appear united in one larger and more

Of Vision.

more distant ring than the two outermost, which will hardly be visible unless the spectacles be farther removed.

A curious circumstance relating to the effect of one eye upon the other, was noticed by M. Æpinus, who observed, that, when he was looking through a hole made in a plate of metal, about the 10th part of a line in diameter, with his left eye, both the hole itself appeared larger, and also the field of view seen through it was more extended, whenever he shut his right eye; and both these effects were more remarkable when that eye was covered with his hand. He found considerable difficulty in measuring this augmentation of the apparent diameter of the hole, and of the field of view; but at length he found, that, when the hole was half an inch, and the tablet which he viewed through it was three feet from his eye, if the diameter of the field when both his eyes were open was 1, it became $1\frac{1}{7}$ when the other eye was shut, and nearly 2 when his hand was laid upon it.

151 When one eye is closed, the pupil of the other is enlarged.

Upon examining this phenomenon, it presently appeared to depend upon the enlargement of the pupil of one eye when the other is closed, the physical cause of which he did not pretend to assign; but he observes, that it is wisely appointed by Providence, in order that when one eye fails, the field of view in the other may be extended. That this effect should be more sensible when the eye is covered with the hand, is owing, he observes, to the eye-lids not being impervious to the light. But the augmentation of the pupil does not enlarge the field of view, except in looking through a hole, as in this particular case; and therefore persons who are blind of one eye can derive no advantage from this circumstance.

A great deal has been written by Gassendi, Le Clerc, Musschenbroek, and Du Tour, concerning the place to which we refer an object viewed by one or both eyes. But the most satisfactory account of this matter that we have met with, will be found in Dr Wells's Essay above quoted.

Sect. VI. *Of the Appearance of Objects seen through Media of different Forms.*

152 The various appearances of objects seen thro' media of different forms stated and investigated.

For the more easy apprehension of what relates to this subject, we shall premise the five following particulars, which either have been already mentioned, or follow from what has been before laid down.

1. That as each point of an object, when viewed by the naked eye, appears in its proper place, and as that place is always to be found in the line in which the axis of a pencil of rays flowing from it enters the eye, or else in the line which Dr Wells calls the common axis; we hence acquire a habit of considering the point to be situated in that line: and, because the mind is unacquainted with what refractions the rays suffer before they enter the eye, therefore, in cases where they are diverted from their natural course, by passing through any medium, it judges the point to be in that line produced back in which the axis of a pencil of rays flowing from it is situated the instant they enter the eye, and not in that it was in before refraction. We shall, therefore, in what follows, suppose the apparent place of an object, when seen through a refracting medium, to be somewhere in that line produced back in which the axis of a pencil of rays flowing from it proceeds after they have passed through the medium.

Appearance of Objects thro' Media of different Forms.

2. That we are able to judge, though imperfectly, of the distance of an object by the degree of divergency, wherein the rays flowing from the same point of the object enter the pupil of the eye, in cases where that divergency is considerable; but because in what follows it will be necessary to suppose an object, when seen through a medium whereby its apparent distance is altered, to appear in some determinate situation, in those cases where the divergency of the rays at their entrance into the eye is considerable, we will suppose the object to appear where those lines which they describe in entering, if produced back, would cross each other: though it must not be asserted, that this is the precise distance; because the brightness, distinctness, and apparent magnitude of the object, on which its apparent distance in some measure depends, will also suffer an alteration by the refraction of the rays in passing through that medium.

3. That we estimate the magnitude of an object by that of the optic angle.

4. That vision is the brighter, the greater the number of rays is which enter the pupil.

5. And that, in some cases, the apparent brightness, distinctness, and magnitude of an object, are the only means by which our judgment is determined in estimating the distance of it.

Prop. I.

An object placed within a medium terminated by a plane surface on that side which is next the eye, if the medium be denser than that in which the eye is (as we shall suppose it to be, unless where the contrary is expressed), appears nearer to the surface of the medium than it is.

Thus, if A (fig. 5.) be a point of an object placed within the medium BCDE, and A b A c be two rays proceeding from thence, these rays passing out of a denser into a rarer medium, will be refracted from their respective perpendiculars $b\,d$, $c\,e$, and will enter the eye at H, suppose in the direction $b\,f$, $c\,g$: let then these lines be produced back till they meet in F; this will be the apparent place of the point A; and because the refracted rays $b\,f$, $c\,g$ will diverge more than the incident ones A b, A c, it will be nearer to the points b and c than the point A; and as the same is true of each point in the object, the whole will appear, to an eye at H, nearer to the surface BC than it is. Plate ccclxxxi. fig. 5.

Hence it is, that when one end of a straight stick is put under water, and the stick is held in an oblique position, it appears bent at the surface of the water; viz. because each point that is under water appears nearer the surface, and consequently higher than it is.

From this likewise it happens, that an object at the bottom of a vessel may be seen when the vessel is filled with water, though it be so placed with respect to the eye, that it cannot be seen when the vessel is empty. To explain this, let ABCD (fig. 6.) represent a vessel, and Fig 6. let E be an object lying at the bottom of it. This object, when the vessel is empty, will not be seen by an eye

Appearance of Objects thro' Media of different Forms.

eye at F, because HB, the upper part of the vessel, will obstruct the ray EH; but when it is filled with water to the height GH, the ray at EK being refracted at the surface of the water into the line KF, the eye at F shall see the object by means of that.

153
An object situated in the horizon appears above its true place.

In like manner, an object situated in the horizon appears above its true place, on account of the refraction of the rays which proceed from it in their passage through the atmosphere. For, first, If the object be situated beyond the limits of the atmosphere, its rays in entering it will be refracted towards the perpendicular; that is, towards a line drawn from the point where they enter, to the centre of the earth, which is the centre of the atmosphere: and as they pass on, they will be continually refracted the same way, because they are all along entering a denser part, the centre of whose convexity is still the same point; upon which account the line they describe will be a curve bending downwards: and therefore none of the rays that come from that object can enter an eye upon the surface of the earth, except what enter the atmosphere higher than they need to do if they could come in a right line from the object: consequently the object must appear above its proper place. Secondly, If the object be placed within the atmosphere, the case is still the same; for the rays which flow from it must continually enter a denser medium whose centre is below the eye; and therefore being refracted towards the centre, that is, downwards as before, those which enter the eye must necessarily proceed as from some point above the object; whence the object will appear above its proper place.

Hence it is, that the sun, moon, and stars, appear above the horizon, when they are just below it; and higher than they ought to do, when they are above it: Likewise distant hills, trees, &c. seem to be higher than they are.

Besides, The lower these objects are in the horizon, the greater is the obliquity with which the rays which flow from them enter the atmosphere, or pass from the rarer into the denser parts of it; and therefore they appear to be the more elevated by refraction: on which account the lower parts of them are apparently more elevated than the rest. This makes their upper and under parts seem nearer than they are; as is evident from the sun and moon, which appear of an oval form when they are in the horizon, their horizontal diameters appearing of the same length that they would do if the rays suffered no refraction, while their vertical ones are thus shortened.

Prop. II.

An object seen through a medium terminated by plane and parallel surfaces, appears nearer, brighter, and larger, than with the naked eye.

154
An object seen thro' a plane medium appears nearer and brighter than seen by the naked eye;
Plate CCCLXXXI. fig. 7.

For instance, let AB (fig. 7.) be the object, CDEF the medium, and GH the pupil of an eye, which is here drawn large to prevent confusion in the figure.—And, 1. Let RK, RL, be two rays proceeding from the point R, and entering the denser medium at K and L; these rays will here by refraction be made to diverge less, and to proceed afterwards, suppose in the lines K *a*, L *b*; at *a* and *b*, where they pass out of the denser medium, they will be as much refracted the contrary way, proceeding in the lines *a c*, *b d*, parallel to their first directions. Produce these lines back till they meet in *e*: this will be the apparent place of the point R; and it is evident from the figure, that it must be nearer the eye than that point; and because the same is true of all other pencils flowing from the object A B, the whole will be seen in the situation *f g*, nearer to the eye than the line AB. 2. As the rays RK, RL would not have entered the eye, but have passed by it in the directions K *r*, L *t*, had they not been refracted in passing through the medium, the object appears brighter. 3. The rays A *h*, B *i*, will be refracted at *h* and *i* into the less converging lines *h k*, *i l*, and at the other surface into *k* M, *l* M, parallel to A *h* and B *i* produced; so that the extremities of the object will appear in the lines M *k*, M *l* produced, viz. in *f* and *g*, and under as large an angle *f* M *g*, as the angle A *q* B under which an eye at *q* would have seen it had there been no medium interposed to refract the rays: and therefore it appears larger to the eye GH, being seen through the interposed medium, than otherwise it would have done. But it is here to be observed, that the nearer the point *e* appears to the eye on account of the refraction of the rays RK, RL, the shorter is the image *f g*, because it is terminated by the lines M *f* and M *g*, upon which account the object is made to appear less; and therefore the apparent magnitude of an object is not much augmented by being seen through a medium of this form.

Farther, it is apparent from the figure, that the effect of a medium of this form depends wholly upon its thickness; for the distance between the lines R *r* and *e c*, and consequently the distance between the points *e* and R, depends upon the length of the line K *a*:—Again, The distance between the lines AM and *f* M depends on the length of the line *h k*; but both K *a* and *k h* depend on the distance between the surfaces CE and DF, and therefore the effect of this medium depends upon its thickness.

Prop. III.

An object seen through a convex lens, appears larger, brighter, and more distant, than with the naked eye.

155
Seen thro' a convex lens, appears larger, brighter, and more distant.
Fig. 8.

To illustrate this, let AB (fig. 8.) be the object, CD the lens, and EF the eye. 1. From A and B, the extremities of the object, draw the lines AY *r*, BX *r*, crossing each other in the pupil of the eye; the angle A *r* B comprehended between these lines, is the angle under which the object would be seen with the naked eye. But by the interposition of a lens of this form, whose property it is to render converging rays more so, the rays AY and BX will be made to cross each other before they reach the pupil. There the eye at E will not perceive the extremities of the object by means of these rays (for they will pass it without entering), but by some others which must fall without the points Y and X, or between them; but if they fall between them, they will be made to concur sooner than they themselves would have done: and therefore, if the extremities of the object could not be seen by them, it will much less be seen by these. It remains therefore, that the rays which will enter the eye from the points A and B after refraction, must fall upon the lens without the points Y and X;

Appearance of Objects thro' Media of different Forms.

X; let then the rays AO and BP be such. These after refraction entering the eye at r, the extremities of the object will be seen in the lines r Q, r T, produced, and under the optic angle Q r T, which is larger than A r B, and therefore the apparent magnitude of the object will be increased.—2. Let GHI be a pencil of rays flowing from the point G; as it is the property of this lens to render diverging rays less diverging, parallel, or converging, it is evident that some of those rays, which would proceed on to F and E, and miss the eye were they to suffer no refraction in passing through the lens, will now enter it; by which means the object will appear brighter. 3. The apparent distance of the object will vary according to the situation of it with respect to the focus of parallel rays of the lens. 1. Then, let us suppose the object placed so much nearer the lens than its focus of parallel rays, that the refracted rays KE and LF, though rendered less diverging by passing through it, may yet have a considerable degree of divergency, so that we may be able to form a judgment of the distance of the object thereby. In this case, the object ought to appear where EK, FL produced back concur; which, because they diverge less than the rays GH, GI, will be beyond G, that is, at a greater distance from the lens than the object is. But because both the brightness and magnitude of the object will at the same time be augmented, prejudice will not permit us to reckon it quite so far off as the point where those lines meet, but somewhere between that point and its proper place. 2. Let the object be placed in the focus of parallel rays, then will the rays KE and LF become parallel; and though in this case the object would appear at an immense distance, if that distance were to be judged of by the direction of the rays KE and LF, yet on account of its brightness and magnitude we shall not think it much farther from us than if it were seen by the naked eye. 3. If the object be situated beyond the focus of parallel rays, as in BA, the rays flowing from it, and falling upon the lens CD, will be collected into their respective foci at a and b, and the intermediate points m, n, &c. and there will form an image of the object AB; and after crossing each other in the several points of it, as expressed in the figure, will pass on diverging as from a real object. Now if an eye be situated at c, where A c, B c, rays proceeding from the extreme points of the object, make not a much larger angle A c B, than they would do if no lens were interposed, and the rays belonging to the same pencil do not converge so much as those which the eye would receive if it were placed nearer to a or b, the object upon these accounts appearing very little larger or brighter than with the naked eye, is seen nearly in its proper place: but if the eye recede a little way towards $a\,b$, the object then appearing both brighter and larger seems to approach the lens: which is an evident proof of what has been so often asserted, viz. that we judge of the distance of an object in some measure by its brightness and magnitude; for the rays converge the more the farther the eye recedes from the lens; and therefore if we judged of the distance of the object by the direction of the rays which flow from it, we ought in this case to conceive it at a greater distance, than when the rays were parallel, or diverged at their entrance into the eye.

Plate CCCLXXXI. fig. 9.

That the object should seem to approach the lens in this case, was a difficulty that puzzled Dr Barrow, and which he pronounces insuperable, and not to be accounted for by any theory we have of vision. Molineux also leaves it to the solution of others, as that which will be inexplicable, till a more intimate knowledge of the visive faculty, as he expresses it, be obtained by mortals.

They imagined, that since an object appears farther off, the less the rays diverge which fall upon the eye, if they should proceed parallel to each other, it ought to appear exceeding remote; and if they should converge, it should then appear more distant still: the reason of this was, because they looked upon the apparent place of an object, as owing only to the direction of the rays whatever it was, and not at all to its apparent magnitude or splendour.

Perhaps it may proceed from our judging of the distance of an object in some measure by its magnitude, that the deception of sight commonly observed by travellers may arise; viz. that upon the first appearance of a building larger than usual, as a cathedral church, or the like, it generally seems nearer to them, than they afterwards find it to be.

Prop. IV.

If an object be placed farther from a convex lens than its focus of parallel rays, and the eye be situated farther from it on the other side than the place where the rays of the several pencils are collected into their proper foci, the object appears inverted, and pendulous in the air, between the eye and the lens.

156 In certain circumstances an object seen through a convex lens appears inverted and pendulous in the air. Fig. 9.

To explain this, let AB represent the object, CD the lens; and let the rays on the pencil ACD be collected in a, and those of BCD in b, forming there an inverted image of the object AB, and let the eye be placed in F: it is apparent from the figure, that some of the refracted rays which pass through each point of the image will enter the eye as from a real object in that place; and therefore the object AB will appear there, as the proposition asserts. But we are so little accustomed to see objects in this manner, that it is very difficult to perceive the image with one eye; but if both eyes are situated in such a manner, that rays flowing from each point of the image may enter both, as at G and H, and we direct our optic axes to the image, it is easy to be perceived.

If the eye be situated in a or b, or very near them on either side, the object appears exceedingly indistinct, viz. if at d, the rays which proceed from the same point of the object converge so very much, and if at e, they diverge so much, that they cannot be collected together upon the retina, but fall upon it as if they were the axes of so many distinct pencils coming through every point of the lens; wherefore little more than one single point of the object is seen at a time, and that appears all over the lens; whence nothing but indistinctness arises.

If the lens be so large that both eyes may be applied to it, as in h and k, the object will appear double; for it is evident from the figure, that the rays which enter the eye at h from either extremity of the object A or B, do not proceed as from the same point with that

Appearance of Objects thro' Media of different Forms

that from whence those which enter the other at k seem to flow; the mind therefore is here deceived, and looks upon the object as situated in two different places, and therefore judges it to be double.

Prop. V.

157
An object through a concave lens is seen nearer, smaller, and less bright than with the naked eye. Fig. 10.

An object seen through a concave lens appears nearer, smaller, and less bright, than with the naked eye.

Thus, let AB (fig. 10.) be the object, CD the pupil of an eye, and EF the lens. Now, as it is the property of a lens of this form to render diverging rays more so, and converging ones less so, the diverging rays GH, GI, proceeding from the point G, will be made to diverge more, and so to enter the eye as from some nearer point g; and the rays AH, BI, which converge, will be made to converge less, and to enter the eye as from the points a and b; wherefore the objects will appear in the situation $a\,g\,h$, less and nearer than without the lens. Further, As the rays which proceed from G are rendered more diverging, some of them will pass by the pupil of the eye, which otherwise would have entered it, and therefore each point of the object will appear less bright.

Prop. VI.

An object seen through a polygonal glass, that is, one which is terminated by several plain surfaces, is multiplied thereby.

Plate CCCLXXXI. fig. 11.

Let A be an object, and BC a polygonous glass terminated by the plane surfaces BD, DE, &c. and let the situation of the eye F be such, that the rays AB being refracted in passing through the glass, may enter it in the direction BF, and the rays AC in the direction CF. Then will the eye, by means of the former, see the object in G, and by the latter in H; and by means of the rays AI, the object will also appear in its proper situation A.

Sect. VII. *On the Reflection of Light.*

158
Some portion of light always reflected from transparent bodies.

When a ray of light falls upon any body, however transparent, the whole of it never passes through the body, but some part is always reflected from it; and it is by this reflected light that all bodies which have no light of their own become visible to us. Of that part of the ray which enters, another part is also reflected from the second surface, or that which is farthest from the luminous body. When this part arrives again at the first surface, part of it is reflected back from that surface; and thus it continues to be reflected between the two surfaces, and to pass backwards and forwards within the substance of the medium, till some part is totally extinguished and lost. Besides this inconsiderable quantity, however, which is lost in this manner, the second surface often reflects much more than the first; so that, in certain positions, scarcely any rays will pass through both sides of the medium. A very considerable quantity is also unaccountably lost at each reflecting surface; so that no body, however transparent, can transmit all the rays which fall upon it; neither, though it be ever so well fitted for reflection, will it reflect them all.

On the Cause of Reflection.

Cause of Reflection.

The reflection of light is not so easily accounted for as refraction. This last property may be accounted for in a satisfactory manner, by the supposition of a attractive power diffused throughout the medium, and extending a very little way beyond it; but with regard to the reflection of light, there seems to be no satisfactory hypothesis hitherto invented. Of the principal opinions on this subject Mr Rowning has given us the following account.

159
Light is not reflected by impinging on the solid parts of bodies at the first surface,

I. It was the opinion of philosophers, before Sir Isaac Newton discovered the contrary, that light is reflected by impinging upon the solid parts of bodies. But that this is not the case is evident from the following reasons.

First, It is not reflected at the first surface of a body by impinging against it. For in order that the light may be regularly reflected, there should be no asperities or unevenness in the reflecting surface large enough to bear a sensible proportion to the magnitude of a ray of light; because if the surface abound with these, the incident rays would be irregularly scattered rather than reflected with that regularity with which light is observed to be from a well polished surface. Now those surfaces, which to our senses appear perfectly smooth and well polished, are far from being so; for to polish, is only to grind off the larger protuberances of the metal with the rough and sharp particles of emery, which must of necessity leave behind them an infinity of asperities and scratches, which, though inconsiderable with regard to the former roughnesses, and too minute to be discerned by us, must nevertheless bear a large proportion to, if not vastly exceed, the magnitude of the particles of light. 160

nor at the second.

Secondly, It is not reflected at the second surface by impinging against any solid particles. That it is not reflected by impinging upon the solid particles which constitute this second surface, is sufficiently obvious from the foregoing argument; the second surfaces of bodies being as incapable of a perfect polish as the first: and it is farther confirmed from this, viz. that the quantity of light reflected differs according to the different density of the medium behind the body. It is likewise not reflected by impinging upon the particles which constitute the surface of the medium behind it, because the strongest reflection at the second surface of a body, is when there is a vacuum behind it. 161

Supposition of a repulsive force;

II. It has been the opinion of some, that light is reflected at the first surface of a body, by a repulsive force equally diffused over it: and at the second, by an attractive force. 162

objected to.

1. If there be a repulsive force diffused over the surface of bodies that repels the rays of light, then, since by increasing the obliquity of a ray we diminish its perpendicular force (which is that only whereby it must make its way through this repulsive force), however weakly that force may be supposed to act, rays of light may be made to fall with so great a degree of obliquity on the reflecting surface, that there shall be a total reflection of them there, and not one particle of light be able to make its way through: which is contrary to observation; the reflection of light at the first surface of a transparent body being never total in any obliquity whatever. 163

Attractive force supposed;

2. As to the reflection at the second surface by the attractive

Cause of Reflection.

attractive force of the body; this may be considered in two respects: first, when the reflection is total; secondly, when it is partial.

First, In cases where the reflection is total, the cause of it is undoubtedly that same attractive force by which light would be refracted in passing out of the same body. This is manifest from that analogy which is observable between the reflection of light at the second surface, and its refraction there. For, otherwise, what can be the reason that the total reflection should begin just when the obliquity of the incident ray, at its arrival at the second surface, is such, that the refracted angle ought to be a right one; or when the ray, were it not to return in reflection, ought to pass on parallel to the surface, without going from it? For in this case it is evident, that it ought to be returned by this very power, and in such a manner that the angle of reflection shall be equal to the angle of incidence; just as a stone thrown obliquely from the earth, after it is so far turned out of its course by the attraction of the earth, as to begin to move horizontally, or parallel to the surface of the earth, is then by the same power made to return in a curve similar to that which is described in its departure from the earth, and so falls with the same degree of obliquity that it was thrown with.

164 Objection.

But, secondly, As to the reflection at the second surface, when it is partial; an attractive force uniformly spread over it, as the abettors of this hypothesis conceive it to be, can never be the cause thereof. Because it is inconceivable, that the same force, acting in the same circumstances in every respect, can sometimes reflect the violet-coloured rays, and transmit the red, and at other times reflect the red and transmit the violet.

This objection, however, is not well founded; for in each colour, the reflection takes place at that angle, and no other, where the refraction of *that* ray would make it parallel to the posterior surface.

This partial reflection and refraction is a great difficulty in all the attempts which have been made to give a mechanical explanation of the phenomena of optics. It is equally a desideratum in that explanation which was proposed by Huygens, by means of the undulations of an elastic fluid, although a vague consideration of undulatory motions seems to offer a very specious analogy. But a *rigid* application of the *knowledge* we have acquired of these motions, will convince us that the phenomena of undulation are essentially dissimilar to the phenomena of light. The inflection and refraction of light, demonstrate that light *is acted on* by moving forces in a direction perpendicular to the surface; and it is equally demonstrable that such forces must, in proper circumstances, produce reflections precisely such as we observe. The only difficulty is to show how there can be forces which produce both reflection and refraction, in circumstances which are similar. The fact is, that such effects are produced: the first logical inference is, that with respect to the light which is reflected and that which is refracted, the circumstances are *not* similar; and our attention should be directed to the discovery of that dissimilarity. All the phenomena of combined reflection and refraction should be examined and classed according to their generality, not doubting but that these points of resemblance will lead to the discovery of their causes. Now the experiments of M. Bouguer show that bodies differ in their powers of thus separating light by reflection and refraction. It is not therefore *a general property of light* to be partly reflected and partly refracted, but a *distinctive* property of *different* bodies; and since we see that they possess it in different degrees, we are authorized to conclude that some bodies may want it altogether. We may therefore expect some success, by considering how bodies are affected by light, as well as how light is affected by bodies. Now, in all the phenomena of the material world we find bodies connected by mutual forces. We know no case where a body A tends towards a body B, or, in common language, is attracted by it, without, at the same time, the body B tending towards A. This is observed in the phenomena of magnetism, electricity, gravitation, corpuscular attraction, impulse, &c. We should therefore conclude from analogy, that as bodies change the motion of light, light also changes the motion of bodies; and that the particles near the surface are put into vibration by the passage of light through among them.

165 The objection obviated.

Suppose a parcel of cork balls all hanging as pendulums in a symmetrical order, and that an electrified ball passes through the midst of them; it is very easy to show that it may proceed through this assemblage in various directions with a sinuated motion, and without touching any of them, and that its ultimate direction will have a certain inclination to its primary direction, depending on the outline of the assemblage, just as is observed in the motion of light; and, in the mean time, the cork balls will be variously agitated. Just so must it happen to the particles of a transparent body, if we suppose that they act on the particles of light by mutual attractions and repulsions.

An attentive consideration of what happens here will show us that the superficial particles will be much more agitated than the rest; and thus a stratum be produced, which, in any instant, will act on those particles of light which are then approaching them in a manner different from that in which they will act on similarly situated particles of light, which come into the place of the first in the following moment, when these acting particles of the body have (by their motion of vibration) changed their own situation. Now it is clearly understood, that, in all motions of vibration, such as the motions of pendulums, there is a moment when the body is in its natural situation, as when the pendulum is in the vertical line. This may happen in the same instant in each atom of the transparent body. The particles of light which then come within the sphere of action may be wholly reflected; in the next moment, particles of light in the very situation of the first may be refracted,

Then will arise a separation of light; and as this will depend on the manner in which the particles of bodies are agitated by it during its passage, and as this again will depend on the nature of the body, that is, on the law of action of those forces which connect the particles with each other, and with the particles of light, it will be different in different bodies. But in all bodies there will be this general resemblance, that the separation will be most copious in great obliquities of incidence, which gives the repulsive forces more time for action, while it diminishes the perpendicular force of the light. Such a resemblance between the phenomena and the

Cause of Reflection.

the legitimate consequences of the assumption (the agitation of the parts of the body), gives us some authority for assigning this as the cause; nor can the assumption be called *gratuitous*. To suppose that the particles of the transparent body *are not thus agitated*, would be a most gratuitous contradiction of a law of nature to which we know no other exception.

Thus the objection stated in N° 164. is obviated, because the reflection and refraction are not here conceived as simultaneous, but as successive.

166 Another hypothesis.

III. Some have supposed, that, by the action of light upon the surface of bodies, their parts are put into an undulatory motion; and that where the surface of it is subsiding light is transmitted, and in those places where it is rising light is reflected.

But to overlook the objections which we have just made to this theory of undulation, we have only to observe, that, were it admitted, it does not seem to advance us a step farther; for in those cases, suppose where red is reflected and violet transmitted, how comes it to pass that the red impinges only on those parts when the waves are rising, and the violet when they are subsiding?

167 Sir I. Newton's hypothesis;

IV. The next hypothesis is that remarkable one of Sir Isaac Newton's fits of easy reflection and transmission, which we shall now explain and examine.

That author, as far as we can apprehend his meaning in this particular, is of opinion, that light in its passage from the luminous body, is disposed to be alternately reflected by, and transmitted through, any refracting surface it may meet with; that these dispositions, which he calls *fits of easy reflection and easy transmission*, return successively at equal intervals; and that they are communicated to it at its first emission out of the luminous body, from which it proceeds probably by some very subtle and elastic substance diffused through the universe, and that in the following manner. As bodies falling into water, or passing through the air, produce undulations in each, so the rays of light may excite vibrations in this elastic substance. The quickness of these vibrations depending on the elasticity of the medium (as the quickness of the vibrations in the air, which propagate sound, depend solely on the elasticity of the air, and not upon the quickness of those in the sounding body), the motion of the particles of it may be quicker than that of the rays, and therefore, when a ray at the instant it impinges upon any surface, is in that part of a vibration of this elastic substance which conspires with its motion, it may be easily transmitted; and when it is in that part of a vibration which is contrary to its motion, it may be reflected. He further supposes, that when light falls upon the surface of a body, if it be not in a fit of easy transmission, every ray is there put into one, so that when they come at the other side (for this elastic substance, pervading the pores of bodies, is capable of the same vibrations within the body as without it), the rays of one colour shall be in a fit of easy transmission, and those of another in a fit of easy reflection, according to the thickness of the body, the intervals of the fits being different in rays of a different kind. This seems to account for the different colours of the bubble and thin plate of air and water; and likewise for the reflection of light at the second surface of a thicker body; for the light thence reflected is also observed to be coloured, and to form rings according to the different thickness of the body, when not intermixed and confounded with other light, as will appear from the following experiment. If a piece of glass be ground concave on one side and convex on the other, both its concavity and convexity having one common centre; and if a ray of light be made to pass through a small hole in a piece of paper held in that common centre; and be permitted to fall on the glass; besides those rays which are regularly reflected back to the hole again, there will be others reflected to the paper, and form coloured rings surrounding the hole, not unlike those occasioned by the reflection of light from thin plates.

168 This hypothesis untenable.

It is ever with extreme reluctance that we venture to call in question the doctrines of Newton; but to his theory of reflection there is this insuperable objection, that it explains nothing, unless the *cause* of the fits of more easy reflection and transmission be held as legitimate, namely, that *they are produced by the undulations of another elastic fluid, incomparably more subtile than light*, acting upon it in the way of impulse. The fits themselves are *matters of fact*, and no way different from what we have endeavoured to account for; but to admit this theory of them would be to transgress every rule of philosophizing.

Of the Laws of Reflection.

169 The fundamental law of reflection.

The fundamental law of the reflection of light, is, that the angle of reflection is always equal to the angle of incidence. This is found by experiment to be the case, and besides may be demonstrated mathematically from the laws of impulse in bodies perfectly elastic. The axiom therefore holds good in every case of reflection, whether it be from plane or spherical surfaces; and hence the seven following propositions relating to the reflection of light from plane and spherical surfaces may be deduced.

I. *Rays of light reflected from a plane surface have the same degree of inclination to one another that their respective incident ones have.*—For the angle of reflection of each ray being equal to that of its respective incident one, it is evident, that each reflected ray will have the same degree of inclination to that portion of the surface from which it is reflected that its incident one has; but it is here supposed, that all those portions of surface from which the rays are reflected, are situated in the same plane; consequently the reflected rays will have the same degree of inclination to each other that their incident ones have, from whatever part of the surface they are reflected.

170 Laws of reflection from a concave surface. Plate cclxxxii. fig. 1.

II. *Parallel rays reflected from a concave surface are rendered converging.*—To illustrate this, let AF, CD, EB, (fig. 1.) represent three parallel rays falling upon the concave surface FB, whose centre is C. To the points F and B draw the lines CF, CB; these being drawn from the centre, will be perpendicular to the surface at those points. The incident ray CD also passing through the centre, will be perpendicular to the surface, and therefore will return after reflection in the same line; but the oblique rays AF and EB will be reflected into the lines FM and BM, situated on the contrary side of their respective perpendiculars CF and CB. They will therefore proceed converging after reflection towards some point, as M, in the line CD.

III. *Converging rays falling on a concave surface, are made*

Laws of Reflection *made to converge more.*—For, every thing remaining as above, let GF, HB, be the incident rays. Now, because these rays have greater angles of incidence than the parallel ones AF and EB in the foregoing case, their angles of reflection will also be larger than those of the others; they will therefore converge after reflection, suppose in the lines FN and BN, having their point of concourse N farther from the point C than M, that to which the parallel rays AF and EB converged to in the foregoing case; and their precise degree of convergency will be greater than that wherein they converged before reflection.

IV. *Diverging rays falling upon a concave surface, are, after reflection, parallel, diverging, or converging.* If they diverge from the focus of parallel rays, they then become parallel; if from a point nearer to the surface than that, they will diverge, but in a less degree than before reflection; if from a point between that and the centre, they will converge after reflection, to some point on the contrary side of the centre, but situated farther from it than the radiant point. If the incident rays diverge from a point beyond the centre, the reflected ones will converge to one on the other side of it, but nearer to it than the radiant point; and if they diverge from the centre, they will be reflected thither again.

1. Let them diverge in the lines MF, MB, proceeding from the radiant point M, the focus of parallel rays; then, as the parallel rays AF and EB were reflected into the lines FM and BM (by Prop. ii.), these rays will now on the contrary be reflected into them.

2. Let them diverge from N, a point nearer to the surface than the focus of parallel rays, they will then be reflected into the diverging lines FG and BH, which the incident rays GF and HB described that were shown to be reflected into them in the foregoing proposition; but the degree of their divergency will be less than their divergency before reflection.

3. Let them diverge from X, a point between the focus of parallel rays and the centre; they then make less angles of incidence than the rays MF and MB, which became parallel by reflection: they will consequently have less angles of reflection, and therefore proceed converging towards some point, as Y; which point will always fall on the contrary side of the centre, because a reflected ray always falls on the contrary side of the perpendicular with respect to that on which its incident one falls; and of consequence it will be farther distant from the centre than X.

4. If the incident rays diverge from Y, they will, after reflection, converge to X; those which were the incident rays in the former case being the reflected ones in this.

5. If the incident rays proceed from the centre, they fall in with their respective perpendiculars; and for that reason are reflected thither again.

171 From a convex surface. Plate CCCLXXXII. fig. 2.

V. *Parallel rays reflected from convex surfaces are rendered diverging.*—For, let AB, GD, EF, be three parallel rays falling upon the convex surface BF, whose centre is C, and let one of them, viz. GD, be perpendicular to the surface. Through B, D, and F, the points of reflection, draw the lines CV, CG, and CT; which, will be perpendicular to the surface at these points. The incident ray GD being perpendicular to the surface, will return after reflection in the same line, but the oblique ones AB and EF will return in the lines BK and FL, situated on the contrary side of their respective perpendiculars BV and FT. They will therefore diverge, after reflection, as from some point M in the line GD produced; and this point will be in the middle between D and C.

Laws of Reflection.

VI. *Diverging rays reflected from convex surfaces are rendered more diverging.*—For, things remaining as above, let GB, GF, be the incident rays. These having greater angles of incidence than the parallel ones AB and EF in the preceding case, their angles of reflection will also be greater; they will therefore diverge after reflection, suppose in the lines BP and FQ, as from some point N, farther from C than the point M; and the degree of their divergency will exceed their divergency before reflection.

VII. *Converging rays reflected from convex surfaces are parallel, converging, or diverging.*—If they tend towards the focus of parallel rays, they then become parallel; if to a point nearer the surface, they converge, but in a less degree than before reflection; if to a point between that and the centre, they will diverge after reflection, as from some point on the contrary side of the centre, but situated farther from it than the point to which they converged; if the incident rays converge to a point beyond the centre, the reflected ones will diverge as from one on the contrary side of it, but nearer to it than the point to which the incident ones converged; and if the incident rays converge towards the centre, the reflected ones will seem to proceed from it.

1. Let them converge in the lines KB and LF, tending towards M, the focus of parallel rays; then, as the parallel rays AB, EF were reflected into the lines BK and FL by (Prop. v.) those rays will now on the contrary be reflected into them.

2. Let them converge in the lines PB, QF, tending towards N a point nearer the surface than the focus of parallel rays, they will then be reflected into the converging lines BG and FG, in which the rays GB, GF proceeded that were shown to be reflected into them by the last proposition: but the degree of their convergency will exceed their convergency before reflection.

3. Let them converge in the lines RB and SF proceeding towards X, a point between the focus of parallel rays and the centre; their angles of incidence will then be less than those of the rays KB and LF, which became parallel after reflection: their angles of reflection will therefore be less; on which account they must necessarily diverge, suppose in the lines BH and FI, from some point, as Y; which point (by Prop. iv.) will fall on the contrary side of the centre with respect to X, and will be farther from it than that.

4. If the incident rays tend towards Y, the reflected ones will diverge as from X; those which were the incident ones in one case being the reflected ones in the other.

5. If the incident rays converge towards the centre, they coincide with their respective perpendiculars; and will therefore proceed after reflection as from that centre.

We have already observed, that in some cases there is a very great reflection from the second surface of a transparent body. The degree of inclination necessary to cause a total reflection of a ray at this surface, is that which requires that the refracted angle (supposing the ray to pass out there) should be equal to or greater than a a right one; and consequently it depends on the refractive power of the medium through which the ray passes, and is therefore different in different media. When a ray passes through glass surrounded with air, and is inclined to its second surface under an angle of 42° or more, it will be wholly reflected there. For, as 11 is to 17 (the ratio of refraction out of glass into air), so is the sine of an angle of 42° to a fourth number that will exceed the sine of a right angle. Hence it follows, that when a ray of light arrives at the second surface of a transparent substance with as great or a greater degree of obliquity than that which is necessary to make a total reflection, it will there be all returned back to the first: and if it proceeds towards that with as great an obliquity as it did towards the other (which it will do if the surfaces of the medium be parallel to each other), it will there be all reflected again, &c. and will therefore never get out, but pass from side to side, till it be wholly extinguished within the body.—From this may arise an obvious inquiry, how it comes to pass, that light falling very obliquely upon a glass window from without, should be transmitted into the room. In answer to this it must be considered, that however obliquely a ray falls upon the surface of any medium whose sides are parallel as those of the glass in a window, it will suffer such a degree of refraction in entering there, that it shall fall upon the second with a less obliquity than that which is necessary to cause a total reflection. For since the medium be glass: then, as 17 is to 11, so is the sine of the greatest angle of incidence with which a ray can fall upon any surface to the sine of a less angle than that of total reflection. Therefore, if the sides of the glass be parallel, the obliquity with which a ray falls upon the first surface cannot be so great, that it shall pass the second without suffering a total reflection there.

When light passes out of a denser into a rarer medium, the nearer the second medium approaches the first in its refractive power, the less of it will be refracted in passing from one to the other; and when their refracting powers are equal, all of it will pass into the second medium.

The above propositions may be all mathematically demonstrated in the following manner:

Prop. I.

Of the reflection of rays from a plane surface.

172 The preceding propositions demonstrated mathematically.

When rays fall upon a plane surface, if they diverge, the focus of the reflected rays will be at the same distance behind the surface, that the radiant point is before it: if they converge, it will be at the same distance before the surface that the imaginary focus of the incident rays is behind it.

This proposition admits of two cases.

Case 1. *Of diverging rays.*

Plate CCCLXXXII. fig. 3.

Let AB, AC be two diverging rays incident on the plane surface DE, the one perpendicularly, the other obliquely: the perpendicular one AB will be reflected to A, proceeding as from some point in the line AB produced; the oblique one AC will be reflected into some line as CF, so that the point G, where the line FG produced intersects the line AB produced also, shall be at an equal distance from the surface DE with the radiant point A. For the perpendicular CH being drawn, ACH and HCF will be the angles of incidence and reflection; which being equal, their complements ACB and FCE are also equal: but the angle BCG is equal to its vertical angle FCE: therefore in the triangles ABC and GBC the angles at C are equal, the side BC is common, and the right angles at B are equal; therefore AB=BG: and consequently the point G, the focus of the incident rays AB, AC, is at the same distance behind the surface, that the point A is before it.

Case 2. *Of converging rays.*

This is the converse of the former case. For supposing FC and AB to be two converging incident rays, CA and BA will be the reflected ones (the angles of incidence in the former case being now the angles of reflection, and *vice versa*), having the point A for their focus; but this is at an equal distance from the reflecting surface with the point G, which in this case is the imaginary focus of the incident rays FC and AB.

It is not here, as in the case of rays passing through a plane surface, where some of the refracted rays proceed as from one point, and some as from another: but they all proceed after reflection as from one and the same point, however obliquely they may fall upon the surface; for what is here demonstrated of the ray AC holds equally of any other, as AI, AK, &c.

The case of parallel rays incident on a plane surface is included in this proposition: for in that case we are to suppose the radiant point infinitely distant from the surface, and then by the proposition the focus of the reflected rays will be so too: that is, the rays will be parallel after reflection, as they were before it.

Prop. II.

Of the reflection of parallel rays from a spherical surface.

When parallel rays are incident upon a spherical surface, the focus of the reflected rays will be the middle point between the centre of convexity and the surface.

This proposition admits of two cases.

Case 1. *Of parallel rays falling upon a convex surface.*

Let AB, DH, represent two parallel rays incident on the convex surface BH, the one perpendicularly, the other obliquely; and let C be the centre of convexity. Suppose HE to be the reflected ray of the oblique one DH, proceeding as from F, a point in the line AB produced. Through the point H draw the line CI, which will be perpendicular to the surface at that point; and the angles DHI and IHE, being the angles of incidence and reflection, will be equal. But HCF=DHI, the lines AC and DH being parallel; and CHF=IHE, wherefore the triangle CFH is isosceles, and consequently CF=FH: but supposing BH to vanish, FH=FB; and therefore upon this supposition FC=FB; that is, the focus of the reflected rays is the middle point between the centre of convexity and the surface. Fig. 4.

Case 2. *Of parallel rays falling upon a concave surface.*

Let AB, DH, be two parallel rays incident, the one perpendicularly, the other obliquely, on the concave surface BH, whose centre of concavity is C. Let BF and HF be the reflected rays meeting each other in F; this will be the middle point between B and C. For drawing through C the perpendicular CH, the angles DHC=FHC, being the angles of incidence and reflection; but HCF=DHC its alternate angle, and therefore the triangle CFH is isosceles. Wherefore CF=FH: but if we suppose BH to vanish, FB=FH, and therefore Fig. 5.

therefore CF=FB; that is, the focal distance of the reflected rays is the middle point between the centre and the surface.

It is here observable, that the farther the line DH, either in fig. 4. or 5. is taken from AB, the nearer the point F falls to the surface. For the farther the point H recedes from B, the greater the triangle CFH will become; and consequently, since it is always isosceles, and the base CH, being the radius, is everywhere of the same length, the equal legs CF and FH will lengthen; but CF cannot grow longer unless the point F approach towards the surface. And the farther H is removed from B, the faster F approaches to it.

This is the reason, that whenever parallel rays are considered as reflected from a spherical surface, the distance of the oblique ray from the perpendicular one is taken so small with respect to the focal distance of that surface, that without any physical error it may be supposed to vanish.

173 Reflected rays from a spherical surface never proceed from the same point. Fig 6.

Hence it follows, that if a number of parallel rays, as AB, CD, EG, &c. fall upon a convex surface, and if BA, DK, the reflected rays of the incident ones AB, CD, proceed as from the point F, those of the incident ones CD, EG, viz. DK, GL, will proceed as from N, those of the incident ones EG, HI, as from O, &c. because the farther the incident ones CD, EG, &c. are from AB, the nearer to the surface are the points F, *f*, *f*, in the line BF, from which they proceed after reflection; so that properly the foci of the reflected rays BA, DK, GL, &c. are not in the line AB produced, but in a curve line passing through the points F, N, O, &c.

The same is applicable to the case of parallel rays reflected from a concave surface, as expressed by the dotted lines on the other half of the figure, where PQ, RS, TV, are the incident rays; QF, S*f*, V*f*, the reflected ones, intersecting each other in the points X, Y, and F; so that the foci of those rays are not in the line FB, but in a curve passing through those points.

174 Rays proceeding from one point, and falling on a parabolic concave surface, are all reflected from one point.

Had the surface BH in fig. 4. or 5. been formed by the revolution of a parabola about its axis having its focus in the point F, all the rays reflected from the convex surface would have proceeded as from the point F, and those reflected from the concave surface would have fallen upon it, however distant their incident ones AB, DH, might have been from each other. For in the parabola, all lines drawn parallel to the axis make angles with the tangents to the points where they cut the parabola (that is, with the surface of the parabola) equal to those which are made with the same tangents by lines drawn from thence to the focus; therefore, if the incident rays describe those parallel lines, the reflected ones will necessarily describe these other, and so will all proceed as from, or meet in, the same point.

Prop. III.

175 Proportional distance of the focus of rays reflected from a spherical surface.

Of the reflection of diverging and converging rays from a spherical surface.

When rays fall upon any spherical surface, if they diverge, the distance of the focus of the reflected rays from the surface is to the distance of the radiant point from the same (or, if they converge, to that of the imaginary focus of the incident rays), as the distance of the focus of the reflected rays from the centre is to the distance of the radiant point (or imaginary focus of the incident rays) from the same.

This proposition admits of ten cases.

Case 1. *Of diverging rays falling upon a convex surface.*

Let RB, RD, represent two diverging rays flowing from the point R as from a radiant, and falling the one perpendicularly, the other obliquely, on the convex surface BD, whose centre is C. Let DE be the reflected ray of the incident one RD; produce ED to F, and through R draw the line RH parallel to FE till it meets CD produced in H. Then RHD=EDH the angle of reflection, and RHD=RDH the angle of incidence; wherefore the triangle DRH is isosceles, and DR=RH. Now the lines FD and RH being parallel, the triangles FDC and RHC are similar, or the sides are cut proportionably, and therefore FD : RH or RD=CF : CR; but BD vanishing, FD and RD differ not from FB and RB: wherefore FB : RB=CF : CR; that is, the distance of the focus from the surface is to the distance of the radiant point from the same, as the distance of the the focus from the centre is to the distance of the radiant point from it. Fig. 7.

Case 2. *Of converging rays falling upon a concave surface.*

Let KD and CB be the converging incident rays, having their imaginary focus in the point R, which was the radiant point in the foregoing case. Then as RD was in that case reflected into DE, KD will in this be reflected into DF; for, since the angles of incidence in both cases are equal, the angles of reflection will be equal also; so that F will be the focus of the reflected rays: but it was there demonstrated, that FB : RB= CF : CR; that is, the distance of the focus from the surface is to the distance (in this case) of the imaginary focus of the incident rays, as the distance of the focus from the centre is to the distance of the imaginary focus of the incident rays from the same.

Case 3. *Of converging rays falling upon a convex surface, and tending to a point between the focus of parallel rays and the centre.*

Let B represent a convex surface whose centre is C, and whose focus of parallel rays is P; and let AB, KD, be two converging rays incident upon it, and having their imaginary focus at R, a point between P and C. Now because KD tends to a point between the focus of parallel rays and the centre, the reflected ray DE will diverge from some point on the other side the centre, suppose F; as explained above. Through D draw the perpendicular CD, and produce it to H; then will KDH=HDE, being the angles of incidence and reflection, and consequently RDC=CDF too. Therefore the triangle RDF is bisected by the line DC: wherefore (3 El. 6.) FD and DR, or BD vanishing, FB : BR=FC : CR; that is, the distance of the focus of the reflected rays is to that of the imaginary focus of the incident ones, as the distance of the former from the centre is to the distance of the latter from the centre. Fig. 8.

Case 4. *Of diverging rays falling upon a concave surface, and proceeding from a point between the focus of parallel rays and the centre.*

Let RB, RD, be the diverging rays incident upon the concave surface BD, having their radiant point in R, Fig. 8.

Laws of Reflection.

R, the imaginary focus of the incident rays in the preceding case. Then as KD was in that case reflected into DE, RD will now be reflected into DF. But we had FB : RB=CF : CR; that is, the distance of the focus is to that of the radiant, as the distance of the former from the centre is to the distance of the latter from the centre.

The angles of incidence and reflection being equal, it is evident, that if, in any case, the reflected ray be made the incident one, the incident will become the reflected one; and therefore the four following cases may be considered respectively as the converse of the four preceding; for in each of them the incident rays are supposed to coincide with the reflected ones in the other. Or they may be thus demonstrated independently of them.

CASE 5. *Of converging rays falling upon a convex surface, and tending to a point nearer the surface than the focus of parallel rays.*

Fig. 7. Let ED, RB be the converging rays incident upon the convex surface BD, whose centre is C, and principal focus P; let the imaginary focus of the incident rays be at F, a point between P and B; and let DR be the reflected ray. From C and R draw the lines CH, RH, the one passing through D, the other parallel to FE. Then RHD=HDE the angle of incidence. But RHD=HDR, the angle of reflection: wherefore the triangle HDR is isosceles, and DR=RH. Now the lines FD and RH being parallel, the triangles FDC and RHC are similar; and therefore RH or RD : FD=CR : CF; but BD vanishing, RD and FD coincide with RB and FB, wherefore RB : FB=CR : CF; that is, the distance of the focus from the surface is to the distance of the imaginary focus of the incident rays, as the distance of the focus from the centre is to the distance of the imaginary focus of the incident rays from the centre.

CASE 6. *Of diverging rays falling upon a concave surface, and proceeding from a point between the focus of parallel rays and the surface.*

Let FD and BF be two rays diverging from the point F, which was the imaginary focus of the incident rays in the preceding case. Then as ED was in that case reflected into DR, FD will be reflected into DK (for the reason mentioned in case 2.), so that the reflected ray will proceed as from the point R: but it was demonstrated in case 5. that RB : FB=CR : CF; that is, the distance of the focus from the surface is to that of the radiant from the surface, as the distance of the former from the centre is to that of the latter from the centre.

Fig. 8. CASE 7. *Of converging rays falling upon a convex surface, and tending towards a point beyond the centre.*

Let AB, ED be the incident rays tending to F, a point beyond the centre C, and let DK be the reflected ray of the incident one ED. Then because the incident ray ED tends to a point beyond the centre, the reflected ray DK will proceed as from one on the contrary side, suppose R; see Prop. vii. Through D draw the perpendicular CD, and produce it to H. Then will EDH=HDK, being the angles of incidence and reflection; but CDF=CDR, being their verticals: consequently the angle FDR is bisected by the line CD; wherefore RD : DF, or (3 Elem. 6.) BD vanishing, RB : BF=RC : CF; that is, the distance of the focus of the reflected rays is to that of the imaginary focus of the incident rays, as the distance of the former from the centre is to the distance of the latter from the centre.

CASE 8. *Of diverging rays falling upon a concave surface, and proceeding from a point beyond the centre.*

Let FB, FD be the incident rays radiating from F, the imaginary focus of the incident rays in the case. Then as ED was in that case reflected into DK, FD will now be reflected into DR; so that R will be the focus of the reflected rays. But it was demonstrated in the case 7. that RB : FB=RC : CF; that is, the distance of the focus of the reflected rays from the surface is to the distance of the radiant from the surface, as the distance of the focus of the reflected rays from the centre is to the distance of the radiant from the centre.

The two remaining cases may be considered as the converse of those under Prop. ii. (p. 234.), because the incident rays in these are the reflected ones in them; or they may be demonstrated in the same manner with the preceding, as follows.

CASE 9. *Converging rays falling upon a convex surface, and tending to the focus of parallel rays, become parallel after reflection.*

Let ED, RB represent two converging rays incident on the convex surface BD, and tending towards F, which we shall now suppose to be the focus of parallel rays; and let DR be the reflected ray, and C the centre of convexity of the reflecting surface. Through C draw CD, and produce it to H, drawing RH parallel to ED produced to F. Now it has been demonstrated (case 5. where the incident rays are supposed to tend to the point F), that RB : FB=RC : CF; but F in this case being supposed to be the focus of parallel rays, it is the middle point between C and B (by Prop. ii.) and therefore FB=FC, consequently RB=RC; which can only be upon the supposition that R is at an infinite distance from B; that is, that the reflected rays BR and DR be parallel. Plate CCCLXXXIII. fig. 7.

CASE 10. *Diverging rays falling upon a concave surface, and proceeding from the focus of parallel rays, become parallel after reflection.*

Let RD, RB be two diverging rays incident upon the concave surface BD, as supposed in case 4. where it was demonstrated that FB : RB=CF : CR. But in the present case RB=CR, because R is supposed to be the focus of parallel rays; therefore FB=FC; which cannot be unless F be taken at an infinite distance from B; that is, unless the reflected rays BF and DF be parallel. Fig. 5.

It may here be observed that in the case of diverging rays falling upon a convex surface, the farther the point D is taken from B, the nearer the point F, the focus of the reflected rays, approaches to B, while the radiant point R remains the same. For it is evident from the curvature of a circle, that the point D may be taken so far from B, that the reflected ray DE shall proceed as from F, G, H, or even from B, or from any point between B and R; and the farther it is taken from B, the faster the point from which it proceeds approaches towards R: as will appear if we draw several incident rays with their respective reflected ones, in such a manner that the angles of reflection may be equal to their respective angles of incidence, as is done in the figure. The like is applicable to any of the other cases of diverging and converging rays incident upon a spherical surface. This is the reason, that, when rays are considered as reflected from a spherical surface, Fig. 9. Fig. 10.

Laws of Reflection.

surface, the distance of the oblique rays from the perpendicular one is taken so small, that it may be supposed to vanish.

From this it follows, that if a number of diverging rays are incident upon the convex surface BD at the several points B, D, D, &c. they will not proceed after reflection as from any point in the line RB produced, but as from a curve line passing through the several points F, *f*, *f*, &c.

Fig. 7. Had the curve BD been a hyperbola, having its foci in R and F, then R being the radiant (or the imaginary focus of incident rays), F would have been the focus of the reflected ones, and *vice versa*, however distant the points B and D might be taken from each other. In

Fig. 8. like manner, had the curve BD been an ellipse having its foci in F and R, the one of these being made the radiant (or imaginary focus of incident rays), the other would have been the focus of reflected ones, and *vice versa*. For both in the hyperbola and ellipse, lines drawn from each of their foci through any point make equal angles with the tangent to that point. Therefore, if the incident rays proceed to or from one of their foci, the reflected ones will all proceed as from or to the other focus. Therefore, in order that diverging or converging rays may be accurately reflected to or from a point, the reflecting surface must be formed by the revolution of an *hyperbola* about its longer axis, when the incident rays are such, that their radiant or imaginary focus of incident rays shall fall on one side of the surface, and the focus of the reflected ones on the other; when they are both to fall on the same side, it must be formed by the revolution of an *ellipse* about its longer axis. However, as spherical surfaces are more easily formed, than those which are generated by the revolution of any of the conic sections about their axes, the latter are very rarely used.

176
Method of finding the focal distance of rays reflected from a convex surface.

Now, because the focal distance of rays reflected from a spherical surface cannot be found by the analogy laid down in the third proposition, without making use of the quantity sought; we shall here give an example whereby the method of doing it in all others will readily appear.

Problem.

Let it be required to find the focal distance of diverging rays incident upon a convex surface, whose radius of convexity is five parts, and the distance of the radiant from the surface is 20.

Call x the focal distance sought; then will the distance of the focus from the centre be $5-x$, and that of the radiant from the same 25, therefore by Prop. iii. we have the following proportion, $x : 20 = 5-x : 25$; and multiplying extremes together and means together, we have $25\,x = 100 - 20x$, or $x = \frac{100}{45}$.

If it should happen in any case that the value of x is a negative quantity, the focal point must then be taken on the contrary side of the surface to that on which it was supposed it would fall in stating the problem.

Because it was observed in the preceding section, that different incident rays, though tending to or from one point, would after refraction proceed to or from different points, a method was there given of determining the distinct point which each separate ray entering a spherical surface converges to, or diverges from, after refraction: the same has been observed here with regard to rays reflected from a spherical surface (see case 2. and case 10.) But the method of determining the distinct point to or from which any incident ray proceeds after reflection, is much more simple. It is only necessary to draw the reflected ray such, that the angle of reflection may be equal to the angle of incidence, which will determine the point it proceeds to or from in any case whatever.

Appearance of Bodies seen by Reflection.

Sect. VIII. *Of the Appearance of Bodies seen by Light reflected from plane and spherical Surfaces.*

Whatever has been said concerning the appearance of bodies seen through lenses, by refracted light, respects also the appearance of bodies seen by reflection. But, besides these, there is one thing peculiar to images by reflection, viz. that each point in the representation of an object made by reflection appears situated somewhere in a right line that passes through its correspondent point in the object, and is perpendicular to the reflecting surface.

The truth of this appears sufficiently from the propositions formerly laid down: in each of which, rays flowing from any radiant point, are shown to proceed after reflection to or from some point in a line that passes through the radiant point, and is perpendicular to the reflecting surface. For instance (fig. 1.) rays flowing from Y are collected in X, a point in the perpendicular CD, which, being produced, passes through Y; Plate CCCLXXXII. fig. 2.
again (fig. 2.), rays flowing from G, proceed, after reflection, as from N, a point in the perpendicular CD, which being produced, passes through G.

This observation, however, except where an object is seen by reflection from a plain surface, relates only to those cases where the representation is made by means of such rays as fall upon the reflecting surface with a very small degree of obliquity; because such as fall at a considerable distance from the perpendicular, do not proceed after reflection as from any point in that perpendicular, but as from other points situated in a certain curve, on which account these rays are neglected, as making an indistinct and deformed representation. And therefore it is to be remembered, that however the situation of the eye with respect to the object and reflecting surface may be represented in the following figures, it is to be supposed as situated in such a manner with respect to the object, that rays flowing from thence and entering it after reflection, may be such only as fall with a very small degree of obliquity upon the surface; that is, the eye must be supposed to be placed almost directly behind the object, or between it and the reflecting surface. The reason why it is not always so placed, is only to avoid confusion in the figures.

177
The appearance of objects reflected from plane surfaces.

I. *When an object is seen by reflection from a plane surface, the image of it appears at the same distance behind the surface that the object is before it, of the same magnitude, and directly opposite to it.*

Fig. 10. To explain this, let AB represent an object seen by reflection from the plane surface SV; and let the rays AF, AG, be so inclined to the surface, that they shall enter an eye at H after reflection; and let AE be perpendicular to the surface: then, by the observation just mentioned, the point A will appear in some part of the line AE produced, suppose I; that is, the oblique rays AF

Appearance of Bodies seen by Reflection from different Surfaces.

AF and AG will proceed after reflection as from that point; and further, because the reflected rays FH, GK, will have the same degree of inclination to one another that their incident ones have, that point must necessarily be at the same distance from the surface that the point A is; the representation therefore of the point A will be at the same distance from the surface that the point itself is before it, and directly opposite to it: consequently, since the like may be shown of any other point B, the whole image IM will appear at the same distance behind the surface that the object is before it, and directly opposite to it; and because the lines AI, BM, perpendicular to the plain surface, are parallel to each other, the image will also be of the same magnitude with the object.

178 From convex surfaces.

II. *When an object is seen by reflection from a convex surface, its image appears nearer to the surface, and less than the object.*

Fig. 12.

Let AB represent the object, SV a reflecting surface whose centre of convexity is C: and let the rays AF, AG, be so inclined to the surface, that after reflection from it, they shall enter the eye at H: and let AE be perpendicular to the surface; then will the oblique rays AF, AG, proceed after reflection as from some point in the line AE produced, suppose from I; which point, because the reflected rays will diverge more than the incident ones, must be nearer to the surface than the point A. And since the same is also true of the rays which flow from any other B, the representation IM will be nearer to the surface than the object; and because it is terminated by the perpendiculars AE and BF, which incline to each other, as concurring at the centre, it will also appear less.

179 From concave surfaces.

III. *When an object is seen by reflection from a concave surface, the representation of it is various, both with regard to its magnitude and situation, according as the distance of the object from the reflecting surface is greater or less.*

1. When the object is nearer to the surface than its principal focus, the image falls on the opposite side of the surface, is more distant from it, and larger than the object.

Fig. 13.

Thus let AB be the object, SV the reflecting surface, F the principal focus, and C its centre. Through A and B, the extremities of the object, draw the lines CE, CR, which will be perpendicular to the surface; and let the rays AR, AG, be incident upon such points of it that they shall be reflected into an eye at H. Now, because the radiant points A and B are nearer the surface than the principal focus F, the reflected rays will diverge, and therefore proceed as from some points on the opposite side of the surface; which points, by the observation laid down at the beginning of this section, will be in the perpendiculars AE, BR, produced, suppose in I and M: but they will diverge in a less degree than their incident ones: and therefore the said points will be farther from the surface than the points A and B. The image therefore will be on the opposite side of the surface with respect to the object: it will be more distant than it; and consequently, being terminated by the perpendiculars CI and CM, it will also be larger.

2. When the object is placed in the principal focus, the reflected rays enter the eye parallel; in which case the image ought to appear at an infinite distance behind the reflecting surface; but the representation of it, for the reasons given in the foregoing case, being large and distinct, we do not reckon it much farther from the surface than the image.

3. When the object is placed between the principal focus and the centre, the image falls on the opposite side of the centre, is larger than the object, and in an inverted position.

Plate CCLXXXII. fig. 14.

Thus let AB be the object, SV the reflecting surface, F its principal focus, and C its centre. Through A and B, draw the lines CE and CN, which will be perpendicular to the surface; and let AR, AG, be a pencil of rays flowing from A. These rays proceeding from a point beyond the principal focus, will after reflection converge towards some point on the opposite side the centre, which will fall upon the perpendicular EC produced, but at a greater distance from C than the radiant A from which they diverged. For the same reason, rays flowing from B will converge to a point in the perpendicular NC produced, which shall be farther from C than the point B; whence it is evident, that the image IM is larger than the object AB, that it falls on the contrary side of the centre, and that their positions are inverted with respect to each other.

4. If the object be placed beyond the centre of convexity, the image is then formed between the centre and the focus of parallel rays, is less than the object, and its position is inverted.

This proposition is the converse of the preceding; for as in that case rays proceeding from A were reflected to I, and from B to M; so rays flowing from I and M will be reflected to A and B: if therefore an object be supposed to be situated beyond the centre in IM, the image of it will be formed in AB between that and the focus of parallel rays, will be less than the object, and inverted.

5. If the middle of the object be placed in the centre of convexity of the reflecting surface, the object and its image will be coincident; but the image will be inverted with respect to the object.

That the place of the image and the object should be the same in this case requires little explication; for the middle of the object being in the centre, rays flowing from it will fall perpendicularly upon the surface, and therefore necessarily return thither again; so that the middle of the image will be coincident with the middle of the object. But that the image should be inverted is perhaps not so clear. To explain this, let AB be the object, having its middle point C in the centre of the reflecting surface from SV; through the centre and the point R draw the line CR, which will be perpendicular to the reflecting surface; join the points AR and BR, and let AR represent a ray flowing from A; this will be reflected into RB; for C being the middle point between A and B, the angle ARC=CRB; and a ray from B will likewise be reflected to A; and therefore the position of the image will be inverted with respect to that of the object. Fig. 15.

In this proposition it is to be supposed, that the object AB is so situated with respect to the reflecting surface, that the angle ACR may be right; for otherwise the angles ARC and BRC will not be equal, and part of the image only will therefore fall upon the object.

6. If

Appearance of Bodies seen by Reflection from different Surfaces.

6. If in any of the three last cases, in each of which the image is formed on the same side of the reflecting surface with the object, the eye be situated farther from the surface than the place where the image falls, the rays of each pencil, crossing each other in the several points of the image, will enter the eye as from a real object situated there; so that the image will appear pendulous in the air between the eye and the reflecting surface, and in the position wherein it is formed, viz. inverted with respect to the object, in the same manner that an image formed by refracted light appears to an eye, placed beyond it; which was fully explained under Prop. iv. and therefore needs not be repeated.

But as what relates to the appearance of the object when the eye is placed nearer to the surface than the image, was not there fully inquired into, that point shall now be more strictly examined under the following case, which equally relates to refracted and reflected light.

7. If the eye be situated between the reflecting surface and the place of the image, the object is then seen beyond the surface; and the farther the eye recedes from the surface towards the place of the image, the more confused, larger, and nearer, the object appears.

Fig. 16. To explain this, let AB represent the object; IM its image, one of whose points M is formed by the concurrence of the reflected rays DM, EM, &c. which before reflection came from B; the other, I, by the concurrence of DI, EI, &c. which came from A: and let *a b* be the pupil of an eye, situated between the surface DP and the image. This pupil will admit the rays H *a*, K *b*; which, because they are tending towards I, are such as came from A, and therefore the point A will appear diffused over the space RS. In like manner the pupil will also receive into it the reflected rays K *a* and L *b*, which, because they are tending towards M, by supposition came from B; and therefore the point B will be seen spread as it were over the space TV, and the object will seem to fill the space RV; but the representation of it will be confused, because the intermediate points of the object being equally enlarged in appearance, there will not be room for them between the points S and T, but they will coincide in part one with another: for instance, the appearance of that point in the object, whose representation falls upon *c* in the image, will fill the space *m n*; and so of the rest. Now, if the same pupil be removed into the situation *e f*, the reflected rays E *e* and G *f* will then enter the eye, and therefore one extremity of the object will appear to cover the space XY; and because the rays O *f* and L *e* will also enter it in their progress towards M, the point B, from which they came, will appear to cover ZV; the object therefore will appear larger and more confused than before. When the eye recedes quite to the image, it sees but one single point of the object, and that appears diffused all over the reflecting surface: for instance, if the eye recedes to the point M, then rays flowing from the point B enter it upon whatever part of the surface they fall. The object also appears nearer to the surface the farther the eye recedes from it towards the place of the image; probably because, as the appearance of the object becomes more and more confused, its place is not so easily distinguished from that of the reflecting surface itself, till at last when it is quite confused (as it is when the eye is arrived at M) they both appear as one, the surface assuming the colour of the object.

180. The apparent magnitude of an object seen by reflection from a concave surface.

As to the precise apparent magnitude of an object seen after this manner, it is such that the angle it appears under shall be equal to that which the image of the same object would appear under were we to suppose it seen from the same place: that is, the apparent object (for such we must call it, to distinguish it from the image of the same object) and the image subtend equal angles at the eye.

Here we must suppose the pupil of the eye to be a point only, because the magnitude of it causes a small alteration in the apparent magnitude of the object. Let the point *a* represent the pupil, then will the extreme rays that can enter it be H *a* and K *a*; the object therefore will appear under the angle H *a* K = M *a* I, the angle under which the image IM would appear were it to be seen from *a*. Again, if the eye be placed in *f*, the object appears under the angle G *f* O = I *f* M, which the image subtends at the same place, and therefore the apparent object and image of it subtend equal angles at the eye.

Now if we suppose the pupil to have any sensible magnitude *a b*; then the object seen by the eye in that situation will appear under the angle HXL, which is larger than the angle H *a* K, under which it appeared before; because the angle at X is nearer than the angle at *a*, to the line IM, which is a subtense common to them both.

From this proposition it follows; that, were the eye close to the surface at K, the real and apparent object would be seen under equal angles (for the real object appears from that place under the same angle that the image does, as will be shown at the end of this section); therefore, when the eye is nearer to the image than that point, the image will subtend a larger angle at it than the object does; and consequently, since the image and apparent object subtend equal angles at the eye, the apparent object must necessarily be seen under a larger angle than the object itself, wherever the eye be placed, between the surface and the image.

As each point in the representation of an object made by reflection is situated somewhere in a right line that passes through its correspondent point in the object, and is perpendicular to the reflecting surface; we may hence deduce the following easy and expeditious method of determining both the magnitude and situation of the image in all cases whatever.

Plate CCCLXXXII. Fig. 17, 18, 19.

Though the extremities of the object AB and the centre C (fig. 17, 18, 19.) draw the lines AC BC, and produce them as the case requires; these lines will be perpendicular to the reflecting surface, and therefore the extremities of the image will fall upon them. Through F the middle point of the object and the centre, draw the line FC, and produce it till it passes through the reflecting surface; this will also be perpendicular to the surface. Through G, the point where this line cuts the surface, draw the lines AG and BG, and produce them this way or that, till they cross the former perpendiculars; and where they cross, there I and M the extremities of the image will fall. For supposing AG to be a ray proceeding from the point A and

Appearance of Bodies seen by Reflection from different Surfaces.

and falling upon G, it will be reflected to B; because FA=FB, and FG is perpendicular to the reflecting surface; and therefore the representation of the point A will be in BG produced as well as in AC; consequently it will fall on the point I, where they cross each other. Likewise the ray BG will for the same reason be reflected to A; and therefore the representation of the point B will be in AG produced, as well as in some part of BC, that is, in M where they cross. Hence the proposition is obvious.

If it happens that the lines will not cross which way soever they are produced, as in fig. 20. then is the object in the focus of parallel rays of that surface, and has no image formed in the place whatever. For in this case the rays AH, AG, flowing from the point A, become parallel after reflection in the lines HC, GB, and therefore do not flow as to or from any point: in like manner, rays flowing from B are reflected into the parallel lines KB and GA; so that no representation can be formed by such reflection.

From this we learn another circumstance relating to the magnitude of the image made by reflection; viz. that it subtends the same angle at the vertex of the reflecting surface that the object does. This appears by inspection of the 17th, 18th, or 19th figure, in each of which the angle IGM=AGB, the angles which the image subtends at G the vertex of the reflecting surface, and which the object subtends at the same place; for in the two first of those figures they are vertical, in the third they are the same.

The angle ICM, which the image subtends at the centre, is also equal to the angle ACB which the object subtends at the same place; for in the two first figures they are the same, in the last they are vertical to each other.

Whence it is evident, that the object and its image are to each other in diameter, either as their respective distances from the vertex of the reflecting surface, or as their distances from the centre of the same.

IV. *As objects are multiplied by being seen through transparent media, whose surfaces are properly disposed, so they may also by reflecting surfaces.*

Plate CCCLXXXII. fig. 21.

1. If two reflecting surfaces be disposed at right angles, as the surfaces AB, BC, an object at D may be seen by an eye at E, after one reflection at F, in the line EF produced; after two reflections, the first at G, the second at H, in the line EH produced; and, also, after one reflection made at A, in the line EA produced.

Fig. 22.

2. If the surfaces be parallel, as AB, CD, (fig. 22.), and the object be placed at E and the eye at F, the object will appear multiplied an infinite number of times: thus it may be seen in the line FG produced, after one reflection at G; in the line FH produced, after two reflections, the first at I, the second at H; and also in FP produced, after several successive reflections of the ray EL, at the points L, M, N, O, and P: and so on *in infinitum*. But the greater the number of reflections are, the weaker their representation will be.

Sect. IX. *Of the apparent Place, Distance, Magnitude, and Motion of Objects.*

Apparent place, &c. of objects.

It had in general been taken for granted, that the place to which the eye refers any visible object seen by reflection or refraction, is that in which the visual rays meet a perpendicular from the object upon the reflecting or refracting plane. But this method of judging of the place of objects was called in question by Dr Barrow, who contended that the arguments brought in favour of the opinion were not conclusive. 181

Dr Barrow's theory respecting the apparent place of objects.

These arguments are, that the images of objects appeared straight in a plane mirror, but curved in a convex or concave one: that a straight thread, when partly immersed perpendicularly in water, does not appear crooked as when it is obliquely plunged into the fluid; but that which is within the water seems to be a continuation of that which is without. With respect to the reflected image, however, of a perpendicular right line from a convex to a concave mirror, he says, that it is not easy for the eye to distinguish the curve that it really makes; and that if the appearance of a perpendicular thread, part of which is immersed in water, be closely attended to, it will not favour the common hypothesis. If the thread is of any shining metal, as silver, and viewed obliquely, the image of the part immersed will appear to detach itself sensibly from that part which is without the water, so that it cannot be true that every object appears to be in the same place where the refracted ray meets the perpendicular; and the same observation, he thinks, may be extended to the case of reflection. According to Dr Barrow, we refer every point of an object to the place from which the pencils of light, that give us the image of it, issue, or from which they would have issued if no reflecting or refracting substance intervened. Pursuing this principle, he proceeds to investigate the place in which the rays issuing from each of the points of an object, and which reach the eye after one reflection or refraction, meet; and he found, that if the refracting surface was plane, and the refraction was made from a denser medium into a rarer, those rays would always meet in a place between the eye and a perpendicular to the point of incidence. If a convex mirror be used, the case will be the same; but if the mirror be plane, the rays will meet in the perpendicular, and beyond it if it be concave. He also determined, according to these principles, what form the image of a right line will take, when it is presented in different manners to a spherical mirror, or when it is seen through a refracting medium.

Though Dr Barrow reckoned the maxim which he endeavoured to establish, concerning the supposed place of visible objects, highly probable, he has the candour to mention an objection to it, of which he was not able to give a satisfactory solution. It is this. Let an object be placed beyond the focus of a convex lens; and if the eye be close to the lens, it will appear confused, but very near to its true place. If the eye be a little withdrawn, the confusion will increase, and the object will seem to come nearer; and when the eye is near the focus, the confusion will be exceedingly great, and the object will seem to be close to the eye. But in this experiment the eye receives no rays but those that are converging: and the point from which they issue is so far from being nearer than the object, that it is beyond it; notwithstanding which, the object is conceived to be much nearer than it is, though no very distinct idea can be formed of its precise distance. It may be observed, that in reality, the rays falling upon the eye in this case in

Apparent place, &c. of objects.

in a manner quite different from that in which they fall upon it in other circumstances, we can form no judgement about the place from which they issue. This subject was afterwards taken up by Berkeley, Smith, Montucla, and others.

182 M. de la Hire's observations.

M. de la Hire made several observations concerning the distance of visible objects, and various other phenomena of vision, which are worthy of notice. He also took particular pains to ascertain the manner in which the eye conforms itself to the view of objects placed at different distances. He enumerates five circumstances, which assist us in judging of the distance of objects, namely their apparent magnitude, the strength of the colouring, the direction of the two eyes, the parallax of the objects, and the distinctness of their small parts. Painters, he says, can only take advantage of the two first-mentioned circumstances, and therefore pictures can never perfectly deceive the eye; but in the decorations of theatres, they, in some measure, make use of them all. The size of objects, and the strength of their colouring, are diminished in proportion to the distance at which they are intended to appear. Parts of the same object which are to appear at different distances, as columns in an order of architecture, are drawn upon different planes a little removed from one another, that the two eyes may be obliged to change their direction, in order to distinguish the parts of the nearer plane from those of the more remote. The small distance of the planes serves to make a small parallax, by changing the position of the eye; and as we do not preserve a distinct idea of the quantity of parallax, corresponding to the different distances of objects, it is sufficient that we perceive there is a parallax, to be convinced that these planes are distant from one another, without determining what that distance is; and as to the last circumstance, viz. the distinctness of the small parts of objects, it is of no use in discovering the deception, on account of the false light that is thrown upon these decorations.

183 M. le Cat's account of the largeness of objects in mist.

To these observations concerning deception of sight, we shall add a similar one of M. le Cat, who took notice that the reason why we imagine objects to be larger when they are seen through a mist, is the dimness or obscurity with which they are then seen; this circumstance being associated with the idea of great distance. This, he says, is confirmed by our being surprised to find, upon approaching such objects, that they are so much nearer to us, as well as so much smaller, than we had imagined.

Among other cases concerning vision, which fell under the consideration of M. de la Hire, he mentions one which it is difficult to solve. It is when a candle, in a dark place, and situated beyond the limits of distinct vision, is viewed through a very narrow chink in a card; in which case a considerable number of candles, sometimes so many as six, will be seen along the chink. This appearance he ascribes to small irregularities in the surface of the humours of the eye, the effect of which is not sensible when rays are admitted into the eye through the whole extent of the pupil, and consequently one principal image effaces a number of small ones; whereas, in this case, each of them is formed separately, and no one of them is so considerable as to prevent the others from being perceived at the same time.

There are few persons, M. de la Hire remarks, who have both their eyes exactly equal, not only with respect to the limits of distinct vision, but also with regard to the colour with which objects appear tinged when they are viewed by them, especially if one of the eyes has been exposed to the impression of a strong light. To compare them together in this respect, he directs us to take two thin cards, and to make in each of them a round hole of a third or a fourth of a line in diameter, and, applying one of them to each of the eyes, to look through the holes on a white paper, equally illuminated, when a circle of the paper will appear to each of the eyes, and, placing the cards properly, these two circles may be made to touch one another, and thereby the appearance of the same object to each of the eyes may be compared to the greatest advantage. To make this experiment with exactness, it is necessary, he says, that the eyes be kept shut some time before the cards be applied to them.

By the following calculation, M. de la Hire gives us an idea of the extreme sensibility of the optic nerves. One may see very easily, at the distance of 4000 toises, the sail of a wind mill, 6 feet in diameter; and the eye being supposed to be an inch in diameter, the picture of this sail, at the bottom of the eye, will be $\frac{1}{8000}$ of an inch, which is less than the 666th part of a line, and is about the 66th part of a common hair, or the 8th part of a single thread of silk. So small, therefore, must one of the fibres of the optic nerve be, which, he says, is almost inconceivable, since each of these fibres is a tube that contains spirits.

184 Berkeley's account of the judgement formed concerning distance by confused vision.

The person who particularly noticed Dr Barrow's hypothesis was the ingenious Dr Berkeley, bishop of Cloyne, who distinguished himself so much by the objections which he started to the reality of a material world, and by his opposition to the Newtonian doctrine of fluxions. In his Essay towards a new Theory of Vision, he observes, that the circle formed upon the retina, by the rays which do not come to a focus, produce the same confusion in the eye, whether they cross one another before they reach the retina, or tend to do it afterwards; and therefore that the judgment concerning distance will be the same in both the cases, without any regard to the place from which the rays originally issued; so that in this case, as, by receding from the lens, the confusion, which always accompanies the nearness of an object, increases, the mind will judge that the object comes nearer.

185 Smith's account.

But, says Dr Smith, if this be true, the object ought always to appear at a less distance from the eye than that at which objects are seen distinctly, which is not the case: and to explain this appearance, as well as every other in which a judgment is formed concerning distance, he maintains, that we judge of it chiefly if not only by the apparent magnitude of objects, so that, since the image grows larger as we recede from the lens through which it is viewed, we conceive the object to come nearer. He also endeavours to show, that in all cases in which glasses are used, we judge of distance by the same rule; from which he concludes, that the apparent distance of an object seen in a glass is to its apparent distance seen by the naked eye, as the apparent magnitude in the naked eye is to its apparent magnitude in the glass.

But that we do not judge of distance merely by the angle

Apparent place, &c. of objects.

angle under which objects are seen, is an observation as old as Alhazen, who mentions several instances, in which, though the angles under which objects appear be different, the magnitudes are universally and instantaneously deemed not to be so. Mr Robins clearly shows the hypothesis of Dr Smith to be contrary to fact in the most common and simple cases. In microscopes, he says, it is impossible that the eye should judge the object to be nearer than the distance at which it has viewed the object itself, in proportion to the degree of magnifying. For when the microscope magnifies much, this rule would place the image at a distance, of which the sight cannot possibly form any opinion, as being an interval from the eye at which no object can be seen. In general, he says, he believes, that whoever looks at an object through a convex glass, and then at the object itself without the glass, will find it to appear nearer in the latter case, though it be magnified in the glass; and in the same trial with the concave glass, though by the glass the object be diminished, it will appear nearer through the glass than without it.

186 Objected to by Mr Robins.

But the following experiment is the most convincing proof that the apparent distance of the image is not determined by its apparent magnitude. If a double convex glass be held upright before some luminous object, as a candle, there will be seen two images, one erect, and the other inverted. The first is made simply by reflection from the nearest surface, the second by reflection from the farther surface, the rays undergoing a refraction from the first surface both before and after the reflection. If this glass has not too short a focal distance when it is held near the object, the inverted image will appear larger than the other, and also nearer; but if the glass be carried off from the object, though the eye remain as near to it as before, the inverted image will diminish so much faster than the other, that, at length, it will appear very much less than it, but still nearer. Here, says Mr Robins, two images of the same object are seen under one view, and their apparent distances, when immediately compared, seem to have no necessary connexion with the apparent magnitude. He also shows how this experiment may be made still more convincing, by sticking a piece of paper on the middle of the lens, and viewing it through a short tube.

187 M. Bouguer adopts Dr Barrow's maxim.

M. Bouguer adopts the general maxim of Dr Barrow, in supposing that we refer objects to the place from which the pencils of rays seemingly converge at their entrance into the pupil. But when rays issue from below the surface of a vessel of water, or any other refracting medium, he finds that there are always two different places of this seeming convergence; one of them of the rays that issue from it in the same vertical circle, and therefore fall with different degrees of obliquity upon the surface of the refracting medium; and another, of those that fall upon the surface with the same degree of obliquity, entering the eye laterally with respect to one another. Sometimes, he says, one of these images is attended to by the mind, and sometimes the other, and different images may be observed by different persons. An object immersed in water affords an example, he says, of this duplicity of images.

Plate cccLxxxiv. fig. 1.

If BA *b* be part of the surface of water, and the object be at O, there will be two images of it in two different places; one at G, on the caustic by refraction, and the other at E, in the perpendicular AO, which is as much a caustic as the other line. The former image is visible by the rays ODM, O *d m*, which are one higher than the other, in their progress to the eye; whereas the image at E is made by the rays ODM, O *e f*, which enter the eye laterally. This, says he, may serve to explain the difficulty of Father Tacquet, Barrow, Smith, and many other authors.

G. W. Kraft has ably supported the opinion of Dr Barrow, that the place of any point, seen by reflection from the surface of any medium, is that in which rays issuing from it, infinitely near to one another, would meet; and considering the case of a distant object, viewed in a concave mirror, by an eye very near to it, when the image, according to Euclid and other writers, would be between the eye and the object, and the rule of Dr Barrow cannot be applied; he says that in this case the speculum may be considered as a plane, the effect being the same, only the image is more obscure.

188 Dr Porterfield's view of the subject.

Dr Porterfield gives a distinct view of the natural methods of judging concerning the distance of objects. The conformation of the eye, he observes, can be of no use to us with respect to objects placed without the limits of distinct vision. As the object, however, does then appear more or less confused, according as it is more or less removed from those limits, this confusion assists the mind in judging of the distance of the object; it being always estimated so much the nearer, or the farther off, as the confusion is greater. But this confusion hath its limits; for when an object is placed at a certain distance from the eye, to which the breadth of the pupil bears no sensible proportion, the rays of light that come from a point in the object, and pass the pupil, are so little diverging, that they may be considered as parallel. For a picture on the retina will not be sensibly more confused, though the object be removed to a much greater distance.

The most general, and frequently the most certain means of judging of the distance of objects is, he says, by the angle made by the optic axis. For our two eyes are like two different stations, by the assistance of which distances are taken; and this is the reason why those persons who are blind of one eye, so frequently miss their marks in pouring liquor into a glass, snuffing a candle, and such other actions as require that the distance be exactly distinguished. To be convinced of the utility of this method of judging of the distance of objects, he directs us to suspend a ring in a thread, so that its side may be towards us, and the hole in it to the right and left hand; and taking a small rod, crooked at the end, retire from the ring two or three paces and having with one hand covered one of our eyes, to endeavour with the other to pass the crooked end of the rod through the ring. This, says he, appears very easy; and yet, upon trial, perhaps once in 100 times we shall not succeed, especially if we move the rod a little quickly.

The use of this second method of judging of distances Dechales limited to 120 feet; beyond which, he says, we are not sensible of any difference in the angle of the optic axis.

A third method of judging of the distance of objects, consists in their apparent magnitudes, on which so much stress was laid by Dr Smith. From this change in the magnitude

Apparent place, &c. of objects.

magnitude of the image upon the retina, we easily judge of the distance of objects, as often as we are otherwise acquainted with their magnitude; but as often as we are ignorant of the real magnitude of bodies, we can never, from their apparent magnitude, form any judgement of their distance.

Hence we may see why we are so frequently deceived in our estimates of distance, by any extraordinary magnitudes of objects seen at the end of it; as, in travelling towards a large city, or a castle, or a cathedral church, or a mountain larger than common, we fancy them to be nearer than they really are. This also is the reason why animals, and little objects, seen in valleys, contiguous to large mountains, appear exceedingly small. For we think the mountain nearer to us than if it were smaller; and we should not be surprised at the smallness of the neighbouring animals, if we thought them farther off. For the same reason, we think them exceedingly small, when they are placed upon the top of a mountain, or a large building; which appear nearer to us than they really are, on account of their extraordinary size.

189 Why objects seen from a high building appear smaller than they are.

Dr Jurin accounts for our imagining objects, when seen from a high building, to be smaller than they are, and smaller than we fancy them to be when we view them at the same distance on level ground. It is, says he, because we have no distinct idea of distance in that direction, and therefore judge of things by their pictures upon the eye only; but custom will enable us to judge rightly even in this case.

Let a boy, says he, who has never been upon any high building, go to the top of a lofty spire, and look down into the street; the objects seen there, as men and horses, will appear so small as greatly to surprise him. But 10 or 20 years after, if in the mean time he has used himself now and then to look down from that and other great heights, he will no longer find the same objects to appear so small. And if he were to view the same objects from such heights as frequently as he sees them upon the same level with himself in the streets, he supposes that they would appear to him just of the same magnitude from the top of the spire, as they do from a window one story high. For this reason it is, that statues placed upon very high buildings ought to be made of a larger size than those which are seen at a nearer distance; because all persons, except architects, are apt to imagine the height of such buildings to be much less than it really is.

The fourth method by which Dr Porterfield says that we judge of the distance of objects, is the force with which their colour strikes upon our eyes. For if we be assured that two objects are of a similar and like colour, and that one appears more bright and lively than the other, we judge that the brighter object is the nearer of the two.

The fifth method consists in the different appearance of the small parts of objects. When these parts appear distinct, we judge that the object is near; but when they appear confused, or when they do not appear at all, we reckon the object to be at a greater distance. For the image of any object, or part of an object, diminishes as its distance increases.

The sixth and last method by which we judge of the distance of objects is, that the eye does not represent to our mind one object alone, but at the same time all those that are placed betwixt us and the principal object, whose distance we are considering; and the more this distance is divided into separate and distinct parts, the greater it appears to be. For this reason, distances upon uneven surfaces appear less than upon a plane: for the inequalities of the surfaces, such as hills, and holes, and rivers, that lie low and out of sight, either do not appear, or hinder the parts that lie behind them from appearing; and so the whole apparent distance is diminished by the parts that do not appear in it. This is the reason that the banks of a river appear contiguous to a distant eye, when the river is low and not seen.

190 Several fallacies of vision explained.

Dr Porterfield very well explains several fallacies in vision which depend upon our mistaking the distances of objects. Of this kind, he says, is the appearance of parallel lines, and long vistas consisting of parallel rows of trees; for they seem to converge more and more as they are farther extended from the eye. The reason of this, he says, is because the apparent magnitudes of their perpendicular intervals are perpetually diminishing, while, at the same time, we mistake their distance. Hence we may see why, when two parallel rows of trees stand upon an ascent, whereby the more remote parts appear farther off than they really are, because the line that measures the length of the vistas now appears under a greater angle than when it was horizontal, the trees, in such a case, will seem to converge less, and sometimes, instead of converging, they will be thought to diverge.

For the same reason that a long vista appears to converge more and more the farther it is extended from the eye, the remoter parts of a horizontal walk or a long floor will appear to ascend gradually; and objects placed upon it, the more remote they are the higher they will appear, till the last be seen on a level with the eye; whereas the ceiling of a long gallery appears to descend towards a horizontal line, drawn from the eye of the spectator. For this reason, also, the surface of the sea, seen from an eminence, seems to rise higher and higher the farther we look; and the upper parts of high buildings seem to stoop, or incline forwards over the eye below, because they seem to approach towards a vertical line proceeding from the spectator's eye; so that statues on the top of such buildings, in order to appear upright, must recline, or bend backwards.

Dr Porterfield also shows the reason why a windmill, seen from a great distance, is sometimes imagined to move the contrary way from what it really does, by our taking the nearer end of the sail for the more remote. The uncertainty we sometimes find in the course of the motion of a branch of lighted candles, turned round at a distance, is owing, he says, to the same cause; as also our sometimes mistaking a convex for a concave surface, more especially in viewing seals and impressions with a convex glass or a double microscope; and lastly, that, upon coming in a dark night into a street, in which there is but one row of lamps, we often mistake the side of the street they are on.

Far more light was thrown upon this curious subject by M. Bouguer.

The proper method of drawing the appearance of two

Apparent place, &c. of objects.

two rows of trees that shall appear parallel to the eye, is a problem which has exercised the ingenuity of several philosophers and mathematicians. That the apparent magnitude of objects decreases with the angle under which they are seen, has always been acknowledged. It is also acknowledged, that it is only by custom and experience that we learn to form a judgement both of magnitudes and distances. But in the application of these maxims to the above-mentioned problem, all persons, before M. Bouguer, made use of the real distance instead of the apparent one; by which only the mind can form its judgment. And it is manifest, that, if any circumstances contribute to make the distance appear otherwise than it is in reality, the apparent magnitude of the object will be affected by it; for the same reason, that, if the magnitude be misapprehended, the idea of the distance will vary.

191 Great light thrown upon the subject by M. Bouguer.

For want of attending to this distinction, Tacquet pretended to demonstrate, that nothing can give the idea of two parallel lines (rows of trees for instance) to an eye situated at one of their extremities, but two hyperbolical curves, turned the contrary way; and M. Varignon maintained, that in order to make a vista appear of the same width, it must be made narrow, instead of wider, as it recedes from the eye.

M. Bouguer observes, that very great distances, and those that are considerably less than they, make nearly the same impression upon the eye. We, therefore, always imagine great distances to be less than they are; and for this reason the ground plan of a long vista always appears to rise. The visual rays come in a determinate direction; but as we imagine that they terminate sooner than they do, we necessarily conceive that the place from which they issue is elevated. Every large plane, therefore, as AB, viewed by an eye at O, will seem to lie in such a direction as A*b*; and consequently lines, in order to appear truly parallel on the plane AB, must be drawn so as that they would appear parallel on the plane A *d*, and be from thence projected to the plane AB.

Plate CCCLXXXIV. fig. 2.

To determine the inclination of the apparent ground-plan A*d* to the true ground plan AB, our ingenious author directs us to draw upon a piece of level ground two straight lines of a sufficient length (for which purpose lines fastened to small sticks are very convenient), making an angle of 3 or 4 degrees with one another. Then a person, placing himself within the angle, with his back towards the angular point, must walk backwards and forwards till he can fancy the lines to be parallel. In this situation, a line drawn from the point of the angle through the place of his eye, will contain the same angle with the true ground-plan which this does with the apparent one.

M. Bouguer then shows other more geometrical methods of determining this inclination; and says; that by these means he has often found it to be 4 or 5 degrees, though sometimes only 2 or $2\frac{1}{2}$ degrees. The determination of this angle, he observes, is variable; depending upon the manner in which the ground is illuminated and the intensity of the light. The colour of the soil is also not without its influence, as well as the particular conformation of the eye, by which it is more or less affected by the same degree of light, and also the part of the eye on which the object is painted. When, by a slight motion of his head, he contrived, that certain parts of the soil, the image of which fell towards the bottom of his eye, should fall towards the top of the retina, he always thought that this apparent inclination became a little greater.

Apparent place, &c. of objects.

But what is very remarkable, is, that if he look towards a rising ground, the difference between the apparent ground-plan and the true one will be much more considerable, so that they will sometimes make an angle of 25 or 30 degrees. Of this he had made frequent observations. Mountains, he says, begin to be inaccessible when their sides make an angle from 35 or 37 degrees with the horizon, as then it is not possible to climb them but by means of stones or shrubs, to serve as steps to fix the feet on. In these cases, both he and his companions always agreed that the apparent inclination of the side of the mountain was 60 or 70 degrees.

Plate CCCLXXXIV. fig 3.

These deceptions are represented in fig. 3. in which, when the ground-plan AM, or AN, is much inclined, the apparent ground-plan A*m*, or A*n*, makes a very large angle with it. On the contrary, if the ground dips below the level, the inclination of the apparent to the true ground-plan diminishes, till, at a certain degree of the slope, it becomes nothing at all; the two plans AP and A*p* being the same, so that parallel lines drawn upon them would always appear so. If the inclination below the horizon is carried beyond the situation AP, the error will increase; and what is very remarkable, it will be on the contrary side; the apparent plan A*r* being always below the true plan AR, so that if a person would draw upon the plan AR lines that shall appear parallel to the eye, they must be drawn converging, and not diverging, as is usual on the level ground; because they must be the projections of two lines imagined to be parallel, on the plan A*r*, which is more inclined to the horizon than AR.

These remarks, he observes, are applicable to different planes exposed to the eye at the same time. For if BH, fig. 4. be the front of a building, at the distance of AB from the eye, it will be reduced in appearance to the distance A*b*; and the front of the building will be *b h*, rather inclined towards the spectator, unless the distance be inconsiderable.

Fig. 4.

After making a great number of observations upon this subject, our author concludes, that when a man stands upon a level plane, it does not seem to rise sensibly but at some distance from him. The apparent plane, therefore, has a curvature in it, at that distance, the form of which is not very easy to determine; so that a man standing upon a level plane, of infinite extent, will imagine that he stands in the centre of a bason. This is also, in some measure, the case with a person standing upon the level of the sea.

He concludes with observing, that there is no difficulty in drawing lines according to these rules, so as to have any given effect upon the eye, except when some parts of the prospect are very near the spectator, and others very distant from him, because, in this case, regard must be had to the conical or conoidal figure of a surface. A right line passing at a small distance from the observer, and below the level of his eye, in that case almost always appears sensibly curved at a certain distance from the eye; and almost all figures in this case are subject to some complicated optical alteration to which the rules of perspective have not as yet been extended. If a circle be drawn near our feet, and within that

Apparent place, &c. of objects.

that part of the ground which appears level to us, it will always appear to be a circle, and at a very considerable distance it will appear an ellipse; but between these two situations, it will not appear to be either the one or the other, but will be like one of those ovals of Descartes, which is more curved on one of its sides than the other.

On these principles a parterre, which appears distorted when it is seen in a low situation, appears perfectly regular when it is viewed from a balcony or any other eminence. Still, however, the apparent irregularity takes place at a greater distance, while the part that is near the spectator is exempt from it. If

Fig. 5.

AB, fig. 5. be the ground-plan, and A *a* be a perpendicular, under the eye, the higher it is situated, at O, to the greater distance will T, the place at which the plane begins to have an apparent ascent along T *b*, be removed.

192 Visible motion of objects.

All the varieties that can occur with respect to the visible motion of objects, are thus succinctly summed up by Dr Porterfield under eleven heads.

1. An object moving very swiftly is not seen, unless it be very luminous. Thus a cannon ball is not seen if it is viewed transversely: but if it be viewed according to the line it describes, it may be seen, because its picture continues long on the same place of the retina; which, therefore, receives a more sensible impression from the object.

2. A live coal swung briskly round in a circle appears a continued circle of fire, because the impressions made on the retina by light, being of a vibrating, and consequently of a lasting nature, do not presently perish, but continue till the coal performs its whole circuit, and returns again to its former place.

3. If two objects, unequally distant from the eye, move with equal velocity, the more remote one will appear the slower; or, if their celerities be proportional to their distances, they will appear equally swift.

4. If two objects, unequally distant from the eye, move with unequal velocities in the same direction, their apparent velocities are in a ratio compounded of the direct ratio of their true velocities, and the reciprocal one of their distances from the eye.

5. A visible object moving with any velocity appears to be at rest, if the space described in the interval of one second be imperceptible at the distance of the eye. Hence it is that a near object moving very slowly, as the index of a clock, or a remote one very swiftly, as a planet, seems to be at rest.

6. An object moving with any degree of velocity will appear at rest, if the space it runs over in a second of time be to its distance from the eye as 1 to 1400.

7. The eye proceeding straight from one place to another, a lateral object, not too far off, whether on the right or left, will seem to move the contrary way.

8. The eye proceeding straight from one place to another, and being sensible of its motion, distant objects will seem to move the same way, and with the same velocity. Thus, to a person running eastwards, the moon on his right hand appears to move the same way, and with equal swiftness; for on account of its distance, its image contines fixed upon the same place of the retina, from whence we imagine that the object moves along with the eye.

9. If the eye and the object move both the same way, only the eye much swifter than the object, the last will appear to go backwards.

Apparent place, &c. of objects.

10. If two or more objects move with the same velocity, and a third remain at rest, the moveable ones will appear fixed, and the quiescent one in motion the contrary way. Thus when the clouds move very swiftly, their parts seem to preserve their situation, and the moon to move the contrary way.

11. If the eye be moved with great velocity, lateral objects at rest appear to move the contrary way. Thus to a person sitting in a coach, and riding briskly through a wood, the trees seem to retire the contrary way; and to people in a ship, &c. the shores seem to recede.

193 Dr Porterfield's account of objects appearing to move to a giddy person when he and they are both at rest.

At the conclusion of these observations, Dr Porterfield endeavours to explain another phenomenon of motion, which, though common and well known, had not been explained in a satisfactory manner. It is this: If a person turns swiftly round, without changing his place, all objects about will seem to move round in a circle the contrary way; and this deception continues not only while the person himself moves round, but, which is more surprising, it also continues for some time after he ceases to move, when the eye, as well as the object, is at absolute rest.

The reason why objects appear to move round the contrary way, when the eye turns round, is not so difficult to explain: for though, properly speaking, motion is not seen, as not being in itself the immediate object of sight; yet by the sight we easily know when the image changes its place on the retina, and thence conclude that either the object, the eye, or both, are moved. But by the sight alone we can never determine how far this motion belongs to the object, how far to the eye, or how far to both. If we imagine the eye at rest, we ascribe the whole motion to the object, though it be truly at rest. If we imagine the object at rest, we ascribe the whole motion to the eye, though it belongs entirely to the object; and when the eye is in motion, though we are sensible of its motion, yet, if we do not imagine that it moves so swiftly as it really does, we ascribe only a part of the motion to the eye, and the rest of it we ascribe to the object, though it be actually at rest. This last, he says, is what happens in the present case, when the eye turns round; for though we are sensible of the motion of the eye, yet we do not apprehend that it moves so fast as it really does; and therefore the bodies about appear to move the contrary way, as is agreeable to experience.

But the great difficulty still remains, viz. Why, after the eye ceases to move, objects should, for some time, still appear to continue in motion, though their pictures on the retina be really at rest, and do not at all change their place. This, he imagined, proceeds from a mistake we are in with respect to the eye, which, though it be absolutely at rest, we nevertheless conceive as moving the contrary way to that in which it moved before; from which mistake, with respect to the motion of the eye, the objects at rest will appear to move the same way which the eye is imagined to move; and, consequently, will seem to continue their motion for some time after the eye is at rest.

194 Dr Wells accounts for this phenomenon.

This is ingenious, but perhaps not just. An account of this matter, which seems to us more satisfactory,

Apparent place, &c. of objects. tory, has been lately given to the public by Dr Wells. "Some of the older writers upon optics (says this ingenious philosopher) imagined the visive spirits to be contained in the head, as water is in a vessel; which, therefore, when once put in motion by the rotation of our bodies, must continue in it for some time after this has ceased; and to this real circular movement of the visive spirits, while the body is at rest, they attributed the apparent motions of objects in giddiness. Dechales saw the weakness of this hypothesis; and conjectured, that the phenomenon might be owing to a real movement of the eyes; but produced no fact in proof of his opinion. Dr Porterfield, on the contrary, supposed the difficulty of explaining it to consist in showing, why objects at rest appear in motion to an eye which is also at rest. The solution he offered of this representation of the phenomenon, is not only extremely ingenious, but is, I believe, the only probable one which can be given. It does not apply, however, to the fact which truly exists; for I shall immediately show, that the eye is not at rest as he imagined. The last author I know of who has touched upon this subject is Dr Darwin. His words are, 'When any one turns round rapidly on one foot till he becomes dizzy, and falls upon the ground, the spectra of the ambient objects continue to present themselves in rotation, or appear to librate, and he seems to behold them for some time in motion.' I do not indeed pretend to understand his opinion fully; but this much seems clear, that if such an apparent motion of the surrounding objects depends in any way upon their spectra, or the illusive representations of those objects, occasioned by their former impressions upon the retinas, no similar motion would be observed, were we to turn ourselves round with our eyes shut, and not to open them till we became giddy; for in this case, as the surrounding objects could not send their pictures to the retinas, there would consequently be no spectra to present themselves afterward in rotation. But whoever will make the experiment, will find, that objects about him appear to be equally in motion, when he has become giddy by turning himself round, whether this has been done with his eyes open or shut. I shall now venture to propose
195 my own opinion upon this subject.

Upon what data we judge visible objects to be in motion or at rest.

"If the eye be at rest, we judge an object to be in motion when its picture falls in succeeding times upon different parts of the retina; and if the eye be in motion, we judge an object to be at rest, as long as the change in the place of its picture upon the retina holds a certain correspondence with the change of the eye's position. Let us now suppose the eye to be in motion, while, from some disorder in the system of sensation, we are either without those feelings which indicate the various positions of the eye, or are not able to attend to them. It is evident, that in such a state of things an object at rest must appear to be in motion, since it sends in succeeding times its picture to different parts of the retina. And this seems to be what happens in giddiness. I was first led to think so from observing, that, during a slight fit of giddiness I was accidentally seized with, a coloured spot, occasioned by looking steadily at a luminous body, and upon which I happened at that moment to be making an experiment, was moved in a manner altogether independent of the positions I conceived my eyes to possess. To determine this point, I again produced the spot, by looking some time at the flame of a candle: then turning myself round till I became giddy, I suddenly discontinued this motion, and directed my eyes to the middle of a sheet of a paper, fixed upon the wall of my chamber. The spot now appeared upon the paper, but only for a moment; for it immediately after seemed to move to one side, and the paper to the other, notwithstanding I conceived the position of my eyes to be in the mean while unchanged. To go on 196

Curious experiments to ascertain this.

with the experiment, when the paper and spot had proceeded to a certain distance from each other, they suddenly came together again; and this separation and conjunction were alternately repeated a number of times, the limits of the separation gradually becoming less, till at length the paper and spot both appeared to be at rest, and the latter to be projected upon the middle of the former. I found also, upon repeating and varying the experiment a little, and when I had turned myself from left to right, the paper moved from right to left, and the spot consequently the contrary way; but that when I had turned from right to left, the paper would then move from left to right. These were the appearances observed while I stood erect. When I inclined, however, my head in such a manner as to bring the side of my face parallel to the horizon, the spot and paper would then move from each other, one upward and the other downward. But all these phenomena demonstrate, that there was a real motion in my eyes at the time I imagined them to be at rest; for the apparent situation of the spot, with respect to the paper, could not possibly have been altered, without a real change of the position of those organs. To have the same thing proved in another way, I desired a person to turn quickly round, till he became very giddy; then to stop himself, and look steadfastly at me. He did so, and I could plainly see, that although he thought his eyes were fixed, they were in reality moving in their sockets, first toward one side and then toward the other." 197

A remarkable deception explained by M. le Cat. Plate ccclxxxiv. fig. 6.

M. Le Cat well explains a remarkable deception, by which a person shall imagine an object to be on the opposite side of a board, when it is not so, and also inverted and magnified. It is illustrated by fig. 6. in which D represents the eye, and CB a large black board, pierced with a small hole. E is a large white board, placed beyond it, and strongly illuminated; and *d* a pin, or other small object, held betwixt the eye and the first board. In these circumstances, the pin shall be imagined to be at F, on the other side of the board, where it will appear inverted and magnified; because what is in fact perceived, is the shadow of the pin upon the retina; and the light that is stopped by the upper part of the pin coming from the lower part of the enlightened board, and that which is stopped by the lower part coming from the upper part of the board, the shadow must necessarily be inverted with respect to the object. This is nothing more than Mr Grey's experiment, in which he saw an inverted image of the pin, and which we have already noticed.

There is a curious phenomena relating to vision, which some persons have ascribed to the inflection of light, but which Mr Melville explains in a very different and very simple manner. 198

A curious phenomenon explained by Mr Melville.

When any opaque body is held at the distance of three or four inches from the eye, so that a part of some more distant luminous object, such as the window, or the flame of a candle, may be seen by rays passing near its edge,

Apparent place, &c. of objects.

edge, if another opaque body, nearer to the eye, be brought across from the opposite side, the edge of the first body will seem to swell outwards, and meet the latter; and in doing so will intercept a portion of the luminous object that was seen before.

Fig. 7. This appearance he explains in the following manner; Let AB represent the luminous object to which the sight is directed, CD the more distant opaque body, GH the nearer, and EF the diameter of the pupil. Join ED, FD, EG, FG, and produce them till they meet AB in K, N, M, and L. It is plain that the parts AN, MB, of the luminous object cannot be seen. But taking any point a between N and K, and drawing a D d, since the portion d F of the pupil is filled with light flowing from that point, it must be visible. Any point b, between a and K, must fill f F, a greater portion of the pupil, and therefore must appear brighter. Again, Any point c between b and K, must appear brighter than b, because it fills a greater portion g F with light. The point K itself, and every other point in the space KL, must appear very luminous, since they send entire pencils of rays EKF, ELF, to the eye; and the visible brightness of every point from L towards M, must decrease gradually, as from K to N, that is, the spaces KN, LM, will appear as dim shadowy borders, or fringes, adjacent to the edges of the opaque bodies.

When the edge G is brought to touch the right line KF, the penumbras unite; and as soon as it reaches NDF, the above phenomenon begins; for it cannot pass that right line without meeting some line a D d, drawn from a point between N and K, and, by intercepting all the rays that fall upon the pupil, render it invisible. In advancing gradually to the line KDE, it will meet other lines b D f, c D g, &c. and therefore render the points b, c, &c. from N to K, successively invisible; and therefore the edge of the fixed opaque body CD must seem to swell outwards, and cover the whole space NK; while GH, by its motion, covers MK. When GH is placed at a greater distance from the eye, CD continuing fixed, the space OP to be passed over in order to intercept NK is less: and therefore, with an equal motion of GH, the apparent swelling of CD must be quicker; which is found true by experience.

If ML represent a luminous object, and REFQ any plane exposed to its light, the space FQ will be entirely shaded from the rays, and the space FE will be occupied by a penumbra, gradually darker, from E to F. Let now GH continue fixed, and CD move parallel to the plane EF; and as soon as it passes the line LF, it is evident that the shadow QF will seem to swell outwards; and when CD reaches ME, so as to cover with its shadow the space RE, QF, by its extension, will cover FE. This is found to hold true likewise by experiment.

Sect. X. *On Aberration of Figure or Sphericity.*

199 Theory of aberration.

The great practical use of the science of optics is to aid human sight; but it has been repeatedly observed during the progress of this article, that in constructing dioptrical instruments for this purpose, great difficulties arise from the aberration of light. It has been shown how to determine the concourse of any refracted ray PF' with the ray RVCF', which passes through the centre C, and therefore falls perpendicularly on the

Plate cclxxviii Figs. 5, 6, &c.

Of Aberration.

spherical surface at the vertex V, and suffers no refraction. This is the conjugate focus to R for the two rays RP, RV, and for another ray flowing from R and falling on the surface at an equal distance on the opposite side to P. In short, it is the conjugate focus for all the rays flowing from R, and falling on the spherical surface in the circumference of a circle described by the revolution of the point P round the axis RVCF; that is, of all the rays which occupy the conical surface described by the revolution of RP, and the refracted rays occupy the conical surface produced by the revolution of PF'.

But no other rays flowing from R are collected at F'; for it appeared in the demonstration of that proposition, that rays incident at a greater distance from the axis RC were collected at a point between C and F'; and then the rays which are incident on the whole arch PC, or the spherical surface generated by its revolution round RC, although they all cross the axis RC, are diffused over a certain portion of it, by what has been called the aberration of figure. It is called also (but improperly) the aberration from the geometrical focus, by which is meant the focus of an infinitely slender pencil of rays, of which the middle ray (or axis of the pencil) occupies the lens RC, and suffers no refraction. But there is no such focus. But if we make mRV—nRC : mRV=VC : VF, the point F is called the geometrical focus, and is the remotest limit from C of all the foci (equally geometrical) of rays flowing from R. The other limit is easily determined by constructing the problem for the extreme point of the given arch.

It is evident from the construction, that while the point of incidence P is near to V, the line CK increases but very little, and therefore CF diminishes little, and the refracted rays are but little diffused from F; and therefore they are much denser in its vicinity than any other point of the axis. It will soon be evident that they are incomparably denser. It is on this account that the point F has been called the conjugate focus to R, and the geometrical focus, and the diffusion has been called *aberration.* A geometrical point R is thus represented by a very small circle at F, and F has drawn the chief attention. And as, in the performance of optical instruments, it is necessary that this extended representation of a mathematical point R be very small, that it may not sensibly interfere with the representations of the points adjacent to R, and thus cause indistinct vision, a limit is thus set to the extent of the refracting surface which must be employed to produce this representation. But this evidently diminishes the quantity of light, and renders the vision *obscure* though distinct. Artists have therefore endeavoured to execute refracting surfaces of forms not spherical, which collect accurately to one point the light issuing from another, and the mathematicians have furnished them with forms having this property: but their attempts have been fruitless. Spherical surfaces are the only ones which can be executed with accuracy. All are done by grinding the refracting substance in a mould of proper materials. When this is spherical, the two work themselves, with moderate attention, into an exact sphere; because if any part is more prominent than another, it is ground away, and the whole gets of necessity one curvature. And it is astonishing to what degree of accuracy this is done. An error of the millionth part of an inch would totally destroy

stroy the figure of a mirror of an inch focal distance, so as to make it useless for the coarsest instrument. Therefore all attempts to make other figures are given up. Indeed other reasons make them worse than spherical, even when accurately executed. They would not collect to accurate focuses the rays of oblique pencils.

It is evident from these observations, that the theory of aberrations is absolutely necessary for the successful construction of optical instruments; and it must be acceptable to the reader to have a short account of it in this place. Enough shall be said here to show the *general* nature and effects of it in optical instruments, and in some of the more curious phenomena of nature. Under the article TELESCOPE the subject will be resumed, in such a manner as to enable the reader who possesses a very moderate share of mathematical knowledge, not only to understand how aberrations are increased and diminished, but also how, by a proper employment of contrary aberrations, their hurtful effects may be *almost entirely* removed in all important cases. And the manner in which the subject shall be treated in the present general sketch, will have the advantage of pointing out at the same time the maxims of construction of the greatest part of optical instruments, which generally produce their effects by means of pencils of rays which are either out of the axis altogether, or are oblique to it; cases which are seldom considered in elementary treatises of optics.

Plate CCCLXXXIV. fig. 1.

Let PV π be a spherical surface of a refracting substance (glass for instance), of which C is the centre, and let an indefinitely slender pencil of rays AP $a\,p$ be incident on it, in a direction parallel to a ray CV passing through the centre. It is required to determine the focus f of this pencil.

200 How to remedy the evils of aberration.

Let AP be refracted into PF. Draw CI, CR the sines of incidence and refraction, and CP the radius. Draw RB perpendicular to CP, and Bf parallel to AP or CV. I say, first, f is the focus of the indefinitely slender pencil, or, more accurately speaking, f is the remotest limit from P of the concourse of rays with PF' refracted by points lying without the arch VP, or the nearest limit for rays incident between V and P.

Draw the radius C$p\,c'$, the line $p\,f$; and draw $p\,g$ parallel to Pf, and Po perpendicular to Pf. It is evident, that if f be the focus, $c'\,p\,f$ is the angle of refraction corresponding to the angle of incidence $a\,p$ C, as C'Pf is the angle corresponding to APC. Also PCp is the increment of the angle of incidence, and the angle $c'\,p\,g$ is equal to the sum of the angle C'Pf and C'C c, and the angle $g\,p\,f$ is equal to the angle $p\,f$P. Therefore $c'pf$=C'Pf+P, Cp+Pfp. Therefore PCp+P$f\,p$ is the corresponding increment of the angle of refraction. Also, because RPo=CPp (being right angles) the angles p P o=RPC, and Po : Pp= PR : PC.

Therefore by a preceding Lemma in this article, we have PCp+Pfp : PCp=tan. ref. : tan. incid.= T, R : T, I; and Pfp : PCp=T, R—T, I : T, I, =diff. : T, I; but Pfp : PC $p=\frac{\mathrm{P}o}{\mathrm{P}f}:\frac{\mathrm{P}p}{\mathrm{P}c}=\frac{\mathrm{PR}}{\mathrm{P}f}:\frac{\mathrm{PC}}{\mathrm{PC}}$, =PR : P$f$,=DR : DB (because DB is parallel to Bf by construction)=tan.CPR—tan.CPI : tan.CPI. Now CPI is the angle of incidence; and therefore CPR is the angle properly corresponding to it as an angle of refraction, and the point f is properly determined.

Hence the following rule. *As the difference of the tangents of incidence and refraction is to the tangent of incidence, so is the radius of the surface multiplied by the cosine of refraction to the distance of the focus of an infinitely slender pencil of parallel incident rays.*

N. B. We here consider the cosine of refraction as a number. This was first done by the celebrated Euler, and is one of the greatest improvements in mathematics which this century can boast of. The sines, tangents, secants, &c. are considered as fractional numbers, of which the radius is unity. Thus CP$\times$sin. 30°, is the same thing with $\frac{1}{2}$CP, or $\frac{\mathrm{CP}}{2}$. And in like manner, CB, drawn perpendicular to the axis $\times$ sin. $19^{\circ}\,28'\,16''\,32'''$, is the same thing with $\frac{1}{3}$ of CB. Also $\frac{\mathrm{CB}}{\mathrm{cos.}\ 60^{\circ}}$ is the same thing with twice CB, &c.

In this manner, BE=BC$\times$sin. BCE, and also BE =CE$\times$tan. BCE, and CB=CE$\times$sec. BCE, &c. &c. This manner of considering the lines which occur in geometrical constructions is of immense use in all parts of mixed mathematics; and nowhere more remarkably than in optics, the most beautiful example of them. Of this an important instance shall now be given.

COR. 1. The distance fG of this lateral focus from the axis CV (that is, from the line drawn through the centre parallel to the incident light) is proportional to the cube of the semi-aperture PH of the spherical surface.

For fG=BE. Now BE=CB$\times$sin. BCE, =CB $\times$sin. CPA; and CB=RC$\times$cos. RCB, =RC$\times$sin. CPR, and RC=CP$\times$sin. CPR: Therefore BE=PC $\times$sin.^{2} CPR$\times$sin. PCA, =PC$\times$sin.^{2} refr. $\times$sin. incid. but sin.^{2} refr. $=\frac{m^2}{n^2}$ sin.^{2} incid. Therefore, finally, BE, or fG=PC$\times\frac{m^2}{n^2}\times$sin.^{3} incid.: But PC, sin. incid. is evidently PH the semi-aperture; therefore the proposition is manifest.

COR. 2. Now let this slender pencil of rays be incident at the vertex V. The focus will now be a point F in the axis, determined by making CV : CF=m—n : m. Let the incident pencil gradually recede from the axis CF, still, however, keeping parallel to it. The focus f will always be found in a curve line DC'F, so constituted that the ordinate G will be as the cube of the line PH, perpendicular to the axis intercepted between the axis and that point of the surface which is cut by a tangent to the curve in f.

All the refracted rays will be tangents to this curve, and the adjacent rays will cross each other in these lateral foci f; and will therefore be incomparably more dense along the curve than anywhere within its area. This is finely illustrated by receiving on white paper the light of the sun refracted through a globe or cylinder of glass filled with water. If the paper is held parallel to the axis of the cylinder, and close to it, the illuminated part will be bounded by two very bright parallel lines, where it is cut by the curve; and these lines will gradually approach each other as the paper is withdrawn from the vessel, till they coalesce into one very bright

Of Aberration.

bright line at F, or near it. If the paper be held with its end touching the vessel, and its plane nearly perpendicular to the axis, the whole progress of the curve will be distinctly seen.

As such globes were used for burning glasses, the point of greatest condensation (which is very near but not exactly in F) was called the *focus*. When these curves were observed by Mr Tchirnhauss, he called them *caustics;* and those formed by refraction he called *diacaustics*, to distinguish them from the *catacaustics* formed by reflection.

It is somewhat surprising, that these curves have been so little studied since the time of Tchirnhauss. The doctrine of aberrations has indeed been considered in a manner independent on their properties. But whoever considers the progress of rays in the eye-piece of optical instruments, will see that the knowledge of the properties of diacaustic curves determines directly, and almost accurately, the foci and images that are formed there. For, let the object-glass of a telescope or microscope be of any dimensions, the pencils incident on the eye-glasses are almost all of this evanescent bulk. These advantages will be shown in their proper places: and we proceed at present to extend our knowledge of aberrations in general, first considering the aberrations of parallel incident rays.

Abiding by the instance represented by the figure, it is evident that the caustic will touch the surface in a point ϕ, so situated that $c\phi : \phi\chi = m : n$. The refracted ray $\phi\,\Phi$ will touch the surface, and will cross the axis in Φ, the nearest limit of diffusion along the axis. If the surface is of smaller extent, as PV, the caustic begins at f, when the extreme refracted ray Pf touches the caustic, and crosses the axis in F', and the opposite branch of the caustic in K. If there be drawn an ordinate KO k to the caustic, it is evident that the whole light incident on the surface PVπ passes through the circle whose diameter is K k, and that the circle is the smallest space which receives *all* the refracted light.

201 How light is distributed over the smallest circle of diffusion.

It is of great importance to consider the manner in which the light is distributed over the surface of this circle of smallest diffusion: for this is the representation of one point of the infinitely distant radiant object. Each point of a planet, for instance, is represented by this little circle; and as the circles representing the different adjacent points must interfere with each other, an indistinctness must arise similar to what is observed when we view an object through a pair of spectacles which do not fit the eye. The indistinctness must be in proportion to the number of points whose circles of diffusion interfere; that is, to the area of these circles, provided that the light is uniformly diffused over them: but if it be very rare at the circumference, the impression made by the circles belonging to the adjacent points must be less sensible. Accordingly, Sir Isaac Newton, supposing it incomparably rarer at the circumference than towards the centre, affirms that the indistinctness of telescopes, arising from the spherical figure of the object-glass, was some thousand times less than that arising from the unequal refrangibility of light; and, therefore, that the attempts to improve them by diminishing or removing this aberration were needless, while the indistinctness from unequal refrangibility remained. It is surprising, that a philosopher so eminent for sagacity and for mathematical knowledge should have made such a mistake, and unfortunate that the authority of his great name hindered others from examining the matter, trusting to his assertion that the light was so rare at the border of this circle. His mistake is surprising, because the very nature of a caustic should have showed him that the light was infinitely dense at the borders of the circle of smallest diffusion. The first person who detected this oversight of the British philosopher was the Abbé Boscovich, who, in a dissertation published at Vienna in 1767, showed, by a very beautiful analysis, that the distribution was extremely different from what Newton had asserted, and that the superior indistinctness arising from unequal refrangibility was incomparably less than he had said. We shall attempt to make this delicate and interesting matter conceived by those who have but small mathematical preparation.

Plate CCCLXXXVI. fig. 2.

Let the curve DVZCI $c\,z\,v\,d$ be the caustic (magnified), EI its axis, I the focus of central rays, B the focus of extreme rays, and IB the line containing the foci of all the intermediate rays, and CO c the diameter of the circle of smallest diffusion.

It is plain, that from the centre O there can be drawn two rays OV, O v, touching the caustic in V, v. Therefore the point O will receive the ray EO, which passes through the vertex of the refracting surface, and all the rays which are incident on the circumference of a circle described on the refracting surface by the extremity of the ray OV, or Ov. The density of the light at O will therefore be indefinitely great.

From the point C there can be drawn two rays; one of them CX touching the caustic in C, and the other C, touching it at d on the opposite side. The rays which touch the caustic in the immediate vicinity of C y, both in the arch CV and the arch CI will cut OC in points indefinitely near to each other; because their distance from each other in the line OC will be to their uniform distance on the refracting surface as the distance between their points of contact with the caustic to the distance of these points from the refracting surface. Here therefore at C the density of the light will also be indefinitely great.

From any point H, lying between O and C, may be drawn three rays. One of them LHT, P, touching the arch CD of the caustic in T, cutting the refracting surface in P, and the axis in L: another t Hp, touching the arch CI of the caustic in t. The third is H $\tau\pi$, touching the arch $c\,d$ of the opposite branch of the caustic in τ.

It will greatly assist our conception of this subject, if we consider a ray of light from the refracting surface as a thread attached at I of this figure, or at F of fig. 1. and gradually unlapped from the caustic DVCI on one side, and then lapped on the opposite branch I $c\,v\,d$; and attend to the point of its intersection with the diameter c OC of the circle of smallest diffusion. Fig. 1.

Therefore, 1. Let the ray be first supposed to pass through the refracting surface at F, the right hand extremity of the aperture. The thread is then folded up on the whole right hand branch ICVD of the caustic; and if the straight part of it FD be produced, it will cut the diameter of the circle of smallest diffusion in the opposite extremity c. Or suppose a ruler in place of the thread, applied to the caustic at D and to the refracting surface at F, the part of it Dc, which

Of Aberration.

which is detached from the caustic, cuts CO c in the point c. 2. Now suppose the ruler to revolve gradually, its extremity moving across the arch FAf of the refracting surface while the edge is applied to the caustic; the point of contact with the caustic will shift gradually down the branch DV of the caustic, while its edge passes across the line cC; and when the point of contact arrives at V, the extremity will be at Y on the refracting surface, and the intersection of the edge will be at O. 3. Continuing the motion, the point of contact shifts from V to Z, the extremity from Y to Q', and the intersection from O to Q, so that $OQ^2 = \frac{OC^2}{2}$, as will presently appear. 4. After this, the point of contact will shift from Z to C, the extremity from Q' to X, half way from F to A, as will soon be shown, and the intersection from Q to C. 5. The point of contact will now shift from C down to I, the extremity will pass from X to A, and the intersection will go back from C to O. 6. The ruler must now be applied to the other branch of the caustic I c z v d, and the point of contact will ascend from I to c, the extremity will pass from A to x, half way to f from A, and the intersection from O to c. 7. The point of contact will ascend from C to z, the extremity passes from x to q', and the intersection from C to q, $O q^2$ being $= \frac{O c^2}{2}$. 8. While the contact of the ruler and caustic shifts from z to v, the extremity shifts from q' to y, and the intersection from q to O. 9. The contact rises from v to d, the extremity passes from y to f, and the intersection from O to C; and then the motion across the refracting surface is completed, the point of contact shifting down from D to I along the branch DVZCI, and then ascending along the other branch I c z v d, while the intersection passes from c to C, back again from C to c, and then back again from c to C, where it ends, having thrice passed through every intermediate point of cC.

202 Density of light.

We may form a notion of the density of the light in any point H, by supposing the incident light of uniform density at the refracting surface, and attending to the constipation of the rays in the circle of smallest diffusion. Their vicinity may be estimated both in the direction of the radii OH, and in the direction of the circumference described by its extremity H, during its revolution round the axis; and the density must be conceived as proportional to the *number* of originally equidistant rays, which are collected into a spot of given area. These have been collected from a corresponding spot or area of the refracting surface; and as the number of rays is the same in both, the density at H will be to the density of the refracting surface, as the area occupied of the refracting surface, to the corresponding area at H. The vicinity of the rays in the direction of the radius depends on the proportion between PT and TH. For the ray adjacent to PTH may be supposed to cross it at the point of contact T; and therefore the uniform distance between them at the surface of that medium is to the distance between the same rays at H as the distance of T from the refracting surface to its distance from H. Therefore the number of rays which occupy a tenth of an inch, for example, of the radius AP, is to the number which would occupy a tenth of an inch at H as TH to TP; and the radial density at P is to the radial density at H, also as TH to TP. In the next place, The circumferential density at P is to that at H as the radius AP to the radius OH. For supposing the figure to turn round its axis AI, the point P of the refracting surface will describe a circumference whose radius is AP, and H will describe a circumference whose radius is OH; and the whole rays which pass through the first circumference pass also through the last, and therefore their circumferential densities will be in the inverse proportion of the spaces into which they are collected. Now the radius AP is to the radius OH as AL to OL; and circumferences have the same proportion with their radii. Therefore the circumferential density at P is to that in H as AL to OL inversely; and it was found that the radial density was as AN to ON inversely, being as TH to TP, which are very nearly in this ratio. Therefore the absolute density (or number of rays collected in a given space) at P will be to that at H, in the ratio compounded of these ratios; that is, in the ratio of ON$\times$OL to AN$\times$AL. But as NL bears but a very small ratio to AN or AL, AN$\times$AL may be taken as equal to AO^2 without any sensible error. It never differs from it in telescopes 100th part, and is generally incomparably smaller. Therefore the density at H may be considered as proportional to ON$\times$OL inversely. And it will afterwards appear that NS is $= 3\,o$L. Therefore the density at H is inversely as ON$\times$NS.

Now describe a circle on the diameter OS, and draw NTφ cutting the circumference $N\varphi^2 = ON \times NS$, and the density at H is as $N\varphi^2$ inversely. This gives us a very easy estimation of the density, viz. draw a line from the point of contact of the ray which touches the part VC of the caustic, and the density is in the inverse subduplicate ratio of the part of this line intercepted between the axis and the circumference SφO. It will afterwards appear that the density corresponding to this ray is one half of the density corresponding to all the three: or a better expression will be had for the density at H by drawing R β perpendicular to R φ, and β o perpendicular to φ β, making φ R in o; then φo is as $\frac{1}{\varphi N^2}$, or is proportional to the density, as is evident.

When H is at O, N is at S, and φo is infinite. As H moves from O, N descends, and φo diminishes, till H comes to Q, and T to z, and φ to ζ, and o to R. When H moves from Q towards C, T descends below z, φo again increases, till it is again infinite, when H is at C, T at C, and N at O.

Thus it appears, without any minute consideration, that the light has a density indefinitely great in the centre O; that the density decreases to a minimum in some intermediate point Q, and then increases again to infinity at the margin C. Hence it follows, that the indistinctness arising from the spherical figure of the refracting surfaces is incomparably greater than Newton supposed; and that the valuable discovery of Mr Dollond of achromatic lenses, must have failed of answering his fond expectations, if his very method of producing them had not, at the same time, enabled him to remove that other indistinctness by employing contrary aberrations. And now, since the discovery by Dr Blair of substances which disperse the different colours in the same proportions, but very different degrees,

Of Aberration.

grees, has enabled us to employ much larger portions of the sphere than Mr Dollond could introduce into his object-glasses, it becomes absolutely necessary to study this matter completely, in order to discover and ascertain the amount of the errors which perhaps unavoidably remain.

203
Contrary aberrations correct each other.

This slight sketch of the most simple case of aberration, namely, when the incident rays are parallel, will serve to give a general notion of the subject; and the reader can now see how contrary aberrations may be employed in order to form an ultimate image which shall be as distinct as possible. For let it be proposed to converge parallel rays accurately to the focus F, by the refraction of spherical surfaces of which V is the vertex. Let PV be a convex lens of such a form, that rays flowing from F, and passing through it immediately round the vertex V, are collected to the conjugate focus R, while the extreme ray FP, incident on the margin of the lens P, is converged to *r*, nearer to V, having the longitudinal aberration R *r*. Let *p* V be a plano-concave lens, of such sphericity that a ray A *p*, parallel to the axis CV, and incident on the point *p*, as far from its vertex V as P in the other lens is from its vertex, is dispersed from *r*, the distance ρ V being equal to r V, while the central rays are dispersed from P, as far from V as R is from V. It is evident, that if these lenses be joined as in fig. 4. a ray A'*p*, parallel to the common axis CV, will be collected at the distance VF equal to VF in the fig. 4. and that rays passing through both lenses in the neighbourhood of the axis will be collected at the same point F.

Plate CCLXXXVI. fig. 3.

This compound lens is said to be without spherical aberration; and it is true that the central and the extreme rays are collected in the same point F: but the rays which fall on the lens between the centre and margin are a little diffused from F, and it is not possible to collect them all to one point. For in the rules for computing the aberration, quantities are neglected which do not preserve, in different apertures, the same ratio to the quantities retained. The diffusion is least when the aberration is corrected, not for the very extremity, but for a certain intermediate point (varying with the aperture, and having no known ratio to it); and when this is done, the compound lens is in its state of greatest perfection, and the remaining aberration is quite insensible. See TELESCOPE.

SECT. VI. *On the different Refrangibility of Light.*

As this property of light solves a great number of the phenomena which could not be understood by former opticians, we shall give an account of it nearly in the words of Sir Isaac Newton, who first discovered it; especially as his account is more full and perspicuous than those of succeeding writers.

Plate CCLXXXIII. fig. 1.

"In a dark chamber, at a round hole F, about one third of an inch broad, made in the shutter of a window, I placed a glass prism ABC, whereby the beam of the sun's light, SF, which came in at that hole, might be refracted upwards, toward the opposite wall of the chamber, and there form a coloured image of the sun, represented at PT. The axis of the prism was, in this and the following experiments, perpendicular to the incident rays. About this axis I turned the prism slowly, and saw the refracted or coloured image of the sun, first to descend, and then to ascend. Between the descent and ascent, when the image seemed stationary, I stopped the prism and fixed it in that posture.

On the different refrangibility of Light.

"Then I let the refracted light fall perpendicularly upon a sheet of white paper, MN, placed at the opposite wall of the chamber, and observed the figure and dimensions of the solar image, PT, formed on the paper by that light. This image was oblong, and not oval, but terminated by two rectilinear and parallel sides and two semicircular ends. On its sides it was bounded pretty distinctly; but on its ends very indistinctly, the light there vanishing by degrees. At the distance of $18\frac{1}{2}$ feet from the prism the breadth of the image was about $2\frac{1}{8}$ inches, but its length was about $10\frac{1}{4}$ inches, and the length of its rectilinear sides about 8 inches; and ACB, the refracting angle of the prism, by which so great a length was made, was 64 degrees. With a less angle the length of the image was less, the breadth remaining the same. It is farther to be observed, that the rays went on in straight lines from the prism to the image, and therefore at their going out of the prism had all that inclination to one another from which the length of the image proceeded. This image PT was coloured, and the more eminent colours lay in this order from the bottom at T to the top at P; red, orange, yellow, green, blue, indigo, violet; together with all their intermediate degrees in a continual succession perpetually varying."

204
Light consists of several sorts of coloured rays differently refrangible.

Our author concludes from this and other experiments, "that the light of the sun consists of a mixture of several sorts of coloured rays, some of which at equal incidences are more refracted than others, and therefore are called *more refrangible*. The red at T, being nearest to the place Y, where the rays of the sun would go directly if the prism was taken away, is the least refracted of all the range; and the orange, yellow, green, blue, indigo, and violet, are continually more and more refracted, as they are more and more diverted from the course of the direct light. For by mathematical reasoning he has proved, that when the prism is fixed in the posture above mentioned, so that the place of the image shall be the lowest possible, or at the limit between its descent and ascent, the figure of the image ought then to be round like the spot at Y, if all the rays that tended to it were equally refracted. Therefore, since it is found by experience that this image is not round, but about five times longer than broad, it follows, that all the rays are not equally refracted. This conclusion is farther confirmed by the following experiments.

Fig. 2.

"In the sunbeam SF, which was propagated into the room through the hole in the window-shutter EG, at the distance of some feet from the hole, I held the prism ABC in such a posture, that its axis might be perpendicular to that beam: then I looked through the prism upon the hole F, and turning the prism to and fro about its axis to make the image *p t* of the hole ascend and descend, when between its two contrary motions it seemed stationary, I stopped the prism; in this situation of the prism, viewing through it the said hole E, I observed the length of its refracted image *p t* to be many times greater than its breadth; and that the most refracted part thereof appeared violet at *p*; the least refracted, at *t*; and the middle parts indigo, blue, green,

yellow,

On the different refrangibility of Light

yellow, and orange, in order. The same thing happened when I removed the prism out of the sun's light, and looked through it upon the hole shining by the light of the clouds beyond it. And yet if the refractions of all the rays were equal according to one certain proportion of the sines of incidence and refraction, as is vulgarly supposed, the refracted image ought to have appeared round, by the mathematical demonstration above mentioned. So then by these two experiments it appears, that in equal incidences there is a considerable inequality of refractions."

For the discovery of this fundamental property of light, which has unfolded the whole mystery of colours, we see our author was not only beholden to the experiments themselves, which many others had made before him, but also to his skill in geometry; which was absolutely necessary to determine what the figure of the refracted image ought to be upon the old principle of an equal refraction of all the rays: but having thus made the discovery, he contrived the following experiment to prove it at sight.

Plate cclxxxiii. fig. 3.

"In the middle of two thin boards, DE *de*, I made a round hole in each, at G and *g*, a third part of an inch in diameter; and in the window-shut a much larger hole being made, at F, to let into my darkened chamber a large beam of the sun's light, I placed a prism, ABC, behind the shut in that beam, to refract it towards the opposite wall; and close behind this prism I fixed one of the boards DE, in such a manner that the middle of the refracted light might pass through the hole made in it at G, and the rest be intercepted by the board. Then at the distance of about 12 feet from the first board, I fixed the other board, *de*, in such manner that the middle of the refracted light, which came through the hole in the first board, and fell upon the opposite wall, might pass through the hole *g* in this other board *de*, and the rest being intercepted by the board, might paint upon it the coloured spectrum of the sun. And close behind this board I fixed another prism *abc*, to refract the light which came through the hole *g*. Then I returned speedily to the first prism ABC, and by turning it slowly to and fro about its axis, I caused the image which fell upon the second board *de*, to move up and down upon that board, that all its parts might pass successively through the hole on that board, and fall upon the prism behind it. And in the mean time I noted the places, *M*, *N*, on the opposite wall, to which that light after its refraction in the second prism did pass; and by the difference of the places at *M* and *N*, I found that the light, which being most refracted in the first prism ABC, did go to the blue end of the image, was again more refracted by the second prism *abc*, than the light which went to the red end of that image. For when the lower part of the light which fell upon the second board *de*, was cast through the hole *g*, it went to a lower place M on the wall; and when the higher part of that light was cast through the same hole *g*, it went to a higher place N on the wall; and when any intermediate part of the light was cast through that hole, it went to some place in the wall between M and N. The unchanged position of the hole in the boards made the incidence of the rays upon the second prism to be the same in all cases. And yet in that common incidence some of the rays were more refracted and others less: and those were more refracted in this prism, which by a greater refraction in the first prism were more turned out of their way; and, therefore, for their constancy of being more refracted, are deservedly called *more refrangible*."

On the different refrangibility of Light.

205 Reflected light differently refrangible.

Sir Isaac shows also, by experiments made with convex glass, that lights, reflected from natural bodies, which differ in colour, differ also in refrangibility; and that they differ in the same manner as the rays of the sun do.

"The sun's light consists of rays differing in reflexibility, and those rays are more reflexible than others which are more refrangible. A prism, ABC, whose two angles, at its base BC, were equal to one another and half right ones, and the third at A a right one, I placed in a beam FM of the sun's light, let into a dark chamber through a hole F one third part of an inch broad. And turning the prism slowly about its axis until the light which went through one of its angles ACB, and was refracted by it to G and H, began to be reflected into the line MN by its base BC, at which till then it went out of the glass; I observed that those rays, as MH, which had suffered the greatest refraction, were sooner reflected than the rest. To make it evident that the rays which vanished at H were reflected into the beam MN, I made this beam pass through another prism VXY, and being refracted by it to fall afterwards upon a sheet of white paper *pt* placed at some distance behind it, and there by that refraction to paint the usual colours at *pt*. Then causing the first prism to be turned about its axis according to the order of the letters ABC, I observed, that when those rays MH, which in this prism had suffered the greatest refraction, and appeared blue and violet, began to be totally reflected, the blue and violet light on the paper which was most refracted in the second prism received a sensible increase at *p*, above that of the red and yellow at *t*: and afterwards, when the rest of the light, which was green, yellow, and red, began to be totally reflected and vanished at G, the light of those colours at *t*, on the paper *pt*, received as great an increase as the violet and blue had received before. Which puts it past dispute, that those rays became first of all totally reflected at the base BC, which before at equal incidences with the rest upon the base BC had suffered the greatest refraction. I do not here take any notice of any refractions made in the sides AC, AB, of the first prism, because the light enters almost perpendicularly at the first side, and goes out almost perpendicularly at the second; and therefore suffers none, or so little, that the angles of incidence at the base BC are not sensibly altered by it; especially if the angles of the prism at the base BC be each about 40 degrees. For the rays FM begin to be totally reflected when the angle CMF is about 50 degrees, and therefore they will then make a right angle of 90 degrees with AC.

Fig. 4.

"It appears also from experiments, that the beam of light MN, reflected by the base of the prism, being augmented first by the more refrangible rays and afterwards by the less refrangible, is composed of rays differently refrangible.

"The light whose rays are all alike refrangible, I call *simple*, *homogeneous*, and *similar*; and that whose rays are some more refrangible than others, I call *compound*, *heterogeneous*, and *dissimilar*. The former light I call *homogeneous*, not because I would affirm it so in all respects;

On the different refrangibility of Light.

spects; but because the rays which agree in refrangibility agree at least in all their other properties which I consider in the following discourse.

206 Colours simple or compound.

"The colours of homogeneous lights I call *primary, homogeneous*, and *simple*; and those of heterogeneous lights, *heterogeneous* and *compound*. For these are always compounded of homogeneous lights, as will appear in the following discourse.

"The homogeneous light and rays which appear red, or rather make objects appear so, I call *rubrific* or *red-making*; those which make objects appear yellow, green, blue, and violet, I call *yellow-making, blue-making, violet-making*; and so of the rest. And if at any time I speak of light and rays as coloured or endowed with colours, I would be understood to speak not philosophically and properly, but grossly, and according to such conceptions as vulgar people in seeing all these experiments would be apt to frame. For the rays, to speak properly, are not coloured. In them there is nothing else than a certain power and disposition to stir up a sensation of this or that colour. For as sound, in a bell or musical string or other sounding body, is nothing but a trembling motion, and in the air nothing but that motion propagated from the object, and in the sensorium it is a sense of that motion under the form of sound; so colours in the object are nothing but a disposition to reflect this or that sort of rays more copiously than the rest: in rays they are nothing but their dispositions to propagate this or that motion into the sensorium; and in the sensorium they are sensations of those motions under the forms of colours. See CHROMATICS.

207 Why the image of the sun, by heterogeneous rays passing through a prism, is oblong. Plate ccclxxxiii. fig. 5.

"By the mathematical proposition above mentioned, it is certain that the rays which are equally refrangible do fall upon a circle answering to the sun's apparent disk, which will also be proved by experiment by and by. Now let AG represent the circle which all the most refrangible rays, propagated from the whole disk of the sun, will illuminate and paint upon the opposite wall if they were alone; EL the circle, which all the least refrangible rays would in like manner illuminate if they were alone; BH, CI, DK, the circles which so many intermediate sorts would paint upon the wall, if they were singly propagated from the sun in successive order, the rest being intercepted; and conceive that there are other circles without number, which innumerable other intermediate sorts of rays would successively paint upon the wall, if the sun should successively emit every sort apart. And seeing the sun emits all these sorts at once, they must all together illuminate and paint innumerable equal circles; of all which, being according to their degrees of refrangibility placed in order in a continual series, that oblong spectrum PT is composed, which was described in the first experiment.

"Now if these circles, whilst their centres keep their distances and positions, could be made less in diameter, their interfering one with another, and consequently the mixture of the heterogeneous rays, would be proportionably diminished. Let the circles AG, BH, CI, &c. remain as before; and let *ag, bh, ci*, &c. be so many less circles lying in a like continual series, between two parallel right lines *ae* and *gl*, with the same distance between their centres, and illuminated with the same sorts of rays: that is, the circle *ag* with the same sort by which the corresponding circle AG was illuminated; and the rest of the circles *bh, ci, dk, cl*, respectively with the same sorts of rays by which the corresponding circles BH, CI, DK, EL, were illuminated. In the figure PT, composed of the great circles, three of those, AG, BH, CI, are so expanded into each other, that three sorts of rays, by which those circles are illuminated, together with innumerable other sorts of intermediate rays, are mixed at QR in the middle of the circle BH. And the like mixture happens throughout almost the whole length of the figure PT. But in the figure *pt*, composed of the less circles, the three less circles *ag, bh, ci*, which answer to those three greater, do not extend into one another; nor are there anywhere mingled so much as any two of the three sorts of rays by which those circles are illuminated, and which in the figure PT are all of them intermingled at QR. So then, if we would diminish the mixture of the rays, we are to diminish the diameters of the circles. Now these would be diminished if the sun's diameter, to which they answer, could be made less than it is, or (which comes to the same purpose), if without doors, at great distance from the prism towards the sun, some opaque body were placed with a round hole in the middle of it to intercept all the sun's light, except so much as coming from the middle of his body could pass through that hole to the prism. For so the circles AG, BH, and the rest, would not any longer answer to the whole disk of the sun, but only to that part of it which could be seen from the prism through that hole; that is, to the apparent magnitude of that hole viewed from the prism. But that these circles may answer more distinctly to that hole, a lens is to be placed by the prism to cast the image of the hole (that is, every one of the circles AG, BH, &c.) distinctly upon the paper at PT; after such a manner, as by a lens placed at a window the pictures of objects abroad are cast distinctly upon the paper within the room. If this be done, it will not be necessary to place that hole very far off, no not beyond the window. And therefore, instead of that hole, I used a hole in the window-shut as follows.

"In the sun's light let into my darkened chamber through a small round hole in my window-shut, at about 10 or 12 feet from the window, I placed a lens MN, Fig. 6. by which the image of the hole F might be distinctly cast upon a sheet of white paper placed at I. Then immediately after the lens I placed a prism ABC, by which the trajected light might be refracted either upwards or sidewise, and thereby the round image which the lens alone did cast upon the paper at I, might be drawn out into a long one with parallel sides, as represented at *pt*. This oblong image I let fall upon another at about the same distance from the prism as the image at I, moving the paper either towards the prism or from it, until I found the just distance where the rectilinear sides of the images *pt* became most distinct. For in this case the circular images of the hole, which compose that image, after the manner that the circles *ag, bh, ci*, &c. do the figure *pt*, were terminated most distinctly, and therefore extended into one another the least that they could, and by consequence the mixture of the heterogeneous rays was now the least of all. The circles *ag, bh, ci*, &c. which compose the image *pt*, are each equal to the circle at I; and therefore, by diminishing the hole F, or by removing the lens farther from it, may be diminished at pleasure, whilst their centres keep the same distances from each other. Thus, by diminishing the

the breadth of the image $p\,t$, the circle of heterogeneal rays that compose it may be separated from each other as much as you please. Yet instead of the circular hole F, it is better to substitute a hole shaped like a parallelogram, with its length parallel to the length of the prism. For if this hole be an inch or two long, and but a 10th or 20th part of an inch broad, or narrower, the light of the image $p\,t$ will be as simple as before, or simpler; and the image being much broader, is therefore fitter to have experiments tried in its light than before.

"Homogeneal light is refracted regularly without any dilatation, splitting, or shattering of the rays; and the confused vision of objects seen through refracting bodies by heterogeneous light, arises from the different refrangibility of several sorts of rays. This will appear by the experiments which will follow. In the middle of a black paper I made a round hole about a fifth or a sixth part of an inch in diameter. Upon this part I caused the spectrum of homogeneous light, described in the former article, so to fall that some part of the light might pass through the hole in the paper. This transmitted part of the light, I refracted with a prism placed behind the paper: and letting the refracted light fall perpendicularly upon a white paper, two or three feet distant from the prism, I found that the spectrum formed on the paper by this light was not oblong, as when it is made in the first experiment, by refracting the sun's compound light, but was, so far as I could judge by my eye, perfectly circular, the length being nowhere greater than the breadth; which shows that this light is refracted regularly without any dilatation of the rays, and is an ocular demonstration of the mathematical proposition mentioned above.

208 The image of the sun by simple and homogeneous light, circular.

"In the homogeneous light I placed a paper circle of a quarter of an inch in diameter: and in the sun's unrefracted, heterogeneous, white light, I placed another paper circle of the same bigness; and going from these papers to the distance of some feet, I viewed both circles through a prism. The circle illuminated by the sun's heterogeneous light appeared very oblong, as in the second experiment, the length being many times greater than the breadth. But the other circle, illuminated with homogeneous light appeared circular, and distinctly defined, as when it is viewed by the naked eye; which proves the whole proposition mentioned in the beginning of this article.

209 Vision more distinct in homogeneous than in heterogeneous light.

"In the homogeneous light I placed flies and such like minute objects, and viewing them through a prism I saw their parts as distinctly defined as if I had viewed them with the naked eye. The same objects placed in the sun's unrefracted heterogeneous light, which was white, I viewed also through a prism, and saw them most confusedly defined, so that I could not distinguish their smaller parts from one another. I placed also the letters of a small print one while in the homogeneous light, and then in the heterogeneous; and viewing them through a prism, they appeared in the latter case so confused and indistinct that I could not read them; but in the former, they appeared so distinct that I could read readily, and thought I saw them as distinct as when I viewed them with my naked eye: in both cases, I viewed the same objects through the same prism, at the same distance from me, and in the same situation. There was no difference but in the lights by which the objects were illuminated, and which in one case was simple, in the other compound; and therefore the distinct vision in the former case, and confused in the latter, could arise from nothing else than from that difference in the lights. Which proves the whole proposition.

"In these three experiments, it is farther very remarkable, that the colour of homogeneous light was never changed by the refractions. And as these colours were not changed by refractions, so neither were they by reflections. For all white, gray, red, yellow, green, blue, violet bodies, as paper, ashes, red lead, orpiment, indigo, bice, gold, silver, copper, grass, blue flowers, violets, bubbles of water tinged with various colours, peacock feathers, the tincture of lignum nephriticum, and such like, in red homogeneous light appeared totally red, in blue light totally blue, in green light totally green, and so of other colours. In the homogeneous light of any colour they all appeared totally of that same colour; with this only difference, that some of them reflected that light more strongly, others more faintly. I never yet found any body which by reflecting homogeneous light could sensibly change its colour.

"From all which it is manifest, that if the sun's light consisted of but one sort of rays, there would be but one colour in the world, nor would it be possible to produce any new colour by reflections and refractions; and by consequence, that the variety of colours depends upon the composition of light.

"The solar image $p\,t$, formed by the separated rays in the 6th experiment, did in the progress from its end p, on which the most refrangible rays fell, unto its end t, on which the least refrangible rays fell, appear tinged with this series of colours; violet, indigo, blue, green, yellow, orange, red, together with all their intermediate degrees in a continual succession perpetually varying; so that there appeared as many degrees of colours as there were sorts of rays differing in refrangibility. And since these colours could not be changed by refractions nor by reflections, it follows that all homogeneal light has its proper colour answering to its degree of refrangibility.

210 Every homogeneous ray is refracted according to one and the same rule.

"Every homogeneous ray considered apart is refracted according to one and the same rule; so that its sine of incidence is to its sine of refraction in a given ratio: that is, every different coloured ray has a different ratio belonging to it. This our author has proved by experiment, and by other experiments has determined by what numbers those given ratios are expressed. For instance, if an heterogeneous white ray of the sun emerges out of glass into air; or, which is the same thing, if rays of all colours be supposed to succeed one another in the same line AC, and AD their common sine of incidence in glass be divided into 50 equal parts, then EF and GH, the sines of refraction into air, of the least and most refrangible rays, will be 77 and 78 such parts respectively. And since every colour has several degrees, the sines of refraction of all the degrees of red will have all intermediate degrees of magnitude from 77 to $77\frac{1}{8}$, of all the degrees of orange from $77\frac{1}{8}$ to $77\frac{1}{5}$, of yellow from $77\frac{1}{5}$ to $77\frac{1}{3}$, of green from $77\frac{1}{3}$ to $77\frac{1}{2}$, of blue from $77\frac{1}{2}$ to $77\frac{2}{3}$, of indigo from $77\frac{2}{3}$ to $77\frac{7}{9}$, and of violet from $77\frac{7}{9}$ to 78." See CHROMATICS, SUPPLEMENT.

Plate CCCLXXXIII fig. 15.

PART

PART II. EXPLANATION OF OPTICAL PHENOMENA.

Sect. I. *Of the Rainbow.*

211 Knowledge of the nature of the rainbow a modern discovery.

The observations of the ancients, and the philosophers of the middle ages, concerning the rainbow, were such as could not have escaped the notice of the most illiterate husbandmen; and their various hypotheses deserve no notice. It is a considerable time, even after the dawn of true philosophy, before we find any discovery of importance on this subject. Maurolycus was the first who pretended to have measured the diameters of the two rainbows with much exactness; and he found that of the inner bow to be 45°, and that of the outer bow 56°; from which Descartes takes occasion to observe, how little we can depend upon the observations of those who were not acquainted with the cause of the phenomena.

Clichtovæus, who died in 1543, had maintained, that the second bow is the image of the first, which he thought was evident from the inverted order of the colours. For, said he, when we look into the water, all the images that we see reflected by it are inverted with respect to the objects themselves; the tops of the trees, for instance, that stand near the brink, appearing lower than the roots.

212 Approach towards it made by Fletcher of Breslaw.

As the rainbow was opposite to the sun, it was natural to imagine, that its colours were produced by some kind of reflection of the rays of light from the drops of rain. No person seems to have thought of ascribing these colours to refraction, till one *Fletcher* of Breslaw, in a treatise published in 1571, endeavoured to account for them by means of a double refraction and one reflection. But he imagined that a ray of light, after entering a drop of rain, and suffering a refraction both at its entrance and exit, was afterwards reflected from another drop, before it reaches the eye of the spectator. He seems to have overlooked the reflection at the posterior surface of the drop, or to have imagined that all the bendings of the light within the drop would not make a sufficient curvature to bring the rays of the sun to the eye of the spectator. That he should think of two refractions, was the necessary consequence of his supposing that the ray entered the drop at all. This supposition, therefore, was all that he instituted to explain the phenomena. B. Porta supposed that the rainbow is produced by the refraction of light in the whole body of rain or vapour, but not in the separate drops.

213 The discovery made by Antonio de Dominis bishop of Spalatro.

It is to a man who had no pretensions to philosophy, that we are indebted for the true explanation. This was Antonio De Dominis, bishop of Spalatro, whose treatise *De Radiis Visus et Lucis*, was published by J. Bartolus in 1611. He first maintained, that the double refraction of Fletcher, with an intervening reflection, was sufficient to produce the colours of the bow, and also to bring the rays that formed them to the eye of the spectator, without any subsequent reflection. He distinctly describes the progress of a ray of light entering the upper part of the drop, where it suffers one refraction, and after being thereby thrown upon the back part of the inner surface, is thence reflected to the lower part of the drop; at which place undergoing a second refraction, it is thereby bent, so as to come directly to the eye. To verify this hypothesis, De Dominis proceeded in a very sensible and philosophical manner. He procured a small globe of solid glass, and viewing it when it was exposed to the rays of the sun, in the same manner in which he had supposed that the drops of rain were situated with respect to them, he actually observed the same colours which he had seen in the true rainbow, and in the same order.

Thus the circumstances in which the colours of the rainbow were formed, and the progress of a ray of light through a drop of water, were clearly understood; but philosophers were a long time at a loss when they endeavoured to assign reasons for all the particular colours, and for the order of them. Indeed nothing but the doctrine of the different refrangibility of the rays of light, could furnish a complete solution of this difficulty. De Dominis supposed that the red rays were those which had traversed the least space in the inside of a drop of water, and therefore retained more of their native force, and consequently, striking the eye more briskly, gave it a stronger sensation; that the green and blue colours were produced by those rays, the force of which had been, in some measure, obtunded in passing through a greater body of water; and that all the intermediate colours were composed (according to the hypothesis which generally prevailed at that time) of a mixture of these three primary ones. That the different colours were produced by some difference in the impulse of light upon the eye, was an opinion which had been adopted by many persons, who had ventured to depart from the authority of Aristotle.

Afterwards the same De Dominis observed, that all the rays of the same colour must leave the drop of water in a part similarly situated with respect to the eye, in order that each of the colours may appear in a circle, the centre of which is a point of the heavens, in a line drawn from the sun through the eye of the spectator. The red rays, he observed, must issue from the drop nearest to the bottom of it, in order that the circle of red may be the outermost, and the most elevated in the bow.

Though De Dominis conceived so justly the manner in which the inner rainbow is formed, he was far from having as just an idea of the cause of the exterior bow. This he endeavoured to explain in the very same manner as the interior, viz. by one reflection of the light within the drop, preceded and followed by a refraction; supposing only that the rays which formed the exterior bow were returned to the eye by a part of the drop lower than that which transmitted the red of the interior bow. He also supposed that the rays which formed one of the bows came from the upper limb of the sun, and those which formed the other from the lower limb, without considering that the bows ought thus to have been contiguous; or rather, that an indefinite number of bows would have had their colours all intermixed.

When Sir Isaac Newton discovered the different refrangibility of the rays of light, he immediately applied the discovery to the phenomena of the rainbow, taking up

Of the Rainbow.

up the subject where De Dominis and Descartes were obliged to leave their investigations imperfect.

214 The true cause of the colours of the rainbow. Plate CCCLXXXIII fig. 8.

Let a be a drop of water, and S a pencil of light; which, on its leaving the drop reaches the eye of the spectator. This ray, at its entrance into the drop, begins to be decomposed into its proper colours; and upon leaving the drop, after one reflection and a second refraction, it is farther decomposed into as many small differently-coloured pencils as there are primitive colours in the light. Three of them only are drawn in this figure, of which the blue is the most, and the red the least, refracted.

The theory of the different refrangibility of light enables us to assign a reason for the size of a bow of each particular colour. Newton, having found that the sines of refraction of the most refrangible and least refrangible rays, in passing from rain water into air, are in the ratio of 185 to 182, when the sine of incidence is 138, computed the size of the bow; and found, that if the sun was only a physical point, the breadth of the inner bow would be 2°; and if to this 30′ were added for the apparent diameter of the sun, the whole breadth would be $2\frac{1}{2}$°. But as the outermost colours, especially the violet, are extremely faint, the breadth of the bow will not appear to exceed two degrees. He found by the same principles, that the breadth of the exterior bow, if it was everywhere equally vivid, would be 4° 20′. But in this case there is a greater deduction to be made, on account of the faintness of the light of the exterior bow; so that it will not appear to be more than 3 degrees broad.

The principal phenomena of the rainbow are explained on Sir Isaac Newton's principles in the following propositions.

Prop. I.

When the rays of the sun fall upon a drop of rain and enter into it, some of them, after one reflection and two refractions, may come to the eye of a spectator who has his back towards the sun, and his face towards the drop.

215 Explanation of the phenomena of the rainbow on the principles of Newton. Fig. 9.

If XY be a drop of rain, and if the sun shine upon it in any lines $s\,f$, $s\,d$, $s\,a$, &c. most of the rays will enter into the drop; some of them only will be reflected from the first surface; those rays which are thence reflected do not come under our present consideration, because they are never refracted at all. The greatest part of the rays then enter the drop, and those passing on to the second surface, will most of them be transmitted through the drop. At the second surface or hinder part of the drop, at $p\,g$, some few rays will be reflected, whilst the rest are transmitted; those rays proceed in some such lines as $n\,r$, $n\,q$: and coming out of the drop in the lines $r\,v$, $q\,t$, may fall upon the eye of the spectator, who is placed anywhere in those lines, with his face towards the drop, and consequently with his back towards the sun, which is supposed to shine upon the drop in the lines $s\,f$, $s\,d$, $s\,a$, &c. These rays are twice refracted and once reflected; they are refracted when they pass out of the air into the drop; they are reflected from the second surface, and are refracted again when they pass out of the drop into the air.

Def. When rays of light reflected from a drop of rain come to the eye, those are called *effectual* which are able to excite a sensation.

Prop. II.

When rays of light come out of a drop of rain, they will not be effectual, unless they are parallel and contiguous.

There are but few rays that can come to the eye at all: for since the greatest part of those rays which enter the drop XY between X and a, pass out of the drop through the hinder surface $p\,g$; only few are thence reflected, and come out through the nearer surface between a and Y. Now, such rays as emerge, or come out of the drop, between a and Y, will be ineffectual, unless they are parallel to one another, as $r\,v$ and $q\,t$ are; because such rays as come out diverging from one another will be so far asunder when they come to the eye, that all of them cannot enter the pupil; and the very few that can enter it will not be sufficient to excite any sensation. But even rays, which are parallel, as $r\,v$, $q\,t$, will not be effectual, unless there are several of them contiguous or very near to one another. The two rays $r\,v$ and $q\,t$ alone will not be perceived, though both of them enter the eye; for so very few rays are not sufficient to excite a sensation. Fig. 9.

Prop. III.

When rays of light come out of a drop of rain after one reflection, those will be effectual which are reflected from the same point, and which entered the drop near to one another.

Any rays, as $s\,b$ and $c\,d$, when they have passed out of the air into a drop of water, will be refracted towards the perpendiculars $b\,l$, $d\,l$; and as the ray $s\,b$ falls farther from the axis $a\,v$ than the ray $c\,d$, $s\,b$ will be more refracted than $c\,d$; so that these rays, though parallel to one another at their incidence, may describe the lines $b\,e$ and $d\,e$ after refraction, and be reflected from the same point e. Now all rays, which are thus reflected from the same point, when they have described the lines $e\,f$, $e\,g$, and after reflection emerge at f and g, will be so refracted, when they pass out of the drop into the air, as to describe the parallel lines $f\,h$, $g\,i$. If these rays were to return from e in the lines $e\,b$, $e\,d$, and were to emerge at b and d, they would be refracted into the lines of their incidence $b\,s$, $d\,c$. But if these rays, instead of being returned in the lines $e\,b$, $e\,d$, are reflected from the same point e in the lines $e\,g$, $e\,f$, the lines of reflection $e\,g$ and $e\,f$ will be inclined to one another and to the surface of the drop, just as much as the lines $e\,b$ and $e\,d$ are. First, $e\,b$ and $e\,g$ make the same angle with the surface of the drop; for the angle $b\,e\,x$, which $e\,b$ makes with the surface of the drop, is the complement of incidence, and the angle $g\,e\,v$, which $e\,g$ makes with the surface, is the complement of reflection; and these two are equal to one another. In the same manner it might be shown, that $e\,d$ and $e\,f$ make equal angles with the surface of the drop. Secondly, The angle $b\,e\,d = f\,e\,g$; or the reflected rays $e\,g$, $e\,f$, and the incident rays $b\,e$, $d\,e$, are equally inclined to each other. For the angle of incidence $b\,e\,l = g\,e\,l$, the angle of reflection, and the angle of incidence $d\,e\,l = f\,e\,l$, the angle Plate CCLXXXIII fig. 10.

Of the Rainbow.

angle of reflection: consequently, the difference between the angles of incidence is equal to the difference between the angles of reflection, or $b\,e\,l - d\,e\,l = g\,e\,l - f\,e\,l$, or $b\,e\,d = g\,e\,f$. Since therefore either the lines $e\,g$, $e\,f$, or the lines $e\,b$, $e\,d$, are equally inclined both to one another and to the surface of the drop; the rays will be refracted in the same manner, whether they return in the lines $e\,b$, $e\,d$, or are reflected in the lines $e\,g$, $e\,f$. But if they return in the lines $e\,b$, $e\,d$, the refraction, when they emerge at b and d, would make them parallel. Therefore, if they are reflected from one and the same point e in the lines $e\,g$, $e\,f$, the refraction, when they emerge at g and f, will likewise make them parallel.

But though such rays as are reflected from the same point in the hinder part of a drop of rain, are parallel to one another when they emerge, and so have one condition that is requisite towards making them effectual, yet there is another condition necessary; for rays that are effectual must be contiguous as well as parallel. And though rays, which enter the drop in different places, may be parallel when they emerge, those only will be contiguous which enter it nearly at the same place.

Fig. 9. Let XY be a drop of rain, $a\,g$ the axis or diameter of the drop, and $s\,a$ a ray of light that enters the drop at a. This ray $s\,a$, being perpendicular to both the surfaces, will pass through the drop in the line $a\,g\,h$ without being refracted; but any collateral rays, such as those that fall about $s\,b$, will be made to converge to the axis, and passing out at n will meet the axis at h: Rays which fall farther from the axis than $s\,b$, such as those which fall about $s\,c$, will likewise be made to converge; but their focus will be nearer to the drop than h. Suppose therefore i to be the focus of the rays that fall about $s\,c$, any ray $s\,c$, when it has described the line $c\,o$ within the drop, and is tending to the focus i, will pass out of the drop at the point o. The rays that fall upon the drop about $s\,d$, will converge to a focus still nearer than i, as at k. These rays therefore go out of the drop at p. The rays, that fall about $s\,c$, will converge to a focus nearer than k, as suppose at l; and the ray $s\,e$, when it has described the line $e\,o$ within the drop, and is tending to l, will pass out at the point o. The rays that fall still more remote from the axis will converge to a focus still nearer Thus the ray $s\,f$ will after refraction converge to a focus at m, which is nearer than l; and having described the line $f\,n$ within the drop, it will pass out to the point n. Now we may here observe, that as any rays $s\,b$ or $s\,c$, fall farther above the axis $s\,a$, the points n, or o, where they pass out behind the drop, will be farther above g; or that, as the incident ray rises from the axis $s\,a$, the arc $g\,n\,o$ increases, till we come to some ray $s\,d$, which passes out of the drop at p; and this is the highest point where any ray that falls upon the quadrant or quarter $a\,x$ can pass out: for any rays $f\,e$, or $s\,f$, that fall higher than $s\,d$, will not pass out on any point above p, but at the points o, or n, which are below it. Consequently, though the arc $g\,n\,o\,p$ increases, whilst the distance of the incident ray from the axis $s\,a$ increases, till we come to the ray $s\,d$; yet afterwards, the higher the ray falls above the axis $s\,a$, this arc $p\,o\,n\,g$ will decrease.

We have hitherto spoken of the points on the posterior part of the drop, where the rays pass out of it; but this was for the sake of determining the points from which those rays are reflected, which do not pass out behind the drop. For, in explaining the rainbow, we have no further reason to consider those rays which go through the drop; since they can never come to the eye of a spectator placed anywhere in the lines $r\,v$ or $q\,t$ with his face towards the drop. Now, as there are many rays which pass out of the drop between g and p, so some rays will be thence reflected: and consequently the several points between g and p, which are the points where some of the rays pass out of the drop, are likewise the points of reflection for the rest which do not pass out. Therefore in respect of those rays which are reflected, we may call $g\,p$ the arc of reflection; and may say, that this arc of reflection increases, as the distance of the incident ray from the axis $s\,a$ increases, till we come to the ray $s\,d$; the arc of reflection is $g\,n$ for the ray $s\,b$, it is $g\,o$ for the ray $s\,c$, and $g\,p$ for the ray $s\,d$. But after this, as the distance of the incident ray from the axis $s\,a$ increases, the arc of reflection decreases; for $o\,g$ less than $p\,g$ is the arc of reflection for the ray $s\,e$, and $n\,g$ is the arc of reflection for the ray $s\,f$.

Hence it is obvious, that some ray, which falls above $s\,d$, may be reflected from the same point with some other ray which falls below $s\,d$. Thus, for instance, the ray $s\,b$ will be reflected from the point n, and the rays $s\,f$ will be reflected from the same point; and consequently, when the reflected rays $n\,r$, $n\,q$, are refracted as they pass out of the drop at r and q, they will be parallel. But since the intermediate rays, which enter the drop between $s\,f$ and $s\,b$, are not reflected from the same point n, these two rays alone will be parallel to one another when they come out of the drop, and the intermediate rays will not be parallel to them. And consequently these rays $r\,v$, $q\,t$, though they are parallel after they emerge at r and q, will not be contiguous, and for that reason will not be effectual; the ray $s\,d$ is reflected from p, which has been shown to be the limit of the arc of reflection; such rays as fall just above $s\,d$, and just below $s\,d$, will be reflected from nearly the same point p, as appears from what has been already shown. These rays therefore will be parallel, because they are reflected from the same point p; and they will likewise be contiguous, because they all of them enter the drop at the same place very near to d. Consequently, such rays as enter the drop at d, and are reflected from p the limit of the arc of reflection, will be effectual; since, when they emerge at the part of the drop between a and y, they will be both parallel and contiguous.

If it can be shown that the rainbow is produced by the rays of the sun which are thus reflected from drops of rain as they fall while the run shines upon them, this proposition may serve to show us, that this appearance is not produced by *any* rays that fall upon *any part*, and are reflected from any part of those drops: since this appearance cannot be produced by any rays but those which are effectual; and effectual rays must always enter each drop at one certain place in the anterior part of it, and must likewise be reflected from one certain place in the posterior surface.

Prop. IV.

When rays that are effectual emerge from a drop of rain after one reflection and two refractions, those which are most refrangible will, at

Of the Rainbow.

at their immersion, make a less angle with the incident rays than those which are least refrangible; and by this means the rays of different colours will be separated from one another.

Plate ccclxxxiii. fig. 10.

Let $f h$ and $g i$ be effectual violet rays emerging from the drop at $f g$; and $f n$, $g p$, effectual red rays emerging from the same drop at the same place. Now, though all the violet rays are parallel to one another, because they are supposed effectual, and though all the red rays are likewise parallel to one another from the same reason; yet the violet rays will not be parallel to the red rays. These rays, as they have different degrees of refrangibility, will diverge from one another; any violet ray $g i$, which emerges at g, will diverge from any red ray $g p$, which emerges at the same place. Now, both the violet ray $g i$, and the red ray $g p$, as they pass out of the drop of water into the air, will be refracted from the perpendicular $l o$. But the violet ray is more refrangible than the red one; and for that reason $g i$, or the refracted violet ray, will make a greater angle with the perpendicular than $g p$ the refracted red ray; or the angle $i g o$ will be greater than the angle $p g o$. Suppose the incident ray $s b$ to be continued in the direction $s k$, and the violet ray $i g$ to be continued backward in the direction $i k$, till it meets the incident ray at k. Suppose likewise the red ray $p g$ to be continued backwards in the same manner, till it meets the incident ray at w. The angle $i k s$ is that which the violet ray, or most refrangible ray at its immersion, makes with the incident ray; and the angle $p w s$, is that which the red ray or least refrangible ray at its immersion, makes with the incident ray. The angle $i k s$ is less than the angle $p w s$. For, in the triangle, $g w k$, $g w s$, or $p w s$, is the external angle at the base, and $g k w$ or $i k s$ is one of the internal opposite angles. (Euc. B. I. Prop. xvi.). What has been shown to be true of the rays $g i$ and $g p$ might be shown in the same manner of the rays $f h$ and $f n$, or of any other rays that emerge respectively parallel to $g i$ and $g p$. But all the effectual violet rays are parallel to $g i$, and all the effectual red rays are parallel to $g p$. Therefore the effectual violet rays at their immersion make a less angle with the incident ones than the effectual red ones. For the same reason, in all the other sorts of rays, those which are most refrangible, at their emersion from a drop of rain after one reflection, will make a less angle with the incident rays, than those do which are less refrangible.

Otherwise: When the rays $g i$ and $g p$ emerge at the same point g, as they both come out of the water into air, and consequently are refracted from the perpendicular, instead of going straight forwards in the line $e g$ continued, they will both be turned round upon the point g from the perpendicular $g o$. Now it is easy to conceive, that either of these lines might be turned in this manner upon the point g as upon a centre, till they became parallel to $s b$ the incident ray. But if either of these lines or rays were refracted so much from $g o$ as to become parallel to $s b$, the ray thus refracted, would, after emersion, make no angle with $s k$, because it would be parallel to it. Consequently that ray which is most turned round upon the point g, or that ray which is most refrangible, will after emersion be nearest parallel to the incident ray, or will make the least angle with it. The same may be proved of all other rays emerging parallel to $g i$ and $g p$ respectively, or of all effectual rays; those which are most refrangible will after emersion make a less angle with the incident rays, than those do which are least refrangible.

But since the effectual rays of different colours make different angles with $s k$ at their emersion, they will be separated from one another: so that if the eye were placed in the beam $f g h i$, it would receive only rays of one colour from the drop $x a g v$; and if it were placed in the beam $f g n p$, it would receive only rays of some other colour.

The angle $s w p$, which the least refrangible or red rays make with the incident ones when they emerge so as to be effectual, is found by calculation to be $42^\circ\ 2'$. And the angle $s k i$, which the most refrangible rays make with the incident ones when they emerge so as to be effectual, is found to be $40^\circ\ 17'$. The rays which have the intermediate degrees of refrangibility, make with the incident ones intermediate angles between $42^\circ\ 2'$, and $40^\circ\ 17'$.

Prop. V.

If a line be supposed to be drawn from the centre of the sun through the eye of the spectator, the angle which any effectual ray, after two refractions and one reflection, makes with the incident ray, will be equal to the angle which it makes with that line.

Let the eye of the spectator be at i, and let $q t$ be the line supposed to be drawn from the centre of the sun through the eye of the spectator; the angle $g i t$, which any effectual ray makes with this line, will be equal to the angle $i k s$, which the same ray makes with the incident ray $s b$ or $s k$. If $s b$ is a ray coming from the centre of the sun, then since $q t$ is supposed to be drawn from the same point, these two lines, upon account of the remoteness of the point from whence they are drawn, may be looked upon as parallel to one another. But the right line $k i$ crossing these two parallel lines will make the alternate angles equal. (Euc. B. I. Prop. xxix.). Therefore $k i t$ or $g i t = s k i$.

Plate ccclxxxiii. fig. 10.

Prop. VI.

When the sun shines upon the drops of rain as they are falling, the rays that come from those drops to the eye of a spectator, after one reflection and two refractions, produce the primary rainbow.

216 Two rainbows seen at once. Fig. 11.

If the sun shines upon the rain as it falls, there are commonly seen two bows, as AFB, CHD; or if the cloud and rain does not reach over that whole side of the sky where the bows appear, then only a part of one or of both bows is seen in that place where the rain falls. Of these two bows, the innermost AFB is the more vivid of the two, and this is called the *primary bow*. The outer part TFY of the primary bow is red, the inner part VEX is violet; the intermediate parts, reckoning from the red to the violet, are orange, yellow, green, blue, and indigo. Suppose the spectator's eye to be at O, and let LOP be an imaginary line drawn

Of the Rainbow.

drawn from the centre of the sun through the eye of the spectator: if a beam of light S coming from the sun fall upon any drop F; and the rays that emerge at F in the line FO, so as to be effectual, make an angle FOP of 42° 2′ with the line LP; then these effectual rays make an angle of 42° 2′ with the incident rays, by the preceding proposition, and consequently these rays will be red, so that the drop F will appear red. All the other rays, which emerge at F, and would be effectual if they fell upon the eye, are refracted more than the red ones, and consequently will pass above the eye. If a beam of light S fall upon the drop E, and the rays that emerge at E in the line EO, so as to be effectual, make an angle of 40° 17′ with the line LP; then these effectual rays make likewise an angle of 40° 17′ with the incident rays, and the drop E will appear of a violet colour. All the other rays, which emerge at E, and would be effectual if they came to the eye, are refracted less than the violet ones, and therefore pass below the eye. The intermediate drops between F and E will for the same reasons be of the intermediate colours.

Thus we have shown why a set of drops from F to E, as they are falling, should appear of the seven primary colours. It is not necessary that the several drops, which produce these colours, should all of them fall at exactly the same distance from the eye. The angle FOP, for example, is the same whether the distance of the drop from the eye is OF, or whether it is in any other part of the line OF something nearer to the eye. And whilst the angle FOP is the same, the angle made by the emerging and incident rays, and consequently the colour of the drop, will be the same. This is equally true of any other drop. So that though in the figure the drops F and E are represented as falling perpendicularly one under the other, yet this is not necessary in order to produce the bow.

But the coloured line FE, which we have already accounted for, is only the breadth of the bow. It still remains to be shewn, why not only the drop F should appear red, but why all the other drops from A to B in the arc ATFYB should appear of the same colour. Now it is evident, that wherever a drop of rain is placed, if the angle which the effectual rays make with the line LP is equal to the angle FOP, that is, if the angle which the effectual rays make with the incident rays is 42° 2′, any of those drops will be red, for the same reason that the drop F is of this colour.

If FOP were to turn round upon the line OP, so that one end of this line should always be at the eye, and the other be at P opposite to the sun; such a motion of this figure would be like that of a pair of compasses turning round upon one of the legs OP with the opening FOP. In this revolution the drop F would describe a circle, P would be the centre, and ATFYB would be an arc in this circle. Now since, in this motion of the line and drop OF, the angle made by FO with OP, that is, the angle FOP, continues the same; if the sun were to shine upon this drop as it revolves, the effectual rays would make the same angle with the incident rays, in whatever part of the arc ATFYB the drop was to be. Therefore, whether the drop be at A, or at T, or at Y, or at B, or wherever else it is in this whole arc, it would appear red, as it does at F.—The drops of rain, as they fall, are not indeed turned round in this manner: but then, as great numbers of them are falling at once in right lines from the cloud, whilst one drop is at F, there will be others at Y, at T, at B, at A, and in every other part of the arc ATFYB: and all these drops will be red for the same reason that the drop F would have been red, if it had been in the same place. Therefore, when the sun shines upon the rain as it falls, there will be a red arc ATFYB opposite to the sun. In the same manner, because the drop E is violet, we might prove that any other drop, which, whilst it is falling, is in any part of the arc AVEXB, will be violet; and consequently, at the same time that the red arc ATFYB appears, there will likewise be a violet arc AVEXB below or within it. FE is the distance between these two coloured arcs; and from what has been said, it follows, that the intermediate space between these two arcs will be filled up with arcs of the intermediate colours, orange, yellow, blue, green, and indigo. All these coloured arcs together make up the primary rainbow.

Prop. VII.

The primary rainbow is never a greater arc than a semicircle.

Plate cclxxxiii. fig. 9.

217 Why the arc of the primary rainbow is never greater than a semicircle.

Since the line LOP is drawn from the sun through the eye of the spectator, and since P is the centre of the rainbow; it follows, that the centre of the rainbow is always opposite to the sun. The angle FOP is an angle of 40° 2′, as was observed, or F the highest part of the bow is 42° 2′ from P the centre of it. If the sun is more than 42° 2′ high, P the centre of the rainbow, which is opposite to the sun, will be more than 42° 2′ below the horizon; and consequently F the top of the bow, which is only 42° 2′ from P, will be below the horizon; that is, when the sun is more than 42° 2′ high, no primary rainbow will be seen. If the altitude of the sun be something less than 40° 2′, then P will be something less than 42° 2′ below the horizon; and consequently F, which is only 42° 2′ from P, will be just above the horizon; that is, a small part of the bow at this height of the sun will appear close to the ground opposite to the sun. If the sun be 20° high, then P will be 20° below the horizon; and F the top of the bow, being 42° 2′ from P, will be 22° 2′ above the horizon; therefore, at this height of the sun, the bow will be an arc of a circle whose centre is below the horizon; and consequently that arc of the circle which is above the horizon, or the bow, will be less than a semicircle. If the sun be in the horizon, then P, the centre of the bow, will be in the opposite part of the horizon; F, the top of the bow, will be 42° 2′ above the horizon; and the bow itself, because the horizon passes through the centre of it, will be a semicircle. More than a semicircle can never appear; because if the bow were more than a semicircle, P the centre of it must be above the horizon; but P is always opposite to the sun, therefore P cannot be above the horizon, unless the sun is below it; and when the sun is set, or is below the horizon, it cannot shine upon the drops of rain as they fall; and consequently, when the sun is below the horizon, no bow at all can be seen.

Prop VIII.

When the rays of the sun fall upon a drop of rain, some of them, after two reflections and two refractions,

Of the Rainbow.

fractions, may come to the eye of a spectator, who has his back towards the sun and his face towards the drop.

Fig. 12. If HGW is a drop of rain, and parallel rays coming from the sun, as $z v$, $y w$, fall upon the lower part of it, they will be refracted towards the perpendiculars $v l$, $w l$, as they enter into it, and will describe some such lines as $v h$, $w i$. At h and i great part of these rays will pass out of the drop; but some of them will be reflected from thence in the lines $h f$, $i g$. At f and g again, great part of the rays that were reflected thither will pass out of the drop. But these rays will not come to the eye of a spectator at o. Here, however, all the rays will not pass out; but some will be reflected from f and g, in some such lines as $f d$, $g h$; and these, when they emerge out of the drop of water into the air at b and d, will be refracted from the perpendiculars, and, describing the lines $d t$, $b o$, may come to the eye of the spectator who has his back towards the sun and his face towards the drop.

Prop. IX.

Those rays, which are parallel to one another after they have been once refracted and once reflected in a drop of rain, will be effectual when they emerge after two refractions and two reflections.

No rays can be effectual, unless they are contiguous and parallel. It appears from what was said, that when rays come out of a drop of rain contiguous to one another, either after one or after two reflections, they must enter the drop nearly at the same place. And if such rays as are contiguous are also parallel after the first reflection, they will emerge parallel, and therefore will be effectual. Let $z v$ and $y w$ be contiguous rays which come from the sun, and are parallel when they fall upon the lower part of the drop; suppose these rays to be refracted at v and w, and to be reflected at h and i; if they are parallel, as $h f$, $g i$, after this first reflection, then, after they are reflected a second time from f and g, and refracted a second time as they emerge at d and b, they will go out of the drop in the parallel lines $d t$ and $b o$, and will therefore be effectual.

The rays $z v$, $y w$, are refracted towards the perpendiculars $v l$, $w l$, when they enter the drop, and will be made to converge. As these rays are very oblique, their focus will not be far from the surface $v w$. If this focus be at k, the rays, after they have passed the focus, will diverge from thence in the directions $k h$, $k i$; and if $k i$ is the principal focal distance of the concave reflecting surface $h i$, the reflected rays $h f$, $i g$, will be parallel. These rays $e f$, $i g$, are reflected again from the concave surface $f g$, and will meet in a focus at e, so that $g e$ will be the principal focal distance of this reflecting surface $f g$. And because $h i$ and $f g$ are parts of the same sphere, the principal focal distances $g e$ and $k i$ will be equal. When the rays have passed the focus e, they will thence diverge in the line $e d$, $e b$: and we are to show, that when they emerge at d and b, and are refracted there, they will become parallel.

Now if the rays $v k$, $w k$, when they have met at k, were to be turned back again in the directions $k v$, $k w$, and were to emerge at v and w, they would be refracted into the lines of their incidence, $v z$, $w y$, and therefore would be parallel. But since $g e = i k$, as has already been shown, the rays $e d$, $e b$, that diverge from e, fall in the same manner upon the drop at d and b, as the rays $k v$, $k w$, would fall upon it at v and w; and $e d$, $e b$, are just as much inclined to the refracting surface $d b$, as $k v$, $k w$ would be to the surface $v w$. Hence it follows, that the rays $e d$, $e b$, emerging at d and b, will be refracted in the same manner, and will have the same direction in respect of one another, as $k v$, $k w$ would have. But $k v$ and $k w$ would be parallel after refraction. Therefore the rays $e d$ and $e b$ will emerge in the lines $d p$, $b o$, parallel to one another, and consequently effectual.

Prop. X.

When rays that are effectual emerge from a drop of rain after two reflections and two refractions, those which are most refrangible will at their emersion make a greater angle with the incident rays than those do which are least refrangible; and by this means the rays of different colours will be separated from one another.

If rays of different colours, which are differently refrangible, emerge at any point b, these rays will not be all of them equally refracted from the perpendicular. Plate CCCLXXXIII. fig. 12. Thus, if $b o$ is a red ray, which is of all others the least refrangible, and $b m$ is a violet ray, which is of all others the most refrangible; when these two rays emerge at b, the violet ray will be refracted more from the perpendicular $b x$ than the red ray, and the refracted angle $x b m$ will be greater than the refracted angle $x b o$. Hence it follows, that these two rays, after emersion, will diverge from one another. In like manner, the rays that emerge at d will diverge from one another; a red ray will emerge in the line $d p$, a violet ray in the line $d t$. So that though all the effectual red rays of the beam $b d m t$ are parallel to one another, and all the effectual red rays of the beam $b d o p$ are likewise parallel, yet the violet will not be parallel to the red beam. Thus the rays of different colours will be separated from one another.

This will appear farther, if we consider what the proposition affirms, That any violet or most refrangible ray will make a greater angle with the incident rays, than any red or least refrangible ray makes with the same incident rays. Thus if $y w$ be an incident ray, $b m$ a violet ray emerging from the point b, and $b o$ a red ray emerging from the same point; the angle which the violet ray makes with the incident one is $y r m$, and that which the red ray makes with it is $y s o$. Now $y r m$ is greater than $y s o$. For in the triangle $b r s$, the internal angle $b r s$ is less than $b s y$ the external angle at the base. (Eucl. B. I. Prop. xvi.). But $y r m$ is the complement of $b r s$ or of $b r y$ to two right ones, and $y s o$ is the complement of $b s y$ to two right ones. Therefore, since $b r y$ is less than $b s y$, the complement of $b r y$ to two right angles will be greater than the complement of $b s y$ to two right angles; or $y r m$ will be greater than $y s o$.

Otherwise: Both the rays $b o$ and $b m$, when they are refracted in passing out of the drop at b, are turned round upon the point b from the perpendicular $b x$. Now either of these lines $b o$ or $b m$ might be turned round

Of the Rainbow.

round in this manner, till it made a right angle with $y\ w$. Consequently, that ray which is most turned round upon b, or which is most refracted, will make an angle with $y\ w$, that will be nearer to a right one than that ray makes with it which is least turned round upon b, or which is least refracted. Therefore that ray which is most refracted will make a greater angle with the incident ray than that which is least refracted.

But since the emerging rays, being differently refrangible, make different angles with the same incident ray $y\ w$, the refraction which they suffer at emersion will separate them from one another.

The angle $y\ r\ m$, which the most refrangible or violet rays make with the incident ones, is found by calculation to be $54^\circ\ 7'$; and the angle $y\ s\ o$, which the least refrangible or red rays make with the incident ones, is found to be $50^\circ\ 57'$: the angles, which the rays of the intermediate colours, indigo, blue, green, yellow, and orange, make with the incident rays, are intermediate angles between $54^\circ\ 7'$ and $50^\circ\ 57'$.

Prop. XI.

If a line is supposed to be drawn from the centre of the sun through the eye of the spectator; the angle which, after two refractions and two reflections, any effectual ray makes with the incident ray, will be equal to the angle which it makes with that line.

Fig. 12. If $y\ w$ is an incident ray, $b\ o$ an effectual ray, and $q\ n$ a line drawn from the centre of the sun through o the eye of the spectator; the angle $y\ s\ o$, which the effectual ray makes with the incident ray, is equal to $s\ o\ n$ the angle which the same effectual ray makes with the line $q\ n$. For $y\ w$ and $q\ n$, considered as drawn from the centre of the sun, are parallel; bo crosses them, and consequently makes the alternate angles $y\ s\ o$, $s\ o\ n$, equal to one another. Eucl. B. I. Prop. xxix.

Prop. XII.

When the sun shines upon the drops of rain as they are falling, the rays, that come from these drops to the eye of a spectator, after two reflections and two refractions, produce the secondary rainbow.

218 The secondary rainbow produced by two reflections and two refractions. Fig. 11.

The secondary rainbow is the outermost CHD. When the sun shines upon a drop of rain H; and the rays HO, which emerge at H so as to be effectual, make an angle HOP of $54^\circ\ 7'$ with LOP a line drawn from the sun through the eye of the spectator; the same effectual rays will make likewise an angle of $54^\circ\ 7'$ with the incident rays S, and the rays which emerge at this angle are violet ones, by what was observed above. Therefore, if the spectator's eye is at O, none but violet rays will enter it: for as all the other rays make a less angle with OP, they will fall above the spectator's eye. In like manner, if the effectual rays that emerge from the drop G make an angle of $50^\circ\ 57'$ with the line OP, they will likewise make the same angle with the incident rays S; and consequently, from the drop G no rays will come to the spectator's eye at O but red ones; for all the other rays making a greater angle with the line OP, will fall below the eye at O. For the same reason, the rays emerging from the intermediate drops between H and G, and coming to the spectator's eye at O, will emerge at intermediate angles, and therefore will have the intermediate colours. Thus if there are seven drops from H to G inclusively, their colours will be violet, indigo, blue, green, yellow, orange, and red. This coloured line is the breadth of the secondary rainbow.

Now, if HOP were to turn round upon the line OP, like a pair of compasses upon one of the legs OP with the opening HOP, it is plain from the supposition, that, in such a revolution of the drop H, the angle HOP would be the same, and consequently the emerging rays would make the same angle with the incident ones. But in such a revolution the drop would describe a circle of which P would be the centre, and CNHRD an arc. Consequently, since, when the drop is at N, or at R, or anywhere else in that arc, the emerging rays make the same angle with the incident ones as when the drop is at H, the colour of the drop will be the same to an eye placed at O, whether the drop is at N, or at H, or at R, or anywhere else in that arc. Now, though the drop does not thus turn round as it falls, and does not pass through the several parts of this arc, yet, since there are drops of rain falling everywhere at the same time, when one drop is at H, there will be another at R, another at N, and others in all parts of the arc; and these drops will all be violet-coloured, for the same reason that the drop H would have been of this colour if it had been in any of those places. In like manner, as the drop G is red when it is at G, it would likewise be red in any part of the arc CWGQD; and so will any other drop when, as it is falling, it comes to any part of that arc. Thus as the sun shines upon the rain, whilst it falls, there will be two arcs produced, a violet-coloured arc CNHRD, and a red one CWGQD; and for the same reasons the intermediate space between these two arcs will be filled up with arcs of the intermediate colours. All these arcs together make up the secondary rainbow.

Prop. XIII.

The colours of the secondary rainbow are fainter than those of the primary rainbow; and are arranged in the contrary order.

The primary rainbow is produced by such rays as have been only once reflected; the secondary rainbow is produced by such rays as have been twice reflected. But at every reflection some rays pass out of the drop of rain without being reflected; so that the oftener the rays are reflected, the fewer of them are left. Therefore the colours of the secondary bow are produced by fewer rays, and consequently will be fainter, than the colours of the primary bow. 219 Why the colours of the secondary rainbow are fainter than those of the primary, and arranged in a contrary order.

In the primary bow, reckoning from the outside of it, the colours are arranged in this order; red, orange, yellow, green, blue, indigo, violet. In the secondary bow, reckoning from the outside, the colours are violet, indigo, blue, green, yellow, orange, red. So that the red, which is the outermost or highest colour in the primary bow, is the innermost or lowest colour in the secondary one.

Now the violet rays, when they emerge so as to be effectual

Concavity of the Sky

Plate CCCLXXXIII. fig. 11.

effectual after one reflection, make a less angle with the incident rays than the red ones; consequently the violet rays make a less angle with the lines OP than the red ones. But, in the primary rainbow, the rays are only once reflected, and the angle which the effectual rays make with OP is the distance of the coloured drop from P the centre of the bow. Therefore the violet drops, or violet arc, in the primary bow, will be nearer to the centre of the bow than the red drops or red arc; that is, the innermost colour in the primary bow will be violet, and the outermost colour will be red. And, for the same reason, through the whole primary bow, every colour will be nearer the centre P, as the rays of that colour are more refrangible.

But the violet rays, when they emerge so as to be effectual after two reflections, make a greater angle with the incident rays than the red ones; consequently the violet rays will make a greater angle with the line OP, than the red ones. But in the secondary rainbow the rays are twice reflected, and the angle which the effectual rays make with OP is the distance of the coloured drop from P the centre of the bow. Therefore the violet drops or violet arc in the secondary bow will be farther from the centre of the bow, than the red drops or red arc; that is, the outermost colour in the secondary bow will be violet, and the innermost colour will be red. And, for the same reason, through the whole secondary bow, every colour will be farther from the centre P, as the rays of that colour are more refrangible.

Sect. II. *Of Coronas, Parhelia, &c.*

Under the articles Corona and Parhelion, a pretty full account is given of the different hypotheses concerning these phenomena, and likewise of the method by which these hypotheses are supported, from the known laws of refraction and reflection. See also the article Chromatics in the Supplement.

Sect. III. *Of the Concave Figure of the Sky.*

220 Extent of the visible horizon on a plane surface.

The apparent concavity of the sky is only an optical deception founded on the incapacity of our organs of vision to take in very large distances. Dr Smith has demonstrated, that, if the surface of the earth were perfectly plane, the distance of the visible horizon from the eye would scarcely exceed the distance of 5000 times the height of the eye above the ground: beyond this distance, all objects would appear in the visible horizon. For, let OP be the height of the eye above the line PA drawn upon the ground; and if an object AB=PO, be removed to a distance PA equal to 5000 times that height, it will hardly be visible by reason of the smallness of the angle AOB. Consequently any distance AC, however great, beyond A, will be invisible. For since AC and BO are parallel, the ray CO will always cut AB in some point D between A and B; and therefore the angle AOC, or AOD, will always be less than AOB, and therefore AD or AC will be invisible. Consequently all objects and clouds, as CE and FG, placed at all distances beyond A, if they be high enough to be visible, or to subtend a bigger angle at the eye than AOB, will appear at the horizon AB; because the distance AC is invisible.

Plate CCCLXXXIV. fig. 8.

221 Why a long row of objects appears circular. Fig. 9.

Hence, if we suppose a long row of objects, or a long wall ABZY, built upon this plane, and its perpendicular distance OA from the eye at O to be equal to or greater than the distance O *a* of the visible horizon, it will not appear straight, but circular, as if it were built upon the circumference of the horizon *a c e g y*: and if the wall be continued to an immense distance, its extreme parts YZ will appear in the horizon at *y z*, where it is cut by a line O *y* parallel to the wall. For, supposing a ray YO, the angle YO *y* will become insensibly small. Imagine this infinite plane OAY *y*, with the wall upon it, to be turned about the horizontal line O like the lid of a box, till it becomes perpendicular to the other half of the horizontal plane LM *y*, and the wall parallel to it, like a vast ceiling overhead; and then the wall will appear like the concave figure of the clouds overhead. But though the wall in the horizon appear in the figure of a semicircle, yet the ceiling will not, but much flatter. Because the horizontal plane was a visible surface, which suggested the idea of the same distances quite round the eye: but in the vertical plane extended between the eye and the ceiling, there is nothing that affects the sense with an idea of its parts but the common line O *y*; consequently the apparent distances of the higher parts of the ceiling will be gradually diminished in ascending from that line. Now when the sky is overcast with clouds of equal gravities, they will all float in the air at equal heights above the earth, and consequently will compose a surface resembling a large ceiling, as flat as the visible surface of the earth. Its concavity therefore is only apparent: and when the heights of the clouds are unequal, since their real shapes and magnitudes are all unknown, the eye can seldom distinguish the unequal distances of those clouds that appear in the same directions, unless when they are very near us, or are driven by contrary currents of the air. So that the visible shape of the whole surface remains alike in both cases. And when the sky is either partly overcast or partly free from clouds, it is matter of fact that we retain much the same idea of its concavity as when it was quite overcast.

222 Why the concavity of the sky appears less than a hemisphere.

The concavity of the heavens appears to the eye, which is the only judge of an apparent figure, to be a less portion of a spherical surface than a hemisphere. Dr Smith says, that the centre of the concavity is much below the eye: and by taking a medium among several observations he found the apparent distance of its parts at the horizon to be generally between three and four times greater than the apparent distance of its parts overhead. For let the arch ABCD represent the apparent concavity of the sky, O the place of the eye, OA and OC the horizontal and vertical apparent distances, whose proportion is required. First observe when the sun or the moon, or any cloud or star, is in such a situation at B, that the apparent arches BA, BC, extended on each side of this object towards the horizon and zenith, seem equal to the eye; then taking the altitude of the object B with a quadrant, or a cross staff, or finding it by astronomy from the given time of observation, the angle AOB is known. Drawing therefore the line OB in the position thus determined, and taking in it any point B, in the vertical line CO produced downwards, find the centre E of a circle ABC, whose arches BA, BC, intercepted between B and the legs of the right angle AOC, shall be equal to each other; then will this arch ABCD represent

Fig. 10.

Blue colour of the Sky. present the apparent figure of the sky. For by the eye we estimate the distance between any two objects in the heavens by the quantity of sky that appears to lie between them; as upon earth we estimate it by the quantity of ground that lies between them. The centre E may be found geometrically by constructing a cubic equation, or as quickly and sufficiently exact by trying whether the chords BA, BC, of the arch ABC drawn by conjecture are equal, and by altering its radius BE till they are so. Now in making several observations upon the sun, and some others upon the moon and stars, they seemed to our author to bisect the vertical arch ABC at B, when their apparent altitudes or the angle AOB was about 23 degrees; which gives the proportion of OC to OA as 3 to 10 or as 1 to $3\frac{1}{3}$ nearly. When the altitude of the sun was 30°, the upper arch seemed always less than the under one; and, in our author's opinion, always greater when the sun was about 18 or 20 degrees high.

Sect. IV. *Of the Blue Colour of the Sky, and of Blue and Green Shadows.*

223 Opinions of the ancients respecting the colour of the sky. The opinions of ancient writers concerning the colour of the sky merit no notice. The first who gave any rational explanation was Fromondus. He supposed that the blueness of the sky proceeded from a mixture of the white light of the sun with the black space beyond the atmosphere, where there is neither refraction nor reflection. This opinion very generally prevailed, and was maintained by Otto Guerick and all his contemporaries, who asserted, that white and black may be mixed in such a manner as to make a blue. M. Bouguer had recourse to the vapours diffused through the atmosphere, to account for the reflection of the blue rays rather than any other. He seems, however, to suppose, that it arises from the constitution of the air itself, from which the fainter-coloured rays are incapable of making their way through any considerable tract of it. Hence he is of opinion, that the colour of the air is properly blue; to which opinion Dr Smith seems also to have inclined.

To this blue colour of the sky is owing the appearance of blue and green shadows in the morning and evening.—

224 Green shadows observed by M. Buffon. These were first observed by M. Buffon in 1742, when he noticed that the shadows of trees which fell upon a white wall were green. He was at that time standing upon an eminence, and the sun was setting in the cleft of a mountain, so that he appeared considerably lower than the horizon. The sky was clear, excepting in the west, which, through free from clouds, was lightly shaded with vapours, of a yellow colour, inclining to red. Then the sun itself was exceedingly red, and was apparently at least four times as large as he appears to be at mid-day. In these circumstances he saw very distinctly the shadows of the trees, which were 30 or 40 feet from the white wall, coloured with a light green inclining to blue. The shadow of an arbour, which was three feet from the wall, was exactly drawn upon it, and looked as if it had been newly painted with verdigrise. This appearance lasted near five minutes; after which it grew fainter, and vanished at the same time with the light of the sun.

225 Blue shadows observed by him. The next morning at sunrise, he went to observe other shadows, upon another white wall; but instead of finding them green as before, he observed that they were of the colour of lively indigo. The sky was serene, except a slight covering of yellowish vapours in the east; and the sun rose behind a hill, so that it was elevated above his horizon. In these circumstances, the blue shadows were only visible three minutes; after which they appeared black, and in the evening of the same day he observed the green shadows exactly as before. On another day at sunset he observed that the shadows were not green, but of a beautiful sky-blue. He also observed that the sky was in a great measure free from vapours at that time, and that the sun set behind a rock, so that it disappeared before it came to his horizon. Afterwards, he often observed the shadows both at sunrise and sunset; but always perceived them to be blue, though with a great variety of shades.

226 Explanation of these phenomena attempted by Abbé Mazeas. The first person who attempted to explain this phenomenon was the Abbé Mazeas. He observed that when an opaque body was illuminated by the moon and a candle at the same time, and the two shadows were cast upon the same white wall, that which was enlightened by the candle was reddish, and that which was enlightened by the moon was blue. He supposed, however, the change of colour to be occasioned by the diminution of the light;

227 Melville's and Bouguer's explanation. but M. Melville and M. Bouguer, both independent of one another, seem to have hit upon the true cause of this curious appearance, and which has been already hinted at. The former of these gentlemen, in his attempts to explain the blue colour of the sky, observes, that since it is certain that no body assumes any particular colour, but because it reflects one sort of rays more abundantly than the rest; and since it cannot be supposed that the constituent parts of pure air are gross enough to separate any colours of themselves; we must conclude with Sir Isaac Newton, that the violet and blue making rays are reflected more copiously than the rest, by the finer vapours diffused through the atmosphere, whose parts are not big enough to give them the appearance of visible opaque clouds. And he shows that in proper circumstances, the bluish colour of the sky light may be actually seen on bodies illuminated by it, as, he says, it is objected should always happen upon this hypothesis. For that if, on a cloudless day, a sheet of white paper be exposed to the sun's beams, when any opaque body is placed upon it, the shadow which is illuminated by the sky only will appear remarkably bluish compared with the rest of the paper, which receives the sun's direct rays.

M. Bouguer, who has taken the most pains with this subject, observes, that as M. Buffon mentions the shadows appearing green only twice, and that at all other times they were blue, this is the colour which they regularly have, and that the blue was changed into green by some accidental circumstance. Green, he says, is only a composition of blue and yellow, so that this accidental change may have arisen from the mixture of some yellow rays in the blue shadow; and that perhaps the walls might have had that tinge, so that the blue is the only colour for which a general reason is required. This, he says, must be derived from the colour of pure air, which always appears blue, and which always reflects that colour upon all objects without distinction; but which is too faint to be perceived when our eyes are strongly affected by the light of the sun, reflected from other objects around us.

To

Blue colour of the Sky.

To confirm this hypothesis, he adds some interesting observations of his own, in which this appearance is agreeably diversified. Being at the village of Boucholtz in July 1764, he observed the shadows projected on the white paper of his pocket-book when the sky was clear.

228 Curious observations on this subject.

At half an hour past six in the evening, when the sun was about 4° high, he observed that the shadow of his finger was of a dark gray, while he held the paper opposite to the sun; but when he inclined it almost horizontally, the paper had a bluish cast, and the shadow upon it was of a beautiful bright blue.

When his eye was placed between the sun and the paper laid horizontally, it always appeared of a bluish cast; but when he held the paper thus inclined between his eye and the sun, he could distinguish, upon every little eminence occasioned by the inequality of the surface of the paper, the chief prismatic colours. This multitude of coloured points, red, yellow, green, and blue, almost effaced the natural colour of the objects.

At $6^{h}\ 45'$ the shadows began to be blue, even when the rays of the sun fell perpendicularly. The colour was the most lively when the rays fell upon it at an angle of 45°; but with a less inclination of the paper, he could distinctly perceive, that the blue shadow had a border of a stronger blue on that side which looked towards the sky, and a red border on that side which was turned towards the earth. To see these borders, it was necessary to place the body that made the shadow very near the paper; and the nearer it was, the more sensible was the red border. At the distance of three inches, the whole shadow was blue. At every observation, after having held the paper towards the sky, he turned it towards the earth, which was covered with verdure; holding it in such a manner, that the sun might shine upon it while it received the shadows of various bodies; but in this position he could never perceive the shadow to be blue or green at any inclination with respect to the sun's rays.

At seven o'clock, the altitude of the sun being still about two degrees, the shadows were of a bright blue, even when the rays fell perpendicularly upon the paper, but were brightest when it was inclined 45°. At this time he was surprised to observe, that a large tract of sky was not favourable to the production of this blue colour, and that the shadow falling upon the paper placed horizontally was not coloured, or at least the blue was very faint. This singularity, he concluded, arose from the small difference between the light of that part of the paper which received the rays of the sun and that which was in the shade in this situation. In a situation precisely horizontal, the difference would vanish, and there could be no shadow. Thus too much or too little of the sun's light produced, but for different reasons, the same effect; for they both made the blue light reflected from the sky become insensible. This gentleman never saw any green shadows; but supposes that the cause of those seen by Buffon might be the mixture of yellow rays, reflected from the vapours, which he observes were of that colour.

229 Blue shadows not confined to the mornings and evenings.

These blue shadows, our author observes, are not confined to the times of the sunrising and sunsetting; on the 19th of July, when the sun has the greatest force, he observed them at three o'clock in the afternoon, but the sun at that time shone through a mist.

If the sky be clear the shadows begin to be blue, when, if they be projected horizontally, they are eight times as long as the height of the body that produces them, that is, when the altitude of the sun's centre is $7^{\circ}\ 8'$. This observation, he says, was made in the beginning of August.

Besides these coloured shadows, which are produced by the interception of the direct rays of the sun, our author observed others similar to them at every hour of the day, in rooms into which the light of the sun was reflected from some white body, if any part of the clear sky could be seen from the place, and all unnecessary light was excluded as much as possible. He remarks, that the blue shadows may be seen at any hour of the day, even with the direct light of the sun; and that this colour will disappear in all those places of the shadow from which the blue sky cannot be seen.

All the observations that our author made upon the yellow or reddish borders of shadows above mentioned, led him to conclude, that they were occasioned by the interception of the sky light, whereby part of the shadow was illuminated either by the red rays reflected from the clouds when the sun is near the horizon, or from some terrestrial bodies in the neighbourhood. This conjecture is favoured by the necessity he was under of placing any body near the paper, in order to produce this bordered shadow, as he says it is easily demonstrated, that the interception of the sky light can only take place when the breadth of the opaque body is to its distance from the white ground on which the shadow falls, as twice the line of half the amplitude of the sky to its cosine.

230 Another kind of shadows.

At the conclusion of his observations on these blue shadows, he gives a short account of another kind of them, which he supposes to have the same origin. These he often saw early in the spring when reading by the light of a candle in the morning, and consequently with the twilight mixed with that of his candle. In these circumstances, the shadow made by intercepting the light of his candle, at the distance of about six feet, was of a beautiful and clear blue, which became deeper as the opaque body which made the shadow was brought nearer to the wall, and was exceedingly deep at the distance of a few inches only. But where the day light did not come, the shadows were all black without the least mixture of blue.

231 New explanation of the colour of the sky.

The explanations of the blue colour of the sky given by Newton and Bouguer are far from satisfactory, and we presume that the following method of accounting for that phenomenon affords the true explanation. The light which flows from any portion of the blue sky is obviously reflected light, which is thrown out into the atmosphere in all directions by the earth, and the clouds and vapours which surround it. The red or least refrangible rays of this light having a greater momentum than the blue or most refrangible rays, penetrate much farther into the atmosphere, and though a few may be reflected, yet almost all of them will be absorbed or lost before they can return to the earth's surface. On the contrary, the blue rays, having less momentum, are not capable of penetrating so far into a resisting medium, and are therefore reflected to the earth's surface, and give a blue colour to the expanse of the heavens. The blue colour of the sky is exactly the converse of the red colour which is perceived at great depths in the sea, and of the red hue of the morning and evening clouds. These phenomena

Irradiations of the Sun's Light, &c. phenomena being produced by transmitted or refracted light; the red rays make their way through the medium to the observer's eye, while the blue ones are reflected or absorbed.

Sect. V. *Of the Irradiations of the Sun's Light appearing through the interstices of the Clouds.*

This is an appearance which every one must have observed when the sky was pretty much overcast, and the clouds have many breaks or openings. At that time several large beams of light, something like the appearance of the light of the sun admitted into a smoky room, will be seen generally with a very considerable degree of divergency, as if the radiant point was situated at no great distance above the clouds. Dr Smith observes that this appearance is one of those which serve to demonstrate that very high and remote objects in the heavens do not appear to us in their real shapes and positions, but according to their perspective projections in the apparent concavity of the sky. He acquaints us, that though these beams are generally seen diverging, as represented in fig. 11. it is not always the case. He himself, in particular, once saw them converging towards a point diametrically opposite to the sun: for, as near as he could conjecture, the point to which they converged was situated as much below the horizon as the sun was then elevated above the opposite part of it. This part is represented by the line t D t, and the point below it in opposition to the sun is E; towards which all the beams $v\,t$, $v\,t$, &c. appeared to converge.

Plate CCLXXXIV. fig. 11.

232 Converging irradiations observed by Dr Smith. Fig. 21.

233 The phenomenon explained by him.

Perceiving that the point of convergency was opposite to the sun, he suspected that this unusual phenomenon was but a case of the usual *apparent divergence* of the beams of the sun from his apparent place among the clouds, as represented in fig. 11.; for though nothing is more common than for rays to diverge from a luminous body, yet the divergence of these beams in such large angles is not real, but apparent. Because it is impossible for the direct rays of the sun to cross one another at any point of the apparent concavity of the sky, in a greater angle than about half a degree. For the diameter of the earth being so very small, in comparison to the distance of the sun, as to subtend an angle at any point of his body of about 20 seconds; and the diameter of our visible horizon being extremely smaller than that of the earth; it is evident, that all the rays which fall upon the horizon from any given point of the sun, must be inclined to each other in the smallest angles imaginable: the greatest of them being as much smaller than that angle of 20″ as the diameter of the visible horizon is smaller than that of the earth. All the rays that come to us from any given point of the sun may therefore be considered as parallel; as the rays e B g from the point e, or f B h from the opposite point f; and consequently the rays of these two pencils that come from opposite points of the sun's real diameter, and cross each other in the sun's apparent place B among the clouds, can form no greater an angle with each other than about half a degree; this angle of their intersection e B f being the same as the sun would subtend to an eye placed among the clouds at B, or (which is much the same) to an eye at O upon the ground. Because the sun's real distance OS is inconceivably greater than his apparent distance OB. Therefore the rays of the sun, as B g, B h, do really diverge from his apparent place B in no greater angles g B h than about half a degree. Nevertheless they appear to diverge from the place B in all possible angles, and even in opposite directions. Let us proceed then to an explanation of this apparent divergence, which is by no means self-evident; though at first sight we are apt to think it is, by not distinguishing the vast difference between the true and apparent distances of the sun.

Fig. 13.

Supposing all the rays of the sun to fall accurately parallel to each other upon the visible horizon, as they do very nearly, yet in both cases they must appear to diverge in all possible angles. Let us imagine the heavens to be partly overcast with a spacious stratum of broken clouds, v, v, v, &c. parallel to the plane of the visible horizon, represented by the line AOD; and when the sun's rays fall upon these clouds in the parallel lines $s\,v$, $s\,v$, &c. let some of them pass through their interstices in the lines $v\,t$, $v\,t$, &c. and fall upon the plane of the horizon at the places t, t, &c. And since the rest of the incident rays $s\,v$, $s\,v$, are supposed to be intercepted from the place of the spectator at O by the cloud x, and from the intervals between the transmitted rays $v\,t$, $v\,t$, &c. by the clouds v, v, &c. a small part of these latter rays $v\,t$, $v\,t$, when reflected every way from some certain kind of thin vapours floating in the air, may undoubtedly be sufficient to affect the eye with an appearance of lights and shades, in the form of bright beams in the places $v\,t$, $v\,t$, &c. and of dark ones in the intervals between them; just as similar beams of light and shade appear in a room by reflections of the sun's rays from smoke or dust flying within it; the lights and shades being here occasioned by the transmission of the rays through some parts of the window, and by their interruption at other parts.

Fig. 14.

Now, if the apparent concavity of this stratum of clouds v, v, to the eye at O, be represented by the arch ABCD, and be cut in the point B by the line OBx parallel to the beams $t\,v$; it will be evident by the rules of perspective, that these long beams will not appear in their real places, but upon the concave AB CD diverging every way from the place B, where the sun himself appears, or the cloud x that covers his body, as represented separately in full view in fig. 11. Fig. 11.

And for the same reason, if the line BO be produced towards E, below the plane of the horizon AOD, and the eye be directed towards the region of the sky directly above E, the lower ends of the same real beams $v\,t$, $v\,t$, will now appear upon the part DF of this concave; and will seem to converge towards the point E, situated just as much below the horizon as the opposite point B is above it: which is separately represented in full view in fig. 12. Fig. 12.

For if the beams $v\,t$, $v\,t$, be supposed to be visible throughout their whole lengths, and the eye be directed in a plane perpendicular to them, here represented by the line OF; they and their intervals will appear broadest in and about this plane, because these parts of them are nearest to the eye; and therefore their remoter parts and intervals will appear gradually narrower towards the opposite ends of the line BE. As a farther illustration of this subject, we may conceive the spectator at O to be situated upon the top of so large a descent OHI towards a remote valley IK, and the sun to be so very low, that the point E, opposite to him, may be seen above the horizon of this shady valley.

Irradiations of the Sun's Light, &c.

ley. In this case it is manifest, that the spectators at O would now see these beams converging so far as to meet each other at the point E in the sky itself.

234 Not observed by moon-light.

This phenomenon is not seen in moonlight, probably because her light is too weak after reflections from any kind of vapours, to cause a sensible appearance of lights and shades so as to form these beams. And in the phenomenon of fig. 12. the converging sunbeams towards the point below the horizon were not quite so bright and strong as those usually are that diverge from him; and the sky beyond them appeared very black (several showers having passed that way), which certainly contributed to this appearance. Hence it is probable that the thinness and weakness of the reflected rays from the vapours opposite the sun, is the chief cause that this appearance is so very uncommon in comparison to that of diverging beams. For as the region of the sky round about the sun is always brighter than the opposite one, so the light of the diverging beams ought also to be brighter than that of the converging ones. For, though rays are reflected from rough unpolished bodies in all directions, yet more of them are reflected forwards obliquely, than are reflected more directly backwards. Besides, in the present case, the incident rays upon the opposite region to the sun, are more diminished by continual reflections from a longer tract of the atmosphere, than the incident rays upon the region next the sun.

235 The phenomenon of diverging beams more frequent in summer than in winter.

The common phenomenon of diverging beams is more frequent in summer than in winter, and also when the sun is lower than when higher up; probably because the lower vapours are denser, and therefore more strongly reflective than the higher; because the lower sky light is not so bright as the upper; because the air is generally more quiet in the mornings and evenings than about noon-day; and lastly, because many sorts of vapours are more plentifully exhaled in summer than in winter, from many kinds of volatile vegetables; which vapours, when the air is cooled and condensed in the mornings and evenings, may become dense enough to reflect a sensible light.

Sect. VI. *Of the Illumination of the Earth's Shadow in Lunar Eclipses.*

The ancient philosophers, who knew nothing of the refractive power of the atmosphere, were much perplexed to account for the body of the moon being visible when totally eclipsed. At such times she generally appears of a dull red colour, like tarnished copper. This,

236 Why the moon is visible when totally eclipsed.

they thought, was the moon's native light, by which she became visible when hid from the brighter light of the sun. Plutarch, indeed, attributes this appearance to the light of the fixed stars reflected to us by the moon; but this is too weak to produce the effect. The true cause of it is the scattered beams of the sun bent into the earth's shadow by refractions through the atmosphere in the following manner.

Plate CCLXXXV. fig. 1.

Let the body of the sun be represented by the circle ab, and that of the earth by cd; and let the lines ace and bde touch them both, and meet in e beyond the earth; then the angular space ced will represent the conical figure of the earth's shadow, which would be totally dark, were none of them bent into it by the refraction of the atmosphere. The rays ah and bi, which touch its opposite sides, will proceed unrefracted, and meet each other at k. Then the two nearest rays

Illumination of the Shadow of the Earth.

to these that flow within them, from the same points a and b, being refracted inwards through the margin of the atmosphere, will cross each other at a point l, somewhat nearer to the earth than k; and in like manner, two opposite rays next within the two last will cross each other at a point m, somewhat nearer to the earth than l, having suffered greater refractions, by passing through longer and denser tracts of air lying somewhat nearer to the earth. The like approach of the successive intersections k, l, m, is to be understood of innumerable couples of rays, till you come to the intersection n of the two innermost; which we may suppose just to touch the earth at the points o and p. It is plain then, that the space bounded by these rays on, np, will be the only part of the earth's shadow wholly unenlightened. Let fmg be part of the moon's orbit when it is nearest the earth, at a time when the earth's dark shadow onp, is longest: in this case, the ratio of tm to tn is about 4 to 3; and consequently the moon, though centrally eclipsed at m, may yet be visible by means of the scattered rays, first transmitted to the moon by refraction through the atmosphere, and thence reflected to the earth.

Fig. 2.

For let the incident and emergent parts aq, rn, of the ray $aqorn$, that just touches the earth at o, be produced till they meet at u, and let aqu produced meet the axis st produced in x; and joining us and um, since the refractions of a horizontal ray passing from o to r, or from o to q, would be alike and equal, the external angle nux is double the quantity of the usual refraction of a horizontal ray; and the angle aus is the apparent measure of the sun's semidiameter seen from the earth; and the angle ust is that of the earth's semidiameter tu seen from the sun (called his *horizontal parallax*); and lastly, the angle umt is that of the earth's semidiameter seen from the moon (called her *horizontal parallax*); because the elevation of the point u above the earth is too small to make a sensible error in the quantity of these angles; whose measures by astronomical tables are as follow:

		′	″	
Sun's least app. semidiam.	$= aus =$	15	50	
Sun's horizontal parallax	$= ust =$	00	10	
Their difference * is	$= txu =$	15	40	* Eucl. I. Prop. xxxii.
Twice horizontal refraction	$= nux =$	67	30	
Their sum † is	$= tnu =$	83	10	† Ibid.
Moon's greatest horiz. parallax	$= tmu =$	62	10	

Therefore (by a preceding prop.) we have $tm : tn =$ (ang. tnu : ang. $tmu = 83'—10'' : 62'—10'' =$) $4 : 3$ in round numbers; which was to be proved. It is easy to collect from the moon's greatest horizontal parallax of $62'—10''$, that her least distance tm is about $55\frac{1}{7}$ semidiameters of the earth; and therefore the greatest length tn of the dark shadow, being three quarters of tm, is about $41\frac{1}{3}$ semidiameters.

The difference of the last-mentioned angles tnu, tmu is $mun = 21'$, that is, about two-thirds of $31'—40''$, the angle which the whole diameter of the sun subtends at u. Whence it follows, that the middle point m of the moon centrally eclipsed, is illuminated by rays which come from two-thirds of every diameter of the sun's disk, and pass by one side of the earth; and also by rays that come from the opposite two-thirds of

every

Illumination of the Shadow of the Earth.

every one of the said diameters, and pass by the other side of the earth. This will appear by conceiving the ray *a q o r n* to be inflexible, and its middle point *a* to slide upon the earth, while the part *r n* is approaching to touch the point *m*; for then the opposite part *q a* will trace over two thirds of the sun's diameter. The true proportion of the angles *n u m*, *a u s*, could not be preserved in the scheme, by reason of the sun's immense distance and magnitude with respect to the earth.

Fig. 3. Having drawn the line *a t α*, it may be observed, that all the incident rays, as *a q*, *α x*, flowing from any one point of the sun to the circumference of the earth, will be collected to a focus *α*, whose distance *t α* is less than *t m* in the ratio of 62 to 67 nearly; and thus an image of the sun will be formed at *α β*, whose rays will diverge upon the moon. For the angle *t α u* is the difference of the angles *x u α*, *u α t* found above; and $t\alpha : tm =$ ang. tmu : ang. $t\alpha u = 62'—10'' : 67—30''$.

The rays that flow next above *a q* and *α x*, by passing through a rarer part of the atmosphere, will be united at a point in the axis *a t α* farther from the earth than the last focus *α*; and the same may be said of the rays that pass next above these, and so on; whereby an infinite series of images of the sun will be formed, whose diameters and degrees of brightness will increase with their distances from the earth.

Hence it is manifest why the moon eclipsed in her perigee appears always duller and darker than in her apogee. The reason why her colour is always of the copper kind, between a dull red and orange, seems to be this: The blue colour of a clear sky shows that the blue rays are more copiously reflected from pure air than those of any other colour; consequently they are less copiously transmitted through it among the rest that come from the sun, and so much the less as the tract of air through which they pass is the longer. Hence the common colour of the sun and moon is whitest in the meridian, and grows gradually more inclined to diluted yellow, orange, and red, as they descend lower, that is, as the rays are transmitted through a longer tract of air; which tract being still lengthened in passing to the moon and back again, causes a still greater loss of the blue rays in proportion to the rest; and so the resulting colour of the transmitted rays must lie between a dark orange and red, according to Sir Isaac Newton's rule for finding the result of a mixture of colours. The circular edge of the shadow in a partial eclipse appears red; because the red-making rays are the least refracted of all others, and consequently are left alone in the conical surface of the shadow, all the rest being refracted into it.

237 Why the moon appears duller when eclipsed in her perigee than in her apogee.

Dr Herschel, who believes that the moon is phosphorescent, and that she shines by her native light, when totally eclipsed by the sun, has endeavoured to shew, by calculation, that the light refracted by the atmosphere cannot in some cases fall upon the moon.

PART III. ON THE CONSTRUCTION OF OPTICAL INSTRUMENTS.

Chap. I. *Description of Optical Instruments.*

OF the mechanism of optical instruments, particular accounts are given in this work under their respective names. These it would be improper to repeat; but as it belongs to the science of optics to explain, by the laws of refraction and reflection, the several phenomena which those instruments exhibit, we must here enumerate the instruments themselves, omitting entirely, or stating very briefly, such facts as are given at large in other places.

Sect. I. *The Multiplying Glass.*

Plate cclxxxvi. fig. 1.

238 Multiplying glass.

The multiplying glass is made by grinding down the convex side *h i k* of a plano-convex glass AB, into several flat surfaces, as *h b*, *b l d*, *d k*. An object C will not appear magnified when seen through this glass by the eye at H; but it will appear multiplied into as many different objects as the glass contains plane surfaces. For, since rays will flow from the object C to all parts of the glass, and each plane surface will refract these rays to the eye, the same object will appear to the eye in the direction of the rays which enter it through each surface. Thus, a ray *g i* H, falling perpendicularly on the middle surface, will go through the glass to the eye without suffering any refraction; and will therefore show the object in its true place at C: whilst a ray *a b* flowing from the same object, and falling obliquely on the plane surface *b h*, will be refracted in the direction *b e*, by passing through the glass; and, upon leaving it, will go on to the eye in the direction *e* H; which will make the same object C appear also at E, in the direction of the ray H *e*, produced in the right line H *e n*. And the ray *c d*, flowing from the object C, and falling obliquely on the plane surface *d k*, will in the same way be refracted to the eye at H; which will cause the same object to appear at D, in the direction H *f m*.—If the glass be turned round the line *g l* H, as an axis, the object C will keep its place, because the surface *b l d* is not removed; but all the other objects will seem to go round C, because the oblique planes, on which the rays *a b c d* fall, will turn round by the motion of the glass.

Sect. II. *Mirrors.*

It has been already observed, that there are three kinds of mirrors principally used in optical experiments (see Catoptrics, Sect. I.); the plane mirror, the spherical convex mirror, and the spherical concave mirror. Of these the plane mirror first claims our attention, as it is more common, and of greater antiquity, than the other two. We have shewn that the image reflected by this mirror appears as far behind the surface as the object is before it; that the image will appear of the same size and in the same position with the object; that every plane mirror will reflect an image of twice its own length and breadth; and that in certain circumstances it will reflect several images of the same object. These phenomena we shall now explain by the laws of reflection.

Plate cclxxxvii. fig. 2.

Let AB be an object placed before the reflecting surface *g h i* of the plane mirror CD; and let the eye be at *o*. Let A *h* be a ray of light flowing from the top A of the object, and falling upon the mirror at *h*, and *h m* be a perpendicular to the surface of the mirror at *h*; the ray A *h* will be reflected from the mirror to the eye at *o*, making an angle *m h o* equal to the angle

Optical Instruments.

A hm: then will the top of the image E appear to the eye in the direction of the reflected ray oh produced to E, where the right line ApE, from the top of the object, cuts the right line ohE, at E. Let Bi be a ray of light issuing from the foot of the object at B to the mirror at i; and ni a perpendicular to the mirror from the point i, where the ray Bi falls upon it; this ray will be reflected in the line io, making an angle nio equal to the angle Bin, with that perpendicular, and entering the eye at o; then will the foot F of the image appear in the direction of the reflected ray oi, produced to F, where the right line BF cuts the reflected ray produced to F. All the other rays that flow from the intermediate points of the object AB, and fall upon the mirror between h and i, will be reflected to the eye at o; and all the intermediate points of the image EF will appear to the eye in the direction of these reflected rays produced. But all the rays that proceed from the object and fall upon the mirror above h, will be reflected back above the eye at o; and all the rays that flow from the object, and fall upon the mirror below i, will be reflected back below the eye at o; so that none of the rays that fall above h, or below i, can be reflected to the eye at o; and the distance between h and i is equal to half the length of the object AB.

239
Size of a looking-glass in which a man may see his whole image.

Hence it appears, that if a man sees his whole image in a plane looking-glass, the part of the glass that reflects his image must be just half as long and half as broad as himself, let him stand at any distance from it whatever; and that his image must appear just as far behind the glass as he is before it. Thus, the man AB viewing himself in the plane mirror CD, which is just half as long as himself, sees his whole image as at EF, behind the glass, exactly equal to his own size. For a ray AC proceeding from his eye at A, and falling perpendicularly upon the surface of the glass at C, is reflected back to his eye, in the same line CA; and the eye of his image will appear at E, in the same line produced to E, beyond the glass. And a ray BD, flowing from his foot, and falling obliquely on the glass at D, will be reflected as obliquely on the other side of the perpendicular abD, in the direction DA; and the foot of his image will appear at F, in the direction of the reflected ray AD, produced to F, where it is cut by the right line BGF, drawn parallel to the right line ACE; just the same as if the glass were taken away, and the real man stood at F, equal in size to the man standing at B: For to his eye at A, the eye of the other man at E would be seen in the direction of the line ACE; and the foot of the man at F would be seen by the eye A, in the direction of the line ADF. (Fig. 3.)

If the glass be brought nearer the man AB, suppose to cb, he will see his image at CDG: for the reflected ray CA (being perpendicular to the glass) will show the eye of the image at C; and the incident ray Bb, being reflected in the line bA, will show the foot of his image at G; the angle of reflection abA being always equal to the angle of incidence Bba; and so of all the intermediate rays from A to B. Hence, if the man AB advances towards the glass CD, his image will approach towards it; and if he recedes from the glass, his image will also recede from it.

If the object be placed before a common looking-glass, and viewed obliquely, three, four, or more images of it, will appear behind the glass.

To explain this, let ABCD represent the glass; and let EF be the axis of a pencil of rays flowing from E, a point in an object situated there. The rays of this pencil will in part be reflected at F, suppose into the line FG. What remains will (after refraction at F, which we do not consider here) pass on to H; from whence (on account of the quicksilver which is spread over the second surface of the glass) they will be strongly reflected to K, where part of them will emerge and enter an eye at L. By this means one representation of the point E will be formed in the line LK produced, suppose in M: Again, Another pencil, whose axis is EN, first reflected at N, then at O, and afterwards at P, will form a second representation of the same point at Q: And, thirdly, Another pencil, whose axis is ER, after successive reflections at the several points R, S, H, T V, will exhibit a third representation of the same point at X; and so on *ad infinitum*. The same being true of each point in the object, the whole will be represented in the like manner; but the representations will be faint, in proportion to the number of reflections which the rays suffer, and the length of their progress within the glass. We may add to these another representation of the same object in the line LO produced, made by such of the rays as fall upon O, and are thence reflected to the eye at L. This experiment may be tried by placing a candle before the glass as at E, and viewing it obliquely, as from L.

Plate CCLXXXII. fig. 11.

240
Why three or four images of objects are seen in plane mirrors.

2. *Of Concave Mirrors.* The effects of these in magnifying and diminishing objects, have in general been already explained; but in order to understand the nature of reflecting telescopes, it will still be proper to subjoin the following particular description of the effects of concave mirrors.

Plate CCLXXXVII. fig. 4.

When parallel rays, as dfa, Cmb, ebc, fall upon a concave mirror AbB, they will be reflected back from that mirror, and meet in a point m, at half the distance of the surface of the mirror from C the centre of its concavity; for they will be reflected at as great an angle from a perpendicular to the surface of the mirror, as they fell upon it with regard to that perpendicular, but on the other side thereof. Thus, let C be the centre of concavity of the mirror AbB; and let the parallel rays dfa, Cmb, and elc, fall upon it at the points a, b, and c. Draw the lines Cia, Cmb, and Chc, from the centre C to these points; and all these lines will be perpendicular to the surface of the mirror. Make the angle Cah=daC, and draw the line amh, which will be the direction of the ray dfa, after it is reflected from the point a of the mirror; so that the angle of incidence daC=Cah, the angle of reflection; the rays making equal angles with the perpendicular Cia on its opposite sides.

Draw also the perpendicular Chc to the point c, where the ray elc touches the mirror; and having made the angle Cci=Cce, draw the line cmi, which will be the course of the ray elc, after it is reflected from the mirror. The ray Cmb passing through the centre of concavity of the mirror, and falling upon it at b, is perpendicular to it; and is therefore reflected back from it in the same line bmC. All these reflected rays meet in the point m; and in that point the image of the body which emits the parallel rays da, Cb, and ec, will be formed; which point is distant from the mirror equal to half the radius bmC of its concavity.

As

As the rays which proceed from any celestial object may be esteemed parallel, the image of that object will be formed at *m*, when the reflecting surface of the concave mirror is turned directly to the object. Hence the focus *m* of parallel rays is not in the centre of the mirror's concavity, but half way between the mirror and that centre.

The rays which proceed from any remote terrestrial object are not strictly parallel, but come diverging to it, in separate pencils, from each point of the side of the object next the mirror; and therefore they will not be converged to a point at the distance of half the radius of the mirror's concavity from it's reflecting surface, but into separate points at a little greater distance from the mirror. The nearer the object is to the mirror, the farther these points will be from it: and an inverted image of the object will be formed in them, which will seem to hang in the air, and will be seen by an eye placed beyond it (with regard to the mirror) in all respects similar to the object, and as distinct as the object itself.

241 Aerial images formed by concave mirrors. Fig. 5.

Let A *c* B be the reflecting surface of a mirror, whose centre of concavity is at C; and let the upright object DE be placed beyond the centre C, and send out a conical pencil of diverging rays from its upper extremity D, to every point of the concave surface of the mirror A *c* B. But to avoid confusion, we only draw three rays of that pencil, as D A, D *c*, D B.

From the centre of concavity C, draw the three right lines C A, C *c*, CB, touching the mirror in the same points where the three rays touch it; and all these lines will be perpendicular to the surface of the mirror. Make CA *d*=DAC, and draw the right line A *d* for the course of the reflected ray DA: make C *c d*=D *c* C, and draw the right line *c d* for the course of the reflected ray D *d*: make also CB *d*=DBC, and draw the right line B *d* for the course of the reflected ray DB. All these reflected rays will meet in the point *d*, where they will form the extremity *d* of the inverted image *e d* similar to the extremity D of the upright object DE.

If the pencil of rays E *f*, E *g*, E *h*, be also continued to the mirror, and their angles of reflection from it be made equal to their angles of incidence upon it, as in the former pencil from D, they will all meet at the point *e* by reflection, and form the extremity *e* of the image *e d*, similar to the extremity E of the object DE. And as each intermediate point of the object, between D and E, sends out a pencil of rays in like manner to every part of the mirror, the rays of each pencil will be reflected back from it, and meet in all the intermediate points between the extremities *e* and *d* of the image; and so the whole image will be formed in an inverted position not at *i*, half the distance of the mirror from its centre of concavity C, but at a greater distance between *i* and the object DE.

This being well understood, the reader will easily understand how the image is formed by the large concave mirror of the reflecting telescope, when he comes to the description of that instrument.

When the object is more remote from the mirror than its centre of concavity C, the image will be less than the object, and between the object and mirror: when the object is nearer than the centre of concavity, the image will be more remote and bigger than the object. Thus, if ED be the object, *d e* will be its image: For as the object recedes from the mirror, the image approaches nearer to it; and as the object approaches nearer to the mirror, the image recedes farther from it; on account of the lesser or greater divergency of the pencil of rays which proceed from the object: for the less they diverge, the sooner they are converged to points by reflection; and the more they diverge, the farther they proceed before they meet.

If the radius of the mirror's concavity, and the distance of the object after refraction, be known, the distance of the image from the mirror is found by this rule: Divide the product of the distance and radius by double the distance made less by the radius, and the quotient is the distance required.

If the object be in the centre of the mirror's concavity, the image and object will be coincident, and equal in bulk.

If a man place himself directly before a large concave mirror, but farther from it than its centre of concavity, he will see an inverted image of himself in the air, between him and the mirror, and of a less size than himself. If he holds out his hand towards the mirror, the hand of the image will come out towards his hand, and coincide with it, of an equal bulk, when his hand is in the centre of concavity; and he will imagine he may shake hands with his image. If he reaches his hand farther, the hand of the image will pass by his hand, and come between his hand and his body: and if he moves his hand towards either side, the hand of the image will move towards the other; so that whatever way the object moves, the image will move the contrary. All the while a bystander will see nothing of the image, because none of the reflected rays that form it enter his eyes.

Sect. III. *Camera Obscura*.

The camera obscura having already been fully described under the word Dioptrics, we shall at present only direct the readers attention to an improvement which has lately been made upon this amusing instrument.

" The improvements (says Dr Brewster) which have been made upon the camera obscura since its first invention, regard chiefly its external form; and no attempts have been made to increase the brilliancy and distinctness of the image. When we compare the picture of external objects, which is formed in a dark chamber by the object-glass of a common refracting telescope, with that which is formed with an achromatic object-glass, we shall find the difference between their distinctness much less than we should have at first expected. Although the achromatic lens form an image of the minutest parts of the landscape, yet when this image is received on paper, these minute parts are obliterated by the small hairs and asperities on its surface, and the effect of the picture is very much impaired. In the Royal Observatory at Greenwich the image is received upon a large concave piece of stucco; but this substance does not seem to be more favourable for the reception of images than a paper ground. In order to obviate these imperfections, I tried a number of white substances of different degrees of smoothness, and several metallic surfaces with different degrees of polish, but did not succeed in finding any surface superior to paper. I happened, however, to receive the image on the silvered back of a looking-glass, and was surprised at the brilliancy and distinctness with which external objects were represented. The little spherical protuberances, however,

ever, which arise from the roughness of the tinfoil, have a tendency to detract from the precision of the image, and certainly injure it considerably when examined narrowly with the eye. In order to remove these small eminences, I ground the surface carefully with a bed of hones which I had used for working the plane specula of Newtonian telescopes. By this operation, which is exceedingly delicate, and may be performed without injuring the mirror, I obtained a surface finely adapted for the reception of images. The minute parts of the landscape, when received on this substance, are formed with so much precision, and the brilliance of the colouring is so uncommonly fine, as to equal, if not surpass the images formed in the air by means of concave specula. Notwithstanding the bluish colour of the metallic ground, white objects are represented in their true colour, and the verdure of the foliage is so rich and vivid, that the image seems to surpass in beauty even the object itself. On account of the metallic lustre of the surface, the distinctness of the image will always be greatest when the eye of the observer is placed in the direction of the inflected rays.

"The common portable camera obscura, which has already been described (see DIOPTRICS), is necessarily on a small scale, and has many disadvantages. These disadvantages are completely remedied in the camera obscura, invented by the Rev. Mr Thomson of Duddingston, which is represented in figures 1. and 2. of Plate CCCLXXXIX. In fig. 1. A is a metallic or wooden ring, in which the four wooden bars AF, AI, AG, AH, move by means of joints at A, and are kept asunder by the cross pieces BC, DE, which move round B and D as centres, and fold up along BA and DA, when the instrument is not used. The surface FIGH, on which the image is received, consists of a piece of silk covered with paper. It is made to roll up at IH, which moves in a joint at I, so that the whole surface FIHG, when winded upon IH, can be folded upon the bar IA. By this means the instrument, which is covered with green silk covered with a black substance, may be put together and carried as an umbrella. It is shewn more fully in fig. 2. where A is the aperture for placing the lens, and BC a semicircular opening for viewing the image. A black veil may be fixed to the circumference of BC, and thrown over the head of the observer to prevent the admission of any extraneous light."

Plate CCCLXXXIX. figs. 1, 2.

SECT. IV. *Microscopes.*

Under the article MICROSCOPE a full account has been given of the external construction of those instruments as they are now made by the most eminent artists.

It did not fall within the plan of that article to explain the way in which an enlarged picture of the object is formed upon the retina by means of the microscope, and the means of ascertaining its magnifying power; but we shall now direct the readers attention to this interesting subject.

1. *The Single Microscope*, the simplest of all microscopes is nothing more than a small globule of glass, or a convex lens whose focal distance is extremely short. The magnifying power of this microscope is thus ascertained by Dr Smith, "A minute object $p\,q$, seen distinctly through a small glass AE by the eye put close to it, appears so much greater than it would to the naked eye, placed at the least distance q L from whence it appears sufficiently distinct, as this latter distance q L is greater than the former q E. For having put your eye close to the glass EA, in order to see as much of the object as possible at one view, remove the object $p\,q$ to and fro till it appear more distinctly, suppose at the distance E q. Then conceiving the glass AE to be removed, and a thin plate, with a pin-hole in it, to be put in its place, the object will appear distinct and as large as before, when seen through the glass, only not so bright. And in this latter case it appears so much greater than it does to the naked eye at the distance q L, either with a pin-hole or without it, as the angle p E q is greater than the angle p L q, or as the latter distance q L is greater than the former q E. Since the interposition of the glass has no other effect than to render the appearance distinct, by helping the eye to increase the refraction of the rays in each pencil, it is plain that the greater apparent magnitude is entirely owing to a nearer view than could be taken by the naked eye. As the human eye is so constructed, as, for reasons already assigned, to have distinct vision only when the rays which fall upon it are parallel or nearly so; it follows that if the eye be so perfect as to see distinctly by pencils of parallel rays falling upon it, the distance E q, of the object from the glass, is then the focal distance of the glass. Now, if the glass be a small round globule, of about $\frac{1}{15}$th of an inch diameter, its focal distance E q, being three quarters of its diameter, is $\frac{1}{20}$th of an inch; and if q L be eight inches, the distance at which we usually view minute objects, this globule will magnify in the proportion of 8 to $\frac{1}{20}$, or of 160 to 1.

Plate CCCLXXXIX. figs. 6, 7.

Mr Gray's *Water Microscope* is represented in Plate CCCLXXXIX. fig. 4. The drop of water taken up on the point of a pin is introduced into the small hole D, $\frac{1}{10}$ of an inch in diameter, in the piece of brass DE, about $\frac{1}{10}$ of an inch thick. The hole D is in the middle of a spherical cavity, about $\frac{1}{8}$ of an inch in diameter, and a little deeper than half the thickness of the brass; on the opposite side of the brass is another spherical cavity, half as broad as the former, and so deep as to reduce the circumference of the small hole to a sharp edge. The water being placed in these cavties, will form a double convex lens with unequal convexities. The object, if it is solid, is fixed upon the point C of the supporter AB, and placed at its proper distance from the water lens by the screw FG. When the object is fluid, it is placed in the hole A, but in such a manner as not to be spherical; and this hole is brought opposite the fluid lens by moving the extremity G of the screw into the slit GH.

2. *The Double or Compound Microscope*, consists of an object-glass $c\,d$, and an eye-glass $e\,f$. The small object $a\,b$ is placed at a little greater distance from the glass $c\,d$ than its principal focus; so that the pencils of rays flowing from the different points of the object, and passing through the glass, may be made to converge, and unite in as many points between g and h, where the image of the object will be formed; which image is viewed by the eye through the eye-glass $e\,f$. For the eye-glass being so placed, that the image $g\,h$ may be in its focus, and the eye much about the same distance on the other side, the rays of each pencil will be parallel after going out of the eye-glass, as at e and f, till they come to the eye at k, where they will begin to converge by the refractive power of the humours; and after Fig. 8.

ter having crossed each other in the pupil, they will be collected into points on the retina, and form upon it the large inverted image AB.

242 Use of several lenses in a compound microscope.

By this combination of lenses, the aberration of the light from the figure of the glass, which in a globule of the kind above mentioned is very considerable, is in some measure corrected. This appeared so sensibly to be the case, even to former opticians, that they very soon began to make the addition of another lens. For, says Mr Martin, it is not only evident from the theory of this aberration, that the image of any point is rendered less confused by refraction through two lenses than by an equal refraction through one; but it also follows, from the same principle, that the same point has its image still less confused when formed by rays refracted through three lenses than by an equal refraction through two; and therefore a third lens added to the other will contribute to make the image more distinct, and consequently the instrument more complete. At the same time the field of view is amplified, and the use of the microscope rendered more agreeable, by the addition of the other lens. Thus also we may allow a somewhat larger aperture to the object lens, and thus increase the brightness of objects, and greatly heighten the pleasure of viewing them. For the same reason, Mr Martin has proposed a four-glass microscope, which answers the purposes of magnifying and of distinct vision still more perfectly.

Fig. 9.

The magnifying power of double microscopes is easily understood, thus: The glass L next the object PQ is very small, and very much convex, and consequently its focal distance LF is very short; the distance LQ of the small object PQ is but a little greater than LF: Greater it must be, that the rays flowing from the object may converge after passing through the glass, and crossing one another, form an image of the object; and it must be but a little greater, that the image $p\,q$ may be at a great distance from the glass, and consequently may be much larger than the object itself. This picture $p\,q$ being viewed through a convex glass AE, whose focal distance is q E, appears distinct as in a telescope. Now the object appears magnified for two reasons; first, because, if we viewed its picture $p\,q$ with the naked eye, it would appear as much greater than the object, at the same distance, as it really is greater than the object, or as much as L q is greater than LQ; and secondly, because this picture appears magnified through the eye-glass as much as the least distance at which it can be seen distinctly with the naked eye, is greater than q E, the focal distance of the eye-glass. If this latter ratio be five to one, and the former ratio of L q to LQ be 20 to 1; then, upon both accounts, the object will appear 5 times 20, or 100 times greater than to the naked eye.

Fig. 10.

The section of a compound microscope with three lenses is represented in fig. 10. By the middle one GK the pencil of rays coming from the object-glass are refracted so as to tend to a focus at O; but being intercepted by the proper eye-glass DF, they are brought together at I, which is nearer to that lens than its proper focus at L; so that the angle DIF, under which the object now appears, is larger than DLF, under which it would have appeared without this additional glass; and consequently the object is more magnified in the same proportion. Dr Hooke informs us, that, in most of his observations, he made use of a double microscope with this broad middle glass when he wanted to see much of an object at one view, and taking it out when he would examine the small parts of an object more accurately; for the fewer refractions there are, the more bright and clear the object appears.

243 Magnifying power of compound microscopes with three lenses.

The following rule for finding the magnifying power of compound microscopes with three lenses, has been given by Dr Brewster in his Appendix to Ferguson's Lectures, vol. ii. p. 468. "Divide the difference between the distance of the two first lenses, or those next the object, and the focal distance of the second or amplifying glass, by the focal distance of the second glass, and the quotient will be a first number. Square the distance between the two first lenses, and divide it by the difference between that distance, and the focal distance of the second glass, and divide this quotient by the focal distance of the third glass, or that next the eye, and a second number will be obtained. Multiply together the *first* and *second* numbers, and the magnifying power of the object glass (as found by one of the following tables), and the product will be the magnifying power of the compound microscope."

244 The magnifying power of Dr Smith's microscope.

Having in the historical part of this article given a short account of the construction of Dr Smith's double reflecting microscope, it may not be improper in this place to point out the method of ascertaining its magnifying power. This we shall do from the author himself, because his symbols, being general, are applicable to such microscopes of all dimensions.

Fig. 11.

Between the centre E and principal focus T of a concave speculum ABC, whose axis is EQTC, place an object PQ; and let the rays flowing from it be reflected from the speculum AB towards an image $p\,q$; but before they unite in it, let them be received by a convex speculum $a\,b\,c$, and thence be reflected, through a hole BC in the vertex of the concave, to a second image $\pi\,\kappa$, to be viewed through an eye-glass l.

The object may be situated between the specula C, c; or, which is better, between the principal focus t and vertex c of the convex one, a small hole being made in its vertex for the incident rays to pass through.

In both cases we have TQ, TE, T q, continual proportionals in some given ratio, suppose of 1 to n; and also $t\,q$, $t\,c$, $t\,\kappa$, continual proportionals in some other given ratio, suppose of 1 to m. Then if d be the usual distance at which we view minute objects distinctly with the naked eye, and $\kappa\,l$ the focal distance of the least eye-glass, through which the object appears sufficiently bright and distinct, it will be magnified in the ratio of $m\,n\,d$ to $\kappa\,l$.

For the object PQ, and its first image $p\,q$, are terminated on one side by the common axis of the specula, and on the other by a line PEp, drawn through the centre E of the concave ABC. Likewise the images $p\,q$ and $\pi\,\kappa$ are terminated by the common axis and by the line $e\,p\,\pi$, drawn through the centre e of the convex $a\,b\,c$ (Euclid, v. 12.). Hence, by the similar triangles $\pi\,\kappa\,e$, $p\,q\,e$, and also $p\,q$ E, PQE, we have $\pi\kappa : p\,q = \kappa\,e : q\,e = m : 1$, and $p\,q : \text{PQ} = q\,\text{E} : \text{QE} = n : 1$; and consequently $\pi\kappa : \text{PQ} = m\,n : 1$ whence $\pi\kappa = m\,n \times \text{PQ}$. Now if $l\,\kappa$ be the focal distance of the eye-glass l, the points P, Q of the object, are seen through it by the rays of two pencils emerging parallel to the lines

$\kappa\,l\,\kappa\,l$

Optical Instruments.

$\pi l \varkappa l$ respectively; that is, PQ appears under an angle equal to $\pi l \varkappa$, which is as $\frac{\pi\varkappa}{\varkappa l}=\frac{mn\text{PQ}}{\varkappa l}$; and to the naked eye at the distance d from PQ, it appears under an angle PoQ which is as $\frac{\text{PQ}}{d}$, and therefore is magnified in the ratio of these angles, that is, of $m\,n\,d$ to $\varkappa\,l$.

COR Having the numbers m, n, d, to find an eye-glass which shall cause the microscope to magnify M times in diameter, take $\varkappa\,l=\frac{m\,n\,d}{\text{M}}$. For the apparent magnitude is to the true as $\text{M}:1=m\,n\,d:\varkappa\,l$.

245 An easy method of ascertaining the magnifying power of the most common microscopes.

We shall conclude this part of our subject with the following easy method of ascertaining the magnifying power of such microscopes as are most in use.

The apparent magnitude of any object, as must appear from what has been already said, is measured by the angle under which it is seen; and this angle is greater or smaller according as the object is nearer to or farther from the eye; and of consequence the less the distance at which it can be viewed, the larger it will appear. The naked eye is unable to distinguish any object brought exceedingly near it: but by looking through a convex lens at an object placed in its focus, however near the focus of that lens be, an object may be distinctly seen; and the smaller the lens is, the nearer will be its focus, and in the same proportion the greater will be its magnifying power. From these principles it is easy to find the reason why the first or greatest magnifiers are so extremely minute; and also to calculate the magnifying power of any convex lens employed in a single microscope: For as the focal distance of the lens is to the distance at which we see objects distinctly with the naked eye, so is 1 to the magnifying power. If the focal length of a convex lens, for instance, be one inch, and the distance at which we look at small objects eight inches, which is the common standard, an object may be seen through that lens at one inch distance from the eye, and will appear in its diameter eight times larger than it does to the naked eye; but as the object is magnified every way, in length as well as in breadth, we must square this diameter to know how much it really is enlarged; and we then find that its superficies is magnified 64 times.

246 Further observations on the magnifying power of microscopes.

Again, Suppose a convex lens whose focal distance is only one-tenth of an inch; as in eight inches, the common distance of distinct vision with the naked eye, there are 80 tenths, an object may be seen through this glass 80 times nearer than with the naked eye. It will, of consequence, appear 80 times longer, and as much broader, than it does to common sight; and is therefore magnified 6400 times. If a convex glass be so small that its focus is only $\frac{1}{20}$th of an inch distant, we find that eight inches contain 160 of these twentieth parts; and consequently the length and breadth of any object seen through such a lens will be magnified 160 times, and the whole surface 25,600 times. As it is easy to melt a drop or globule of a much smaller diameter than a lens can be ground, and as the focus of a globule is no farther off than one-fourth of its own diameter, it must therefore magnify to a prodigious degree. But this excessive magnifying power is much more than counterbalanced by its admitting so little light, want of distinctness, and showing such a small portion of the object to be examined; for which reason, these globules, though greatly valued some time ago, are now almost entirely rejected. According to Mr Folkes's description of the single microscopes of convex lenses which Leeuwenhoek left to the Royal Society, they were all exceedingly clear, and showed the object very bright and distinct; which Mr Folkes considered as owing to the great care this gentleman took in the choice of his glass, his exactness in giving it the true figure, and afterwards reserving only such for his use as upon trial he found to be most excellent. Their powers of magnifying are different, as different objects may require: and as on the one hand, being all ground glasses, none of them are so small, or consequently magnify to so great a degree, as some of the globules frequently used in other microscopes; yet the distinctness of these very much exceeds those which are commonly used.

In order to find the magnifying power of a single microscope, no more is necessary than to bring it to its true focus, the exact place of which will be known by an object's appearing perfectly distinct and sharp when placed there. Then, with a pair of small compasses, measure, as nearly as possible, the distance from the centre of the glass to the object which is viewed, and how many parts of an inch that distance is. When this is known, compute how many times those parts of an inch are contained in eight inches, and the result will give the number of times the diameter is magnified: squaring the diameter will give the superficies; and if the solid content is wanted, it will be shown by multiplying the superficies by the diameter.

The superficies of one side of an object only can be seen at one view; and to compute how much that is magnified, is most commonly sufficient: but sometimes it is satisfactory to know how many minute objects are contained in a larger; as suppose we desire to know how many animalcules are contained in the bulk of a grain of sand: and to answer this, the cube, as well as the surface, must be taken into the account. For the satisfaction of those who are not much versant in these subjects, we shall here subjoin the following tables taken from the Appendix to Ferguson's Lectures.

247 Tables of the magnifying power of microscopes.

The first column contains the focal length of the convex lens in hundredths of an inch. The second contains the number of times which such a lens will magnify the diameter of objects: The third shews the number of times that the surface is magnified; and the fourth the number of times that the cube of the object is magnified. A table of a similar kind, though upon a much smaller scale, has already been published; but the nearest distance at which the eye can see distinctly, is there supposed to be *eight* inches, which we are confident, from experience, is too large an estimate for the generality of eyes. Table I. is therefore computed upon the supposition that the distance alluded to is *seven* inches.

" When we consider however (says the editor of the work now quoted) that the eye examines very minute objects at a less distance than it does objects of a greater magnitude, we shall find that the magnifying power of lenses ought to be deduced from the *distance at which the eye examines objects really microscopic*. This circumstance has been overlooked by every writer on optics, and merits our attentive consideration. We have now before us two specimens of engraven characters

racters. The one is so large that it can be easily read at the distance of ten inches; and the other is so exceedingly minute that it cannot be read at a greater distance than five inches. Now we maintain that if these two kinds of engraving are seen through the *same microscope*, the one will be *twice* as much magnified as the other. This indeed is obvious; for as the magnifying power of a lens is equal to the distance at which the object is examined by the naked eye divided by the focal length of the lens, we shall have $\frac{5}{x}$ for the number of times which the minute engraving is magnified, and $\frac{10}{x}$ for the number of times that the large engraving is magnified, x being the focal length of the lens. It follows, therefore, that the number of times that any lens magnifies objects really microscopic should be determined, by making the distance at which they are examined by the naked eye about five inches.

Upon this principle we have computed TABLE II. which contains the magnifying power of convex lenses when employed to examine microscopic objects.

TABLE I.

A NEW TABLE of the magnifying power of small convex lenses or single microscopes, the distance at which the eye sees distinctly being seven inches.

Focal distance of the lens or microscope. Inches and parts of an inch.	100dths of an inch.	Number of times that the *diameter* of an object is magnified. Times. Dec. of a time. 	1	500.00	250000	125000000

The greatest magnifier in Mr Leeuwenhoek's cabinet of microscopes, presented to the Royal Society, has its focus nearly at one-twentieth of an inch distance from its centre; and consequently magnifies the diameter of an object 160 times, and the superficies 25,600. But the greatest magnifier in Mr Wilson's single microscopes, as they are now made, has usually a focal length only of the 50th part of an inch; whereby it has a power of enlarging the diameter of an object 400, and its superficies 160,000 times.

248 The magnifying power of the solar microscope calculated differently from that of others.

The magnifying power of the solar microscope must be calculated in a different manner; for here the distance of the screen or sheet on which the image of the object is cast, divided by the focal length of the lens, gives its magnifying power. Suppose, for instance, the lens made use of has its focus at half an inch, and the screen is placed at the distance of five feet, the object will then appear magnified 20 times, and the superficies 14,400 times; and, by putting the screen at a greater distance, you may magnify the object almost as much as you please: but the screen should be placed just at that distance where the object is seen most distinct and clear.

Optical Instruments. With regard to the double reflecting microscope, Mr Baker observes, that the power of the object-lens is indeed greatly increased by the addition of two eye-glasses; but as no object-lens can be used with them of so minute a diameter, or which magnifies of itself near so much as those that can be used alone, the glasses of this microscope, upon the whole, magnify little or nothing more than those of Mr Wilson's single one; the chief advantage arising from a combination of lenses being the sight of a larger portion of the object.

Sect. V. *Telescopes.*

I. The Refracting Telescope.

249 Of the astronomical telescope. 1. *The Astronomical Telescope.*—From what has been said concerning the compound microscope, the nature of the common astronomical telescope will easily be understood: for it differs from the microscope only in this, that the object is placed at so great a distance from it, that the rays of the same pencil flowing from the object, may be considered as falling parallel upon the object-glass; and therefore the image made by that lens is considered as coincident with its focus of parallel rays.

Plate ccclxxxvii. fig. 12. 1. This will appear very plain from fig. 4. in which AB is the object emitting the several pencils of rays A *c d*, B *c d*, &c. but supposed to be at so great a distance from the object-glass, *c d*, that the rays of the same pencil may be considered as parallel to each other; they are therefore supposed to be collected into their respective foci at the points *m* and *p*, situated at the focal distance of the object-glass *c d*. Here they form an image E, and crossing each other proceed diverging to the eye-glass *h g*; which being placed at its own focal distance from the points *m* and *p*, the rays of each pencil, after passing through that glass, will become parallel among themselves; but the pencils themselves will converge considerably with respect to one another, even so as to cross at *e*, very little farther from the glass *g h* than its focus; because, when they entered the glass, their axes were almost parallel, as coming through the object-glass at the point *k*, to whose distance the breadth of the eye-glass in a long telescope bears very small proportion. So that the place of the eye will be nearly at the focal distance of the eye-glass, and the rays of each respective pencil being parallel among themselves, and their axes crossing each other in a larger angle than they would do if the object were to be seen by the naked eye, vision will be distinct, and the object will appear magnified.

250 Its magnifying power. The magnifying power in this telescope is as the focal length of the object-glass to the focal length of the eye-glass.

In order to prove this, we may consider the angle A *k* B as that under which the object would be seen by the naked eye; for in considering the distance of the object, the length of the telescope may be omitted, as bearing no proportion to it. Now the angle under which the object is seen by means of the telescope is *g e h*, which is to the other A *k* B, or its equal *g k h*, as the distance from the centre of the object-glass to that of the eye-glass. The angle, therefore, which an object subtends to an eye assisted by a telescope of this kind, is to that under which it subtends to the naked eye, as the focal length of the object-glass to the focal length of the eye-glass.

It is evident from the figure, that the visible area, or space which can be seen at one view, when we look through this telescope, depends on the breadth of the eye-glass, and not of the object-glass; for if the eye-glass be too small to receive the rays *g m*, *p h*, the extremities of the object could not have been seen at all: a larger breadth of the object-lass conduces only to the rendering each point of the image more luminous, by receiving a larger pencil of rays from each point of the object.

251 Objects seen thro' it inverted. It is in this telescope as in the compound microscope, where we see not the object itself, but only its image CED: now that image being inverted with respect to the object, because the axis of the pencils that flow from the object cross each other at *k*, objects seen through a telescope of this kind necessarily appear inverted.

This is a circumstance not at all regarded by astronomers: but for viewing objects upon the earth, it is convenient that the instrument should represent them in their natural posture; to which use the telescope with three eye-glasses, as represented fig. 13. is peculiarly adapted. Plate cccLxxxviii. fig. 13.

AB is the object sending out the several pencils A *c d*, B *c d*, &c. which passing through the object-glass *c d*, are collected into their respective foci in CD, where they form an inverted image. From this they proceed to the first eye-glass *e f*, whose focus being at *l*, the rays of each pencil are rendered parallel among themselves, and their axes, which were nearly parallel before, are made to converge and cross each other: the second eye-glass *g h*, being so placed that its focus shall fall upon *m*, renders the axes of the pencils which diverge from thence parallel, and causes the rays of each, which were parallel among themselves, to meet again at its focus EF on the other side, where they form a second image inverted with respect to the former, but erect with respect to the object. Now this image being seen by the eye at *a b* through the eye-glass *i k*, affords a direct representation of the object, and under the same angle that the first image CD would have appeared, had the eye been placed at *l*, supposing the eye-glasses to be of equal convexity; and therefore the object is seen equally magnified in this as in the former telescope, that is, as the focal distance of the object-glass to that of any one of the-glasses, and appears erect. 252 Common refracting telescope shows objects erect.

253 Galilean telescope. 2. The *Galilean Telescope* with the concave eye-glass is constructed as follows.

Plate cccLxxxviii. fig. 1. AB is an object sending forth the pencils of rays *g h i*, *k l m*, &c. which, after passing through the object-glass *c d*, tend towards *e* E *f* (where we shall suppose the focus of it to be), in order to form an inverted image there as before; but in their way to it are made to pass through the concave glass *n o*, so placed that its focus may fall upon E, and consequently the rays of the several pencils which were converging towards those respective focal points *e*, E, *f*, will be rendered parallel, but the axes of those pencils crossing each other at F, and diverging from thence, will be rendered more diverging, as represented in the figure. Now these rays entering the pupil of an eye, will form a large and distinct image *a b* upon the retina, which will be inverted with

Optical Instruments.

with respect to the object, because the axis of the pencils cross in F. The object of course will be seen erect, and the angle under which it will appear will be equal to that which the lines a F, b F, produced back through the eye-glass, form at F.

It is evident, that the less the pupil of the eye is, the less is the visible area seen through a telescope of this kind; for a less pupil would exclude such pencils as proceed from the extremities of the object AB, as is evident from the figure. This inconvenience renders this telescope unfit for many uses; and is only to be remedied by the telescope with the convex eye-glasses, where the rays which form the extreme parts of the image are brought together in order to enter the pupil of the eye, as explained above.

It is apparent also, that the nearer the eye is placed to the eye-glass of this telescope, the larger is the area seen through it; for, being placed close to the glass, as in the figure, it admits rays that come from A and B, the extremities of the object, which it could not if it was placed farther off.

254 Magnifying power.

The degree of magnifying in this telescope is in the same proportion with that in the other, viz. as the focal distance of the object glass is to the focal distance of the eye-glass.

Plate cccLXXXVII. Plate cccLXXXVIII.

For there is no other difference but this, viz. that as the extreme pencils in that telescope were made to converge and form the angle $g\ e\ h$ or $i\ n\ k$ (fig. 13.), these are now made to diverge and form the angle a F b (fig. 1.); which angles, if the concave glass in one has an equal refractive power with the convex one in the other, will be equal, and therefore each kind will exhibit the object magnified in the same degree.

There is a defect in all these kinds of telescopes, not to be remedied in a single lens by any means whatever, which was thought only to arise from the spherical aberration of the object-glass. But it was discovered by Sir Isaac Newton, that the imperfection of this sort of telescope, so far as it arises from the spherical form of the glasses, bears little proportion to that which is owing to the different refrangibility of light. This diversity in the refraction of rays is about a 28th part of the whole; so that the object-glass of a telescope cannot collect the rays which flow from any one point in the object into less space than a circle whose diameter is about the 56th part of the breadth of the glass.

Plate cccLXXXVIII.

To show this, let AB represent a convex lens, and let CDF be a pencil of rays flowing from the point D; let H be the point at which the least refrangible rays are collected to a focus; and I, that where the most refrangible concur. Then, if IH be the 28th part of EH, IK will be a proportionable part of EC (the triangles HIK and HEC being similar): consequently LK will be the 28th part of FC. But MN will be the least space into which the rays will be collected, as appears by their progress represented in the figure. Now MN is but about half of KL; and therefore it is about the 56th part of the breadth of that part of the glass through which the rays pass; which was to be shown.

Since therefore each point of the object will be represented in so large a space, and the centres of those spaces will be contiguous, because the points in the object the rays flow from are so; it is evident, that the image of an object made by such a glass must be a most confused representation, though it does not appear so when viewed through an eye-glass that magnifies in a moderate degree; consequently the degree of magnifying in the eye-glass must not be too great with respect to that of the object-glass, lest the confusion become sensible.

Notwithstanding this imperfection, a dioptrical telescope may be made to magnify in any given degree, provided it be of sufficient length; for the greater the focal distance of the object-glass is, the less may be the proportion which the focal distance of the eye-glass may bear to that of the object-glass, without rendering the image obscure. Thus, an object-glass, whose focal distance is about four feet, will admit of an eye-glass whose focal distance shall be little more than an inch, and consequently will magnify almost 48 times; but an object-glass of 40 feet focus will admit of an eye-glass of only four inches focus, and will therefore magnify 120 times; and an object-glass of 100 feet focus will admit of an eye-glass of little more than six inches focus, and will therefore magnify almost 200 times.

255 Refracting telescopes magnify in proportion to their length.

The reason of this disproportion in their several degrees of magnifying may be explained thus: Since the diameter of the spaces, into which rays flowing from the several points of an object are collected, are as the breadth of an object-glass, it is evident that the degree of confusedness in the image is as the breadth of that glass; for the degree of confusedness will only be as the diameters or breadth of those spaces, and not as the spaces themselves. Now the focal length of the eye-glass, that is, its power of magnifying, must be as that degree; for, if it exceeds it, it will render the confusedness sensible; and therefore it must be as the breadth or diameter of the object-glass. The diameter of the object-glass, which is as the square root of its aperture or magnitude, must be as the square root of the power of magnifying in the telescope; for unless the aperture itself be as the power of magnifying, the image will want light: the square root of the power of magnifying will be as the square root of the focal distance of the object-glass; and therefore the focal distance of the eye-glass must be only as the square root of that of the object-glass. So that in making use of an object-glass of a longer focus, suppose, than one that is given, you are not obliged to apply an eye-glass of a proportionably longer focus than what would suit the given object-glass, but such a one only whose focal distance shall be to the focal distance of that which will suit the given object-glass, as the square root of the focal length of the object-glass you make use of, is to the square root of the focal length of the given one. And this is the reason that longer telescopes are capable of magnifying in a greater degree than shorter ones, without rendering the object confused or coloured.

Upon these principles the following new table, taken from the appendix to Ferguson's Lectures, vol. ii. p. 471. second edition, has been computed. It is founded on a telescope of Huygens, mentioned in his *Astroscopia Compendiaria*, which had an object-glass 34 feet in focal length, and which bore an eye-glass of $2\frac{1}{7}$ inches focal distance, and therefore magnified 163 times. The table for refracting telescopes, which has been given by preceding optical writers, was copied from Smith's Optics,

Optical Instruments.

tics, as the production of the celebrated Huygens, while it was calculated only by the editors of his Dioptrics, from a telescope made by that celebrated optician; which, however, seems to have been inferior to that which is the foundation of the following table. The table is suited to Rhinland measure; but the second and third columns may be converted into English measure by dividing them by .7, the focal distances of the object-glasses being supposed English feet.

Sect. VI. *On Achromatic Telescopes.*

256 Their imperfections remedied by Dollond and Blair.

The inconveniency of very long telescopes is so great, that different attempts have been made to remove it. Of these, the most successful have been by Dollond and Blair; and the general principles upon which these eminent opticians proceeded have been mentioned in the historical part of this article, and in the preceding section. A fuller account of Dr Blair's discovery will be seen in the Transactions of the Royal Society of Edinburgh; and of Dollond's, it may be sufficient to observe, in addition to what has been already said, that the object-glasses of his telescopes are composed of three distinct lenses, two convex and one concave; of which the concave one is placed in the middle, as is represented in fig. 3. where *a* and *c* show the two convex lenses, and *b b* the concave one, which is by the British artists placed in the middle. The two convex ones are made of London crown glass, and the middle one of white flint glass; and they are all ground to spheres of different radii, according to the refractive powers of the different kinds of glass and the intended focal distance of the object-glass of the telescope. According to Boscovich, the focal distance of the parallel rays for the concave lens is one-half, and for the convex glass one-third of the combined focus. When put together, they refract the rays in the following manner. Let *a b*, *a b*, be two red rays of the sun's light falling parallel on the first convex lens *c*. Supposing there was no other lens present but that one, they would be converged into the lines *b e*, *b e*, and at last meet in the focus *q*. Let the lines *g h*, *g h*, represent two violet rays falling on the surface of the lens. These are also refracted, and will meet in a focus; but as they have a greater degree of refrangibility than the red rays, they must of consequence converge more by the same power of refraction in the glass, and meet sooner in a focus, suppose at *r*.—Let now the concave lens *d d* be placed in such a manner as to intercept all the rays before they come to their focus. Were this lens made of the same materials, and ground to the same radius with the convex one, it would have the same power to cause the rays diverge that the former had to make them converge. In this case, the red rays would become parallel, and move on in the line *o o*, *o o*: But the convex lens, being made of flint glass, and upon a shorter radius, has a greater refractive power, and therefore they diverge a little after they come out of it; and if no third lens was interposed, they would proceed diverging in the lines *o p t*, *o p t*; but, by the interposition of the third lens *o v o*, they are again made to converge, and meet in a focus somewhat more distant than the former, as at *x*. By the concave lens the violet rays are also refracted, and made to diverge; but having a greater degree of refrangibility, the same power of refraction makes them diverge somewhat more than the red ones; and thus, if no third lens was interposed, they would proceed in such lines as *l m n*, *l m n*. Now as the differently coloured rays fall upon the third lens with different degrees of divergence, it is plain, that the same power of refraction in that lens will operate upon them in such a manner as to bring them all together to a focus very nearly at the same point. The red rays, it is true, require the greatest power of refraction to bring them to a focus; but they fall upon the lens with the least degree of divergence. The violet rays, though they require the least power of refraction, yet have the greatest degree of divergence; and thus all meet together in the point *x*, or nearly so.

Fig. 3. Fig. 4.

But, though we have hitherto supposed the refraction of the concave lens to be greater than that of the convex ones, it is easy to see how the errors occasioned by the first lens may be corrected by it, though it should have even a less power of refraction than the convex one. Thus, let *a b*, *a b*, be two rays of red light falling upon the convex lens *c*, and refracted into the focus *q*; let also *g h*, *g h*, be two violet rays converged into a focus at *r*; it is not necessary, in order to their convergence into a common focus at *x*, that the concave lens should make them *diverge*: it is sufficient if the glass has

Plate cclxxxviii fig. 5.

Optical Instruments.

has a power of dispersing the violet rays somewhat more than the red ones; and many kinds have this power of dispersing some kinds of rays, without a very great power of refraction. It is better, however, to have the object-glass composed of three lenses; because there is then another correction of the aberration by means of the third lens; and it might be impossible to find two lenses, the errors of which would exactly correct each other. It is also easy to see, that the effect may be the same whether the concave glass is a portion of the same sphere with the others or not; the effect depending upon a combination of certain circumstances, of which there is an infinite variety.

By means of this correction of the errors arising from the different refrangibility of the rays of light, it is possible to shorten refracting telescopes considerably, and yet leave them equal magnifying powers. The reason of this is, that the errors arising from the object-glass being removed, those which are occasioned by the eye-glass are inconsiderable: for the error is always in proportion to the length of the focus in any glass; and in very long telescopes it becomes exceedingly great, being no less than $\frac{1}{18}$th of the whole; but in glasses of a few inches focus it becomes trifling. Refracting telescopes, which go by the name of *Dollond's*, are therefore now constructed in the following manner. Let AB represent an object-glass composed of three lenses as above described, and converging the rays 1, 2, 3, 4, &c. to a very distant focus as at *x*. By means of the interposed lens CD, however, they are converged to one much nearer, as at *y*, where an image of the object is formed. The rays diverging from thence fall upon another lens EF, where the pencils are rendered parallel, and an eye placed near that lens would see the object magnified and very distinct. To increase the magnifying power still more, however, the pencils thus become parallel are made to fall upon another at GH; by which they are again made to converge to a distant focus: but, being intercepted by the lens IK, they are made to meet at the nearer one *z*; whence diverging to LM, they are again rendered parallel, and the eye at N sees the object very distinctly.

Fig. 6.

From an inspection of the figure it is evident, that Dollond's telescope thus constructed is two telescopes combined together; the first ending with the lens EF, and the second with LM. In the first we do not perceive the object itself, but the image of it formed at *y*; and in the second we perceive only the image of that image formed at *z*. Such telescopes are nevertheless exceedingly distinct, and represent objects so clearly as to be preferred, in viewing terrestrial things, even to reflectors. The latter indeed have greatly the advantage in their powers of magnifying, but they are much deficient in point of light. Much more light is lost by reflection than by refraction: and as in these telescopes the light must unavoidably suffer two reflections, a great deal of it is lost; nor is this loss counterbalanced by the greater aperture which these telescopes will bear, which enables them to receive a greater quantity of light than the refracting ones. The metals of reflecting telescopes also are very much subject to tarnish, and require much more dexterity to clean them than the glasses of refractors; which makes them more troublesome and expensive, though for making discoveries in the heavens they are undoubtedly the only proper instruments which have been hitherto constructed.

II. The Reflecting Telescope.

257 Newtonian telescope.

The inconveniences arising from the great length of refracting telescopes, before the discovery of the achromatic telescope, are sufficiently obvious; and these, together with the difficulties occasioned by the different refrangibility of light, induced Sir Isaac Newton to turn his attention to the subject of reflection, and endeavour to realize the ideas of himself and others concerning the possibility of constructing telescopes upon that principle.—The instrument which he contrived is represented, fig. 7. where ABCD is a large tube, open at AD and closed at BC, and of a length at least equal to the distance of the focus from the metallic spherical concave speculum GH placed at the end BC. The rays EG, FH, &c. proceeding from a remote object PR, intersect one another somewhere before they enter the tube, so that EG, *e g*, are those that come from the lower part of the object, and *f h*, FH from its upper part: these rays after falling on the speculum GH, will be reflected so as to converge and meet in *m n*, where they will form a perfect image of the object.—But as this image cannot be seen by the spectator, they are intercepted by a small plane metallic speculum KK, intersecting the axis at an angle of 45°, by which the rays tending to *m n* will be reflected towards a hole LL in the side of the tube, and the image will be less distinct, because some of the rays which would otherwise fall on the concave speculum GH, are intercepted by the plane speculum: nevertheless it will appear in a considerable degree distinct, because the aperture AD of the tube, and the speculum GH, are large. In the lateral hole LL is fixed a convex lens, whose focus is at S*q*; and therefore this lens will refract the rays that proceed from any point of the image, so as at their exit they will be parallel, and those that proceed from the extreme points S *q* will converge after refraction, and form an angle at O, where the eye is placed; which will see the image S *q*, as if it were an object through the lens LL; consequently the object will appear enlarged, inverted, bright, and distinct. In LL lenses of different convexities may be placed, which by being moved nearer to the image or farther from it, would represent the object more or less magnified, provided that the surface of the speculum GH be of a perfectly spherical figure. If, in the room of one lens LL, three lenses be disposed in the same manner with the three eye-glasses of the refracting telescope, the object will appear erect, but less distinct than when it is observed with one lens.

Fig. 7.

258 New finder for Newtonian telescope.

On account of the position of the eye in this telescope, it is extremely difficult to direct the instrument towards any object. Huygens, therefore, first thought of adding to it a small refracting telescope, the axis of which is parallel to that of the reflector. This is called a *finder* or *director*. When the Newtonian telescope is large, and placed upon its lower end to view bodies in great altitudes, the common finder can be of no use, from the difficulty of getting the eye to the eye-piece. On this account Dr Brewster proposes (Appendix to Ferguson's Lectures, vol. ii. p. 478.) to bend the tube of the finder to a right angle, and place a plane mirror at the angular point, so as to throw the image above the upper part of the tube that

that the eye-piece of the finder may be as near as possible to the eye-piece of the telescope. The angular part where the plain mirror is to be fixed, should be placed as near as possible to the focal image, in order that only a small part of the finder may stand above the tube; and in this way the eye can be transferred with the greatest facility from the one eye-piece to the other. The advantages of this construction will be understood from fig. 3. Plate CCCLXXXIX. where TT is part of a Newtonian telescope, D the eye-piece, and ABC the finder. The image formed by the object-glass A is reflected upwards by the plain mirror B, placed at an angle of 45° with the axis of the tube, and the image is viewed with the eye-glass AC. Those who have been in the habit of using the Newtonian telescope with the common finder will be sensible of the convenience resulting from this contrivance.

Plate CCCLXXXIX. fig. 3.

259 Magnifying power of Newtonian telescopes.

In order to determine the magnifying power of this telescope, it is to be considered that the plane speculum KK is of no use in this respect. Let us then suppose, that one ray proceeding from the object coincides with the axis GLIA of the lens and speculum; let *b b* be another ray proceeding from the lower extreme of the object, and passing through the focus I of the speculum KH: this will be reflected in the direction *b i d*, parallel to the axis G L A, and falling on the lens *d* L *d*, will be refracted to G; so that G L will be equal to L *l*, and *d* G = *d* I. To the naked eye the object would appear under the angle I *b i* = *b* I A; but by means of the telescope it appears under the angle *d*GL = *d*IL = I*di*: and the angle I *di* is to the angle I *b i* :: I *b* : I *d*; consequently the apparent magnitude by the telescope is to that by the naked eye as the distance of the focus of the speculum from the speculum, to the distance of the focus of the lens from the lens.

Plate cccLXXXVIII. fig. 8.

The following new table of the apertures and magnifying power of Newtonian telescopes is taken from the Appendix to Ferguson's Lectures, vol. ii. p. 480. It is founded on a Newtonian telescope constructed by Hadley, in which the focal length of the great speculum was three feet three inches, and the magnifying power 226. Its aperture varied from three and a half to four and a half inches according to the want of brightness in the objects to be examined. The first column contains the focal length of the great speculum in feet, and the second its linear aperture in inches, and hundredths of an inch. The third and fourth columns contain Sir Isaac Newton's numbers, by means of which the apertures of any kind of reflecting telescopes may be easily computed. The fifth column contains the focal length of the eye-glasses in thousandths of an inch, and the sixth contains the magnifying power of the instrument.

A NEW TABLE of the apertures and magnifying power of Newtonian Telescopes.

Let TYYT be a brass tube, in which L *l d* D is a metallic concave speculum, perforated in the middle at X; and EF a less concave mirror, so fixed by the arm or strong wire RT, which is moveable by means of a long screw on the outside of the tube, as to be moved nearer to or farther from the larger speculum L *l d* D, its axis being kept in the same line with that of the great one. Let AB represent a very remote object, from each part of which issue pencils of rays, e. g. *c d*, CD, from A the upper extreme of the object, and IL, *i l*, from the lower part B; the rays IL, CD, from the extremes crossing one another before they enter the tube. These rays falling upon the larger mirror L D, are reflected from it into the focus K H, where they form an inverted image of the object A B, as in the Newtonian telescope. From this image the rays, issuing as from an object, fall upon the small mirror EF, the centre of which is at *e*; so that after reflection they would meet in their foci at QQ, and there form an erect image. But since an eye at that place could see but a small part of an object, in order to bring rays from more distant parts of it into the pupil, they are intercepted by the plano-convex lens MN, by which means a smaller erect image is formed at P V, which is viewed from

260 Gregorian telescope.

Plate cccLXXXVIII. fig. 9.

from the meniscus SS by an eye at O. This meniscus both makes the rays of each pencil parallel and magnifies the image PV. At the place of this image all the foreign rays are intercepted by the perforated partition ZZ. For the same reason the hole near the eye O is very narrow. When nearer objects are viewed by this telescope, the small speculum EF is removed to a greater distance from the larger LD, so that the second image may be always formed in PV; and this distance is to be adjusted (by means of the screw on the outside of the great tube) according to the form of the eye of the spectator. It is also necessary, that the axis of the telescope should pass through the middle of the speculum EF, and its centre, the centre of the speculum LL, and the middle of the hole X, the centres of the lenses MN, SS, and the hole near O. As the hole X in the speculum LL can reflect none of the rays issuing from the object, that part of the image which corresponds to the middle of the object must appear to the observer more dark and confused than the extreme parts of it. Besides, the speculum EF will also intercept many rays proceeding from the object; and therefore unless the aperture TT be large, the object must appear in some degree obscure.

In the best reflecting telescopes, the focus of the small mirror is never coincident with the focus of the great one, where the first image KH is formed, but a little beyond it (with respect to the eye), as at *n*; the consequence of which is, that the rays of the pencils will not be parallel after reflection from the small mirror, but converge so as to meet in points about Q *q* Q, where they would form a larger upright image than PV, if the glass R was not in their way; and this image might be viewed by means of a single eye-glass properly placed between the image and the eye; but then the field of view would be less, and consequently not so pleasant; for which reason, the glass R is still retained, to enlarge the scope or area of the field.

261 Its magnifying power.

To find the magnifying power of this telescope, mutiply the focal distance of the great mirror by the distance of the small mirror from the image next the eye, and multiply the focal distance of the small mirror by the focal distance of the eye-glass; then divide the former product by the latter, and the quotient will express the magnifying power. For a table of the apertures and powers of Gregorian telescopes, see Appendix to Ferguson's Lectures, vol. ii. p. 472, 473.

One great advantage of the reflecting telescope is, that it will admit of an eye-glass of a much shorter focal distance than a refracting telescope; and consequently it will magnify so much the more: for the rays are not coloured by reflection from a concave mirror, if it be ground to a true figure, as they are by passing through a convex glass, let it be ground ever so true.

The nearer an object is to the telescope, the more its pencils of rays will diverge before they fall upon the great mirror, and therefore they will be the longer of meeting in points after reflection; so that the first image KH will be formed at a greater distance from the large mirror, when the object is near the telescope, than when it is very remote. But as this image must be formed farther from the small mirror than its principal focus *n*, this mirror must be always set at a greater distance from the larger one, in viewing near objects, than in viewing remote ones. And this is done by turning the screw on the outside of the tube, until the small mirror be so adjusted, that the object (or rather its image) appears perfect.

In looking through any telescope towards an object, we never see the object itself, but only that image of it which is formed next the eye in the telescope. For if a man holds his finger or a stick between his bare eye and an object, it will hide part (if not the whole) of the object from his view: But if he ties a stick across the mouth of a telescope before the object-glass, it will hide no part of the imaginary object he saw through the telescope before, unless it covers the whole mouth of the tube: for all the effect will be, to make the object appear dimmer, because it intercepts part of the rays. Whereas, if he puts only a piece of wire across the inside of the tube, between the eye-glass and his eye, it will hide part of the object which he thinks he sees; which proves, that he sees not the real object, but its image. This is also confirmed by means of the small mirror EF, in the reflecting telescope, which is made of opaque metal, and stands directly between the eye and the object towards which the telescope is turned; and will hide the whole object from the eye at O, if the two glasses ZZ and SS are taken out of the tube.

262 Cassegrainian telescope.

If the small mirror of the preceding instrument be convex instead of concave, it is then called the *Cassegrainian telescope*. As the small mirror is in this case placed between the great speculum and its focus, a Cassegrainian telescope will be shorter than a Gregorian one of the same magnifying power by twice the real length of the small mirror. For a table of the apertures, &c. of this instrument, see Appendix to Ferguson's Lectures, vol. ii. p. 474, 475.

Sect. VII. *On the Merits of different Microscopes and Telescopes.*

263 Merits of microscopes and telescopes compared.

The advantages arising from the use of microscopes and telescopes depend, in the first place, upon their property of magnifying the minute parts of objects, so that they can by that means be more distinctly viewed by the eye; and, secondly, upon their throwing more light into the pupil of the eye than what is done without them. The advantages arising from the magnifying power would be extremely limited, if they were not also accompanied by the latter: for if the same quantity of light is spread over a large portion of surface, it becomes proportionably diminished in force; and therefore the objects, though magnified, appear proportionably dim. Thus, though any magnifying glass should enlarge the diameter of the object 10 times, and consequently magnify the surface 100 times, yet if the focal distance of the glass was about eight inches (provided this was possible), and its diameter only about the size of the pupil of the eye, the object would appear 100 times more dim when we looked through the glass, than when we beheld it with our naked eyes; and this, even on a supposition that the glass transmitted all the light which fell upon it, which no glass can do. But if the focal distance of the glass was only four inches, though its diameter remained as before, the inconvenience would be vastly diminished, because the glass could then

Merits of Micro-scopes and Telescopes compared.

then be placed twice as near the object as before, and consequently would receive four times as many rays as in the former case, and therefore we would see it much brighter than before. Going on thus, still diminishing the focal distance of the glass, and keeping its diameter as large as possible, we will perceive the object more and more magnified, and at the same time very distinct and bright. It is evident, however, that with regard to optical instruments of the microscopic kind, we must sooner or later arrive at a limit which cannot be passed. This limit is formed by the following particulars. 1. The quantity of light lost in passing through the glass. 2. The diminution of the glass itself, by which it receives only a small quantity of rays. 3. The extreme shortness of the focal distance of great magnifiers, whereby the free access of the light to the object which we wish to view is impeded, and consequently the reflection of the light from it is weakened. 4. The aberrations of the rays, occasioned by their different refrangibility.

To understand this more fully, as well as to see how far these obstacles can be removed, let us suppose the lens made of such a dull kind of glass, that it transmits only one half of the light which falls upon it. It is evident that such a glass, of four inches focal distance, and which magnifies the diameter of an object twice, still supposing its own breadth equal to that of the pupil of the eye, will show it four times magnified in surface, but only half as bright as if it was seen by the naked eye at the usual distance; for the light which falls upon the eye from the object at eight inches distance, and likewise the surface of the object in its natural size, being both represented by 1, the surface of the magnified object will be 4, and the light which makes that magnified object visible only 2: because though the glass receives four times as much light as the naked eye does at the usual distance of distinct vision, yet one half is lost in passing through the glass. The inconvenience in this respect can therefore be removed only as far as it is possible to increase the clearness of the glass, so that it shall transmit nearly all the rays which fall upon it; and how far this can be done, hath not yet been ascertained.

The second obstacle to the perfection of microscopic glasses is the small size of great magnifiers, by which, notwithstanding their near approach to the object, they receive a smaller quantity of rays than might be expected. Thus suppose, a glass of only $\frac{1}{10}$th of an inch focal distance; such a glass would increase the visible diameter 80 times, and the surface 6400 times. If the breadth of the glass could at the same time be preserved as great as that of the pupil of the eye, which we shall suppose $\frac{2}{10}$ths of an inch, the object would appear magnified 6400 times, at the same time that every part of it would be as bright as it appears to the naked eye. But if we suppose that this magnifying glass is only $\frac{1}{10}$th of an inch in diameter, it will then only receive $\frac{1}{4}$th of the light which otherwise would have fallen upon it; and therefore, instead of communicating to the magnified object a quantity of illumination equal to 6400, it would communicate only one equal to 1600, and the magnified object would appear four times as dim as it does to the naked eye. This inconvenience, however, is still capable of being removed, not indeed by increasing the diameter of the lens, because this must be in proportion to its focal distance, but by throwing a greater quantity of light on the object. Thus, in the above-mentioned example, if four times the quantity of light which naturally falls upon it could be thrown upon the object, it is plain that the reflection from it would be four times as great as in the natural way; and consequently the magnified image, at the same time that it was as many times magnified as before, would be as bright as when seen by the naked eye. In transparent objects this can be done very effectually by a concave speculum, as in the reflecting microscope already described: but in opaque objects the case is somewhat more doubtful; neither do the contrivances for viewing these objects seem entirely to make up for the deficiencies of the light from the smallness of the lens and shortness of the focus.—When a microscopic lens magnifies the diameter of an object forty times, it hath then the utmost possible magnifying power, without diminishing the natural brightness of the object.

The third obstacle arises from the shortness of the focal distance in large magnifiers: but in transparent objects, where a sufficient quantity of light is thrown on the object from below, the inconvenience arises at last from straining the eye, which must be placed nearer the glass than it can well bear; and this entirely supersedes the use of magnifiers beyond a certain degree.

The fourth obstacle arises from the different refrangibility of the rays of light, and which frequently causes such a deviation from truth in the appearances of things that many people have imagined themselves to have made surprising discoveries, and have even published them to the world: when in fact they have been only as many optical deceptions, owing to the unequal refractions of the rays. For this there seems to be no remedy, except the introduction of achromatic glasses into microscopes as well as telescopes. How far this is practicable, hath not yet been tried; but when these glasses shall be introduced (if such introduction is practicable,) microscopes will then undoubtedly have received their ultimate degree of perfection.

364 Dollond's and Blair's refracting telescopes superior to others.

With regard to telescopes, those of the refracting kind have evidently the advantage of all others, where the aperture is equal, and the aberrations of the rays are corrected according to Mr Dollond's method; because the image is not only more perfect, but a much greater quantity of light is transmitted than what can be reflected from the best materials hitherto known. Unluckily, however, the imperfections of the glass set a limit to these telescopes, as has been already observed, so that they cannot be made above three feet and a half long. On the whole, therefore, the reflecting telescopes are preferable in this respect, that they may be made of dimensions greatly superior; by which means they can both magnify to a greater degree, and at the same time throw much more light into the eye.

With regard to the powers of telescopes, however, they are all of them exceedingly less than what we would be apt to imagine from the number of times which they magnify the object. Thus, when we hear of a telescope which magnifies 200 times, we are apt to imagine, that, on looking at any distant object through it, we should perceive it as distinctly as we would with our naked eye at the 200th part of the

Merits of Microscopes and Telescopes compared. the distance. But this is by no means the case; neither is there any theory capable of directing us in this matter: we must therefore depend entirely on experience.

The best method of trying the goodness of any telescope is to observe how much farther off you are able to read with it than with the naked eye. But that all deception may be avoided, it is proper to choose something to be read where the imagination cannot give any assistance, such as a table of logarithms, or something which consists entirely of figures; and hence the truly useful power of the telescope is easily known. In this way Mr Short's large telescope, which magnifies the diameter of objects 1200 times, is yet unable to afford sufficient light for reading at more than 200 times the distance at which we can read with our naked eye.

265 The Gregorian telescope superior for common use to the Newtonian. With regard to the form of reflecting telescopes, it is now pretty generally agreed, that when the Gregorian ones are well constructed, they have the advantage of those of the Newtonian form. One advantage evident at first sight is, that with the Gregorian telescope an object is perceived by looking directly through it, and consequently is found with much greater ease than in the Newtonian telescope, where we must look into the side. The unavoidable imperfection of the specula common to both, also gives the Gregorian an advantage over the Newtonian form. Notwithstanding the utmost care and labour of the workmen, it is found impossible to give the metals either a perfectly spherical or a perfectly parabolical form. Hence arises some indistinctness of the image formed by the great speculum; which is frequently corrected by the little one, provided they are properly matched. But if this is not done, the error will be made much worse; and hence many of the Gregorian telescopes are far inferior to the Newtonian ones; namely, when the specula have not been properly adapted to each other. There is no method by which the workman can know the specula which will fit one another without a trial; and therefore it is necessary to have many specula ready made of each sort, that in fitting up a telescope those may be chosen which best suit each other.

The brightness of any object seen through a telescope, in comparison with its brightness when seen by the naked eye, may in all cases be easily found by the following formula. Let n represent the natural distance at which an object can be distinctly seen; and let d represent its distance from the object-glass of the instrument. Let m be the magnifying power of the instrument; that is, let the visual angle subtended at the eye by the object when at the distance n, and viewed without the instrument, be to the visual angle produced by the instrument as 1 to m. Let a be the diameter of the object-glass, and p that of the pupil. Let the instrument be so constructed, that no parts of the pencils are intercepted for want of sufficient apertures of the intermediate glasses. Lastly, Let the light lost in reflection or refraction be neglected.

The brightness of vision through the instrument will be expressed by the fraction $\frac{a^2 n^2}{m^2 p^2 d^2}$, the brightness of natural vision being 1. But although this fraction may exceed unity, the vision through the instrument will not be brighter than natural vision. For, when this is the case, the pupil does not receive all the light transmitted through the instrument.

In microscopes, n is the nearest limits of distinct vision, nearly *seven* inches. But a difference in this circumstance, arising from a difference in the eye, makes no change in the formula, because m changes in the same proportion with n.

In telescopes n and d may be reckoned equal, and the formula becomes $\frac{a^2}{m^2 p^2}$.

A view of the history and construction of the telescope is given in the article ACHROMATIC GLASSES, in the SUPPLEMENT.

SECT. VIII. *Apparatus for Measuring the Intensity of Light.*

That some luminous bodies give a stronger, and others a weaker light, and that some reflect more light than others, was always known; but no person, before M. Bouguer hit upon a tolerable method of ascertaining the proportion that two or more lights bear to one another. The methods he most commonly used were the following. 266 M. Bouguer's contrivances for measuring light.

He took two pieces of wood or pasteboard EC and CD, in which he made two equal holes P and Q, over which he drew pieces of oiled or white paper. Upon these holes he contrived that the light of the different bodies he was comparing should fall; while he placed a third piece of pasteboard FC, so as to prevent the two lights from mixing with one another. Then placing himself sometimes on one side, and sometimes on the other, but generally on the opposite side of this instrument, with respect to the light, he altered their position till the papers in the two holes appeared to be equally enlightened. This being done, he computed the proportion of their light by the squares of the distances at which the luminous bodies were placed from the objects. If, for instance, the distances were as three and nine, he concluded that the lights they gave were as nine and eighty-one. Where any light was very faint, he sometimes made use of lenses, in order to condense it; and he enclosed them in tubes or not as his particular application of them required. Plate CCCLXXXV. fig. 4.

To measure the intensity of light proceeding from the heavenly bodies, or reflected from any part of the sky, he contrived an instrument which resembles a kind of portable camera obscura. He had two tubes, of which the inner was black, fastened at their lower extremities by a hinge C. At the bottom of these tubes were two holes, R and S, three or four lines in diameter, covered with two pieces of fine white paper. The two other extremities had each of them a circular aperture, an inch in diameter; and one of the tubes consisted of two, one of them sliding into the other, which produced the same effect as varying the aperture at the end. When this instrument is used, the observer has his head, and the end of the instrument C, so covered, that no light can fall upon his eye, besides that which comes through the two holes S and R, while an assistant manages the instrument, and draws out or shortens the tube DE, as the observer directs. When the two holes appear equally illuminated, the intensity of the lights is judged to be inversely as the squares of the tubes. Fig. 5.

[illegible] of the ob- [illegible] aperture & [illegible], for, other- [illegible] no effect. To [illegible] of an incon- [illegible] is too narrow, [illegible]. He constructs an [illegible], consisting of two ob- [illegible], exactly equal, fixed in the [illegible] feet, or, in some cases, [illegible] their foci at the other [illegible]. At the bottoms of these tubes B, are two holes, [illegible] in diameter, covered with a piece of [illegible] paper, and this instrument is used exactly like the former.

If the two objects to be observed by this instrument be not equally luminous, the light that issues from them must be reduced to an equality, by diminishing the aperture of one of the object glasses; and then the remaining surface of the two glasses will give the proportion of their lights. But for this purpose, the central parts of the glass must be covered in the same proportion with the parts near the circumference, leaving the aperture such as is represented (fig. 7.), because the middle part of the glass is thicker and less transparent than the rest.

Fig. 7.

If all the objects to be observed lie nearly in the same direction, Bouguer remarks, that these two long tubes may be reduced into one, the two object-glasses being placed close together, and one eye-glass sufficing for them both. The instrument will then be the same with that of which he published an account in 1748, and which he called a *heliometer*, or *astrometer*.

267
These instruments measure only the intensity of light.

It is not, however, the absolute quantity, but only the intensity of the light, that is measured by these two instruments, or the number of rays, in proportion to the surface of the luminous body; and it is of great importance that these two things be distinguished. The intensity of light may be very great, when the quantity, and its power of illuminating other bodies, may be very small, on account of the smallness of its surface; or the contrary may be the case, when the surface is large.

Having explained these methods which M. Bouguer took to measure the different proportions of light, we shall subjoin a few examples of his application of them.

It is observable, that when a person stands in a place where there is a strong light, he cannot distinguish objects that are placed in the shade; nor can he see any thing upon going immediately into a place where there is very little light. It is plain, therefore, that the action of a strong light upon the eye, and also the impression which it leaves upon it, makes it insensible to the effect of a weaker light. M. Bouguer had the curiosity to endeavour to ascertain the proportion between the intensities of the two lights in this case; and by throwing the light of two equal candles upon a board, he found [illegible] shadow made by intercepting the light of one [illegible] could not be perceived by his eye, upon the [illegible]ightened by the other, at little more than eight [illegible] distance; from whence he concluded, that [illegible] light is eight times eight, or 64 times less [illegible] other, its presence or absence will not be per[illegible]. He allows, however, that the effect may be different on different eyes; and supposes that the boundaries in this case, with respect to different persons, may lie between 60 and 80.

Apparatus for Measuring Light.

Applying the two tubes of his instrument, mentioned above, to measure the intensity of the light reflected from different parts of the sky; he found that when the sun was 25 degrees high, the light was four times stronger at the distance of eight or nine degrees from his body, than it was at 31 or 32 degrees. But what struck him the most was to find, that when the sun is 15 or 20 degrees high, the light decreases on the same parallel to the horizon to 110 or 120 degrees, and then increases again to the place exactly opposite to the sun.

The light of the sun, our author observes, is too strong, and that of the stars too weak, to determine the variation of their light at different altitudes; but as, in both cases, it must be in the same proportion with the diminution of the light of the moon in the same circumstances, he made his observations on that luminary, and found, that its light at 19° 16′, is to its light at 66° 11′, as 1681 to 2500; that is, the one is nearly two thirds of the other. He chose those particular altitudes, because they are those of the sun at the two solstices at Croisic, where he then resided. When one limb of the moon touched the horizon of the sea, its light was 2000 times less than at the altitude of 66° 11′. But this proportion he acknowledges must be subject to many variations, the atmosphere near the earth varying so much in its density. From this observation he concludes, that [illegible] light is diminished in the proportion of [illegible] to 1681, in traversing 7469 toises of [illegible] air.

268
Great variation of the light of the moon at different altitudes.

M. Bouguer [illegible] applied his instrument to the different [illegible], and found that the centre [illegible] than the extremities of [illegible] the observation, it [illegible] part of the disk [illegible] of [illegible] proportion of 35 to [illegible] than in the proportion of [illegible] of the angles of obliquity. On the other hand, he observes, that both the primary and secondary planets are more luminous at their edges than near their centres.

269
Variation in different parts of the disks of the sun and planets.

The comparison of the light of the sun and moon is a subject that has frequently exercised the thoughts of philosophers; but we find nothing but random conjectures, before Bouguer applied his accurate measures in this case. In general, the light of the moon is imagined to bear a much greater proportion to that of the sun than it really does: and not only are the imaginations of the vulgar, but those of philosophers also, imposed upon with respect to it. It was a great surprise to M. de la Hire to find that he could not, by the help of any burning mirror, collect the beams of the moon in a sufficient quantity to produce the least sensible heat. Other philosophers have since made the like attempts with mirrors of greater power, though without any greater success; but this will not surprise us, when we see the result of M. Bouguer's observations on this subject.

In order to solve this curious problem concerning the comparison of the light of the sun and moon, he compared each of them to that of a candle in a dark room, one in the day-time, and the other in the night following,

270
M. Bouguer's calculation concerning the light of the moon.

Apparatus for Measuring Light.

ing, when the moon was at her mean distance from the earth; and, after many trials, he concluded that the light of the sun is about 300,000 times greater than that of the moon; which is such a disproportion, that, as he observes, it can be no wonder that philosophers have had so little success in their attempts to collect the light of the moon with burning glasses. For the largest of them will not increase the light 1000 times; which will still leave the light of the moon, in the focus of the mirror, 300 times less than the intensity of the common light of the sun.

To this account of the proportion of light which we actually receive from the moon, it cannot be displeasing to the reader, if we compare it with the quantity which would have been transmitted to us from that opaque body, if it reflected all the light it receives. Dr Smith thought that he had proved, from two different considerations, that the light of the full moon would be to our day-light as 1 to about 90,900, if no rays were lost at the moon.

271 Dr Smith's calculation.

In the first place, he supposes that the moon enlightened by the sun, is as luminous as the clouds are at a medium. He therefore supposed the light of the sun to be equal to that of a whole hemisphere of clouds, or as many moons as would cover the surface of the heavens. But on this Dr Priestley observes, that it is true, the light of the sun shining perpendicularly upon any surface would be equal to the light reflected from the whole hemisphere, if every part reflected all the light that fell upon it; but the light that would in fact be received from the whole hemisphere (part of it being received obliquely) would be only one-half as much as would be received from the whole hemisphere, if every part of it shone directly upon the surface to be illuminated.

In his Remarks, par. 97. Dr Smith demonstrates his method of calculation in the following manner.

Plate cccLxxiv. fig. 8.

"Let the little circle *cfdg* represent the moon's body half enlightened by the sun, and the great circle *a e b*, a spherical shell concentric to the moon, and touching the earth; *a b*, any diameter of that shell perpendicular to a great circle of the moon's body, represented by its diameter *c d*; *e* the place of the shell receiving full moon light from the bright hemisphere *f d g*. Now, because the surface of the moon is rough like that of the earth, we may allow that the sun's rays, incident upon any small part of it, with any obliquity, are reflected from it every way alike, as if they were emitted. And, therefore, if the segment *d f* shone alone, the points *a*, *e*, would be equally illuminated by it; and likewise if the remaining bright segment *d g* shone alone, the points *b e* would be equally illuminated by it. Consequently, if the light at the point *a* was increased by the light at *b*, it would become equal to the full moon light at *e*. And conceiving the same transfer to be made from every point of the hemispherical surface *h b i k* to their opposite points in the hemisphere *k a c h*, the former hemisphere would be left quite dark, and the latter would be uniformly illuminated with full moon light; arising from a quantity of the sun's light, which immediately before its incidence on the moon, would uniformly illuminate a circular plane equal to a great circle of her body, called her *disk*. Therefore the quantities of light being the same upon both surfaces, the density of the sun's incident light is to the density of full moon light, as that hemispherical surface *h e k* is to the said disk; that is, as any other hemispherical surface whose centre is at the eye, to that part of it which the moon's disk appears to possess very nearly, because it subtends but a small angle at the eye: that is, as radius of the hemisphere to the versed sine of the moon's apparent semidiameter, or as 10,000,000 to $1106\frac{2}{7}$ or as 90,400 to 1; taking the moon's mean horizontal diameter to be 16′ 7″.

"Strictly speaking, this rule compares moon light at the earth with day light at the moon; the medium of which, at her quadratures, is the same as our day-light; but is less at her full in the duplicate ratio of 365 to 366, or thereabout, that is, of the sun's distances from the earth and full moon; and therefore full moon light would be to our day light as about 1 to 90,900, if no rays were lost at the moon.

"Secondly, I say that full moon light is to any other moon light as the whole disk of the moon to the part that appears enlightened, considered upon a plane surface. For now let the earth be at *b*, and let *d l* be perpendicular to *f g*, and *g m* to *c d*: then it is plain, that *g l* is equal to *d m*; and that *g l* is equal to a perpendicular section of the sun's rays incident upon the arch *d g* which at *b* appears equal to *d m*; the eye being unable to distinguish the unequal distances of its parts. In like manner, conceiving the moon's surface to consist of innumerable physical circles parallel to *c f d g*, as represented at A, the same reason holds for every one of these circles as for *c f d g*. It follows then, that the bright part of the surface visible at *b*, when reduced to a flat as represented at B, by the crescent *p d q m p*, will be equal and similar to a perpendicular section of all the rays incident on that part, represented at C by the crescent *p g q l p*. Now the whole disk being in proportion to this crescent as the quantities of light incident upon them; and the light falling upon every rough particle, being equally rarefied in diverging to the eye at *b*, considered as equidistant from them all; it follows, that full moon light is to this moon light as the whole disk *p d q c* to the crescent *p d q m p*. Fig. 9.

"Therefore by compounding this ratio with that in the former remark, day-light is to moon-light as the surface of an hemisphere whose centre is at the eye, to the part of that surface which appears to be possessed by the enlightened part of the moon."

272 Mr Michell's calculation.

Mr Michell made his computation in a much more simple and easy manner, and in which there is much less danger of falling into any mistake. Considering the distance of the moon from the sun, and that the density of the light must decrease in the proportion of the square of that distance, he calculated the density of the sun's light, at that distance, in proportion to its density at the surface of the sun; and in this manner he found, that if the moon reflected all the light it receives from the sun, it would only be the 45,000th part of the light we receive from the greater luminary. Admitting, therefore, that moon-light is only a 300,000th part of the light of the sun, Mr Michell concludes, that it reflects no more than between the 6th and 7th part of what falls upon it.

273 Rumford's photometer.

Could Rumford, has constructed a *photometer*, in which the shadows, instead of being thrown upon a paper spread out upon the wainscot, or side of the room, are projected upon the inside of the back part

Apparatus for Measuring Light.

In using this instrument, it is necessary that the object should subtend an angle larger than the aperture A or D, seen from the other end of the tube; for, otherwise, the lengthening of the tube has no effect. To avoid, in this case, making the instrument of an inconvenient length, or making the aperture D too narrow, he has recourse to another expedient. He constructs an instrument, represented (fig. 6.), consisting of two object-glasses, AE and DF, exactly equal, fixed in the ends of two tubes six or seven feet, or, in some cases, 10 or 12 feet long, and having their foci at the other ends. At the bottoms of these tubes B, are two holes, three or four lines in diameter, covered with a piece of white paper; and this instrument is used exactly like the former.

Fig. 6.

If the two objects to be observed by this instrument be not equally luminous, the light that issues from them must be reduced to an equality, by diminishing the aperture of one of the object-glasses; and then the remaining surface of the two glasses will give the proportion of their lights. But for this purpose, the central parts of the glass must be covered in the same proportion with the parts near the circumference, leaving the aperture such as is represented (fig. 7.), because the middle part of the glass is thicker and less transparent than the rest.

Fig. 7.

If all the objects to be observed lie nearly in the same direction, Bouguer remarks, that these two long tubes may be reduced into one, the two object-glasses being placed close together, and one eye-glass sufficing for them both. The instrument will then be the same with that of which he published an account in 1748, and which he called a *heliometer*, or *astrometer*.

267 These instruments measure only the intensity of light.

It is not, however, the absolute quantity, but only the intensity of the light, that is measured by these two instruments, or the number of rays, in proportion to the surface of the luminous body; and it is of great importance that these two things be distinguished. The intensity of light may be very great, when the quantity, and its power of illuminating other bodies, may be very small, on account of the smallness of its surface; or the contrary may be the case, when the surface is large.

Having explained these methods which M. Bouguer took to measure the different proportions of light, we shall subjoin a few examples of his application of them.

It is observable, that when a person stands in a place where there is a strong light, he cannot distinguish objects that are placed in the shade; nor can he see any thing upon going immediately into a place where there is very little light. It is plain, therefore, that the action of a strong light upon the eye, and also the impression which it leaves upon it, makes it insensible to the effect of a weaker light. M. Bouguer had the curiosity to endeavour to ascertain the proportion between the intensities of the two lights in this case; and by throwing the light of two equal candles upon a board, he found that the shadow made by intercepting the light of one of them, could not be perceived by his eye, upon the place enlightened by the other, at little more than eight times the distance; from whence he concluded, that when one light is eight times eight, or 64 times less than another, its presence or absence will not be perceived. He allows, however, that the effect may be different on different eyes; and supposes that the boundaries in this case, with respect to different persons, may lie between 60 and 80.

Applying the two tubes of his instrument, mentioned above, to measure the intensity of the light reflected from different parts of the sky; he found that when the sun was 25 degrees high, the light was four times stronger at the distance of eight or nine degrees from his body, than it was at 31 or 32 degrees. But what struck him the most was to find, that when the sun is 15 or 20 degrees high, the light decreases on the same parallel to the horizon to 110 or 120 degrees, and then increases again to the place exactly opposite to the sun.

268 Great variation of the light of the moon at different altitudes.

The light of the sun, our author observes, is too strong, and that of the stars too weak, to determine the variation of their light at different altitudes; but as, in both cases, it must be in the same proportion with the diminution of the light of the moon in the same circumstances, he made his observations on that luminary, and found, that its light at 19° 16′, is to its light at 66° 11′, as 1681 to 2500; that is, the one is nearly two thirds of the other. He chose those particular altitudes, because they are those of the sun at the two solstices at Croisic, where he then resided. When one limb of the moon touched the horizon of the sea, its light was 2000 times less than at the altitude of 66° 11′. But this proportion he acknowledges must be subject to many variations, the atmosphere near the earth varying so much in its density. From this observation he concludes, that at a medium light is diminished in the proportion of about 2500 to 1681, in traversing 7469 toises of dense air.

269 Variation in different parts of the disks of the sun and planets.

M. Bouguer also applied his instrument to the different parts of the sun's disk, and found that the centre is considerably more luminous than the extremities of it. As near as he could make the observation, it was more luminous than a part of the disk ¾ths of the semidiameter from it, in the proportion of 35 to 28; which, as he observes, is more than in the proportion of the sines of the angles of obliquity. On the other hand, he observes, that both the primary and secondary planets are more luminous at their edges than near their centres.

The comparison of the light of the sun and moon is a subject that has frequently exercised the thoughts of philosophers; but we find nothing but random conjectures, before Bouguer applied his accurate measures in this case. In general, the light of the moon is imagined to bear a much greater proportion to that of the sun than it really does: and not only are the imaginations of the vulgar, but those of philosophers also, imposed upon with respect to it. It was a great surprise to M. de la Hire to find that he could not, by the help of any burning mirror, collect the beams of the moon in a sufficient quantity to produce the least sensible heat. Other philosophers have since made the like attempts with mirrors of greater power, though without any greater success; but this will not surprise us, when we see the result of M. Bouguer's observations on this subject.

270 M. Bouguer's calculation concerning the light of the moon.

In order to solve this curious problem concerning the comparison of the light of the sun and moon, he compared each of them to that of a candle in a dark room, one in the day-time, and the other in the night following,

Apparatus for Measuring Light.

ing, when the moon was at her mean distance from the earth; and, after many trials, he concluded that the light of the sun is about 300,000 times greater than that of the moon; which is such a disproportion, that, as he observes, it can be no wonder that philosophers have had so little success in their attempts to collect the light of the moon with burning glasses. For the largest of them will not increase the light 1000 times; which will still leave the light of the moon, in the focus of the mirror, 300 times less than the intensity of the common light of the sun.

To this account of the proportion of light which we actually receive from the moon, it cannot be displeasing to the reader, if we compare it with the quantity which would have been transmitted to us from that opaque body, if it reflected all the light it receives. Dr Smith thought that he had proved, from two different considerations, that the light of the full moon would be to our day-light as 1 to about 90,900, if no rays were lost at the moon.

271 Dr Smith's calculation.

In the first place, he supposes that the moon enlightened by the sun, is as luminous as the clouds are at a medium. He therefore supposed the light of the sun to be equal to that of a whole hemisphere of clouds, or as many moons as would cover the surface of the heavens. But on this Dr Priestley observes, that it is true, the light of the sun shining perpendicularly upon any surface would be equal to the light reflected from the whole hemisphere, if every part reflected all the light that fell upon it; but the light that would in fact be received from the whole hemisphere (part of it being received obliquely) would be only one-half as much as would be received from the whole hemisphere, if every part of it shone directly upon the surface to be illuminated.

In his Remarks, par. 97. Dr Smith demonstrates his method of calculation in the following manner.

Plate cclxxxiv. fig. 8.

"Let the little circle $cfdg$ represent the moon's body half enlightened by the sun, and the great circle aeb, a spherical shell concentric to the moon, and touching the earth; ab, any diameter of that shell perpendicular to a great circle of the moon's body, represented by its diameter cd; e the place of the shell receiving full moon light from the bright hemisphere fdg. Now, because the surface of the moon is rough like that of the earth, we may allow that the sun's rays, incident upon any small part of it, with any obliquity, are reflected from it every way alike, as if they were emitted. And, therefore, if the segment df shone alone, the points a, e, would be equally illuminated by it; and likewise if the remaining bright segment dg shone alone, the points be would be equally illuminated by it. Consequently, if the light at the point a was increased by the light at b, it would become equal to the full moon light at e. And conceiving the same transfer to be made from every point of the hemispherical surface $hbik$ to their opposite points in the hemisphere $kach$, the former hemisphere would be left quite dark, and the latter would be uniformly illuminated with full moon light; arising from a quantity of the sun's light, which immediately before its incidence on the moon, would uniformly illuminate a circular plane equal to a great circle of her body, called her *disk*. Therefore the quantities of light being the same upon both surfaces, the density of the sun's incident light is to the density of full moon light, as that hemispherical surface hek is to the said disk; that is, as any other hemispherical surface whose centre is at the eye, to that part of it which the moon's disk appears to possess very nearly, because it subtends but a small angle at the eye: that is, as radius of the hemisphere to the versed sine of the moon's apparent semidiameter, or as 10,000,000 to $1106\frac{2}{7}$ or as 90,400 to 1; taking the moon's mean horizontal diameter to be $16' 7''$.

"Strictly speaking, this rule compares moon light at the earth with day light at the moon; the medium of which, at her quadratures, is the same as our day-light; but is less at her full in the duplicate ratio of 365 to 366, or thereabout, that is, of the sun's distances from the earth and full moon; and therefore full moon light would be to our day light as about 1 to 90,900, if no rays were lost at the moon.

"Secondly, I say that full moon light is to any other moon light as the whole disk of the moon to the part that appears enlightened, considered upon a plane surface. For now let the earth be at b, and let dl be perpendicular to fg, and gm to cd: then it is plain, that gl is equal to dm; and that gl is equal to a perpendicular section of the sun's rays incident upon the arch dg which at b appears equal to dm; the eye being unable to distinguish the unequal distances of its parts. In like manner, conceiving the moon's surface to consist of innumerable physical circles parallel to $cfdg$, as represented at A, the same reason holds for every one of these circles as for $cfdg$. It follows then, that the bright part of the surface visible at b, when reduced to a flat as represented at B, by the crescent $pdqmp$, will be equal and similar to a perpendicular section of all the rays incident on that part, represented at C by the crescent $pgqlp$. Now the whole disk being in proportion to this crescent as the quantities of light incident upon them; and the light falling upon every rough particle, being equally rarefied in diverging to the eye at b, considered as equidistant from them all; it follows, that full moon light is to this moon light as the whole disk $pdqc$ to the crescent $pdqmp$. Fig. 9.

"Therefore by compounding this ratio with that in the former remark, day-light is to moon-light as the surface of an hemisphere whose centre is at the eye, to the part of that surface which appears to be possessed by the enlightened part of the moon."

272 Mr Michell's calculation.

Mr Michell made his computation in a much more simple and easy manner, and in which there is much less danger of falling into any mistake. Considering the distance of the moon from the sun, and that the density of the light must decrease in the proportion of the square of that distance, he calculated the density of the sun's light, at that distance, in proportion to its density at the surface of the sun; and in this manner he found, that if the moon reflected all the light it receives from the sun, it would only be the 45,000th part of the light we receive from the greater luminary. Admitting, therefore, that moon-light is only a 300,000th part of the light of the sun, Mr Michell concludes, that it reflects no more than between the 6th and 7th part of what falls upon it.

273 Rumford's photometer.

Could Rumford, has constructed a *photometer*, in which the shadows, instead of being thrown upon a paper spread out upon the wainscot, or side of the room, are projected upon the inside of the back part

 of

Apparatus for Measuring Light.

of a wooden box $7\frac{1}{4}$ inches wide, $10\frac{1}{2}$ inches long, and $3\frac{1}{4}$ inches deep, in the clear. The light is admitted into it through two horizontal tubes in the front, placed so as to form an angle of 60°; their axes meeting at the centre of the field of the instrument. In the middle of the front of the box, between these two tubes, is an opening through which is viewed the field of the photometer (see fig. 5.). This field is formed of a piece of white paper, which is not fastened immediately upon the inside of the back of the box, but is pasted upon a small pane of very fine ground glass; and this glass, thus covered, is let down into a groove, made to receive it, in the back of the box. The whole inside of the box, except the field of the instrument, is painted of a deep black dead colour. To the under part of the box is fitted a ball and socket, by which it is attached to a stand which supports it; and the top or lid of it is fitted with hinges, in order that the box may be laid quite open, as often as it is necessary to alter any part of the machinery it contains.

Plate CCCLXXXIX. fig. 5.

The count had found it very inconvenient to compare two shadows projected by the same cylinder, as these were either necessarily too far from each other to be compared with certainty, or, when they were nearer, were in part hid from the eye by the cylinder. To remedy this inconvenience, he now makes use of two cylinders, which are placed perpendicularly in the bottom of the box just described, in a line parallel to the back part of it, distant from this back $2\frac{2}{10}$ inches, and from each other 3 inches, measuring from the centres of the cylinders; when the two lights made use of in the experiment are properly placed, these two cylinders project four shadows upon the white paper upon the inside of the back part of the box, or the *field* of the instrument; two of which shadows are in contact, precisely in the middle of that field; and it is these two alone that are to be attended to. To prevent the attention being distracted by the presence of unnecessary objects, the two outside shadows are made to disappear; which is done by rendering the field of the instrument so narrow, that they fall without it, upon a blackened surface, upon which they are not visible. If the cylinders be each $\frac{4}{10}$ of an inch in diameter, and $2\frac{2}{10}$ inches in height, it will be quite sufficient that the field be $2\frac{7}{10}$ inches wide; and as an unnecessary height of the field is not only useless, but disadvantageous, as a large surface of white paper not covered by the shadows produces too strong a glare of light, the field ought not to be more than $\frac{1}{10}$ of an inch higher than the tops of the cylinders. That its dimensions, however, may be occasionally augmented, the covered glass should be made $5\frac{1}{2}$ inches long, and as wide as the box is deep, viz. $3\frac{1}{4}$ inches; since the field of the instrument can be reduced to its proper size by a screen of black pasteboard, interposed before the anterior surface of this covered glass, and resting immediately upon it. A hole in this pasteboard, in the form of an oblong square, $1\frac{7}{10}$ inch wide, and two inches high, determines the dimensions, and forms the boundaries of the field. This screen should be large enough to cover the whole inside of the back of the box, and it may be fixed in its place by means of grooves in the sides of the box, into which it may be made to enter. The position of the opening above mentioned is determined by the height of the cylinders; the top of it being $\frac{1}{10}$ of an inch higher than the tops of the cylinders; and as the height of it is only two inches, while the height of the cylinders is $2\frac{2}{10}$ inches, it is evident that the shadows of the lower parts of the cylinders do not enter the field. No inconvenience arises from that circumstance; on the contrary, several advantages are derived from that arrangement.

That the lights may be placed with facility and precision, a fine black line is drawn through the middle of the field, from the top to the bottom of it, and another (horizontal) line at right angles to it, at the height of the top of the cylinders. When the tops of the shadows touch this last mentioned line, the lights are at a proper height; and farther, when the two shadows are in contact with each other in the middle of the field, the lights are then in their proper directions.

We have said that the cylinders, by which the shadows are projected, are placed perpendicularly in the bottom of the box; but as the diameters of the shadows of these cylinders vary in some degree, in proportion as the lights are broader or narrower, and as they are brought nearer to or removed farther from the photometer, in order to be able in all cases to bring these shadows to be of the same diameter, which is very advantageous, in order to judge with greater facility and certainty when they are of the same density, the count renders the cylinders moveable about their axes, and adds to each a vertical wing $\frac{5}{10}$ of an inch wide, $\frac{1}{10}$ of an inch thick, and of equal height with the cylinder itself, and firmly fixed to it from the top to the bottom. This wing commonly lies in the middle of the shadow of the cylinder, and as long as it remains in that situation it has no effect whatever; but when it is necessary that the diameter of one of the shadows be increased, the corresponding cylinder is moved about its axis, till the wing just described, emerging out of the shadow, and intercepting a portion of light, brings the shadow projected upon the field of the instrument to be of the width or diameter required. In this operation it is always necessary to turn the cylinder outwards, or in such a manner that the augmentation of the width of the shadow may take place on that side of it which is opposite to the shadow corresponding to the other light. The necessity for that precaution will appear evident to any one who has a just idea of the instrument in question, and of the manner of making use of it. They are turned likewise without opening the box, by taking hold of the ends of their axes, which project below its bottom.

As it is absolutely necessary that the cylinders should constantly remain precisely perpendicular to the bottom of the box, or parallel to each other, it will be best to construct them of brass; and, instead of fixing them immediately to the bottom of the box (which, being of wood, may warp), to fix them to a strong thick piece of well-hammered plate brass; which plate of brass may be afterwards fastened to the bottom of the box by means of one strong screw. In this manner two of the count's best instruments are constructed; and, in order to secure the cylinders still more firmly in their vertical positions, they are furnished with broad flat rings, or projections, where they rest upon the brass plate; which rings are $\frac{1}{10}$ of an inch thick, and equal in diameter to the projection of the wing of the cylinder, to the bottom of which they afford a firm support. These cylinders are likewise forcibly pushed, or rather pulled, against

Apparatus for Measuring Light.

against the brass plate upon which they rest, by means of compressed spiral springs placed between the under side of that plate and the lower ends of the cylinders. Of whatever material the cylinders be constructed, and whatever be their forms or dimensions, it is absolutely necessary that they, as well as every other part of the photometer, except the field, should be well painted of a deep black dead colour.

In order to move the lights to and from the photometer with greater ease and precision, the observer should provide two long and narrow, but very strong and steady, tables; in the middle of each of which there is a straight groove, in which a sliding carriage, upon which the light is placed, is drawn along by means of a cord which is fastened to it before and behind, and which, passing over pulleys at each end of the table, goes round a cylinder; which cylinder is furnished with a winch, and is so placed, near the end of the table adjoining the photometer, that the observer can turn it about, without taking his eye from the field of the instrument.

Many advantages are derived from this arrangement: First, the observer can move the lights as he finds necessary, without the help of an assistant, and even without removing his eye from the shadows; secondly, each light is always precisely in the line of direction in which it ought to be, in order that the shadows may be in contact in the middle of the vertical plane of the photometer; and, thirdly, the sliding motion of the lights being perfectly soft and gentle, that motion produces little or no effect upon the lights themselves, either to increase or diminish their brilliancy.

These tables must be placed at an angle of 60 degrees from each other, and in such a situation, with respect to the photometer, that lines drawn through their middles, in the direction of their lengths, meet in a point exactly under the middle of the vertical plane or field of the photometer, and from that point the distances of the lights are measured; the sides of the tables being divided into English inches, and a vernier, shewing tenths of inches, being fixed to each of the sliding carriages upon which the lights are placed, and which are so contrived that they may be raised or lowered at pleasure; so that the lights may be always in a horizontal line with the tops of the cylinders of the photometer.

In order that the two long and narrow tables or platforms, just described, may remain immoveable in their proper positions, they are both firmly fixed to the stand which supports the photometer; and, in order that the motion of the carriages which carry the lights may be as soft and gentle as possible, they are made to slide upon parallel brass wires, 9 inches asunder, about $\frac{1}{10}$ of an inch in diameter, and well polished, which are stretched out upon the tables from one end to the other.

Plate CCLXXXIX. fig 5.

The structure of the apparatus will be clearly understood by a bare inspection of Plate CCLXXXIX. Fig. 5. is a plan of the inside of the box, and the adjoining parts of the photometer. Fig. 6. Plan of the two tables belonging to the photometer. Fig. 7. The box of the photometer on its stand. Fig. 8. Elevation of the photometer, with one of the tables and carriages.

Having sufficiently explained all the essential parts of this photometer, it remains for us to give some account of the precautions necessary to be observed in using it. And, first, with respect to the distance at which lights, whose intensities are to be compared, should be placed from the field of the instrument, the ingenious and accurate inventor found, that when the weakest of the lights in question is about as strong as a common wax candle, that light may most advantageously be placed from 30 to 36 inches from the centre of the field; and when it is weaker or stronger, proportionally nearer or farther off. When the lights are too near, the shadows will not be well defined; and when they are too far off, they will be too weak.

It will greatly facilitate the calculations necessary in drawing conclusions from experiments of this kind, if some steady light, of a proper degree of strength for that purpose, be assumed as a standard by which all others may be compared. Our author found a good Argand's lamp much preferable for this purpose to any other lamp or candle whatever. As it appears, he says, from a number of experiments, that the quantity of light emitted by a lamp, which burns in the same manner with a clear flame, and *without smoke*, is in all cases as the quantity of oil consumed, there is much reason to suppose, that, if the Argand's lamp be so adjusted as always to consume a given quantity of oil in a given time, it may then be depended on as a just standard of light.

In order to abridge the calculation necessary in these inquiries, it will always be advantageous to place the standard-lamp at the distance of 100 inches from the photometer, and to assume the intensity of its light at its source equal to unity; in this case (calling this standard light A, the intensity of the light at its source $=x=1$, and the distance of the lamp from the field of the photometer $=m=100$), the intensity of the illumination at the field of the photometer $\left(=\frac{x}{m^2}\right)$ will be expressed by the fraction $\frac{1}{100^2}=\frac{1}{10000}$; and the relative intensity of any other light which is compared with it, may be found by the following proportion: Calling this light B, putting $y=$ its intensity at its source, and $n=$ its distance from the field of the photometer, expressed in English inches, as it is $\frac{y}{n^2}=\frac{x}{m^2}$, or, instead of $\frac{x}{m^2}$, writing its value $=\frac{1}{10000}$, it will be $\frac{y}{n^2}=\frac{1}{10000}$; and consequently y is to 1 as n^2 is to 10000; or the intensity of the light B at its source, is to the intensity of the standard light A at its source, as the square of the distance of the light B from the middle of the field of the instrument, expressed in inches, is to 10000; and hence it is $y=\frac{n^2}{10000}$.

Or, if the light of the sun, or that of the moon, be compared with the light of a given lamp or candle C, the result of such comparison may be best expressed in words, by saying, that the light of the celestial luminary in question, *at the surface of the earth*, or, which is the same thing, at the field of the photometer, is equal to the light of the given lamp or candle, *at the distance found by the experiment*; or, putting $a=$ the intensity of the light of this lamp C at its source, and $p=$ its distance,

Apparatus for Measuring Light.

distance, in inches, from the field, when the shadows corresponding to this light, and that corresponding to the celestial luminary in question, are found to be of equal densities, and putting $z=$ the intensity of the rays of the luminary at the surface of the earth, the result of the experiment may be expressed thus, $z=\frac{a}{p^2}$; or the real value of a being determined by a particular experiment, made expressly for that purpose with the standard lamp, that value may be written instead of it. When the standard lamp itself is made use of, instead of lamp C, then the value of A will be 1.

The count's first attempts with his photometer were to determine how far it might be possible to ascertain, by direct experiments, the certainty of the assumed law of the diminution of the intensity of the light emitted by luminous bodies; namely, that the intensity of the light is everywhere as the squares of the distances from the luminous body inversely. As it is obvious that this law can hold good only when the light is propagated through perfectly transparent spaces, so that its intensity is weakened merely by the divergency of its rays, he instituted a set of experiments to ascertain the transparency of the air and other mediums.

With this view, two equal wax candles, well trimmed, and which were found, by a previous experiment, to burn with exactly the same degree of brightness, were placed *together*, on one side, before the photometer, and their united light was counterbalanced by the light of an Argand's lamp, well trimmed, and burning very equally, placed on the other side over against them. The lamp was placed at the distance of 100 inches from the field of the photometer, and it was found that the two burning candles (which were placed as near together as possible, without their flames affecting each other by the currents of air they produced) were just able to counterbalance the light of the lamp at the field of the photometer, when they were placed at the distance of 60.8 inches from that field. One of the candles being now taken away and extinguished, the other was brought nearer to the field of the instrument, till its light was found to be just able, singly, to counterbalance the light of the lamp; and this was found to happen when it had arrived at the distance of 43.4 inches. In this experiment, as the candles burnt with equal brightness, it is evident that the intensities of their united and single lights were as 2 to 1, and in that proportion ought, according to the assumed theory, the squares of the distances, 60.8 and 43.4, to be; and, in fact, $\overline{60.8}^2=3696.64$ is to $\overline{43.4}^2=1883.56$ as 2 is to 1 very nearly.

Again, in another experiment, the distances were,

With two candles = 54 inches. Square = 2916
With one candle = 38.6 - = 1489.96

Upon another trial,

With two candles = 54.6 inches. Square = 2981.16
With one candle = 39.7 - = 1576.09

And, in the fourth experiment,

With two candles = 58.4 inches. Square = 3410.56
With one candle = 42.2 - - = 1780.84

And, taking the mean of the results of these four experiments,

	Squares of the distances With two candles.		With one candle.
In the experiment N° 1.	3696.64	—	1883.56
N° 2.	2916	—	1489.96
N° 3.	2981.16	—	1576.09
N° 4.	3410.56	—	1780.84
	4)13004.36		4)6730.45
Means	3251.09	and	1682.61

which again are very nearly as 2 to 1.

With regard to these experiments, it may be observed, that were the resistance of the air to light, or the diminution of the light from the imperfect transparency of air, sensible within the limits of the inconsiderable distances at which the candles were placed from the photometer, in that case the distance of the two equal lights united ought to be, to the distance of one of them single, in a ratio less than that of the square root of 2 to the square root of 1. For if the intensity of a light emitted by a luminous body, *in a space void of all resistance*, be diminished in the proportion of the squares of the distances, it must of necessity be diminished in a still higher ratio when the light passes through a resisting medium, or one which is not perfectly transparent; and from the difference of those ratios, namely, that of the squares of the distances, and that other higher ratio found by the experiment, the resistance of the medium might be ascertained. This he took much pains to do with respect to air, but did not succeed; the transparency of air being so great, that the diminution which light suffers in passing through a few inches, or even through several feet of it, is not sensible.

Having found, upon repeated trials, that the light of a lamp, properly trimmed, is incomparably more equal than that of a candle, whose wick, continually growing longer, renders its light extremely fluctuating, he substituted lamps to candles in these experiments, and made such other variations in the manner of conducting them as he thought bid fair to lead to a discovery of the resistance of the air to light, were it possible to render that resistance sensible within the confined limits of his machinery. But the results of them, so far from affording means for ascertaining the resistance of the air to light, do not even indicate any resistance at all; on the contrary, it might almost be inferred, from some of them, that the intensity of the light emitted by a luminous body in air is diminished in a ratio *less* than that of the squares of the distances; but as such a conclusion would involve an evident absurdity, namely, that light moving in air, its absolute quantity, instead of being diminished, actually goes on to *increase*, that conclusion can by no means be admitted.

Why not? Theories must give place to facts; and if this fact can be fairly ascertained, instead of rejecting the conclusion, we ought certainly to rectify our notions of light, the nature of which we believe no man fully comprehends. Who can take it upon him to say, that the substance of light is not latent in the atmosphere, as heat or caloric is now acknowledged to be latent, and that the agency of the former is not called forth by the passage of a ray through a portion of air, as the agency of the latter is known to be excited by

Apparatus for Measuring Light

by the combination of oxygen with any combustible substance?

The ingenious author's experiments all conspired to shew that the resistance of the air to light is too inconsiderable to be perceptible, and that the assumed law of the diminution of the intensity of light may be depended upon with safety. He admits, however, that means may be found for rendering the air's resistance to light apparent; and he seems to have thought of the very means which occurred for this purpose to M. de Saussure.

274 Contrivances of Saussure.

That eminent philosopher, wishing to ascertain the transparency of the atmosphere, by measuring the distances at which determined objects cease to be visible, perceived at once that his end would be attained, if he should find objects of which the disappearance might be accurately determined. Accordingly, after many trials, he found that the moment of disappearance can be observed with much greater accuracy when a black object is placed on a white ground, than when a white object is placed on a black ground: that the accuracy was still greater when the observation was made in the sun than in the shade; and that even a still greater degree of accuracy was obtained, when the white space surrounding a black circle, was itself surrounded by a circle or ground of a dark colour. This last circumstance was particularly remarkable, and an observation quite new.

If a circle totally black, of about two lines in diameter, be fastened on the middle of a large sheet of paper or pasteboard, and if this paper or pasteboard be placed in such a manner as to be exposed fully to the light of the sun, if you then approach it at the distance of three or four feet, and afterwards gradually recede from it, keeping your eye constantly directed towards the black circle, it will appear always to decrease in size the farther you retire from it, and at the distance of 33 or 34 feet will have the appearance of a point. If you continue still to recede, you will see it again enlarge itself; and it will seem to form a kind of cloud, the darkness of which decreases more and more according as the circumference becomes enlarged. The cloud will appear still to increase in size the farther you remove from it; but at length it will totally disappear. The moment of the disappearance, however, cannot be accurately ascertained: and the more experiments were repeated, the more were the results different.

M. de Saussure, having reflected for a long time on the means of remedying this inconveniency, saw clearly, that as long as this cloud took place, no accuracy could be obtained; and he discovered that it appeared in consequence of the contrast formed by the white parts which were at the greatest distance from the black circle. He thence concluded, that if the ground was left white near this circle, and the parts of the pasteboard at the greatest distance from it were covered with a dark colour, the cloud would no longer be visible, or at least almost totally disappear.

This conjecture was confirmed by experiment. M. de Saussure left a white space around the black circle equal in breadth to its diameter, by placing a circle of black paper a line in diameter, on the middle of a white circle three lines in diameter, so that the black circle was only surrounded by a white ring a line in breadth. The whole was pasted upon a green ground. A green colour was chosen, because it was dark enough to make the cloud disappear, and the easiest to be procured.

The black circle surrounded in this manner with white on a green ground, disappeared at a much less distance than when it was on a white ground of a large size.

If a perfectly black circle, a line in diameter, be pasted on the middle of a white ground exposed to the open light, it may be observed at the distance of from 44 to 45 feet; but if this circle be surrounded by a white ring a line in breadth, while the rest of the ground is green, all sight of it is lost at the distance of only $15\frac{1}{2}$ feet.

According to these principles M. de Saussure delineated several black circles, the diameters of which increased in a geometrical progression, the exponent of which was $\frac{3}{2}$. His smallest circle was $\frac{1}{5}$ or 0.2 of a line in diameter; the second, 0.3; the third, 0.45; and so on to the sixteenth, which was 87.527, or about 7 inches $3\frac{1}{2}$ lines. Each of these circles was surrounded by a white ring, the breadth of which was equal to the diameter of the circle, and the whole was pasted on a green ground.

M. de Saussure, for his experiments, selected a straight road or plain of about 1200 or 1500 feet in circumference, which towards the north was bounded by trees or an ascent. Those who repeat them, however, must pay attention to the following remarks: When a person retires backwards, keeping his eye constantly fixed on the pasteboard, the eye becomes fatigued, and soon ceases to perceive the circle; as soon therefore as it ceases to be distinguishable, you must suffer your eyes to rest; not, however, by shutting them, for they would when again opened be dazzled by the light, but by turning them gradually to some less illuminated object in the horizon. When you have done this for about half a minute, and again directed your eyes to the pasteboard, the circle will be again visible, and you must continue to recede till it disappear once more. You must then let your eyes rest a second time in order to look at the circle again, and continue in this manner till the circle becomes actually invisible.

If you wish to find an accurate expression for the want of transparency, you must employ a number of circles, the diameters of which increase according to a certain progression; and a comparison of the distances at which they disappear will give the law according to which the transparency of the atmosphere decreases at different distances. If you wish to compare the transparency of the atmosphere on two days, or in two different places, two circles will be sufficient for the experiment.

According to these principles, M. de Saussure caused to be prepared a piece of white linen cloth eight feet square. In the middle of this square he sewed a perfect circle, two feet in diameter, of beautiful black wool; around this circle he left a white ring two feet in breadth, and the rest of the square was covered with pale green. In the like manner, and of the same materials, he prepared another square; which was, however, equal to only $\frac{1}{11}$ of the size of the former, so that each side of it was 8 inches; the black circle in the middle was two inches in diameter, and the white space around the circle was 2 inches also.

If two squares of this kind be suspended vertically and

Apparatus for Measuring Light.

and parallel to each other, so that they may be both illuminated in an equal degree by the sun; and if the atmosphere, at the moment when the experiment is made, be perfectly transparent, the circle of the large square, which is twelve times the size of the other, must be seen at twelve times the distance. In M. de Saussure's experiments the small circle disappeared at the distance of 314 feet, and the large one at the distance of 3588 feet, whereas it should have disappeared at the distance of 3768. The atmosphere, therefore, was not perfectly transparent. This arose from the thin vapours which at that time were floating in it. M. de Saussure, calls his instrument a *diaphanometer;* but it serves one of the purposes of a photometer.

From a number of experiments made with the *photometer*, Count Rumford found, that, by passing through a pane of fine, clear, well polished glass, such as is commonly made use of in the construction of looking-glasses, light loses .1973 or its whole quantity, i. e. of the quantity which impinged on the glass; that when light is made to pass through two panes of such glass standing parallel, but not touching each other, the loss is .3184 of the whole; and that in passing through a very thin, clear, colourless pane of window-glass, the loss is only .1263. Hence he infers, that this apparatus might be very usefully employed by the optician, to determine the degree of transparency of glass, and direct his choice in the provision of that important article of his trade. The loss of light when reflected from the very best plain glass mirror, the author ascertained, by five experiments, to be ⅓d of the whole which fell upon the mirror.

275 Leslie's photometer. An ingenious photometer has also been invented by Professor Leslie, and fully described in his celebrated work on Heat, to which we must refer the reader for a complete description of this instrument. It measures the calorific effect of heat, and is founded upon this principle, "that if a body be exposed to the sun's rays, it will, in every possible case, be found to indicate a measure of heat exactly proportioned to the quantity of light which it has absorbed." See *Essay on Heat*, p. 103.

Chap. II. *On the method of forming the Lenses and Specula, of Refracting and Reflecting Telescopes.*

Sect. I. *On the Method of grinding and polishing Lenses.*

276 On grinding lenses. Having fixed upon the proper aperture and focal distance of the lens, take a piece of sheet copper, and strike a fine arch upon its surface, with a radius equal to half that distance, if it is to be plano-convex, and let the length of this arch be a little greater than the given aperture. Remove with a file that part of the copper which is without the circular arch, and a *convex gage* will be formed. Strike another arch with the same radius, and having removed that part of the copper which is within it, a *concave gage*, will be obtained.

Method of Grinding and Polishing Lenses.

277 Formation of the gages. Prepare two circular plates of brass, about $\frac{1}{10}$ of an inch thick, and half an inch greater in diameter than the breadth of the lens, and solder them upon a cylinder of lead of the same diameter, and about an inch high.

278 Formation of the tools. These tools are then to be fixed upon a turning lathe, and one of them turned into a portion of a concave sphere, so as to suit the convex gage; and the other into a portion of a convex sphere, so as to answer the concave gage. After the surfaces of the brass plates are turned as accurately as possible, they must be ground upon one another, alternately, with flour emery; and when the two surfaces exactly coincide, the grinding tools will be ready for use.

279 Formation of the glass. Procure a piece of glass whose dispersive power is as small as possible, if the lens is not for achromatic instruments, and whose surfaces are parallel; and by means of a pair of large scissars or pincers, cut it into a circular shape, so that its diameter may be a little greater than the required aperture of the lens. When the roughness is removed from its edges by a common grindstone (A), it is to be fixed with black pitch to a wooden handle of a smaller diameter than the glass, and about an inch high, so that the centre of the handle may exactly coincide with the centre of the glass.

280 Mode of grinding. The glass being thus prepared, it is then to be ground with fine emery upon the concave tool, if it is to be convex, and upon the convex tool, if it is to be concave. To avoid circumlocution, we shall suppose that the lens is to be convex. The concave tool, therefore, which is to be used, must be firmly fixed to a table or bench, and the glass wrought upon it with circular strokes, so that its centre may never go beyond the edges of the tool. For every 6 circular strokes, the glass should receive 2 or 3 cross ones along the diameter of the tool, and in different directions. When the glass has received its proper shape, and touches the tool in every point of its surface, which may be easily known by inspection, the emery is to be washed away, and finer kinds (B) successively substituted in its room, till by the same alternation of circular and transverse strokes, all the scratches and asperities are removed from its surface. After the finest emery has been used, the roughness which remains may be taken away, and a slight polish superinduced by grinding the glass with pounded pumice-stone in the same manner as before. While the operation of grinding is going on, the convex tool should, at the end of every five

(A) When the focal distance of the lens is to be short, the surface of the piece of glass should be ground upon a common grindstone, so as to suit the gage as nearly as possible; and the plates of brass, before they are soldered on the lead, should be hammered as truly as they can be done into their proper form. By this means much labour will be saved both in turning and grinding.

(B) Emery of different degrees of fineness may be made in the following manner. Take five or six clean vessels, and having filled one of them with water, put into it a considerable quantity of flour emery. Stir it well with a piece of wood, and after standing for 5 seconds pour the water into the second vessel. After it has stood about 12 seconds, pour it out of this into a third vessel, and so on with the rest; and at the bottom of each vessel will be found emery of different degrees of fineness, the coarsest being in the first vessel, and the finest in the last.

Method of Grinding and Polishing Lenses.

five minutes, be wrought upon the concave one for a few seconds, in order to preserve the same curvature to the tools and the glass. When one side is finished off with the pumice-stone, the lens must be separated from its handle by inserting the point of a knife between it and the pitch, and giving it a gentle stroke. The pitch which remains upon the glass may be removed by rubbing it with a little oil, or spirits of wine; and after the ground side of the glass is fixed upon the handle, the other surface is to be wrought and finished in the very same manner.

281
Mode of polishing.

When the glass is thus brought into its proper form, the next and the most difficult part of the operation is to give it a fine polish. The best, though not the simplest way of doing this, is to cover the concave tool with a layer of pitch, hardened by the addition of a little rosin, to the thickness of one-fifteenth of an inch. Then having taken a piece of thin writing paper, press it upon the surface of the pitch with the convex tool, and pull the paper quickly from the pitch before it has adhered to it; and if the surface of the pitch is marked everywhere with the lines of the paper, it will be truly spherical, having coincided exactly with the surface of the convex tool. If any paper remains on the surface of the pitch, it may be removed by soap and water; and if the marks of the paper should not appear on every part of it, the operation must be repeated till the polisher, or bed of pitch, is accurately spherical. The glass is then to be wrought on the polisher by circular and cross strokes, with the oxide of tin, called the flowers of putty in the shops, or with the red oxide of iron, otherwise called colcothar of vtriol, till it has received on both sides a complete polish (C). The polishing will advance slowly at first, but will proceed rapidly when the polisher becomes warm with the friction. When it is nearly finished, no more putty or water should be put upon the polisher, which should be kept warm by breathing upon it; and if the glass moves with difficulty from its adhesion to the tool, it should be quickly removed, lest it spoil the surface of the pitch. When any particles of dust or pitch insinuate themselves between the glass and the polisher, which may be easily known from the very unpleasant manner of working, they should be carefully removed, by washing both the polisher and the glass, otherwise the lens will be scratched, and the bed of pitch materially injured.

282
By means of pitch.

283
By means of cloth.

The operation of polishing may also be performed by covering the layer of pitch with a piece of cloth, and giving it a spherical form by pressing it with the convex tool when the pitch is warm. The glass is wrought as formerly, upon the surface of the cloth, with putty or colcothar of vitriol, til a sufficient polish is induced. By this mode the operation is slower, and the polish less perfect; though it is best fitted for those who have but little experience, and would therefore be apt to injure the figure of the lens by polishing it on a bed of pitch.

In this manner the small lenses of simple and compound microscopes, the eye-glasses and the object-glasses of telescopes, are to be ground. In grinding concave lenses, Mr Imison* employs leaden wheels with the same radius as the curvature of the lens, and with their circumferences of the same convexity as the lens is to be concave. These spherical zones are fixed upon a turning lathe, and the lens, which is held steadily in the hand, is ground upon them with emery, while they are revolving on the spindle of the lathe. In the same way convex lenses may be ground and polished, by fixing the concave tool upon the lathe; but these methods, however simple and expeditious they may be, should never be adopted for forming the lenses of optical instruments, where an accurate spherical figure is indispensable. It is by the hand alone that we can perform with accuracy those circular and transverse strokes, the proper union of which is essential to the production of a spherical surface. Appendix to Ferguson's Lectures, vol. ii. p. 452.

284
Impropriety of grinding, &c. on a lathe.

Sect. II. *On the Method of Casting, Grinding, and Polishing the Specula of Reflecting Telescopes.*

285
Composition of the metal.

The metals of reflecting telescopes are generally composed of 32 parts of copper, and 15 of grain tin, with the addition of two parts of arsenic, to render the composition more white and compact. The Reverend Mr Edwards found, from a variety of experiments, that if one part of brass, and one of silver, be added to the preceding composition, and only one part of arsenic used, a most excellent metal will be obtained, which is the whitest, hardest, and most reflective, that he ever met with. The superiority of this composition, indeed, has been completely evinced by the excellence of Mr Edwards' telescopes, which excel other reflectors in brightness and distinctness, and show objects in their natural colours. But as metals of this composition are extremely difficult to cast, as well as to grind and polish, it will be better for those who are inexperienced in the art, to employ the composition first mentioned.

286
Method of casting the metal.

After the flasks of sand (D) are prepared, and a mould made for the metal by means of a wooden or metallic pattern, so that its face may be downwards, and a few small holes left in the sand at its back, for the free egress of the included air;—melt the copper in a crucible by itself, and when it is reduced to a fluid state, fuse the tin in a separate crucible, and mix it with the melted copper, by stirring them together with a wooden spatula. The proper quantity of powdered arsenic, wrapt up in a piece of paper, is then to be added, the operator retaining his breath till its noxious fumes are completely dissipated; and when the scoria is removed from the fluid mass, it is to be poured out as quickly as possible into the flasks. As soon as the metal is become solid, remove it from the sand into some hot ashes or coals, for the purpose of annealing

(C) As colcothar of vitriol is obtained by the decomposition of martial vitriol, it sometimes retains a portion of this salt. When this portion of martial vitriol is decomposed by dissolution in water, the yellow ochre which results penetrates the glass, forms an incrustation upon its surface, and gives it a dull and yellowish tinge, which is communicated to the image which it forms.

(D) The finest sand which we have met with in this country, is to be found at Roxburgh castle, in the neighbourhood of Kelso.

Method of Grinding and Polishing Lenses.

annealing it, and let it remain among them till they are completely cold. The ingate is then to be taken from the metal by means of a file; and the surface of the speculum must be ground upon a common grindstone, till all the imperfections and asperities are taken away. When Mr Edwards' composition is employed, the copper and tin should be melted according to the preceding directions, and, when mixed together, should be poured into cold water, which will separate the mass into a number of small particles. These small pieces of metal are then to be collected and put into the crucible, along with the silver and brass, after they have been melted together in a separate crucible; the proper quantity of arsenic is to be added, and a little powdered rosin thrown into the fluid metal before it is poured into the flasks.

287 Grinding tools, &c.

When the metal is cast, and prepared by the common grindstone for receiving its proper figure, the gages and grinding tools are to be formed in the same manner as for convex lenses, with this difference only, that the radius of the gages must always be double the focal length of the speculum. In addition to the convex and concave brass tools, which should be only a little broader than the metal itself, a convex elliptical tool of lead and tin should also be formed with the same radius, so that its transverse may be to its conjugate diameter as 10 to 9, the latter being exactly equal to the diameter of the metal. On this tool the speculum is to be ground with flour emery, in the same manner as lenses, with circular and cross strokes alternately, till its surface is freed from every imperfection, and ground to a spherical figure. It is then to be wrought with great circumspection, on the convex brass tool, with emery of different degrees of fineness, the concave tool being sometimes ground upon the convex one, to keep them all of the same radius; and when every scratch and appearance of roughness is removed from its surface, it will be fit for receiving the final polish. Before the speculum is brought to the polisher, it has been the practice to smooth it on a bed of hones, or a convex tool made of common blue hones. This additional tool, indeed, is absolutely necessary, when silver and brass enter into the composition of the metal, in order to remove that roughness which will always remain after the finest emery has been used; but when these metals are not ingredients in the speculum, there is no occasion for the bed of hones. Without the intervention of this tool I have finished several specula, and given them as exquisite a lustre as they could possibly have received. Mr Edwards does not use any brass tools in his process, but transfers the metal from the elliptical leaden tool to the bed of hones. By this means the operation is simplified, but we doubt much if it is, in the least degree, improved. As a bed of hones is more apt to change its form than a tool of brass, it is certainly of great consequence that the speculum should have as true a figure as possible before it is brought to the hones; and we are persuaded, from experience, that this figure may be better communicated on a brass tool, which can always be kept at the same curvature by its corresponding tool, than on an elliptical block of lead. We are certain, however, that when the speculum is required to be of a determinate focal length, this length will be obtained more precisely with the brass tools than without them. But Mr Edwards has observed, that these tools are not only unnecessary, but 'really detrimental.' That Mr Edwards found them unnecessary, we cannot doubt, from the excellence of the specula which he formed without their assistance; but it seems inconceivable how the brass tools can be in the least degree detrimental. If the mirror is ground upon 20 different tools before it is brought to the bed of hones, it will receive from the last of these tools a certain figure, which it would have received even if it had not been ground on any of the rest; and it cannot be questioned, that a metal wrought upon a pair of brass tools, is equally, if not more, fit for the bed of hones, than if it had been ground merely on a tool of lead.

288 Method of polishing the metal.

When the metal is ready for polishing, the elliptical leaden tool is to be covered with black pitch, about one-twentieth of an inch thick, and the polisher formed in the same way as in the case of lenses, either with the concave brass tool, or with the metal itself. The colcothar of vitriol should then be triturated between two surfaces of glass, and a considerable quantity of it applied at first to the surface of the polisher. The speculum is then to be wrought in the usual way upon the polishing tool till it has received a brilliant lustre, taking care to use no more of the colcothar, if it can be avoided, and only a small quantity of it, if it should be found necessary. When the metal moves stifly on the polisher, and the colcothar assumes a dark muddy hue, the polish advances with great rapidity. The tool will then grow warm, and would probably stick to the speculum, if its motion were discontinued for a moment. At this stage of the process, therefore, we must proceed with great caution, breathing continually on the polisher till the friction is so great as to retard the motion of the speculum. When this happens, the metal is to be slipped off the tool at one side, cleaned with soft leather, and placed in a tube for the purpose of trying its performance; and if the polishing has been conducted with care, it will be found to have a true *parabolic* figure. Appendix to Ferguson's Lectures vol. ii. p. 457.

INDEX.

S.

Optimates, Optio.

OPTIMATES, one of the divisions of the Roman people, opposed to *populares*. It is not easy to ascertain the characteristic differences betwixt these two parties. Some say the optimates were warm supporters of the dignity of the chief magistrate, and promoters of the grandeur of the state, who cared not if the inferior members suffered, provided the commanding powers were advanced: Whereas the populares boldly stood up for the rights of the people, pleaded for larger privileges, and laboured to bring matters nearer to a level. In short, they resembled, according to this account, the court and country parties amongst the people of this island.

Tully says, that the optimates were the best citizens, who wished to deserve the approbation of the better sort; and that the populares courted the favour of the populace, not so much considering what was right, as what would please the people and gratify their own thirst of vain glory and empty applause.

OPTIO, an officer in the Roman army, being an assistant or lieutenant to every centurion. The *optio* was so called because he was the choice or option of the centurion in later times; at first, however, he had been chosen by the tribune, or chief commander of the legion. These *optiones* are also sometimes called *succenturiones* and *tergiductores*; the last name was given them because their post was in the rear of the company. Some authors make mention of *sub-optiones* or sub-lieutenants.

Optio, Option.

It is proper, however, to add, that optiones were not peculiar to the camp, but were also used in a variety of other offices of life.

OPTION, the power or faculty of wishing, or choosing; or the choice a person makes of any thing.

When a new suffragan bishop is consecrated, the archbishop of the province, by a customary prerogative, claims the collation of the first vacant benefice, or dignity, in that see, according as he shall choose; which choice is called the archbishop's *option*.

But in case the bishop dies, or is translated, before the

the present incumbent of the promotion chosen by the archbishop shall die or be removed, it is generally supposed that the option is void; inasmuch as the granter, singly and by himself, could not convey any right or title beyond the term of his continuance in that see. And if the archbishop dies before the avoidance shall happen, the right of filling up the vacancy shall go to his executors or administrators.

OPUNTIA, a species of cactus. See CACTUS, BOTANY *Index*.

OR, the French word for gold, by which this metal is expressed in heraldry. In engraving it is denoted by small points all over the field or bearing. It may be supposed to signify of itself, *generosity*, *splendour*, or *solidity;* according to G. Leigh, if it is compounded with

Gul.	it signifies	Courage.
Azu.		Trust.
Ver.		Joy.
Pur.		Charity.
Sab.		Constancy.

ORA, in antiquity, was a term equivalent to an ounce: but it has been much debated among our antiquaries, whether the ora, the mention of which so often occurs, was a coin or only money of account. Dr Hickes observes, that the mode of reckoning money by marks and oras was never known in England till after the Danish settlements; and by examining the old nummulary estimates among the principal Gothic states upon the Baltic, it appears, that the ora and solidus were synonymous terms, and that the ora was the eighth part of the mark. From several of the Danish laws, it likewise appears, that the Danish ora, derived by corruption from *aureus*, was the same as the Frank solidus of twelve pence. As a weight, the ora was regarded as the uncia or unit, by which the Danish mark was divided; and in Doomsday book the ora is used for the ounce, or the twelfth part of the nummulary Saxon pound, and the fifteenth of the commercial; as a coin it was an aureus, or the Frank solidus of twelve pence. And from the accidental coincidence of the Frank aureus with the eighth part of their mark, the Danes probably took occasion to give it the new name of *ora*. There was another ora mentioned in the rolls of the 27th of Henry III. the value of which was sixteen pence; and this was probably derived from the half mancus of the Saxons. Such, in all appearance, was the original of these two oras; as there were no aurei of that period, to which these two denominations of money of sixteen and twelve pence can possibly be ascribed. It is observed farther, that the name *ora* distinguishes the gold coins in several parts of Europe to this day. The Portuguese moidore is nothing else but *moeda d'oro*, from the Latin *moneta de auro;* the French *Louis d'ors* come from the same use of the word, and owe their appellation to the ora. See Clarke on Coins.

ORACH. See ATRIPLEX, } BOTANY *Index*.
Wild ORACH. See CHENOPODIUM, }

ORACLE, among the heathens, was the answer which the gods were supposed to give to those who consulted them upon any affair of importance. It is also used for the god who was thought to give the answer, and for the place where it was given.

The credit of oracles was so great that in all doubts and disputes their determinations were held sacred and inviolable: whence vast numbers flocked to them for advice about the management of their affairs; and no business of any consequence was undertaken, scarce any peace concluded, any war waged, or any new form of government instituted, without the advice and approbation of some oracle. The answers were usually given by the intervention of the priest or priestess of the god who was consulted; and generally expressed in such dark and unintelligible phrases, as might be easily wrested to prove the truth of the oracle whatever was the event. It is not, therefore, to be wondered at, that the priests who delivered them were in the highest credit and esteem, and that they managed this reputation so as greatly to promote their own particular advantage. They accordingly allowed no man to consult the gods, before he had offered costly sacrifices, and made rich presents to them. And to keep up the veneration for their oracles, and to prevent their being taken unprepared, they admitted persons to consult the gods only at certain stated times; and sometimes they were so cautious, that the greatest personages could obtain no answer at all. Thus Alexander himself was peremptorily denied by the Pythia, or priestess of Apollo, till she was by downright force obliged to ascend the tripos; when, being unable to resist any longer, she cried out, *Thou art invincible:* and these words were accepted instead of a farther oracle.

Of the ambiguity of oracles, the following, out of a great many examples, may be mentioned. Crœsus having received from the Pythoness this answer, That by passing the river Halys, he would destroy a great empire; he understood it to be the empire of his enemy, whereas he destroyed his own.—The oracle consulted by Pyrrhus gave him an answer, which might be equally understood of the victory of Pyrrhus, and the victory of the Romans his enemies:

Aio te, Æacida, Romanos vincere posse.

The equivocation lies in the construction of the Latin tongue, which cannot be rendered in English.—The Pythoness advised Crœsus to guard against the mule. The king of Lydia understood nothing of the oracle, which denoted Cyrus descended from two different nations; from the Medes, by Mandana his mother, the daughter of Astyages; and from the Persians, by his father Cambyses, whose race was by far less grand and illustrious.—Nero had for answer, from the oracle of Delphos, that seventy-three might prove fatal to him. He believed he was safe from all danger till that age; but, finding himself deserted by every one, and hearing Galba proclaimed emperor, who was 73 years of age, he was sensible of the deceit of the oracle.

When men began to be better instructed by the lights philosophy had introduced into the world, the false oracles insensibly lost their credit. Chrysippus filled an entire volume with false or doubtful oracles. Oenomaus, to be revenged of some oracle that had deceived him, made a compilation of oracles, to show their ridiculous vanity. Eusebius has preserved some fragments of this criticism on oracles by Oenomaus. "I might (says Origen) have recourse to the authority of Aristotle and the Peripatetics, to make the Pythoness much suspected: I might extract from the writings

writings of Epicurus and his sectators an abundance of things to discredit oracles; and I might show that the Greeks themselves made no great account of them."

The reputation of oracles was greatly lessened when they became an artifice of politics. Themistocles, with a design of engaging the Athenians to quit Athens, and to embark, in order to be in a better condition to resist Xerxes, made the Pythoness deliver an oracle, commanding them to take refuge in wooden walls. Demosthenes said, that the Pythoness *Philippized;* to signify that she was gained over by Philip's presents.

The cessation of oracles is attested by several profane authors; as Strabo, Juvenal, Lucan, and others. Plutarch accounts for it, by saying, that the benefits of the gods are not eternal as themselves are; or that the genii, who presided over oracles, are subject to death; or that the exhalations of the earth had been exhausted. It appears that the last reason had been alleged in the time of Cicero, who ridicules it in his second book of Divination, as if the spirit of prophecy, supposed to be excited by subterraneous effluvia, had evaporated by length of time, as wine or pickle by being long kept.

Suidas, Nicephorus, and Cedrenus, relate, that Augustus, having consulted the oracle of Delphos, could obtain no other answer but this: "The Hebrew child, whom all the gods obey, drives me hence, and sends me back to hell: get out of this temple without speaking one word." Suidas adds, that Augustus dedicated an altar in the Capitol, with this inscription, "To the eldest son of God." Notwithstanding these testimonies, the answer of the oracle of Delphos to Augustus seems very suspicious. Cedrenus cites Eusebius for this oracle, which is not now found in his works; and Augustus's peregrination into Greece was 18 years before the birth of Christ.

Suidas and Cedrenus give an account also of an ancient oracle delivered to Thulis, a king of Egypt, which they say is well authenticated. The king having consulted the oracle of Serapis, to know if there ever was, or would be, one so great as himself, received this answer: First God, next the Word, and the Spirit with them. They are equally eternal, and make but one whose power will never end. But thou, mortal, go hence, and think that the end of the life of man is uncertain."

Van Dale, in his treatise of oracles, does not believe that they ceased at the coming of Christ. He relates several examples of oracles consulted till the death of Theodosius the Great. He quotes the laws of the emperors Theodosius, Gratian, and Valentinian, against those who consulted oracles, as a certain proof that the superstition of oracles still subsisted in the time of those emperors.

According to others, the opinion of those who believe that demons had no share in the oracles, and that the coming of the Messiah made no change in them, and the contrary opinion of those who pretend that the incarnation of the Word imposed a general silence on all oracles, should be equally rejected. They allege, that two sorts of oracles ought to be distinguished: the one dictated by the spirits of darkness, who deceived men by their obscure and doubtful answers; the other, the pure artifice and cheat of the priests of false divinities. As to the oracles given out by demons, the reign of Satan was destroyed by the coming of the Saviour; truth shut the mouth of lies; but Satan continued his old craft among idolaters. All the devils were not forced to silence at the same time by the coming of the Messiah; it was on particular occasions that the truth of Christianity, and the virtue of Christians, imposed silence on the devils. St Athanasius tells the Pagans, that they have been witnesses themselves that the sign of the cross puts the devils to flight, silences oracles, and dissipates enchantments. This power of silencing oracles, and putting the devils to flight, is also attested by Arnobius, Lactantius, Prudentius, Minutius Felix and several others. Their testimony is a certain proof that the coming of the Messiah had not imposed a general silence on oracles.

Plutarch relates, that the pilot Thamus heard a voice in the air, crying out, "The great Pan is dead;" whereupon Eusebius observes, that the accounts of the death of the demons were frequent in the reign of Tiberius, when Christ drove out the wicked spirits.

The same judgment, it is said, may be passed on oracles as on *possessions*. It was on particular occasions, by the divine permission, that the Christians cast out devils, or silenced oracles, in the presence, and even by the confession, of the Pagans themselves. And thus it is we should, it seems, understand the passages of St Jerome, Eusebius, Cyril, Theodoret, Prudentius, and other authors, who said that the coming of Christ had imposed silence on the oracles.

As to the second sort of oracles, which were pure artifices and cheats of the priests of false divinities, and which probably exceeded the number of those that immediately proceeded from demons, they did not cease till idolatry was abolished, though they had lost their credit for a considerable time before the coming of Christ. It was concerning this more common and general sort of oracles that Minutius Felix said, they they began to discontinue their responses, according as men began to be more polite. But, however oracles were decried, impostors always found dupes, the grossest cheats having never failed.

Daniel discovered the imposture of the priests of Bel, who had a private way of getting into the temple to take away the offered meats, and who made the king believe that the idol consumed them.—Mundus, being in love with Paulina, the eldest of the priestesses of Isis, went and told her, that the god Anubis, being passionately fond of her, commanded her to give him a meeting. She was afterwards shut up in a dark room, where her lover Mundus, whom she believed to be the god Anubis, was concealed. This imposture having been discovered, Tiberius ordered those detestable priests and priestesses to be crucified, and with them Idæa, Mundus's free woman, who had conducted the whole intrigue. He also commanded the temple of Isis to be levelled with the ground, and her statue to be thrown into the Tiber; and, as to Mundus, he contented himself with sending him into banishment.

Theophilus, bishop of Alexandria, not only destroyed the temples of the false gods, but discovered the cheats of the priests, by showing that the statues, some of which were of brass, and others of wood, were hollow within, and led into dark passages made in the wall.

Lucian, in discovering the impostures of the false prophet Alexander, says, that the oracles were chiefly afraid of the subtilties of the Epicureans and Christians. The false prophet Alexander sometimes feigned himself seized with a divine fury, and by means of the herb sopewort, which he chewed, frothed at the mouth in so extraordinary a manner, that the ignorant people attributed it to the strength of the god he was possessed by. He had long before prepared a head of a dragon made of linen, which opened and shut its mouth by means of a horse hair. He went by night to a place where the foundations of a temple were digging: and having found water, either of a spring, or rain that had settled there, he hid in it a goose egg, in which he had enclosed a little serpent that had been just hatched. The next day, very early in the morning he came quite naked into the street, having only a scarf about his middle, holding in his hand a scythe, and tossing about his hair as the priests of Cybele; then getting a-top of a high altar, he said that the place was happy to be honoured by the birth of a god.—Afterwards, running down to the place where he had hid the goose egg, and going into the water, he began to sing the praises of Apollo and Æsculapius, and to invite the latter to come and show himself to men. With these words, he dips a bowl into the water, and takes out the mysterious egg, which had a god enclosed in it; and when he had it in his hand, he began to say that he held Æsculapius. Whilst all were eager to have a sight of this fine mystery, he broke the egg, and the little serpent starting out, twisted itself about his fingers.

These examples show clearly, that both Christians and Pagans were so far agreed as to treat the *greater number* of oracles as purely human impostors. That, in fact ALL of them were so, will be concluded by those who give equal credit to demoniacal *inspiration*, and demoniacal *possession*. The most ancient oracle was that of Dodona (see DODONA); but the most famous was that of Delphi, to which article we also refer for farther particulars on this subject, so famous in Pagan antiquity. Another celebrated one was the oracle of Trophonius, in the neighbourhood of Lebadia, a city of Bœotia, which was held in high estimation. It received its name from Trophonius, brother of Agamedes, who lived in a subterraneous dwelling near Lebadia, and pretended to the faculty of foretelling future events. He died in his cave, and was deified as an oracular god. This oracle owed its reputation to one Saon.

Those who repaired to this cave for information, were required to offer certain sacrifices, to anoint themselves with oil, and to bathe in a certain river: They were then clothed in a linen robe, took a honeyed cake in their hands, and descended into the subterraneous chamber by a narrow passage. Here it was that futurity was unfolded to them, either by visions or extraordinary sounds. The return from the cave was by the same passage, but the persons consulting were obliged to walk backwards. They generally came out astonished, melancholy, and dejected; hence the proverb εις Τροφωνιου μεμαντευται. The priests on their return placed them on an elevated seat, called *the seat of Mnemosyne*, where an account was taken of what they had seen and heard. They were then conducted to the chapel of good Genius by their companions, where, by degrees, they recovered their usual composure and cheerfulness.

Besides these three principal oracles of Greece, it is proper to take notice of that of Amphiaraus at Oropius in Attica. It was so called from Amphiaraus, the son of Oicleus, a man skilled in magic, the interpretation of dreams, &c. and who after his death was deified and delivered oracles in a temple erected to his divinity. (See AMPHIARAUS). They who applied to them for information, were to purify themselves, offer sacrifice, fast twenty-four hours, abstain from wine two days, and make an offering of a ram to Amphiaraus; on the skin of which they were to sleep, and see their destiny in a dream. Near the temple was Amphiaraus's fountain, which was sacred, and the waters of it forbidden to be used for ordinary purposes.

At Delos also there was an oracle of the Delian Apollo; in Milesia was that of the Branchidæ, with others of less note, which require not a particular description, such as that of the camps at Lacedæmon, that of Nabarcha, that of Chrysopolis, that of Claros in Ionia, that of Mallos, that of Patarea, that of Pella, that of Phasellides, that of Sinope, that of Orpheus's head, &c.

Though the Romans consulted the Grecian oracles upon many occasions, and had few oracles in their own country; yet we must not omit mentioning the Cumæan oracles which were delivered by the Sibyl of Cumæ. For an account of the Sibyls, see the article SIBYL. See also DÆMON and DÆMONIAC.

We have hitherto only considered the oracles of false gods, of which there was a far greater number than our limits permit us to observe, and before either Greeks or Romans had risen to any distinction. Oracle is in sacred history sometimes used for the mercy seat, or the cover of the ark of the covenant; and by others it is taken for the sanctuary, or for the most holy place, wherein the ark was deposited.

Among the Jews we may distinguish several sorts of *real* oracles. They had first oracles that were delivered *viva voce;* as when God spake to Moses face to face, as one friend speaks to another, (Numb. xii. 8.). Secondly, Prophetical dreams sent by God; as the dreams which God sent to Joseph, and which foretold his future greatness, (Gen. xxxvii. 5, 6.). Thirdly, Visions; as when a prophet in an ecstasy, being neither properly asleep nor awake, had supernatural revelations, (Gen. xv. 1. xlvi. 2.). Fourthly, The oracle of Urim and Thummim, which was accompanied with the ephod or the pectoral worn by the high priest, and which God had endued with the gift of foretelling things to come, (Numb. xii. 6. Joel ii. 28.). This manner of inquiring of the Lord was often made use of, from Joshua's time to the erection of the temple at Jerusalem. Fifthly, After the building of the temple, they generally consulted the prophets, who were frequent in the kingdoms of Judah and Israel. From Haggai, Zechariah, and Malachi, who are the last of the prophets that have any of their writings remaining, the Jews pretend that God gave them what they call *Bathcol*, the daughter of the voice, which was a supernatural manifestation of the will of God, which was performed either by a strong inspiration or internal voice, or else by a sensible and

and external voice, which was heard by a number of persons sufficient to bear testimony of it. For example, such was the voice that was heard at the baptism of Jesus Christ, saying, This is my beloved Son, &c. (Matth. iii. 17.).

The Scripture affords us examples likewise of profane oracles. Balaam, at the instigation of his own spirit, and urged on by his avarice, fearing to lose the recompense that he was promised by Balak king of the Moabites, suggests a diabolical expedient to this prince, of making the Israelites fall into idolatory and fornication (Numb. xxiv. 14. xxxi. 16.), by which he assures him of a certain victory, or at least of considerable advantage against the people of God.

Micaiah the son of Imlah, a prophet of the Lord, says (1 Kings xxii. 21, &c.), that he saw the Almighty sitting upon his throne, and all the host of heaven round about him; and the Lord said, who shall tempt Ahab king of Israel, that he may go to war with Ramoth-gilead, and fall in the battle? One answered after one manner, and another in another. At the same time an evil spirit presented himself before the Lord, and said, I will seduce him. And the Lord asked him, How? To which Satan answered I will go and be a lying spirit in the mouth of his prophets. And the Lord said, Go and thou shalt prevail. This dialogue clearly proves these two things: *first*, that the devil could do nothing by his own power; and, *secondly*, that with the permission of God, he could inspire the false prophets, sorcerers, and magicians, and make them deliver false oracles.

Respecting the cessation of profane oracles there have been a variety of opinions; some of which we have already remarked. It has been generally held, indeed, that oracles ceased at the birth of Jesus Christ: Yet some have endeavoured to maintain the contrary, by showing that they were in being in the days of Julian, commonly called the *Apostate*, and that this emperor himself consulted them; nay, farther, say they, history makes mention of several laws published by the Christian emperors Theodosius, Gratian, and Valentinian, to punish persons who interrogated them, even in their days; and that the Epicureans were the first who made a jest of this superstition, and exposed the roguery of its priests to the people. As we suspect most of the facts here asserted should be understood in a qualified sense, we shall endeavour to discuss this point of controversy in as few words as possible, although it is undoubtedly a matter of some consequence.

1st, The question, properly stated, is not, Whether oracles became extinct *immediately upon the birth of Christ*, or from the very moment he was born; but, If they fell gradually into disesteem and ceased, as Christ and his gospel became known to mankind. And that they did so, is most certain from the concurrent testimonies of the fathers, which, whoever would endeavour to invalidate, may equally give up the most respectable traditions and relations of every kind.

2dly, But did not Julian the apostate consult these oracles? We answer in the negative: he had indeed recourse to magical operations, but it was because oracles had already ceased; for he bewailed the loss of them, and assigned pitiful reasons for it; which St Cyril has vigorously refuted, adding, that *he never could have offered such, but from an unwillingness to acknowledge, that when the world had received the light of Christ, the dominion of the devil was at an end.*

3dly, The Christian emperors do indeed seem to condemn the superstition and idolatry of those who were still for consulting oracles; but the edicts of those princes do not prove that oracles actually existed in their times, any more than that they ceased in consequence of their laws. It is certain that they were for the most part extinct before the conversion of Constantine.

4thly, Some Epicureans might *make a jest of this superstition*: however, the Epicurean philosopher Celsus, in the second century of the church, was for crying up the excellency of several oracles, as appears at large from Origen's seventh book against him.

ORÆA, certain solemn sacrifices of fruits which were offered in the four seasons of the year, in order to obtain mild and temperate weather. They were offered to the goddesses who presided over the seasons, who attended upon the sun, and who received divine worship at Athens.

ORAL, something delivered by word of mouth, without being committed to writing; in which sense we say oral law, oral tradition, &c.

ORAN, a very strong town of Africa, in Barbary, with several forts, and an excellent harbour. It is seated partly on the side of a hill, and partly on a plain, about a stonecast from the sea, almost opposite to Carthagena in Spain, and is about a mile and a half in circumference. In 1790, 2000 of the inhabitants perished by an earthquake which nearly destroyed the whole town. It was taken by the Spaniards in 1509, and retaken by the Algerines in 1708; but in 1732 the Spaniards became masters of it, and have continued so ever since. E. Long. 0. 8. N. Lat. 36. 2.

ORANG OUTANG. See SIMIA, MAMMALIA *Index*.

ORANGE, a city, and capital of a province of the same name, united to Dauphiny, with a university and a bishop's see, suffragan of Arles. It is seated in a fine large plain, watered by a vast number of little rivulets on the east side of the river Rhone, and in the department of Vaucluse. It is a very large ancient place, and was considerable in the time of the Romans, who adorned it with several buildings, of which there are still some ruins left, particularly of an amphitheatre, and a triumphal arch which is almost entire, dedicated to Marius. The town contained 7270 inhabitants in 1800. The wall was in 1682 entirely demolished by order of Louis XIV. and the inhabitants were exposed to the fury of the soldiers. The town was restored to King William by the treaty of Ryswick; but after his death the French took it again, and expelled the Protestant inhabitants. By the treaty of Utrecht it was confirmed to the crown of France, though the title is still retained in the house of Nassau. The title was first introduced into the family of Nassau, by the marriage of Claude de Chalons, the prince of Orange's sister, with the count of Nassau, 1530. The principality is a very small district, it being only twelve miles in length and nine in breadth, and the revenue amounts to about 5000l. a-year. The country is pleasant, and abounds with corn and fruit, but is exposed to violent winds. E. Long. 4. 49. N. Lat. 44. 9.

Maurice Prince of ORANGE. See MAURICE.

ORANGE *River*, also known by the name of the Great

Great river, is situated in southern Africa, and is of considerable extent. It seems to take its rise about S. Lat. 30°, and E. Long. 28° from Greenwich, and joins the sea, after a west by north course for a number of leagues, between the great and little Namaquas, two tribes supposed to be of the same origin with the Hottentots. There are high cataracts in it, and it is subjet to inundations like the Nile. Carnelians, calcedonies, agates, and variolites are found upon the shores. The rains in the great mountains along the foot of which the Orange river runs, collecting their streams in its passage, commence in the month of November, and cause the inundations to take place towards the Namaqua country in the month of December. The nauseous custom of greasing the skin, from the great scarcity of water in many parts of South Africa, is rendered unnecessary among the people who inhabit the banks of this grand river; and of consequence they exhibit none of that filthy appearance which is characteristic of the Hottentots on the skirts of the colony.

Orange-Tree, in *Botany*. See Citrus, Botany *Index*.—Orange flowers are justly esteemed one of the finest perfumes; and though little used in medicine, yet the water distilled from them is accounted stomachic, cordial, and carminative. The fruit is cooling, and good in feverish disorders, and particularly in diarrhœas. Orange-peel is an agreeable aromatic, proper to repair and strengthen the stomach, and gives a very grateful flavour to any infusions or tinctures into whose compositions it enters. It is particularly useful in preparations of the bark: gives an agreeable warmth to the infusion; and, according to Dr Percival, considerably increases its virtue.
